Useful information on CPU firmware versions and STEP 7 versions

CPUs and engineering software for configuring the CPUs is constantly developed further to improve performance and security. New versions that have some special features with respect to the interaction of the components are created in this way. The sections below describe the special features of the S7-1200 CPUs with firmware version V4 as compared to firmware versions V1 to V3.

For a detailed comparison of the range of functions, read the S7-1200 System Manual (description of new instructions, new organization blocks and advanced configuration options).

Required engineering software

S7-1200 CPUs V4 can be configured with STEP 7 as of V13.

Compatibility between memory card content and firmware version of the CPU

Memory cards (transfer cards or program cards) with configuration and program for an S7-1200 CPU V1, V2 or V3 do not work with an S7-1200 CPU V4.
Memory cards with configuration and program for an S7-1200 CPU V4 do not work with an S7-1200 CPU V1, V2 or V3.

You must change an S7-1200 CPU V1 to V3 configuration to an S7-1200 CPU V4 configuration (device replacement) and then download it to the CPU. A gradual device replacement is required for an S7-1200 CPU V1-V2 (see below).

When you insert the memory card into a CPU with an incompatible firmware version, the CPU does not start up. When you insert a memory card for a CPU V1, V2 or V3 into an S7-1200 CPU V4, this CPU outputs a version error.

Going online and loading

When you have configured an S7-1200 CPU with firmware version V1, V2 or V3 with STEP 7, the CPU to which you want to go online or which you want to download must have one of these firmware versions. You cannot go online to an S7-1200 CPU V4 with a configured S7-1200 CPU V1, V2 or V3.

On the other hand, you cannot go online to an S7-1200 CPU V1, V2 or V3 with a configured S7-1200 CPU V4 or download this CPU.

Replacing an existing CPU

You can replace a configured S7-1200-CPU V1, V2 or V3 with a new CPU with a firmware version greater than or equal to 4. In case of an existing S7-1200 CPU V1 or V2, you must start by replacing the device with an S7-1200 CPU V3: It is not possible to directly replace it with an S7-1200 CPU V4.

1. S7-1200 CPU V1 (V2) > S7-1200 CPU V3
2. S7-1200 CPU V3 > S7-1200 CPU V4

As long as you do not download the configuration, you can undo the device replacement ("Undo" command in the "Edit" menu). When you download the configuration for the new CPU firmware version ("V4 configuration") to the CPU, you can no longer return to version V3.

This means you should save the existing project, for example, with a V3 configuration as project archive so that you can access it later.

Special notes for device replacement (V3 > V4):

- The interrupt behavior of interrupt OBs remains the same; they are not configured as interruptible. This is also the default behavior of S7-1200 CPUs V1-V3. The interrupt behavior of the interrupt OB can be configured for S7-1200 V4 CPUs. If you drag an S7-1200 CPU V4 directly from the hardware catalog into the network view, this option is activated (interrupt OBs are interruptible).
- The behavior for PUT/GET access of remote partners remains the same; access is permitted. This is also the default behavior of S7-1200 CPUs V1-V3. The access via PUT/GET communication by means of remote partners can be configured for S7-1200 V4 CPUs ("Protection" area of CPU parameters). If you drag an S7-1200 CPU V4 directly from the hardware catalog into the network view, access is not permitted and must be explicitly enabled.
- The wording for the protection levels changes but the effect of the settings remains the same. You can also select the access level "No access (complete protection)".
- The web server settings for activation of the web server and HTTP/HTTPS settings are applied. You also have the option to create users and assign them specific rights (Web server area > User management of CPU parameters). Web server users only have access to standard websites when you do not configure users. An S7-1200 CPU V4 no longer supports the user "admin" and his/her password.

Communication with HMI devices

When you connect an HMI device to an S7-1200 CPU V4, make sure that you use the appropriate Runtime software version of the HMI device.

You may have to transfer the latest HMI Runtime version by means of the WinCC engineering software.

You must compile the HMI configuration once again and download it to the HMI device for the CPU-HMI communication to work.

Useful information on memory cards (Page 1169)

10.1.6.2 Identification systems

RFID systems

Ident profile and Ident blocks

You will find detailed information on the Ident profile in the manual "Ident Profile and Ident Blocks, Standard Function for Ident Systems" on the pages of "Product Support (http://support.automation.siemens.com/WW/view/en/10805817)".

Communications module RF120C

Reader parameter group

The "Reader" parameter group contains the following:

- Diagnostics: Setting to decide whether or not hardware diagnostics messages are output.
- Reader System: Selection of the connected RFID system. Depending on the selection you make, the "Reader System" parameter group is adapted.

"Diagnostics" parameter

Parameter assignment options:

- None
  Apart from standard diagnostics messages, no other diagnostics messages are generated.
- Hard Errors
  Extended diagnostics messages are generated if the following events occur.
  - Hardware error (memory test)
  - Firmware error (checksum)
  - Connection to reader lost
  - Short-circuit fault/interruption if supported by the hardware

Further information

For further information on diagnostics, refer the documentation for the RF120C communications module with application blocks for S7-1200 and S7-1500.

Reader System parameter group

The parameters for the selected identification system are set in the "Reader system" parameter group.

The table shows the parameters that exist for all identification systems (RFID and code reader systems).

Table 10-76 Standard parameters for all identification systems

Parameter	Parameter value	Default value	Description
Baud rate reader	19.2 kBd 57.6 kBd 115.2 kBd	115.2 kBd	After changing the baud rate, the reader must be turned off and on again.
Presence Check	On Off (RF field off) Off (RF field on)	On	On = presence is reported as soon as there is a transponder in the antenna field of the reader Off (RF field on) = the presence check in the FB is suppressed. The antenna on the reader is nevertheless turned on as long as it has not been turned off by a command. Off (RF field off) = the antenna is turned on only when a command is sent and it then turns itself off again (RF300 only)
Reset ERR-LED	On Off	Off	On = the flashing of the error LED on the RF120C is reset by each FB reset. Off = the error LED always indicates the last error. The display can only be reset by turning off the RF120C.

The following parameters are system specific according to the selection you made in the "Reader" parameter group.

RF200

Table 10-77 RF200 general

Parameter	Parameter value	Default value	Description
-	-	-	Only the standard parameters are available.

Table 10-78 RF290R

Parameter	Parameter value	Default value	Description
RF power	0.50 - 5.00 W	1.00 W	Setting for the output power of the reader.

RF300

Table 10-79 RF300 general

Parameter	Parameter value	Default value	Description
Transponder type	RF300 ISO 15693	RF300	Selection of the transponders used.

Table 10-80 RF380R

Parameter	Parameter value	Default value	Description
RF power	0.50 - 2.00 W	1.25 W	Setting for the output power of the reader.
Transponder type	RF300 ISO 15693	RF300	Selection of the transponders used.

RF600

Table 10-81 Reader System: RF600

Parameter	Parameter value	Default value	Description
Max. no. of transponders	1 - 80	1	Number of transponders expected in the antenna field. Permitted values: • 1 - 40 for RF620R • 1 - 80 for RF630R with 2 antennas • 1 - 40 for RF630R with 1 antenna The value stored in "multitag" defines the expected number of transponders to be read (EPC-ID) in the inventory. The value does not restrict the number of transponders to be processed in the antenna field. To ensure an efficient inventory of transponders in the antenna field, make sure that the values specified here do not deviate by more than approximately 10% from the maximum number of transponders to be expected in the antenna field.
Reader type	RF620R ETSI RF620R FCC RF620R CMIIT RF630R ETSI RF630R FCC RF630R CMIIT	RF620R ETSI	Selection of the reader used. By selecting a reader, you open the "Reader type" parameter group. The parameters are described in the following table.

Reader type (RF600 only)

In the "Reader type" parameter group further specific parameters are set for the reader type selected in the "Reader system" parameter group.

Table 10-82 RF600 menu: Reader type

Parameter	Parameter value	Default value	Description
Wireless profile	-	-	Selection of the relevant wireless profile for ETSI, FCC or CMIIT.
Multitag mode	UID = EPC-ID (8 bytes) UID = Handle ID (4 bytes)	UID = EPC-ID (8 bytes)	• UID = EPC-ID (8 bytes) 8 byte UID of the bytes 5-12 of the 12 byte long EPC-ID • UID = handle ID (4 bytes) 4 byte UID as handle ID for access to transponders with an EPC-ID of any length
Intelligent Single Tag Mode (ISTM)	On Off	Off	Enable/disable the "Intelligent Single Tag Mode ISTM" algorithm [1]
Black List	On Off	Off	Enable/disable the "Black list" [1]
Radiated power internal antenna (RF620R)	0 - B	4	Setting the radiated power for the internal antenna [1] [2]
Internal antenna (RF620R)	-	-	Enable/disable the internal antenna. With the RF620R, either only the internal or only the external antenna can be set.
Transmit power (external antenna RF620R)	0 - 9	4	Setting the transmit power for the external antenna [1] [2]
External antenna (SetAnt block required) (RF620R)	-	-	Enable/disable the external antenna. With the RF620R, either only the internal or only the external antenna can be set.
Transmit power ANT 1 (RF630R)	0 - 9	4	Setting the transmit power for antenna 1 [1] [2]
Transmit power ANT 2 (RF630R)	0 - 9	4	Setting the transmit power for the antenna 2 [1] [2]
Communications speed	Reliable detection Fast detection	Reliable detection	[1]
Tag hold	On Off	Off	Enable/disable "Tag hold" [1]
Scanning mode	On Off	Off	Enable/disable the "Scanning mode" [1]
Channel assignment (only with wireless profile ETSI)	-	-	Selection of the wireless channels to be used [1]

[1] You will find further information in the "Configuration manual RF620R/RF630R". *

[2] The values for the transmit/radiated power of the antennas can be found in the following table.

***** You will find the configuration manual RF620R/RF630R here (http://support.automation.siemens.com/WW/view/en/10805817).

Table 10-83 Transmit / radiated power of the antennas

Hex value	RF630R transmit power	RF620R radiated power (internal antenna)			RF620R transmit power
	dBm / (mW)	ETSI dBm / (mW) ERP	FCC dBm / (mW) EIRP	CMIIT dBm / (mW) ERP	dBm / (mW)
0	18 / (63)	18 / (63)	20 / (100)	18 / (65)	18 / (63)

B (...F)	27 / (501)	29 / (794)	31 / (1259)	29 / (794)	27 / (501)

SLG D10S

Table 10-84 SLG D10S

Parameter	Parameter value	Default value	Description
RF power	0.50 - 10.00 W	1.00 W	Setting for the output power of the reader.
Transponder type	ISO I-Code (e.g. MDS D139)	ISO	Selection of the transponders used.

SLG D11S/D12S

Table 10-85 SLG D11S/D12S

Parameter	Parameter value	Default value	Description
Transponder type	ISO I-Code (e.g. MDS D139)	ISO	Selection of the transponders used.

MOBY U

Table 10-86 MOBY U

Parameter	Parameter value	Default value	Description
Standby time	0 - 1400 ms	0 ms	Standby time (scanning_time) for the transponder. If the transponder receives a further command before the standby time has elapsed, this command can be executed immediately. If the transponder receives a command after standby time has elapsed, command execution is delayed by the "sleep_time" of the transponder.
Range limitation	0.2 m 0.5 m 1.0 m 1.5 m 2.0 m 2.5 m 3.0 m 3.5 m	1.5 m	-
Max. no. of transponders	1 - 12	1	Maximum number of transponders that can be processed at the same time in the antenna field.
BERO mode	Without BEROs 1 or 2 BEROs 1st BERO on, 2nd BERO off Synchronization by cable connection	Without BEROs	• Without BEROs No reader synchronization • 1 or 2 BEROs The BEROs are logically ORed. The antenna field is turned on during the actuation of a BERO. • 1st BERO on, 2nd BERO off 1st BERO turns on the antenna field and the 2nd BERO turns the antenna field off. If there are two BEROs present and "BERO time in s" is set, the antenna field is turned off automatically if the 2nd BERO does not switch within this BERO time. If no "BERO time in s" is set, the antenna field remains turned on until the 2nd BERO is activated. • Synchronization by cable connection Enable reader synchronization via cable connection (see manual on configuration, installation and service for MOBY U).
BERO time in s	0 - 255 s	0 s	Can only be set if the BERO mode is set to "1st BERO on, 2nd BERO off". • 0 The time monitoring is disabled. To turn off the field, the 2nd BERO is required. • 1 ... 255 s Operating time for the reader field

General Reader

Table 10-87 General Reader

Parameter	Parameter value	Default value	Description
Input box for byte sequence (hexadecimal)	00000000	00000000	Expert mode With this function, you can specify the reset parameters directly in hexadecimal notation. This setting may only be selected if you have previously received the hexadecimal string for the setting from a member of the SIEMENS staff.

Parameters via FB / code readers

Table 10-88 Parameters via FB / code readers

Parameter	Parameter value	Default value	Description
MOBY mode	RF200, RF300, RF600, MOBY D/U, MV	RF200, RF300, RF600, MOBY D/U, MV	Only the mode "RF200, RF300, RF600, MOBY D/U, MV" is supported. For further information on resetting a function block, refer to the documentation for the RF120C communications module with application blocks for S7-1200 and S7-1500. *

* You will find information on the documentation here (http://support.automation.siemens.com/WW/view/en/10805817).

ASM 475

What you should know about the ASM 475

Introduction

Up to eight ASM 475 interface modules can be plugged in and operated in a rack of the SIMATIC S7-300. If you have a configuration with several racks (max. four racks), the ASM 475 can be plugged in and operated in each rack. This means that with the maximum configuration of a SIMATIC S7-300, 32 ASM 475 modules can be operated.

A maximum of two SLGs (write/read devices) can be connected to the ASM 475. The processing of the connected SLGs is parallel. FC45 allows simple programming using the SIMATIC S7 tools.

FC45 can be used both in the S7-300 and S7-400.

With S7-400, the ASM 475 is connected via an ET 200M.

Note that the

- IM 153-1 must have at least order number 6ES7 153-1AA03-0XB0 or 6ES7 153-1AA83-0XB0 and
- IM 153-2 at least order number 6ES7 153-2AA02-0XB0 or 6ES7 153-2AB01-0XB0.

Access to the MDS data is with normal addressing.

Physical addressing of the MDS (mobile data storage)

The physical addressing of an MDS is also known as **normal addressing**. Users set up the structure of the MDS themselves. They know the physical MDS address to which data is written. The addressing of the MDS storage generally begins at 0000 hex and ends at an end address corresponding to the size of the MDS storage.

File handler addressing of the MDS

For file handler addressing, the user specifies a file name for access to the data. The file name consists of eight ASCII characters. The file handler manages the user data independently on the MDS. The user does not need to configure data structures on the MDS.

Prior to use, the MDS needs to be formatted.

10.1.6.3 Distributed I/O

Distributed I/O systems

SIMATIC ET 200 - The right solution for all applications

SIMATIC ET 200 provides the most varied range of distributed I/O systems.

- Solutions for use in the control cabinet
- Solutions without control cabinet directly at the machine

Additionally, there are also components that can be used in explosive areas. SIMATIC ET 200 systems for construction without a control cabinet are contained in robust, glass-fibre reinforced plastic casing and are therefore shock-resistant, resistant to dirt and watertight.

Their modular design allows the ET 200 systems to be easily scaled and expanded in small steps. Fully-integrated auxiliary modules lower costs and also provide a wide range of possible applications. There are several combination possibilities available:

- Digital and analog I/OS
- Intelligent modules with CPU functions,
- Safety technology,
- Pneumatics,
- Frequency converters
- Various technology modules.

Communication via PROFIBUS and PROFINET, uniform engineering, clear diagnostic possibilities as well as optimal connection to SIMATIC controller and HMI devices vouch for the unique consistency provided by Totally Integrated Automation.

The following table provides an overview of I/O devices for use in the control cabinet:

I/O device	Properties
ET 200S	• Highly modular design with multiple conductor connections • Multifunctional due to a wide range of modules • Use in explosive areas (Zone 2)
ET 200S COMPACT	• Highly modular design with multiple conductor connections • Multifunctional due to a wide range of modules • Use in explosive areas (Zone 2) • Integrated DE/DA
ET 200L	• Cost-effective digital block I/OS • Digital electronic blocks up to 32 channels
ET 200M	• Modular design with standard modules from SIMATIC-S7-300 • Failsafe I/O modules • Use in explosive areas up to Zone 2, sensors and actuators up to Zone 1 • High level of plant availability, for example by plugging and unplugging when in operation
ET 200iSP	• Modular design, also possible with redundancy • Robust and intrinsically safe design • Use in explosive areas up to Zone 1/21; sensors and actuators even up to Zone 0/20 • High level of plant availability, for example by plugging and unplugging when in operation

The following table provides an overview of I/O devices for use without a control cabinet:

I/O device	Properties
ET 200pro	• Modular design with compact housing • Easy assembly • Multifunctional due to a wide range of modules • High level of availability due to plugging and unplugging in operation and permanent wiring • Comprehensive diagnostics
ET 200eco PN	• Cost-efficient, space-saving block I/OS • Digital modules up to 16 channels (also configurable) • Analog modules, IO-link master and load voltage distributor • PROFINET connection with 2-port switch in each module • Can be flexibly distributed via PROFINET in line or star shape directly within the plant
ET 200eco	• Cost-effective digital block I/OS • Flexible connection possibilities • Failsafe modules • High level of plant availability
ET 200R	• Specially for use on robots • Assembled directly on the chassis • Resistant to weld spatter due to robust metal housing

Configuring HART variables

Introduction

Numerous HART field devices make available additional measured quantities (e.g. sensor temperature). These can be read if they are set accordingly in the field device configuration. Using the HART variables. it is possible to apply the set measured values directly from the field device into the I/O area of your automation system.

Regardless of the number of configured channels, a maximum of 8 HART variables can be assigned for HART modules and no more than 4 HART variables per channel. You assign the HART variables to a channel in the properties for the module ("HART variable settings" area). To do this, check the manual of the corresponding module.

Address assignment

By default, the HART modules occupy 16 input/output bytes (user data). If you configure HART variables, the modules occupy an additional 5 bytes for each HART variable.

If you use all 8 HART variables, the HART input module occupies a total of 56 input/output bytes (16 bytes + 8 x 5 bytes = 56 bytes).

The "None" configuration occupies no additional input bytes.

Configuration of HART variables

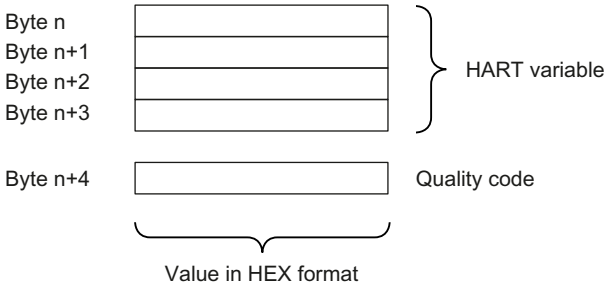
You can configure up to 4 HART variables for a channel

- PV (Primary Variable)
- SV (Secondary Variable)
- TV (Tertiary Variable)
- QV (Quaternary Variable)

CiR is a placeholder that reserves the address space for a HART variable. You must configure the HART variables you are not using with the "None" parameter.

Configuration of HART variables

Each HART variable occupies 5 bytes of input data and is structured as follows:



The quality code can accept different values depending on the module. To do this, check the manual of the corresponding module.

Documentation for HART analog modules (http://support.automation.siemens.com/WW/view/en/22063748)

ET 200iSP

ET 200iSP Distributed I/O Station

Definition

The ET 200iSP distributed I/O station is a highly modular and intrinsically safe DP slave with degree of protection IP 30.

Area of application

The ET 200iSP distributed I/O station can be operated in potentially explosive atmospheres characterized by gas and dust:

Approval	ET 200iSP Station*	Inputs and outputs
ATEX	Zone 1, Zone 21	up to Zone 0, Zone 20 **
IECEx	Zone 2, Zone 22	up to Zone 0, Zone 20 **
* In combination with an appropriate enclosure ** for electronic module 2 DO Relay UC60V/2A: up to Zone 1, Zone 21		

The ET 200iSP distributed I/O station can, of course, also be used in the safety area.

You can insert almost any combination of ET 200iSP I/O modules directly next to the interface module that transfers the data to the DP master. This means you can adapt the configuration to suit your on-site requirements.

Every ET 200iSP consists of a power supply module, an interface module and a maximum of 32 electronic modules (for example digital electronics modules). Remember not to exceed the maximum current consumption.

Terminal modules and electronic modules

In principle, the ET 200iSP distributed I/O station consists of various passive terminal modules onto which you plug the power supply and the electronic modules.

The ET 200iSP is connected to PROFIBUS RS 485-IS by means of a connector on terminal module TM-IM/EM. Every ET 200iSP is a DP slave on the PROFIBUS RS 485-IS.

DP master

All ET 200iSP modules support communication with DP masters that are compliant with *IEC 61784-1:2002 Ed1 CP 3/1* and operate with "DP" transmission protocol (DP stands for distributed peripherals or distributed I/O).

Documentation on ET 200iSP (http://support.automation.siemens.com/WW/view/de/28930789/0/en)

Assigning the channel and IEEE tag

Properties

Analog electronic modules 4 AI I 2WIRE/HART, 4 AI I 4WIRE/ HART and 4 AO I HART support up to four IEEE tags.

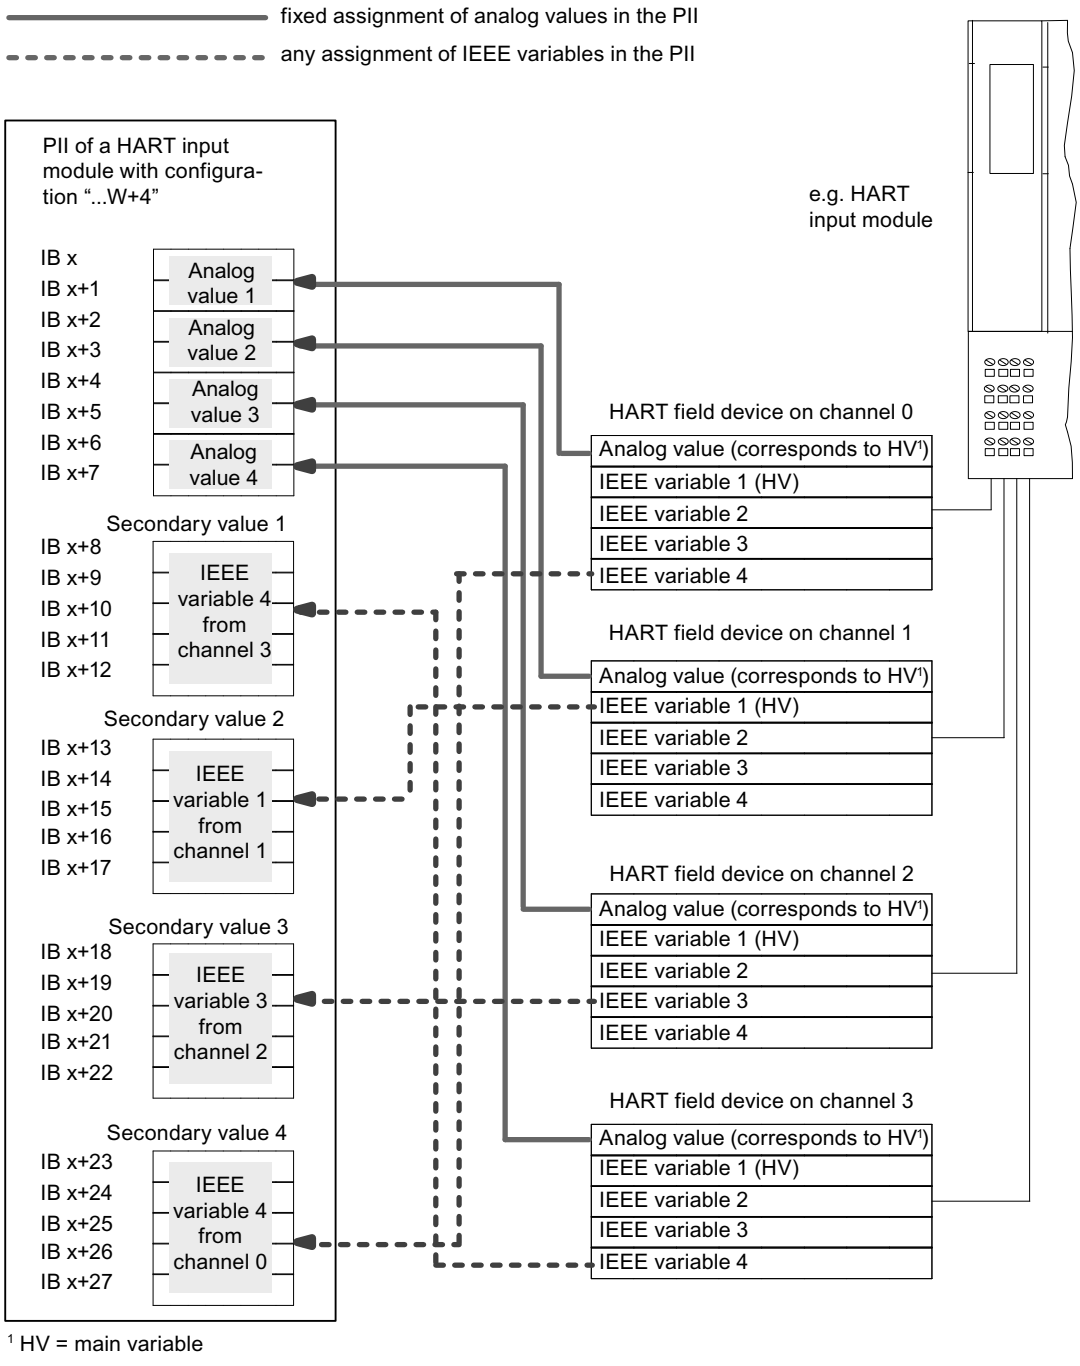
The process input image (PII) provides up to 20 bytes per module for the IEEE tags. Thus, four blocks of 5 bytes each are available for the four IEEE tags within the PII.

Requirements

The HART field device must support the assigned number of IEEE tags.

Assigning IEEE tags

You assign the IEEE tags of the field devices to any one of the four blocks in the PII.



[1] HV = main variable

Assigning parameters to reference junctions for thermocouples

Compensation of the reference junction temperature

There are various ways of obtaining the reference junction temperature in order to get an absolute temperature value from the temperature difference between the reference junction and the measuring point.

Table 10-89 Compensation of the reference junction temperature

Option	Explanation	Reference junction parameters
No compensation	You record not only the temperature of the measurement point. The temperature of the reference junction (transition from Cu line to thermocouple line) also affects the thermo-electromotive force. The measured value then includes an error.	None
Use of a Pt100 Climatic Range resistance thermometer to record the reference junction temperature (best method)	You can record the reference junction temperature using a resistance thermometer (Pt100 Climatic Range). If parameterized accordingly, this temperature value is distributed to the 4 AI TC modules in the ET 200iSP where it is offset against the temperature value obtained at the measuring location. Number of reference junctions: 2	The parameter assignment of the IM 152 and the 4 AI TC must be coordinated: • 4 AI RTD assigned parameters for Pt100 climatic range in correct slot; • 4 AI TC: Reference junction : "yes"; select reference junction number "1" or "2" • IM 152-1:Assignment of the reference junction to a slot with 4 AI RTD; channel selection;
Internal compensation 4 AI TC	The TC sensor module (temperature sensor) is mounted onto the terminals of terminal module EM 4 AI TC. The temperature sensor reports the temperature of the terminals to the 4 AI TC. This value is then calculated together with the measured value from the channel of the electronic module.	• 4 AI TC: Reference junction number "internal"

Compensation by means of a resistance thermometer at the 4 AI RTD

If thermocouples that are connected to the inputs of the 4 AI RTD have the same reference junction, compensate by means of a 4 AI RTD.

For both channels of the 4 AI TC module, you can select "1", "2" or "internal" as the reference junction number. If you select "1" or "2", the same reference junction (RTD channel) is always used for all four channels.

Setting parameters for the reference junction

You set the reference junctions for the 4 AI TC electronic modules by means of the following parameters:

Table 10-90 Reference junction parameters

Parameter	Module	Range of values	Explanation
Slot reference junction 1 to slot 2	IM 152	none, 4 to 35	With this parameter, you can assign up to 2 slots (none, 4 to 35), on which the channels for reference temperature measurement (calculating the compensation value) are located.
Input reference junction 1 to 4 input reference junction	IM 152	RTD on channel 0 RTD on channel 1 RTD on channel 2 RTD on channel 3	This parameter allows you to set the channel (0/1/2/3) for measuring the reference temperature (calculation of the compensation value) for the assigned slot.
Reference junction E0 to reference junction E3	4 AI TC	None yes	This parameter allows you to enable the use of the reference junction.
Reference junction number	4 AI TC	1 2 Internal	This parameter allows you to assign the reference junction (1, 2) that contains the reference temperature (compensation value).

Fundamentals of Time Stamping

Properties

Time stamping is possible with the IM 152 in customer applications using FB 62 (FB TIMESTMP).

Principle of operation

A modified input signal is assigned a time stamp and stored in a buffer (data record). If time stamped signals exists or a data record is full, a hardware interrupt is generated to the DP master. The buffer is evaluated with "Read data record". Special messages are generated for events that influence the time stamping (communication with the DP master interrupted, frame failure of time master, ...).

Parameter Assignment

With the parameter assignment you define which IM 152 user data will be monitored. For the time stamping these are digital inputs that are monitoring for signal changes.

Parameter	Setting	Description
Time stamping	• disabled • enabled	Activate the time staming for the channels of the electronics module 8 DI NAMUR.
Edge evaluation incoming event	• rising edge • falling edge	Determine the type of signal change that will be time-stamped.

Counting

Count properties

Counting functions

The 8 DI NAMUR electronics module has configurable counting functions:

- 2 x 16-bit up counters (standard counting function) or
- 2 x 16-bit down counters (standard counting function) or
- 1 x 32-bit down counter (cascading counter function)
- Setting a setpoint with the PIQ
- GATE function
- You can configure the control signals of the counters:
  - Configuration channel 0..1: "Counter", channel 2..7: "DI": Two counters are configured. The control signals of the counters are stored in the PIQ (process image output).
  - Configuration channel 0..1: "Counter", channel 2..7: "Control": Two counters are configured. The control signals of the counters are stored in the PIQ (process image output). They are also controlled by the digital inputs of the 8 DI NAMUR.

Principle of operation (Page 1253)

Configuring counters (Page 1256)

Assigning parameters to counters (Page 1258)

Principle of operation

16-bit up counters (standard counting function)

The counting range is 0 to 65,535.

With each count pulse at the digital input, the count is incremented by 1. Once the count limit is reached, the counter is reset to 0 and it counts up again from this value.

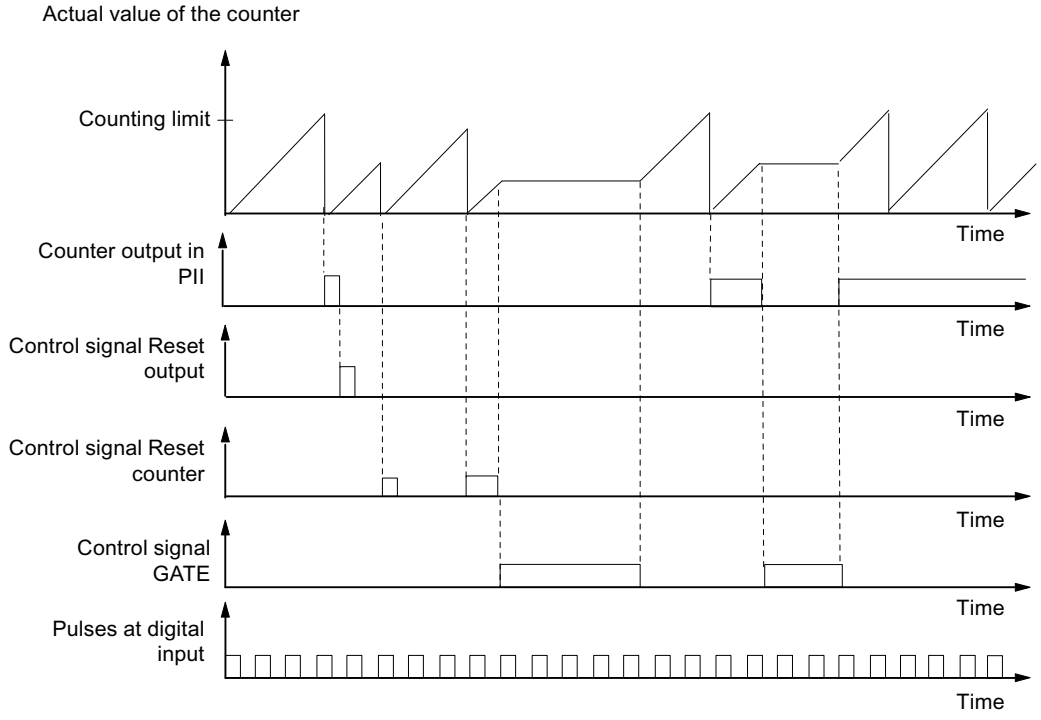
If there is counter overflow, the corresponding output is set in the PII.

A positive edge of the *Reset output* control signal resets the output in the PII. This does not affect the current count value.

In 16-bit up counting operations, the system does not set any outputs in the PIQ. These are always reset.

The positive edge of the *Reset counter* control signal sets the counter to 0 and resets the set counter output.

The *GATE* control signal pauses the counting on a positive edge. Count pulses are processed at the digital input again, but only at the negative edge. The *Reset counter* control signal is also effective when *GATE* is active.



16-bit down counters (periodic counting function)

The maximum counting range is always 65,535 to 0.

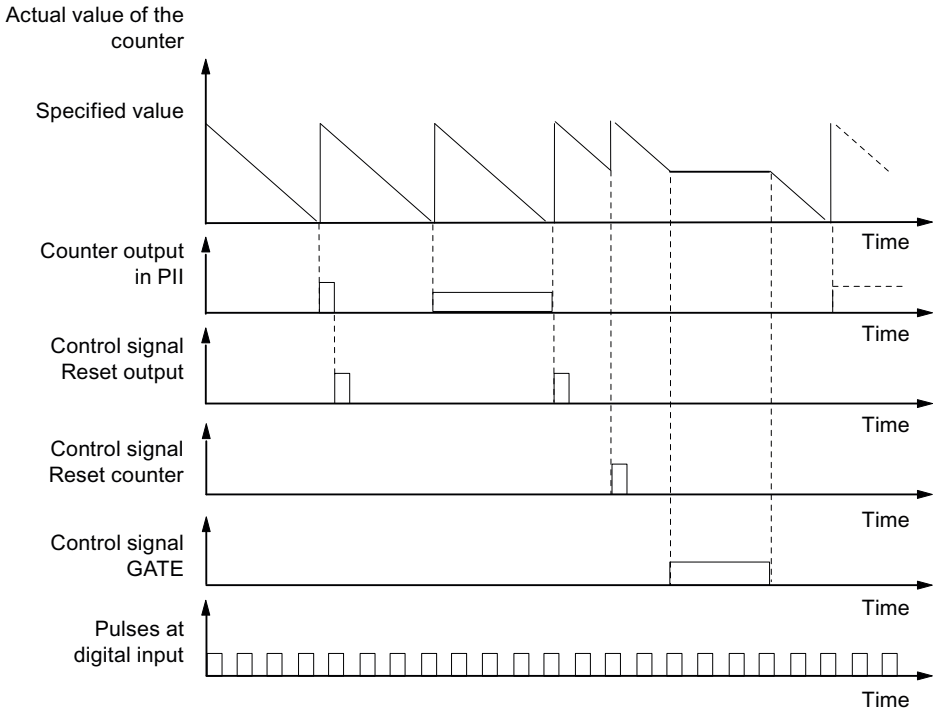
When the counter is started, the actual value is set to the selected setpoint. Each counted pulse reduced the actual value by 1. Once the actual value reaches 0, the corresponding output in the PII is turned on and the actual value is set to the selected setpoint. The counter then counts down from this value.

The positive edge of the *Reset counter* control signal resets the selected setpoint and the corresponding output in the PII.

A positive edge of the *Reset output* control signal resets the output in the PII. This does not affect the current count value.

The *GATE* control signal pauses the counting on a positive edge. At the same time, the assigned output in the PII is reset. Count pulses are processed at the digital input again, but only at the negative edge. The *Reset output* and *Reset counter* control signals are also effective when *GATE* is active.

The setpoint of the counter is set and changed using the PIQ. The setpoint is adopted on a positive edge of the *Reset counter* control signal or when the counter has reached zero.



32-bit down counter (cascading counter function)

The maximum counting range is always 4294967295 to 0.

The principle of operation is identical to that of the 16-bit down counter. Channel 1 has no function.

Count properties (Page 1253)

Configuring counters

Procedure

1. Using the mouse, pull module 8 DI Namur from the hardware catalog into distributed I/O station ET 200iSP.
2. Select the required configuration (channel 0..1: "Counter", channel 2..7: "DI" or "Control"). In the module properties (inspector window), you can find this setting under "Parameters > Inputs > Configuration".

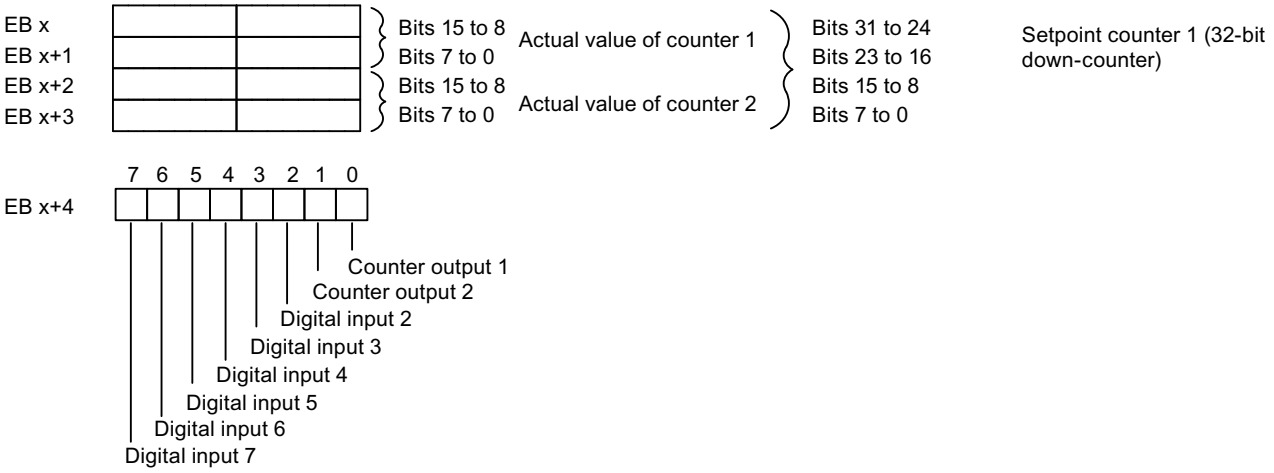
Configuration channel 0..1: "Counter", channel 2..7: "DI"

- Assignment of the digital inputs on the electronic module 8 DI NAMUR

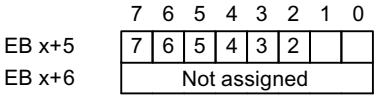
Table 10-91 Assignment of digital inputs for channel 0..1: "Counter", channel 2..7: "DI":

Digital input	Terminal	Assignment
Channel 0	1, 2	Counter 1
Channel 1	5, 6	Counter 2 (does not apply to 32-bit down counters)
Channel 2	9, 10	Digital input 2
Channel 3	13, 14	Digital input 3
Channel 4	3, 4	Digital input 4
Channel 5	7, 8	Digital input 5
Channel 6	11, 12	Digital input 6
Channel 7	15, 16	Digital input 7

- Assignment of the process image input (PII)

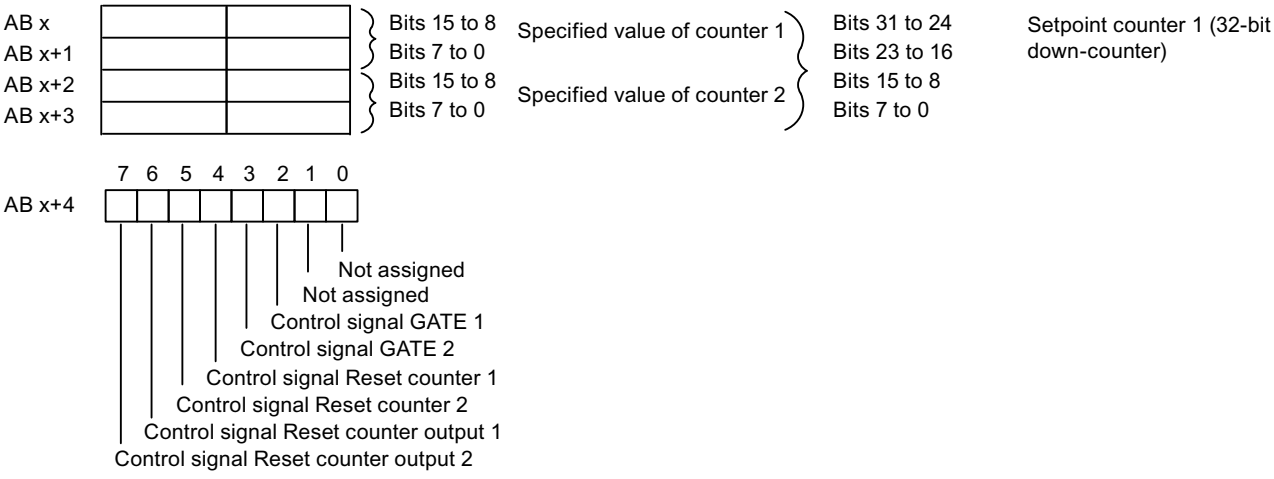


S7 format



Value status for channels 2 to 7:
1_B: Input signal is valid
0_B: Input signal is invalid

- Assignment of the process image output (PIQ)



Configuration channel 0..1: "Counter", channel 2..7: "CONTROL"

With this configuration, you can also control the counters over the digital inputs.

- Assignment of the digital inputs on electronic module 8 DI NAMUR
  For further information on input assignments, refer to the technical data for electronic module 8 DI NAMUR.

Table 10-92 Assignment of the digital inputs for 2 Count/ 6 Control

Digital input	Terminal	Assignment
Channel 0	1, 2	Counter 1
Channel 1	5, 6	Counter 2 (does not apply to 32-bit down counters)
Channel 2	9, 10	control signal *GATE 1*
Channel 3	13, 14	control signal *GATE 2*
Channel 4	3, 4	control signal *Reset counter 1*
Channel 5	7, 8	control signal *Reset counter 2*
Channel 6	11, 12	control signal *Reset counter output 1*
Channel 7	15, 16	control signal *Reset counter output 2*

- Assignment of the process image input (PII)
  Assignment is identical to configuration 0..1: "Counter", channel 2..7: "DI".
- Assignment of the process image output (PIQ)
  Assignment is identical to configuration 0..1: "Counter", channel 2..7: "DI".

Count properties (Page 1253)

Frequency measurement

Frequency measurement properties

Properties

The electronic module 8 DI NAMUR allows the frequencies to be measured on channel 0 and 1:

- 2 frequency meters from 1 Hz to 5 kHz
- Configurable metering window (GATE)
- The signals of the frequency meter are read in by means of the digital inputs of the electronic module.

See also

Principle of operation (Page 1259)

Configuring frequency meters (Page 1260)

Assigning parameters for the frequency meters (Page 1262)

Principle of operation

Frequency measurement

The signal frequencies are identified from the input signals of channel 0 or 1 of the electronic module. To calculate the frequency the signals are measured within a configurable gate.

The frequency is displayed as 16-bit value in fixed-point format and transferred to the PII.

The frequency meter calculates the frequency according to the follow formula:

$$\text{Frequency [Hz]} = \frac{\text{Number of rising edges at digital input}}{\text{Measuring window [s]}}$$

Exceeding the input frequency

If the input frequency exceeds 5kHz, $7FFF_H$ is reported as actual value. If the input frequency is above approx. 8 kHz it is no longer possible to display correct actual values.

ET 200eco PN

ET 200eco PN Distributed I/O Device

Definition

The ET 200eco PN distributed I/O device is a compact PROFINET IO device in degree of protection IP 65/66 or IP 67 and UL Enclosure Type 4x, Indoor use only.

Field of application

The fields of application of the ET 200eco PN are derived from its special properties.

- A robust design and degree of protection IP 65/66 or IP 67 make the ET 200eco PN distributed I/O device suitable in particular for use in rugged industrial environments.
- The compact design of the ET 200eco PN is particularly favorable for applications in confined areas.
- The easy handling of ET 200eco PN facilitates efficient commissioning and maintenance.

Properties

The ET 200eco PN has the following properties:

- Integrated switch with 2 ports
- Supported Ethernet services:
  - ping
  - arp
  - Network diagnostics (SNMP)
  - LLDP
- Interrupts
  - Diagnostics interrupts
  - Maintenance interrupts
- Port diagnostics
- Isochronous real-time communication
- Prioritized startup
- Device replacement without programming device
- Media redundancy
- Connection to intelligent sensors/actuators via IO link master interface module.

IO Controller

The ET 200eco PN can communicate with all IO Controllers that conform to IEC 61158.

ET 200eco PN can be configured on a CPU with advanced diagnostics.

Documentation on ET 200eco PN (http://support.automation.siemens.com/WW/view/en/29999018)

Parameter description analog input

Group diagnostics

You can generally enable and disable the diagnostics function of the device with this parameter.

The "Fault" and "Parameter assignment error" diagnostics functions are always independent of the group diagnostics.

Diagnostics, missing 1L+

If you enable this parameter, the check for missing supply voltage is enabled.

Diagnostics, sensor supply short circuit

If you enable this parameter, a diagnostics event is generated if a short-circuit of the sensor supply to ground is detected and the channel is enabled. The sensor supply is monitored for connectors X1, X3, X5 and X7. It is not possible to differentiate which connector has experienced the sensor short circuit.

Interference frequency suppression

With this parameter, you set the integration time of the device, based on the selected interference frequency. Select the frequency of the supply voltage used. Interference frequency suppression **Off** means 500 Hz, which corresponds to an integration time of 2 ms for a measurement channel.

Temperature unit

Specify the unit of the temperature measurement here.

Measurement type (channel-wise)

With this parameter, you set the measurement type, for example, voltage. For any unused channels, you must select the **disabled** setting. For a disabled channel, the conversion time and integration time of the channel = 0 s and the cycle time is optimized.

Measuring range

With this parameter, you set the measuring range of the selected measurement type.

Temperature coefficient (for RTD, thermoresistor)

The correction factor for the temperature coefficients (α-value) indicates by what extent the resistance of specific material changes relatively if the temperature increases by 1 °C.

The α-values conform to EN 60751, GOST 6651, JIS C 1604 and ASTM E-1137.

The temperature coefficient depends on the chemical composition of the material.

Smoothing

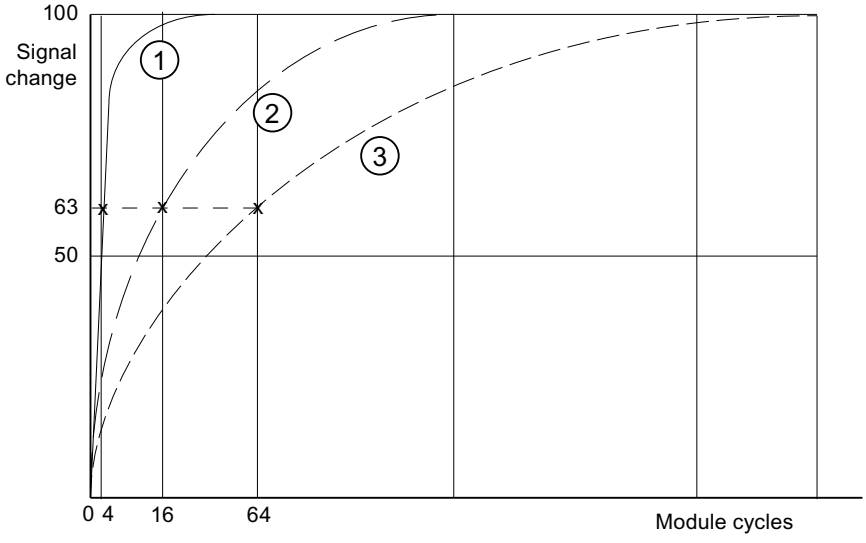
Smoothing of the analog values produces a stable analog signal for further processing. The smoothing of analog values is useful when handling wanted signals (measured values) with a slow rate of change, for example, temperature measurements.

The measured values are smoothed by digital filtering. To achieve smoothing, the device generates a mean value from a specified number of converted (digitized) analog values.

You assign a maximum of four levels for the smoothing (none, weak, medium, strong). The level determines the number of module cycles, from which the mean value is generated.

The stronger the smoothing, the more stable the smoothed analog value and the longer it takes until the smoothed analog value is applied following a signal change (see the example below).

The figure below shows the number of cycles a module requires to apply the smoothed analog value at almost 100% after a step response, based on the smoothing function settings. The figure applies to all signal changes at the analog input. The smoothing value defines the number of cycles a module requires to reach 63% of the end value of the changed signal.



① Smoothing, weak
② Smoothing, medium
③ Smoothing, strong

Diagnostics, wire break

When this parameter is enabled, the **Wire break** diagnostics event is generated when a wire break is detected.

Observe the rules outlined below to handle a wire break in the 1 to 5 V and 4 to 20 mA measuring ranges:

Parameter	Event	Measured value	Explanation
Enable wire break[1]	Wire break	$7FFF_H$	Diagnostics, **wire break**
Wire break disabled[1] Underflow enabled	Wire break	8000_H	Measured value after leaving the underrange Diagnostic message **Lower limit value undershot**
Wire break disabled[1] Underflow disabled	Wire break	8000_H	Measured value after leaving the underrange
[1] Measuring range limits for wire break detection and measuring range undershoot detection: • 1 to 5 V: At 0.296 V • 4 to 20 mA: At 1.185 mA			

Diagnostics, underflow

If you enable this parameter, the **Underflow** diagnostics event is generated when the measured value reaches the underflow range.

Diagnostics, overflow

If you enable this parameter, the **Overflow** diagnostics event is generated when the measured value reaches the overflow range.

Reference junction for thermoresistor (TC)

A difference in temperature between the measuring point and the free ends of the thermocouple (terminal point) generates a voltage between the free ends, namely the thermoelectric voltage. The value of this thermoelectric voltage is determined by the temperature difference between the measuring point and the free ends and by the type of material combination of the thermocouple. Since a thermocouple always measures a temperature difference, the free ends at the reference junction must be maintained at a known temperature in order to determine the temperature of the measuring point.

If you specify **Internal compensation**, the temperature of the measuring point in the housing of the I/O device is measured. With the **External compensation** setting, you can connect a compensation box in series in order to increase the accuracy of the temperature measurement.

Parameter description analog output

Group diagnostics

You can generally enable and disable the diagnostics function of the device with this parameter.

The "Fault" and "Parameter assignment error" diagnostics functions are always independent of the group diagnostics.

Diagnostics, missing 1L+

If you enable this parameter, the check for missing supply voltage is enabled.

Diagnostics, sensor supply short circuit

When this parameter is enabled, the system generates a diagnostics event if it detects a short-circuit of the sensor supply to ground. This diagnostics function is activated when the group diagnostics function is enabled.

Response to CPU/Master STOP

Select how the module's outputs will respond to a CPU STOP:

- Shut down
  The I/O device goes to the safe state. The process image output is deleted (=0).
- Keep last value
  The I/O device retains the last value to be output before STOP.
- Substitute value
  The I/O device outputs the value for the channel set beforehand.

Note

Make sure that the plant is always in a safe state if "Keep last value" is selected.

Type of output

With this parameter, you set the output type, for example, voltage. For any unused channels, select the **disabled** setting. For a disabled channel, the conversion time and integration time of the channel = 0 s, and the cycle time is optimized.

Output range

With this parameter, you set the output range of the selected output type.

Diagnostics, wire break (in current mode)

When this parameter is enabled, the **Wire break** diagnostics event is generated when a wire break is detected. This diagnostics event cannot be detected in the zero range.

Diagnostics, short circuit (in voltage mode)

If you enable this parameter, a diagnostics event is generated in the event of a short circuit in the output line. This diagnostics event cannot be detected in the zero range.

Diagnostics, overload

If you enable this parameter, the diagnostics event is generated in the event of an overload.

Substitute values

With this parameter, you enter a substitute value that the module is to output in CPU-STOP mode. The substitute value must be in the nominal range, overrange, or underrange.

ET 200SP

ET 200SP distributed I/O system

Definition

The ET 200SP distributed I/O system is a scalable, highly flexible distributed I/O system for connection of process signals to a central controller via a field bus.

Application area

The ET 200SP is a multi-functional distributed I/O system for various fields of application. The scalable design allows you to configure the system exactly to the specific requirements on location.

The ET 200SP is approved for degree of protection IP 20 and for installation in a control cabinet.

Structure

The ET 200SP is mounted on a mounting rail and comprises:

- An interface module which can communicate with all IO controllers that conform to the PROFINET standard IEC 61158
- Up to 32 I/O modules which can be inserted on passive BaseUnits in any combination
- A server module that completes the design of the ET 200SP.

Expanding ET 200SP with ET 200AL modules

Introduction

The ET 200SP is a distributed I/O system for installation in a control cabinet.

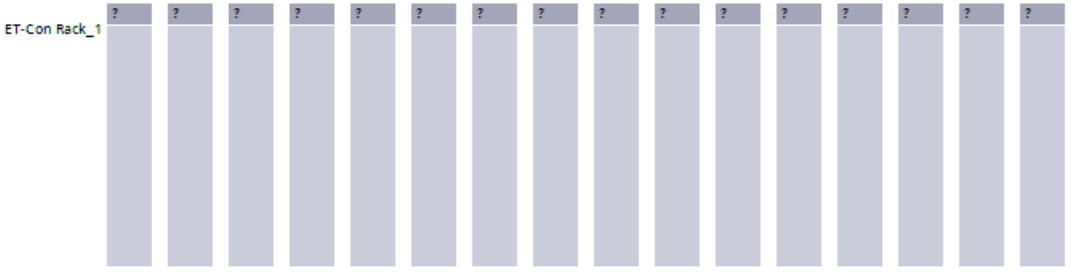
The system can be expanded with modules of the ET 200AL series with IP65/67 degree of protection. ET 200AL modules can be mounted on site, for example on a machine.

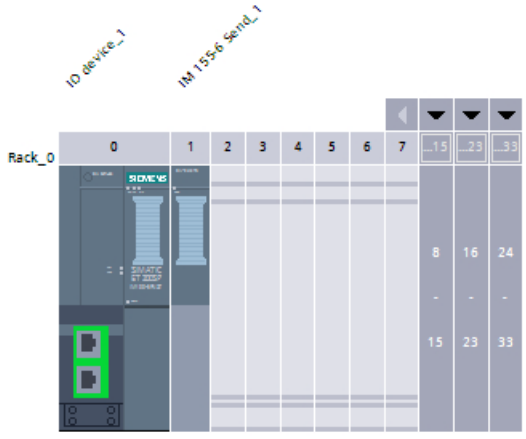
The following section describes how you expand an ET 200SP station with ET 200AL modules in STEP 7.

Procedure

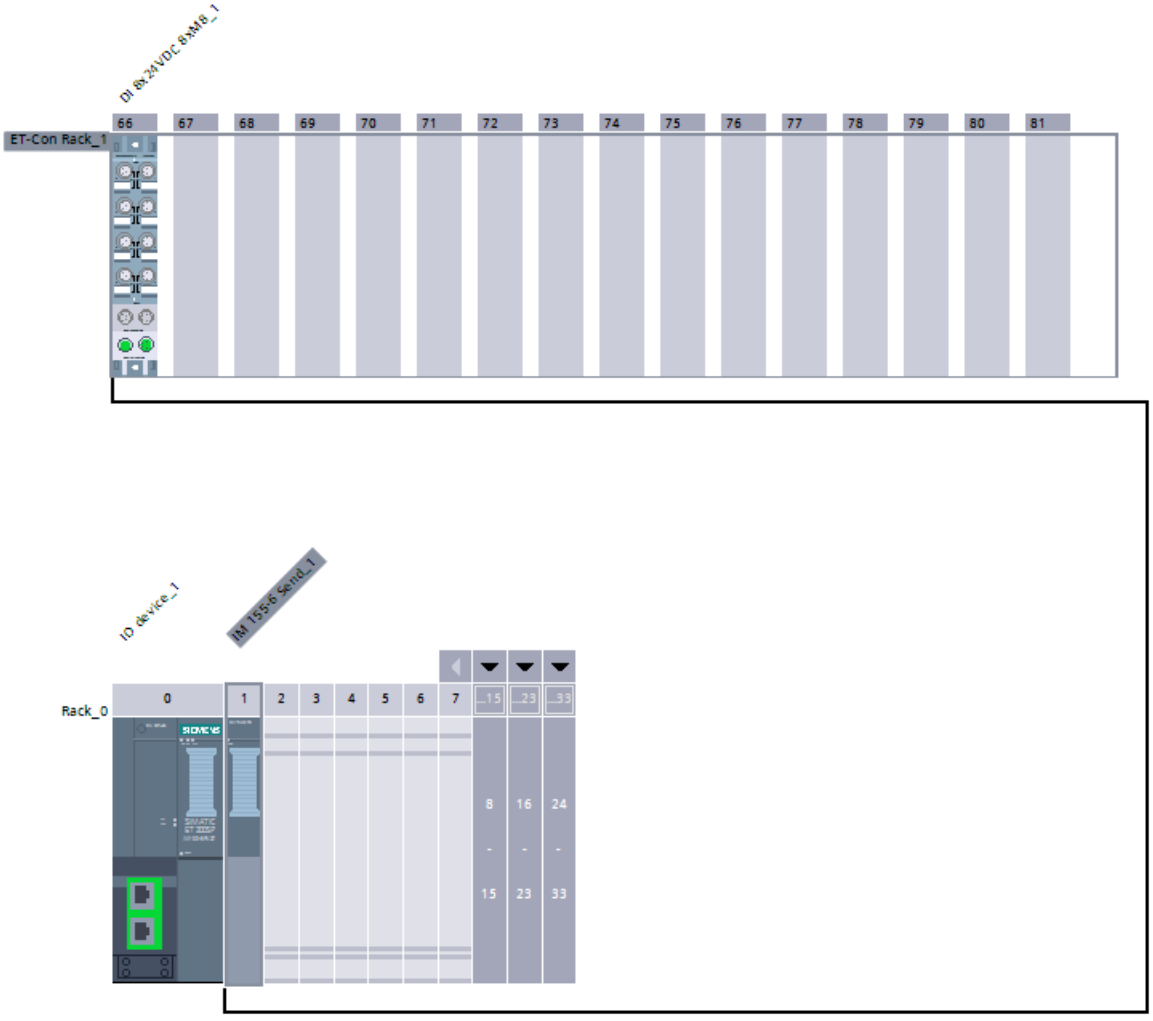
Follow the steps below to configure an ET 200SP with ET 200AL modules:

1. Drag an interface module (PROFINET or PROFIBUS) from the ET 200SP series to the network view.
2. Go to the device view. You do this by clicking twice on the icon of the module you have just inserted.
3. Insert the module "BA Send 1xFC" into slot 1 of the ET 200SP.
   STEP 7 now generates an ET-Connection rack with 16 slots for ET 200AL modules (figure below).
   An ET-Connection rack is a virtual rack that sets the order of the connected ET 200AL modules.
   Question marks are displayed above the slots as an ET 200AL module has yet to be connected to BA-Send.

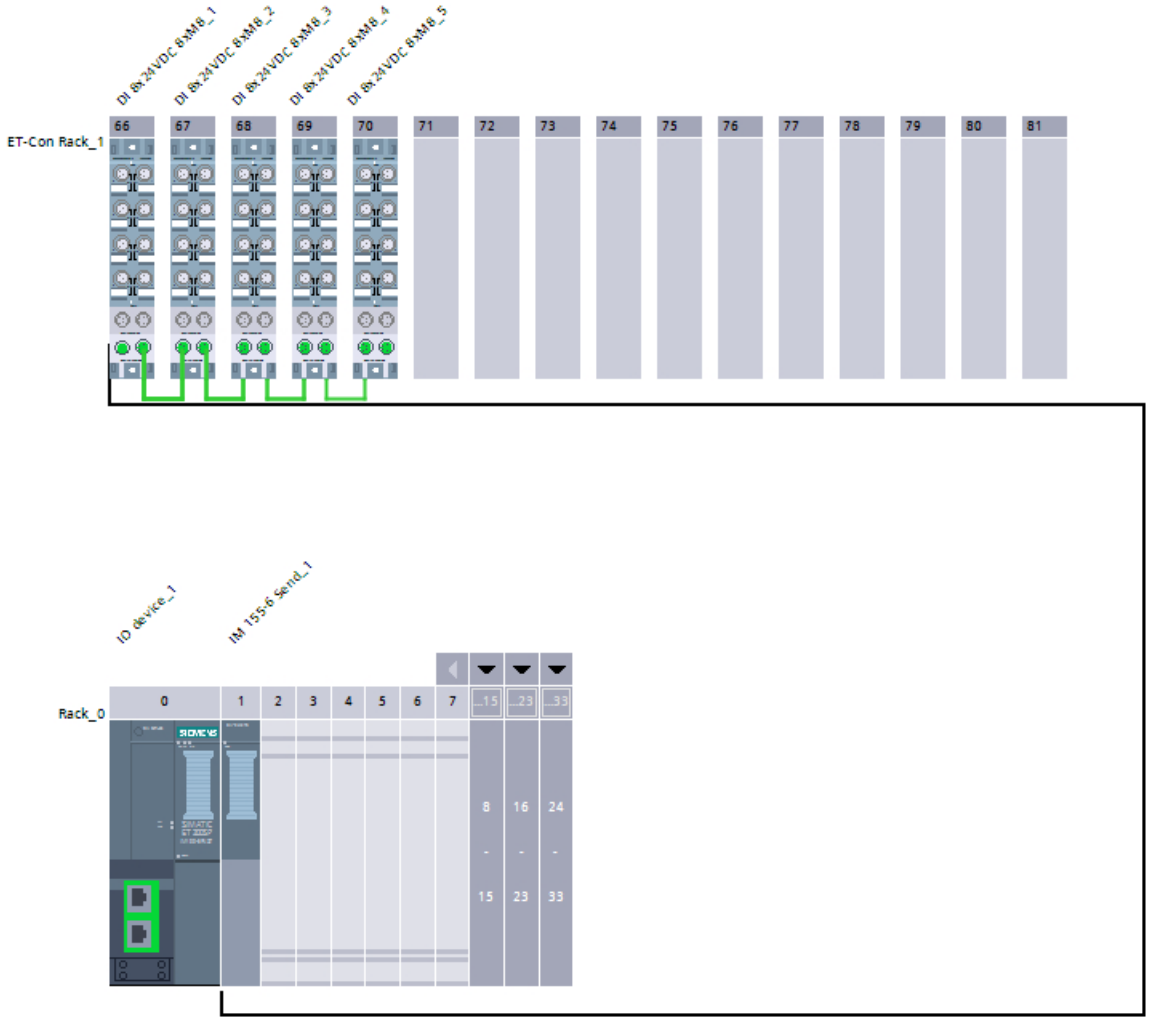




4. From the hardware catalog (subfolder ET 200AL in the ET 200SP folder), select the first ET 200AL module to be connected to the ET 200SP: Drag this module to the 1st slot in the ET-Connection rack.
   From this module, STEP 7 generates a line to the "BA-Send 1xFC" module and allocates the slot numbers 66 to 81 (figure below).
   If you configure the ET 200SP with a DP interface module, STEP 7 assigns the slot numbers 34 to 49 for the ET 200AL modules.



5. Now drag all other ET 200AL modules into the free slots in the ET-Connection rack.
   STEP 7 automatically inserts the ET-Connection between the individual ET 200AL modules (green loops).
   In the configuration below, five ET 200AL modules are connected in series.



6. Complete the configuration of the ET 200SP: Drag all ET 200SP modules from the hardware catalog to the slots in the ET 200SP.
   Five ET 200SP modules are plugged in the configuration example below: The PN interface module in slot 0, the module "BA-Send 1xFC" in slot 1, one input module each in slots 2 and 3, and a server module in slot 4:

Rules

- The module "BA-Send 1xFC" must be plugged in slot 1 of the ET 200SP if the ET 200SP is to be expanded with ET 200AL modules
- The ET 200AL modules must be configured with no gaps.

Configuration control with ET 200AL (Page 1316)

Interface module parameters

Status bytes

Status bytes

If you enable the "Status bytes" option, 4 bytes of input data are reserved for the status of the supply voltage of each I/O module.

	7	6	5	4	3	2	1	0
Byte 0	8	7	6	5	4	3	2	1
Byte 1	16	15	14	13	12	11	10	9
Byte 2	24	23	22	21	20	19	18	17
Byte 3	32	31	30	29	28	27	26	25

I/O module slots

Bit = 0: Load voltage missing or I/O module not present

Bit = 1: Load voltage and I/O module present

Note

An inserted or missing server module always reports for the slot bit = 0.

Group diagnostics, missing supply voltage L+

Group diagnostics, missing supply voltage L+

This diagnostics is a group diagnostics that covers the supply voltage status of all I/O modules of a potential group which are defined by BaseUnits with incoming power supply (light-colored BaseUnit BU...D).

The group diagnostics is formed from the states of the supply voltage of the inserted I/O modules within the potential group.

The group diagnostics does not depend on the "Missing supply voltage L+" parameter of the I/O modules being enabled.

The server module does not influence the missing supply voltage L+ group diagnostics.

Requirements for the correct operation of the group diagnostics for missing supply voltage L+:

- I/O modules or BU covers must be inserted on the light-colored and dark-colored BaseUnits. If no I/O module is inserted on a light-colored BaseUnit, the start of this potential group will not be detected by the interface module; the I/O modules of this potential group will thus belong to the previous potential group. A supply voltage L+ group error will then be assigned to the wrong potential group.
  When an I/O module is inserted on the light-colored BaseUnit, the interface module detects the new potential group, re-evaluates the status, and reports a new group diagnostics in the case of an error.
- The server module must be inserted.
  The server module itself does not influence the missing supply voltage L+ group diagnostics.

Configuration control with ET 200SP

Operating principle

Configuration control allows you to operate various real configurations (options) with a single configuration of the distributed I/O device ET 200SP.

Configuration control provides you with the option of configuring the ET 200SP distributed I/O device with its maximum configuration and nevertheless operating it with missing modules. If missing modules are retrofitted later, no new configuration is required and the hardware configuration does not have to be reloaded either.

Using control data record 196, which is transferred to the interface module in the user program, you define a current preset configuration.

- The configured module is not present on a slot.
  - A BU cover can be inserted in this slot instead of the configured I/O module. As there is no configured module on the slot, the term "Configuration control with empty slots" is also used.
  - The module that is configured to the right of the missing module can be inserted on this slot instead of the configured module. The missing module makes the actual configuration appear pushed together. As the configured module is missing but no gap arises in the configuration, this is also referred to as a "Configuration without empty slots".
- The configuration is extended by an already configured module.
  - In the case of configuration control with empty spaces, you extend the configuration by inserting the configured module on the corresponding empty slot.
  - In the case of configuration control without empty spaces, insert the configured module on the right-hand side next to the last module of the ET 200SP.

Requirement

- STEP 7 Professional version V13 SP1 or higher
- The CPU startup parameter "Compare preset to actual configuration" is set to Startup even if mismatch (default setting). This setting is also selected for the startup parameters of the individual modules of the ET 200SP.

Enabling configuration control

In the properties of the interface module under Module parameters > General > Configuration control, select "Enable reconfiguration of device via user program". This activates configuration control.

Control data record 196 for ET 200SP

The figure below shows the data block 196 for the configuration control of an ET 200SP with four modules.

The value "12" is in the "block_length" element.

If you configure an ET 200SP in STEP 7 with more modules, the data block will be longer. The data record for the maximum configuration with 65 modules is 134 bytes long (configuration with PN interface module).

There are two bytes in the data record for each module.

The positions of these two bytes in the data record each code a module in the original configuration with STEP 7:

- "slot_1" and "info_slot_1" (bytes 4 and 5 in the data record, see figure below) correspond to the module in slot 1 in configuration with STEP 7.
- "slot_2" and "info_slot_2" (bytes 6 and 7) correspond to the module in slot 2 in configuration with STEP 7.
- "slot_3" and "info_slot_3" (bytes 8 and 9) correspond to the module in slot 3 in configuration with STEP 7.
- etc.

"slot_x" byte

The current slot is coded by the figure that is assigned to "slot_x" (by its value). Examples:

- The value "1" in byte 4 means you are assigning the module originally inserted in slot 1 to slot 1 in the current configuration (slot_1 = 1).
- The value "2" in byte 4 means you are assigning the module originally inserted in slot 1 to slot 2 in the current configuration (slot_1 = 2).
- The value "3" in byte 4 means you are assigning the module originally inserted in slot 1 to slot 3 in the current configuration (slot_1 = 3).
- etc.
- The value "1" in byte 6 means you are assigning the module originally inserted in slot 2 to slot 1 in the current configuration (slot_2 = 1).
- The value "2" in byte 6 means you are assigning the module originally inserted in slot 2 to slot 2 in the current configuration (slot_2 = 2).
- The value "3" in byte 6 means you are assigning the module originally inserted in slot 2 to slot 3 in the current configuration (slot_2 = 3).
- etc.

If a BU cover can be inserted instead of a module, code this by adding 128 to the slot (bit 7 of the "slot_x" byte is set). Examples:

- The value "129" in slot_1 means you are also assigning the module originally inserted in slot 1 to slot 1 in the current configuration. A BU cover can also be used instead of this module. In the real plant configuration, either the module or a BU cover is inserted.
- The value "130" in slot_1 means you are assigning the module originally inserted in slot 1 to slot 2 in the current configuration. A BU cover can also be used instead of this module. In the real plant configuration, either the module or a BU cover is inserted.
- The value "131" in slot_1 means you are assigning the module originally inserted in slot 1 to slot 3 in the current configuration. A BU cover can also be used instead of this module. In the real plant configuration, either the module or a BU cover is inserted.

"info_slot_x" byte

If a new potential group is opened with the module, assign the "info_slot_x" byte the value 1 (bit 0 of the byte is set). Examples:

- The value "1" in the "info_slot_2" byte means that a new potential group is opened with module 2.
- The value "1" in the "info_slot_3" byte means that a new potential group is opened with module 3.
- The value "1" in the "info_slot_4" byte means that a new potential group is opened with module 4.

Exception: A new potential group is automatically assigned to the first module in the original configuration in STEP 7. This is not coded in the data record. You can enter any value in "info_slot_1".

You can choose any name for the components of the control data record (for example "slot_1").

Example of control data record 196 for ET 200SP

The figure below shows control data record 196 for an ET 200SP with four modules.

The module inserted in slot 2 in the configuration in STEP 7 can also be inserted in slot 2 in this configuration. It can also be inserted in slot 2 of a BU cover. Otherwise, nothing has changed compared to the original configuration.

Record_196_ET_200SP

	Name	Data type	Default value
1	block_length	USInt	12
2	block_ID	USInt	196
3	version	USInt	2
4	subversion	USInt	0
5	slot_1	USInt	1
6	info_slot_1	USInt	0
7	slot_2	USInt	130
8	info_slot_2	USInt	0
9	slot_3	USInt	3
10	info_slot_3	USInt	0
11	slot_4	USInt	4
12	info_slot_4	USInt	0

Addressing the interface module using the HW identifier

To transfer data record 196 with the instruction WRREC, you must enter the HW identifier of the IM submodule with the extension "~Head" as the input parameter for the instruction. The system constant of this HW identifier is, for example, "IO-Device_2~Head". The system constants of a selected device are, for example, displayed in the network view in the "System constants" tab. Use the corresponding value for addressing.

Readback data record 197 for ET 200SP

Readback data record 197 is used to read the actual configuration of a station (in this case, of an ET 200SP).

This readback data record allows you to check the real configuration of the ET 200SP (actual configuration). The readback data record for each configured module specifies whether or not it is actually available.

- The value "1" means that the correct module is inserted in the correct slot.
- The value "0" codes all other options (wrong module, empty slot, BU cover).

Configuration details:

The configuration of the data block corresponds to the original configuration of the ET 200SP with STEP 7.

There are two bytes in the data record for each module. The position of these two bytes in the data record corresponds to the position of a module in the original configuration with STEP 7.

Sequence of bytes:

- "status_slot_1" and "reserve_1" (bytes 4 and 5 in the data record) correspond to the module in slot 1 in the configuration,
- "status_slot_2" and "reserve_2" (bytes 6 and 7) correspond to the module in slot 2 in the configuration
- "status_slot_3" and "reserve_3" (bytes 8 and 9) correspond to the module in slot 3 in the configuration,
- etc.

Example

The original configuration in STEP 7 has been changed by a control data record 196 (see example above): In the modified configuration, module 2 can either be inserted in slot 2 or be replaced by a BU cover.

The figure below shows readback data record 197 which ET 200SP outputs to indicate that there is a module in slot 2: The "status_slot_2" byte has the value "1".

The other modules are also available and are inserted in the correct slots.

Record_197_ET_200SP

	Name	Data type	Default value
1	block_length	USInt	12
2	block_ID	USInt	197
3	version	USInt	2
4	subversion	USInt	0
5	status_slot_1	USInt	1
6	reserve_1	USInt	0
7	status_slot_2	USInt	1
8	reserve_2	USInt	0
9	status_slot_3	USInt	1
10	reserve_3	USInt	0
11	status_slot_4	USInt	1
12	reserve_4	USInt	0

The figure below displays the readback data record 197 which ET 200SP outputs to indicate that a BU cover is being used in slot 2: The "status_slot_2" byte has the value "0".

The other modules are available and are inserted in the correct slots.

Record_197_ET_200SP			
	Name	Data type	Default value
1	block_length	USInt	12
2	block_ID	USInt	197
3	version	USInt	2
4	subversion	USInt	0
5	status_slot_1	USInt	1
6	reserve_1	USInt	0
7	status_slot_2	USInt	0
8	reserve_2	USInt	0
9	status_slot_3	USInt	1
10	reserve_3	USInt	0
11	status_slot_4	USInt	1
12	reserve_4	USInt	0

Reading readback data record 197

You can read readback data record 197 from the ET 200SP with the instruction RDREC. RDREC operates asynchronously. If you call RDREC in the startup OB, you must call the instruction multiple times using a loop until the "BUSY" or "DONE" output parameter indicates that the data record has been read.

To read data record 197 with the instruction RDREC, you must enter the HW identifier of the IM submodule with the extension "~Head" as the input parameter for the instruction. The system constant of this HW identifier is, for example, "IO-Device_2~Head". The system constants of a selected device are, for example, displayed in the network view in the "System constants" tab. Use the corresponding value for addressing.

Further information and examples

Specific examples of configuration control can be found in this application description (http://support.automation.siemens.com/WW/view/en/29430270).

Further information on ET 200SP can be found in the manuals IM 155-6 PN (http://support.automation.siemens.com/WW/view/en/73184046) and IM 155-6 DP (http://support.automation.siemens.com/WW/view/en/73098660)

Configuration control with ET 200AL (Page 1316)

Configuration control for ET 200SP with integrated ET 200AL modules (Page 1278)

Configuration control for ET 200SP with integrated ET 200AL modules

ET 200SP with integrated ET 200AL modules

Configuration control for ET 200SP and ET 200AL is described in separate texts. See the links under "See also".

The steps outlined also apply to configuration control of an ET 200SP with integrated AL modules. The procedure is different for control data record 196 and readback data record 197.

The following help text describes control data record 196 and the readback data record 197 for an ET 200SP expanded with ET 200AL modules.

Control data record 196

The two figures below show parts of control data record 196 for a configuration of an ET 200SP expanded with ET 200AL modules.

This configuration is given as an example:

- The module "BA Send 1xFC" is in slot 1 "slot_1". This module allows you to integrate ET 200AL modules into an ET 200SP. In our configuration example, 16 AL modules are connected to the BA-Send (maximum configuration). If a BA-Send is being used, this module must be inserted in slot 1.
- All slots from 2 to 64 are assigned ET 200SP modules.
- A server module is inserted in slot 65.
- There are 16 AL modules in slots 66 to 81.

The ET 200SP with integrated AL modules, originally configured with STEP 7, is now to be reconfigured from the user program.

The new configuration has the following properties:

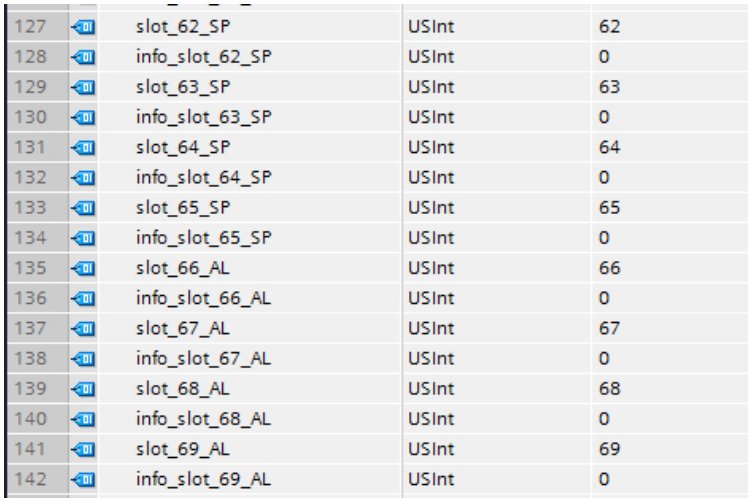
- The "BA Send 1xFC" module is inserted in "slot_1_BA-Send" (fixed setting).
- Module 2 "slot_2" is not available in the modified configuration (value "0").
- Module 3 "slot_3" is in slot 2 in the modified configuration (value "2").
- Module 4 "slot_4" is in slot 3 in the modified configuration (value "3").
- All modules from slot 5 to slot 81 are operated in the original configuration with STEP 7.

Configuration_ET200SP_with_AL-Modules

		Name	Data type	Start value
1		Static		
2		block_length	USInt	166
3		block_ID	USInt	196
4		version	USInt	2
5		subversion	USInt	0
6		slot_1_BA-Send	USInt	1
7		info_slot_1_BA-Send	USInt	0
8		slot_2	USInt	0
9		info_slot_2	USInt	0
10		slot_3	USInt	2
11		info_slot_3	USInt	0
12		slot_4	USInt	3
13		info_slot_4	USInt	0
14		slot_5	USInt	5
15		info_slot_5	USInt	0
16		slot_6	USInt	6
17		info_slot_6	USInt	0
18		slot_7	USInt	7
19		info_slot_7	USInt	0

The components of control data record 196 (figure above):

- block_length: Note the length of the control data record here; in the example: 166 (bytes). The length of the control data block is calculated using the formula "2 x number of slots + 4".
- block_ID: Enter the figure 196 here.
- version: The ET 200SP uses version 2 of control data record 196.
- subversion: The ET 200SP uses subversion 0 of control data record 196.



127	slot_62_SP	USInt	62
128	info_slot_62_SP	USInt	0
129	slot_63_SP	USInt	63
130	info_slot_63_SP	USInt	0
131	slot_64_SP	USInt	64
132	info_slot_64_SP	USInt	0
133	slot_65_SP	USInt	65
134	info_slot_65_SP	USInt	0
135	slot_66_AL	USInt	66
136	info_slot_66_AL	USInt	0
137	slot_67_AL	USInt	67
138	info_slot_67_AL	USInt	0
139	slot_68_AL	USInt	68
140	info_slot_68_AL	USInt	0
141	slot_69_AL	USInt	69
142	info_slot_69_AL	USInt	0

The components of control data record 196 (figure above):

- slot_65_SP: This byte relates to the server module in the ET 200SP rack. It ends the backplane bus of the ET 200SP.
- From "slot_66_AL" come the 16 configured ET 200AL modules: Our configuration example does not change the configuration with STEP 7. The byte "slot_66_AL" has the value "66", the byte "slot_67_AL" has the value "67", the byte "slot_68_AL" has the value "68", etc.

Definition of control data record 196

A control data record 196 containing a slot assignment is defined for configuration control.

Byte	Component	Value	Description	
0	block_length	e.g. 166 for maximum configuration with 65 ET-200SP modules and 16 ET 200AL modules (with DP interface module, maximum of 33 ET 200SP modules and 16 ET 200AL modules)	The length of the data record is calculated using the formula: 4 + "number of modules" x 2	Header
1	Block ID	196	ID for control data record 196	
2	version	2	Version 2 of control data record 196	
3	subversion	0	Subversion 0 of control data record 196	
4	slot_1_BA-Send	Real slot for SP module 1 Possible value: 1	When AL modules are integrated in ET 200SP, the module "BA Send 1xFC" must always be inserted in slot 1.	1. Slot for SP modules Assignment for the configured SP module 1 to a real slot
5	info_slot_1_BA-Send	0 or 1	The value "1" means that a new potential group is opened with this module. (Not evaluated in this byte)	
6	slot_2	Real slot for SP module 2 Possible values: 2 to 65 (not 66 to 81, reserved for AL modules) 0 (if the configured module 2 is not available)	The configured SP module 2 can be inserted in any real slot from 2 to slot 65 (2 to 33 for a DP interface module). Slots 66 to 81 are for AL modules (34 to 49 with DP interface module).	2. Slot for SP modules Assignment for the configured SP module 2 to a real slot
7	info_slot_2	1	The value "1" means that a new potential group is opened with this module. A new potential group must always be opened in this byte as BA-Send cannot open a new potential group.	

8	slot_3	Real slot for SP module 3 Possible values: 2 to 65 (not 66 to 81, reserved for AL modules) 0 (if the configured module 3 is not available)	The configured SP module 3 can be inserted in any real slot from 2 to slot 65 (2 to 33 for a DP interface module). Slots 66 to 81 are for AL modules (34 to 49 with DP interface module).	3. Slot for SP modules Assignment for the configured SP module 3 to a real slot
9	info_slot_3	1	The value "1" means that a new potential group is opened with this module. .	
:	:	:	:	:
132	slot_65	Real slot for SP module 65 Possible values: 2 to 65 (not 66 to 81, reserved for AL modules) 0 (if the configured module 65 is not available)	The configured SP module 65 can be inserted in any real slot from 2 to slot 65 (2 to 33 for a DP interface module). Slots 66 to 81 are for AL modules (34 to 49 with DP interface module)	65. Slot for SP modules Assignment for the configured SP module 65 to a real slot
133	info_slot_65	0 or 1	The value "1" means that a new potential group is opened with this module (the value is not evaluated in this slot).	
134	slot_66	Real slot for AL module 1 Possible values: 66 to 81 (not 1 to 65, reserved for SP modules) 0 (if the configured AL module 1 is not available)	The configured AL module 1 can be inserted in any slot from 66 to slot 81 (34 to 49 for PROFIBUS).	1. Slot for AL modules Assignment for the configured AL module 1 to a real slot
135	info_slot_66	-	Reserve	
:	:	:	:	:

164	slot_81	Real slot for AL module 16 Possible values: 66 to 81 (not 1 to 65, reserved for SP modules) 0 (if the configured AL module 16 is not available)	The configured AL module 16 can be inserted in any slot from 66 to slot 81 (34 to 49 for DP interface module).	16. Slot for AL modules Assignment for the configured AL module 16 to a real slot
165	info_slot_81	-	Reserve	

Rules

- If the "BA Send 1xFC" module is being used, it must be inserted in slot 1.
- ET 200SP modules are inserted in slots 2 to 65 (slots 2 to 33 for DP interface module).
- AL modules are inserted in slots 66 to 81 (slots 34 to 49 for DP interface module).
- If you expand an ET 200SP with ET 200 AL modules, the 1st AL module is always coded in bytes 134 and 135 of the control data record, the 2nd AL module in bytes 136 and 137, etc., even if not all SP slots are to be assigned SP modules. Non-assigned SP slots are coded with the value "0".

Error messages

The following error messages are returned if an error occurs when writing control data record 196:

Table 10-95 Error messages

Error code	Meaning
16#80A2	DP protocol error on layer 2. Indicates that a data record has not been acknowledged due to the system.
16#80B1	Invalid length; the length information in data record 196 is not correct.
16#80B5	Configuration control parameters not assigned.
16#80B2	Invalid slot: The configured slot is not assigned.
16#80B8	Parameter error; module signals invalid parameters.
16#80C5	DP slave or module not available. Indicates that a data record has not been acknowledged due to the system.

Readback data record 197 for ET 200SP with AL modules

The actual configuration of an ET 200SP with AL modules can be checked with readback data record 197.

Data record 197 largely corresponds to readback data record 197 for ET 200SP without AL modules; however, it is longer as the additional AL modules also need to be coded.

There are two bytes in the data record for each module. The position of these two bytes in the data record codes a module in the original configuration with STEP 7.

In the figure below:

- The components "status_slot_1" and "reserve_1" (bytes 4 and 5 in the data record) correspond to the module in slot 1 in the configuration with STEP 7,
- "status_slot_2" and "reserve_slot_2" (bytes 6 and 7) correspond to the module in slot 2,
- "status_slot_3" and "reserve_slot_3" (bytes 8 and 9) correspond to the module in slot 3,
- etc.

The following data record is structured for configuration with 65 SP modules and 16 AL modules. The value "166" therefore appears in the "block_length" element of the data record.

If you configure an ET 200SP in STEP 7 with fewer AL modules, the data block will be shorter.

If you use fewer SP modules in a configuration, this has no effect on the length of data record 197 (with an expansion of ET 200SP with ET 200AL modules).

The "reserve_x" component of readback data record 197 is reserved for future applications.

You can choose any name for the components of the readback data record (for example "status_slot_1").

The figure below shows the start of readback data record 197 for reading the actual configuration of an ET 200SP with AL modules.

DB_read_back_ET_200SP_with_AL

	Name	Data type	Start value
1	Static		
2	block_length	USInt	166
3	block_ID	USInt	197
4	version	USInt	2
5	subversion	USInt	0
6	status_slot_1	USInt	1
7	reserve_slot_1	USInt	0
8	status_slot_2	USInt	1
9	reserve_slot_2	USInt	0
10	status_slot_3	USInt	1
11	reserve_slot_3	USInt	0
12	status_slot_4	USInt	1
13	reserve_slot_4	USInt	0
14	status_slot_5	USInt	1
15	reserve_slot_5	USInt	0
16	status_slot_6	USInt	1
17	reserve_slot_6	USInt	0

It does not show the components "status_slot_7" to "reserve_81" (maximum configuration of an ET 200SP with PN interface module) or "status_slot_7" to "reserve_slot_49" (maximum configuration of an ET 200SP with DP interface module).

Meaning of "status_slot_x":

- The value "1" in status_slot_x means that module x is inserted in the correct slot
- The value "0" codes all other options (wrong module, empty slot, BU cover).

The figure below shows part of readback data record 197 for reading the actual configuration of an ET 200SP with AL modules (and PN interface module). ET 200SP modules are inserted up to slot 65, and then the AL modules. For example, a value of "1" in the byte "status_slot_66_AL" means that the 1st AL module is actually available in the plant and inserted in the correct slot.

128	status_slot_62_SP	USInt	1
129	reserve_slot_62_SP	USInt	0
130	status_slot_63_SP	USInt	1
131	reserve_slot_63_SP	USInt	0
132	status_slot_64_SP	USInt	1
133	reserve_slot_64_SP	USInt	0
134	status_slot_65_SP	USInt	1
135	reserve_slot_65_SP	USInt	0
136	status_slot_66_AL	USInt	1
137	reserve_slot_66_AL	USInt	0
138	status_slot_67_AL	USInt	1
139	reserve_slot_67_AL	USInt	0
140	status_slot_68_AL	USInt	1
141	reserve_slot_68_AL	USInt	0
142	status_slot_69_AL	USInt	1
143	reserve_slot_69_AL	USInt	0

Reading readback data record 197

You can read readback data record 197 from the ET 200SP with the instruction RDREC. RDREC operates asynchronously. If you call RDREC in the startup OB, you must call the instruction multiple times using a loop until the "BUSY" or "DONE" output parameter indicates that the data record has been read.

Further information and examples

Specific examples of configuration control can be found here in this application description (http://support.automation.siemens.com/WW/view/en/29430270).

Further information on ET 200SP can be found in the manuals for IM 155-6 PN (http://support.automation.siemens.com/WW/view/en/73184046) and IM 155-6 DP (http://support.automation.siemens.com/WW/view/en/73098660)

Further information on ET 200AL is available here (http://support.automation.siemens.com/WW/view/en/89254863).

Configuration control with ET 200SP (Page 1274)

Configuration control with ET 200AL (Page 1316)

Output module parameters

Substitute value reaction

Substitute value reaction

In the ET 200SP, the substitute value reaction is executed by the IO controller per slot.

The respective output reacts according to its set substitute value reaction:

- "Turn off"
- "Output substitute value"
- "Keep last value"

This substitute value reaction is triggered in the following cases:

- IO controller in STOP
- Controller failure (connection interruption)
- Firmware update
- Reset to factory settings
- More than one I/O module withdrawn simultaneously
- Disable the IO device
- Station stop
  - Missing server module
  - More than one I/O module withdrawn simultaneously
  - At least one I/O module is inserted on the wrong BaseUnit

Note

Reducing a configuration

If you reduce the configuration of the ET 200SP and download the configuration to the CPU, the modules which are no longer configured but still present retain their original substitute value reaction. This applies until the supply voltage on the BaseUnit BU...D or on the interface module is turned off.

Input module parameters

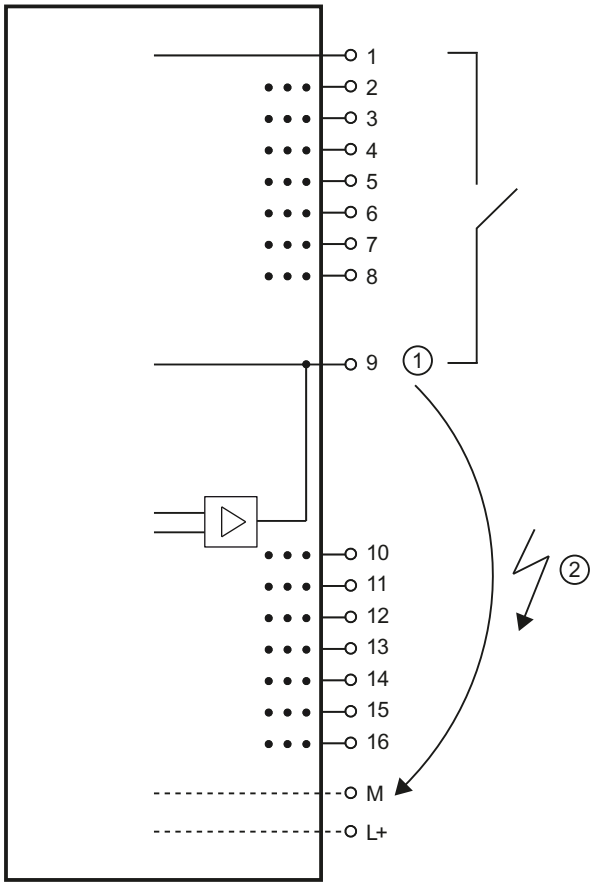
Parameters of the digital input modules

Diagnostics missing supply voltage L+

Enabling of the diagnostics for missing or insufficient supply voltage L+.

Diagnostics short-circuit to ground

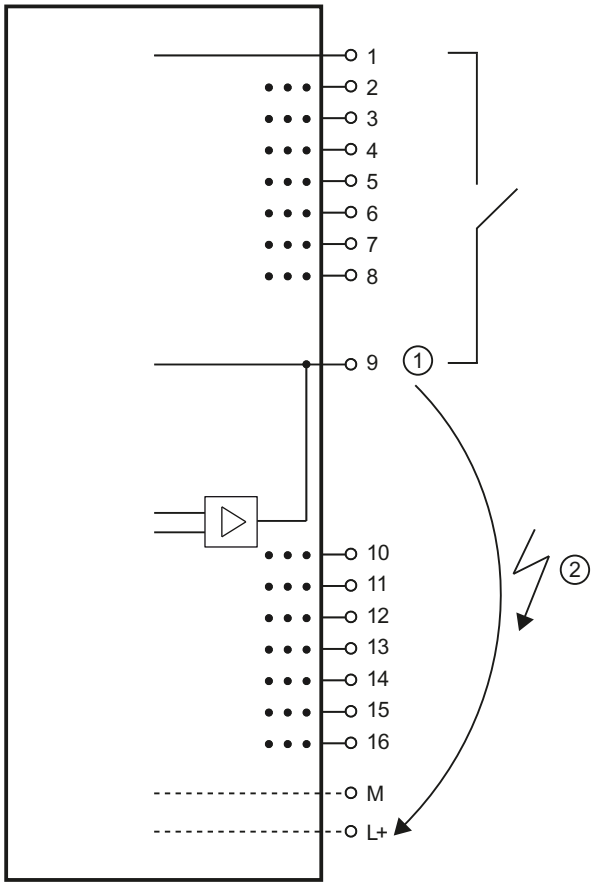
Enabling of the diagnostics if a short-circuit of the actuator supply to ground occurs.



① Encoder supply
② Short-circuit

Diagnostics short-circuit to L+

Enabling of the diagnostics if a short-circuit of the encoder supply to L+ occurs.



① Encoder supply
② Short-circuit

Diagnostics wire break

Enabling diagnostics if the line to the encoder is interrupted.

Operating mode

Determines whether a channel is enabled or disabled.

Pulse extension (only High Feature modules)

Pulse extension is a function for changing a digital input signal. A pulse at a digital input is extended to at least the configured length. If the input pulse is already longer than the configured length, the pulse is not changed.

Pulse extension is started whenever the state of the input signal changes and no pulse extension is active for this channel.

Potential group of the left module / new potential group

Specifies whether the I/O module is located on a base unit with supply voltage feed (new potential group) or whether it is it located on a base unit without supply voltage feed (in which case it belongs to the potential group of the left module).

Parameters of the analog input modules

Missing supply voltage L+

Enabling of the diagnostics, with missing or too little supply voltage L+.

Reference junction (AI 4xRTD/TC 2-/3-/4-wire HF)

A BaseUnit with internal temperature sensor (BU..T) or the channel 0 of the I/O module can be used as reference junction, provided this has been configured as "Thermal resistor Pt100 climatic range Celsius".

A possible parameter assignment is shown below (see also Information about reference channel mode (Page 1292)):

Table 10-96 RTD channel

Setting	Description
No reference channel operation	Temperature value at channel 0 can be used as module-wide reference value if the parameters of the other channels are assigned accordingly.
Reference channel of Group x	The channel acts as sender for the reference junction temperature of Group x. Distribution is performed via the interface module.

Table 10-97 TC channel

Setting	Description
Reference channel of the module	The corresponding TC channel uses the channel 0 of the same module as reference junction temperature. This must be set as "Thermal resistor Pt 100 climatic range Celsius" and "No reference channel operation"; otherwise, reference junction diagnostics is triggered.
Internal reference junction	The reference junction temperature is read by an internal temperature sensor on the BaseUnit. Reference junction diagnostics is triggered if there is a wrong BaseUnit type.
Reference channel of Group x	With the setting "TC" (thermocouple...), the channel acts as receiver for the reference junction temperature of Group x.
Fixed reference temperature	No temperature compensation occurs. The linearization is executed with an assumed reference junction temperature of 0 °C.

Overflow

Enabling of the diagnostics if the measured value exceeds the overflow range.

Underflow

Enabling of the diagnostics if the measured value falls below the underflow range.

Wire break

Enabling of the diagnostics if the module has no current flow or too low a current flow for the measurement on the corresponding configured input.

Smoothing

The individual measurements are smoothed using digital filtering. The smoothing can be set in 4 stages, whereby the smoothing factor k multiplied by the cycle time of the I/O module corresponds to the time constant of the smoothing filter. The larger the smoothing, the larger the time constant of the filter.

The following figure shows the step response for the various smoothing factors depending on the number of module cycles.

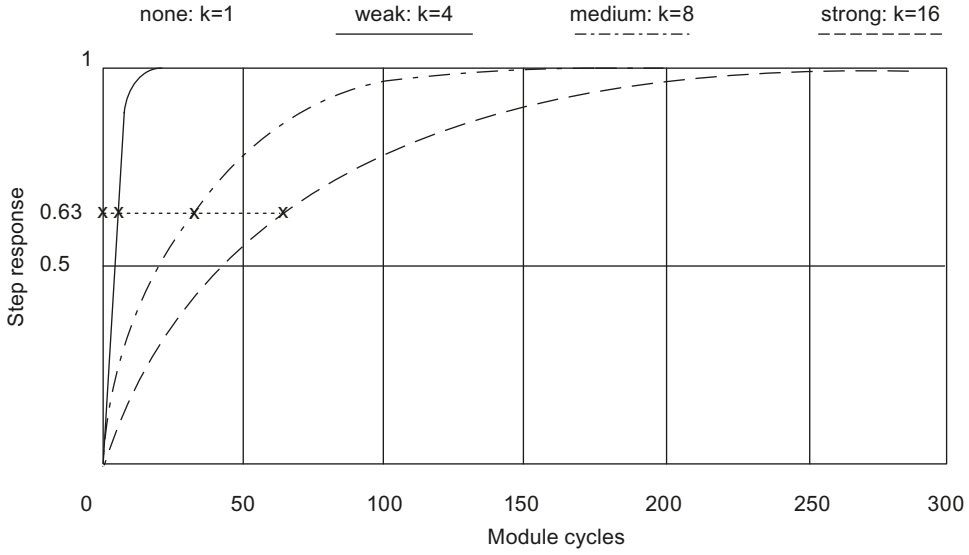


Figure 10-5 Smoothing with AI 4×RTD/TC 2-/3-/4-wire HF

Interference frequency suppression

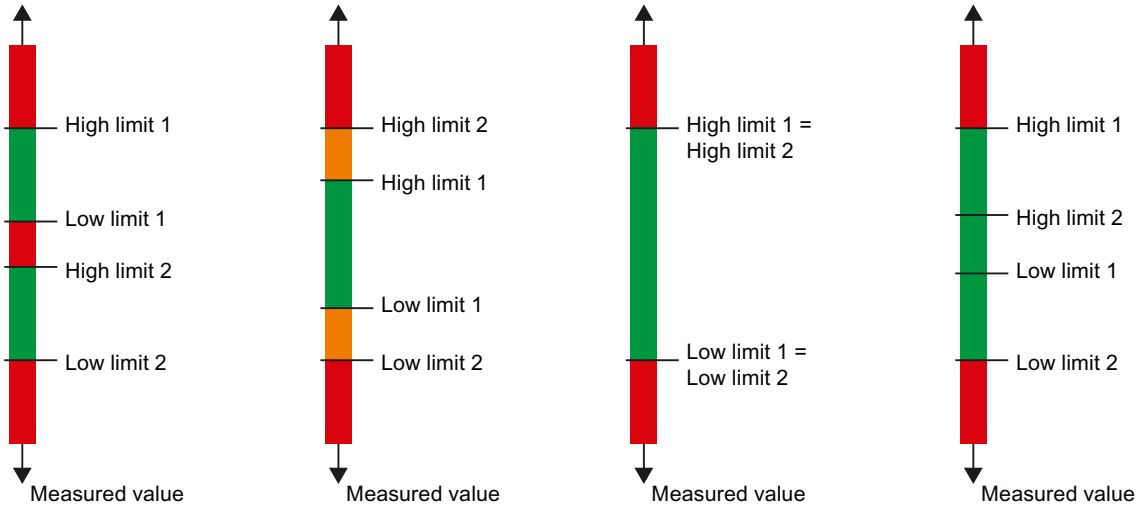
With analog input modules, suppresses the disturbance caused by the frequency of the AC network used.

The frequency of the AC network may interfere with measured values, particularly for measurements within low voltage ranges and when thermocouples are being used. This parameter is used to define the predominant power frequency of the system.

Hardware interrupt limits

If the high limit 1/2 or the low limit 1/2 is violated, the module triggers a hardware interrupt.

Below are some examples for the selection of the limits 1 and 2.



Low limit 1/2

Specify a threshold whose undershoot triggers a hardware interrupt.

High limit 1/2

Specify a threshold whose overrange triggers a hardware interrupt.

Potential group of the left module/New potential group

Specifies whether the I/O module is located on a BaseUnit with supply voltage infeed (new potential group) or on a BaseUnit without supply voltage feed (in which case, it belongs to the potential group of the left module).

Temperature coefficient (measurement type thermoresistor)

The correction factor for the temperature coefficient (α value) defines the relative rate of change of the resistance of a specific material at a temperature rise of 1 °C.

The temperature coefficient depends on the chemical composition of the material. In Europe, only one value is used per sensor type (default value).

The further values facilitate a sensor-specific setting of the temperature coefficient and enhance accuracy.

Special features of AI 4xRTD/TC 2-/3-/4-wire HF (Page 1300)

Information about reference channel mode

An RTD/TC module of the ET 200SP works in reference channel mode when a channel sends the reference temperature to other channels of the station. The receiving channels use the reference temperature for temperature compensation when measuring with thermocouples.

Structure and use of thermocouples

The thermocouple consists of two wires with different metals or alloys that are welded together at the end. The weld is called measuring point.

The other end of the two wires is open. This end is called reference junction.

A thermal voltage, which depends on the temperature at the measuring point, occurs between the two metals/alloys at the measuring point. Other thermal voltages also occur at the reference junction - with transition from thermocouple to copper lines, for example - that falsify the actual measured value and need to be compensated. No compensation is required for a reference junction temperature of 0 °C.

Different methods are used to compensate the reference junction temperature:

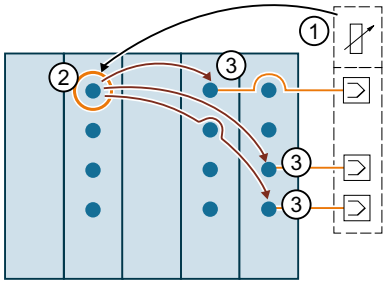
- Fixed reference temperature: The reference junction is permanently set to a specific temperature, for example, to 0 °C by an icewater bath (no compensation required).
- Internal reference junction: The reference junction is the terminal of the BaseUnit on which the analog module is plugged. If you select the "Internal reference junction" compensation type, you have to use BaseUnits with integrated temperature measurement to compensate the reference junction temperature. These BaseUnits have the designation "BU..T". The module records the temperature at the reference junction and uses this to determine the actual temperature at the measuring point.
- Reference channel of Group x: An external thermal resistor records the temperature at the reference junction for the Group x (group of channels within a station). The actual temperature at the respective measuring point can be determined as a result. One external thermal resistor is required for each group. The thermal resistors are each connected to one channel of an analog module. These channels are called senders (for the temperature at the reference junction).
  The mode of operation and settings are described in the section "Station-wide distribution of reference temperature".
- Reference channel of the module: The mode of operation is comparable with "Reference channel of Group x". You connect an external thermal resistor to channel 0 of the module to measure the temperature at the reference junction. Other channels of the same module use this reference temperature for temperature compensation.
  The mode of operation and settings are described in the section "Module-wide distribution of reference temperature".

You can find information about the structure and mode of operation of a thermocouple in the Analog value processing (http://support.automation.siemens.com/WW/view/en/67989094) manual.

Station-wide distribution of the reference temperature

You can record the temperature at the reference junction x using a thermal resistor on a channel (sender of the reference temperature) and send it to other channels within a station (receivers). All channels that receive the temperature at a reference junction x form the Group x.

For each group, you assign parameters to exactly one channel as sender of the reference temperature.



① Thermal resistor at the reference junction

② Channel records temperature at the reference junction and sends it to the other channels within a station (sender of Group x). The temperature value is used for the compensation of the reference junction temperature.

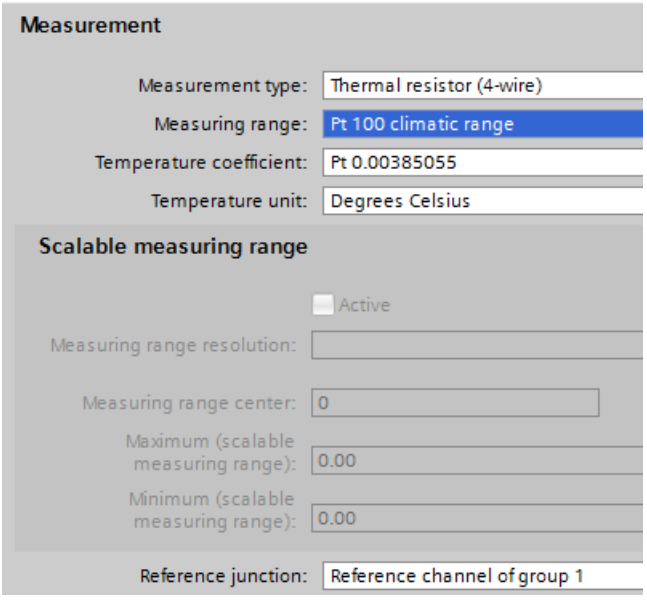
③ Channels of the Group x receive the temperature at the reference junction (receivers)

Parameter assignment of a channel as reference channel (sender for Group 1)

Parameter assignment is described below using Group 1 as example:

1. Open the project in STEP 7
2. Select the required analog module (RTD/TC) in the device view.
3. Then select a channel that is to work as sender of the reference junction temperature.
   The following settings are required:
   "Measurement type": "Thermal resistor", for example, "Thermal resistor (4-wire connection)"
   "Measuring range": "Pt 100 climatic range"
   "Temperature unit": "Degrees Celsius"
   "Reference junction": "Reference channel of Group 1"

The following figure shows the parameter assignment.

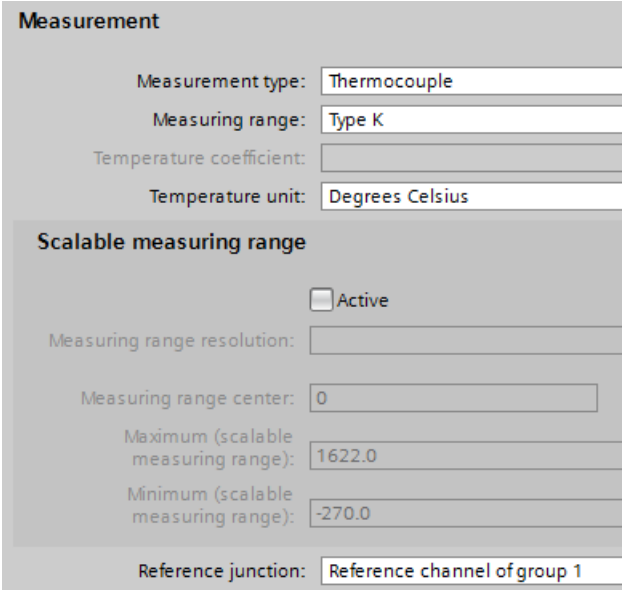


The channel configured in this way (thermal resistor measurement type) works as reference channel of Group 1 and sends the measured temperature to all channels (thermocouple measurement type) that are configured as receivers of Group 1.

In the next section, you will learn how to assign parameters for channels that are receivers of Group 1.

Parameter assignment of a channel as receiver of Group 1

The figure below shows the parameter assignment of a channel that receives the temperature at the reference junction of Group 1.

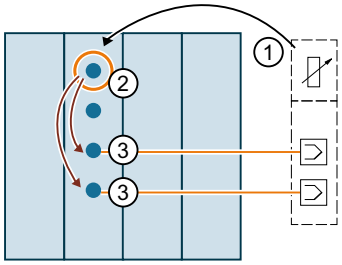


The following settings are required:

- "Measurement type": "Thermocouple"
- "Reference junction": "Reference channel of Group 1"

Module-wide distribution of the reference temperature

You can record the temperature on a reference junction using the channel 0 of the module and use the temperature value for the channels 1, 2, 3... of this module. The recorded temperature value is not sent to the channels of the other modules within the station (no reference channel mode).



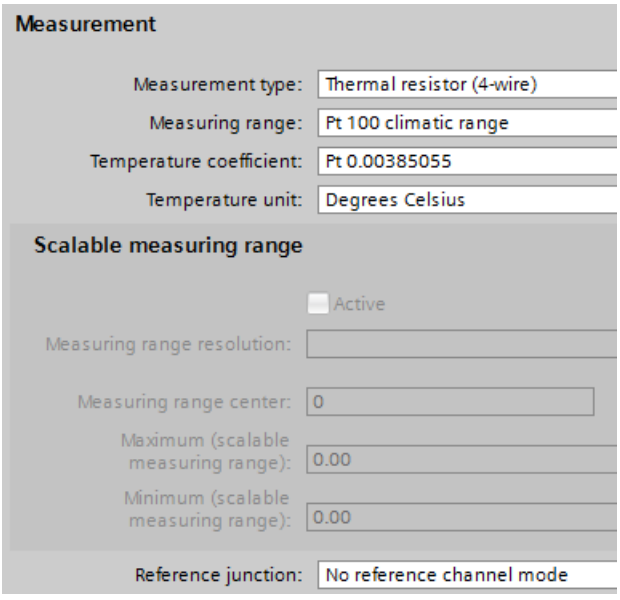
① Thermal resistor at the reference junction

② Channel records temperature at the reference junction, "Reference junction" parameter: "No reference channel mode"

③ Channels of the same module use the temperature value for the compensation of the reference junction temperature for the measurement with thermocouples, "Reference junction" parameter: "Reference channel of the module"

Parameter assignment of channel 0 as reference channel of the module

The figure below shows the parameter assignment of channel 0 of a module that is to be used for recording the temperature at the reference junction:

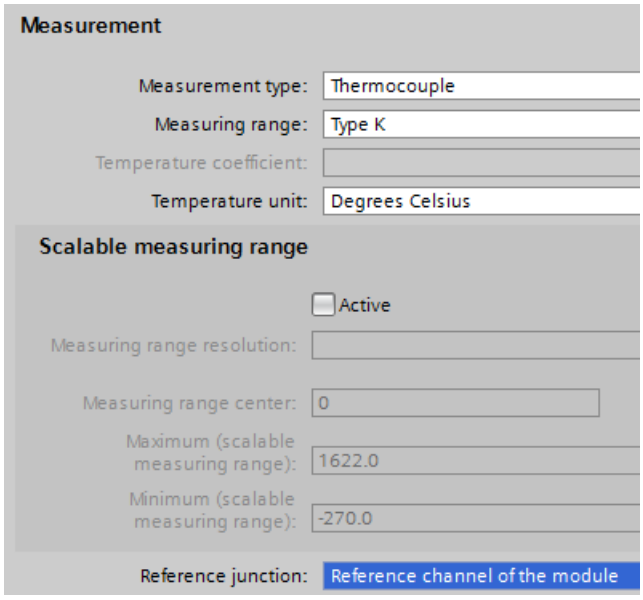


The following settings are required:

- "Measurement type": "Thermal resistor", for example, "Thermal resistor (4-wire connection)"
- "Measuring range": "Pt 100 climatic range"
- "Temperature unit": "Degrees Celsius"
- "Reference junction": "No reference channel mode"

Parameter assignment of a channel that uses channel 0 as reference channel

The figure below shows how parameters have to be assigned for a channel that uses the channel 0 of this module as reference channel for temperature compensation.



The settings below are required for the channels of the module that compensate the temperature of the reference junction using channel 0:

- "Measurement type": "Thermocouple"
- "Reference junction": "Reference channel of the module"

Parameters of the analog input modules (Page 1289)

Information about the Oversampling function

High-speed analog modules (HS) are available to meet high performance and speed requirements. The main characteristics of these HS analog modules compared to Standard analog modules (ST) is their shorter cycle times. To achieve this goal, the input and output modules are equipped with components with extremely short throughput and conversion times. In addition, the entire architecture of the modules is designed for faster signal processing.

HS analog modules convert the output of measured values and output values at the same time. Each channel within the module has its own A/D or D/A converter. This means the cycle time is basically the conversion time and independent of the number of activated channels. This is true for analog input modules as well as analog output modules. This means HS modules can be used in fast isochronous mode.

Apart from isochronous mode, the HS analog modules also provide benefits in non-isochronous (free-running) mode. Due to the fast processing of the process signals, HS analog modules are able to detect changes in the process values more quickly and to respond to

these events with the appropriate program blocks (for example, hardware interrupt or cyclic interrupt organization blocks).

Isochronous mode

Isochronous mode refers to synchronous coupling

- Of signal acquisition and output via the distributed I/O
- Of signal transmission via PROFIBUS or PROFINET
- Of program processing with the constant bus cycle time of the PROFIBUS or PROFINET.

The result is a system that acquires its input signals in constant time intervals, processes them and outputs the output signals. Isochronous mode guarantees reproducible and defined process reaction times as well as equidistant and synchronous signal processing with distributed I/O.

The bus system and the I/O modules work synchronously with configured isochronous mode. The transmitted input and output data are linked to an "isochronous task" in the CPU. As a result, the data of a cycle are always consistent. All data of a process image belong together logically and in time. Jitter in the user program caused by the acquisition of outdated values is therefore almost impossible.

Even fast processes can be perfectly controlled by the exact timely reproducibility of all processes. Isochronous mode thus contributes to high control quality and hence to greater manufacturing precision. While possible fluctuations of the process reaction times are drastically reduced. The time-assured processing can be utilized to improve machine cycle times. Shorter cycle times increase the processing speed and help to lower production costs.

Oversampling

The use of the oversampling function in analog input or analog output modules requires an isochronous configuration.

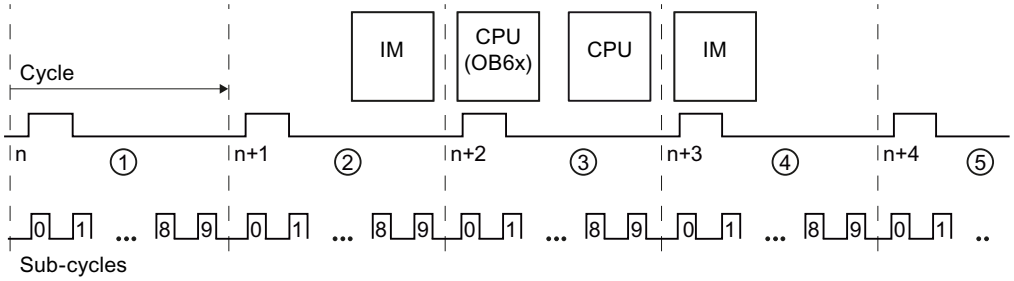
With analog input modules, the set send clock is divided into time-equidistant sub-cycles. The send clocks can be subdivided into 2 to 16 sub-cycles. Each sub-cycle reads in a measured value. The read-in measured values of a data cycle are copied to the interface module (IM) in the next send clock and are then available to the processing CPU one clock later.

With analog output modules, the set send clock is also divided into time-equidistant sub-cycles. The send clocks can be subdivided into 2 to 16 sub-cycles. Each sub-cycle returns an output value. The output values are copied to the interface module by the CPU within the same send clock and are written to the process one send clock later.

The read-in and output values are transmitted in the user data of the analog module. In this way, the address space of the module is extended from 2 bytes of user data per channel to 16 x 2 bytes of user data per channel (with 16 sub-cycles). If you subdivide the send clock into fewer than 16 sub-cycles, the unused addresses are assigned the error value 0x7FFF during input. For output, the values of the unused addresses are ignored.

Because the sub-cycles have to be within a send clock, oversampling needs an additional clock to copy the data to the interface module, unlike the 3-cycle model of isochronous mode. The result is a 5-cycle model.

Isochronous mode



① Send clock is divided into sub-cycles which record the measured value (in this case: 10 sub-cycles)

② Measured values are copied to the IM

③ Measured values are processed and output values determined

④ Output values are copied by the CPU to the IM

⑤ Output values are written to the process

Higher sampling rates through oversampling

Due to the configured modules, the IO device has a minimum possible update time. Within this update period, the IO device/IO controller of the PROFINET IO system is supplied once with new data.

The following applies with respect to the channels of a single standard module in the I/O device: The shortest update time ("sampling rate") is exactly one send clock.

If you want to shorten the update time for the channels of a standard module, you have to shorten the send clock. Because of the properties of the involved components and the structure of the I/O system, this is only possible to a certain extent (e.g., down to 0.25 ms).

Modules with oversampling, however, offer the option of further reducing the update time ("sampling rate") for their channels without having to shorten the send clock for the entire IO device at the same time.

The subdivision of the send clock into time-equidistant sub-cycles enables the processing of faster processes through higher sampling rates.

Example

In practice, the use of oversampling makes sense when the isochronous system works with only one specific send clock (for example, 1 ms) due to the modules used and when faster sampling of the process values is required. By using oversampling and subdividing the send clock into 4 sub-cycles, for example, you can sample the process values in intervals of 250 µs.

Configuring oversampling

Enable the option "Isochronous mode" in the IO device used, and set the corresponding parameters ("Send clock", etc.).

With the distributed analog input modules (e.g. AI 2xU/I 2,4-wire HS), you specify the number of sub-cycles using the "Sampling rate" parameter.

With the distributed analog output modules (e.g. AQ 2xU/I HS), you specify the number of sub-cycles using the "Sampling rate" parameter.

If, for example, you configure a "Sampling rate" of 4 "Values/cycle" for a send clock of 1 ms, the send clock is subdivided into 4 sub-cycles and the process values are sampled at intervals of 250 µs.

Reference

You can find additional information in the manuals on the high-speed analog modules and in the Analog value processing (http://support.automation.siemens.com/WW/view/en/67989094) function manual.

Special features of AI 4xRTD/TC 2-/3-/4-wire HF

Use of Cu10 sensors

- Select "3-wire thermal resistor" and "Cu10" in the parameter assignment.
- Wire the Cu10 sensor using 3-wire connection technology.
- An automatic, internal compensation of the line resistance of the missing measuring line takes place during operation.

Note

To ensure optimum line compensation for Cu10, please note the following:

- The sum of cable resistance and measuring resistance must not exceed 31 Ω.
- Cable resistance should not exceed 8 Ω if you want to use the temperature range up to over 312 °C.
  Example: A 200 m long copper cable with 0.5 mm^2 core cross-section has approx. 7 Ω.
  A lower cross-section reduces the permissible cable length accordingly.

Use of PTC resistors

PTCs are suitable for temperature monitoring of or as thermal protective equipment for complex drives or transformer windings.

- Select "2-wire resistor" and "PTC" in the parameter assignment.
- Connect the PTC using 2-wire technology.
- Use type A PTC resistors (PTC thermistors) in accordance with DIN/VDE 0660, Part 302.
- If the "Over-/underflow" diagnostics is enabled, a "low limit violation" diagnostics which shows a short circuit is generated for resistance values < 18 Ω.
- Sensor data on PTC resistance:

Table 10-98 Use of PTC resistors

Property	Technical specifications	Note
Switching points	**Reaction to rising temperature**	
	< 550 Ω	**Normal range:** • SIMATIC S7: bit 0 = "0", bit 2 = "0" (in the PII)
	550 Ω to 1650 Ω	**Prewarning range:** • SIMATIC S7: bit 0 = "0", bit 2 = "1" (in the PII)
	< 1650 Ω	**Response range:** • SIMATIC S7: bit 0 = "1", bit 2 = "0" (in the PII)
	Reaction to falling temperature	
	< 750 Ω	**Response range:** • SIMATIC S7: bit 0 = "1", bit 2 = "0" (in the PII)

- Assignment in the process image inputs (PII) with SIMATIC S7

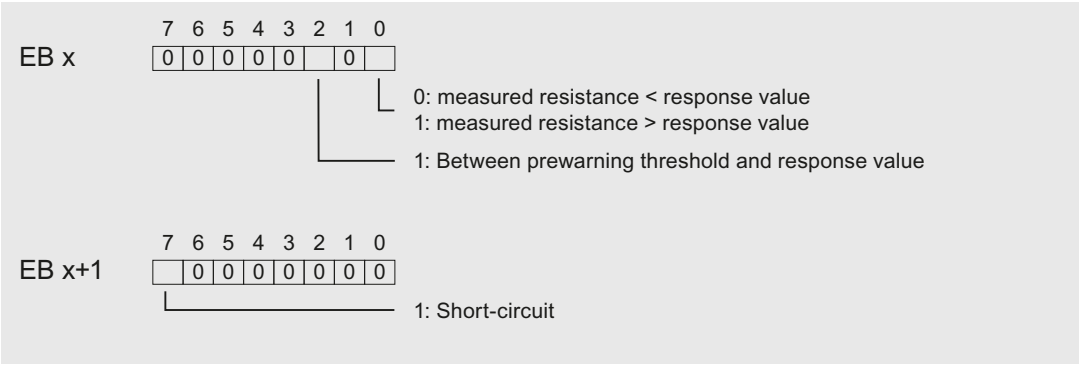

Figure 10-6 Assignment in the process image inputs (PII)

- Notes on programming

Note

Only the bits 0+2 are relevant for the evaluation in the process image inputs. You can use the bits 0+2 to monitor the temperature, for example, of a motor.

The bits 0+2 in the process image inputs have no latching function. When you are assigning parameters, take into consideration that a motor, for example, starts up in a controlled manner (via an acknowledgment).

Bits 0+2 can never be set simultaneously, but are instead set consecutively.

For safety reasons, always evaluate the diagnostic entries of the AI 4×RTD/TC 2-/3-/4-wire HF, as no measurement is possible if I/O modules are unplugged, if the supply voltage of the I/O module has failed, or if there is a wire break or short circuit of the measuring lines.

Example

The following diagram shows the temperature variation and the associated switching points.

Parameters of the analog input modules (Page 1289)

What you should know about the scalable measuring range (Page 1303)

What you should know about the scalable measuring range

The scalable measuring range

The scalable measuring range is a section from the temperature measuring range of an analog input module (for example, the ET 200SP module "AI 8xRTD/TC 2-wire HF").

In this section, a higher resolution of the measured values is possible, comparable with a magnifier that allows a subsection to be viewed in greater detail.

The scalable measuring range is supported for the following measurement types:

- Thermal resistor (RTD) standard
- Thermocouple

The scalable measuring range is not available with the following measurement types:

- Voltage
- Resistance
- Thermal resistor climatic

Position and resolution of the scalable measuring range

The position and resolution of the scalable measuring range can be set (scaled):

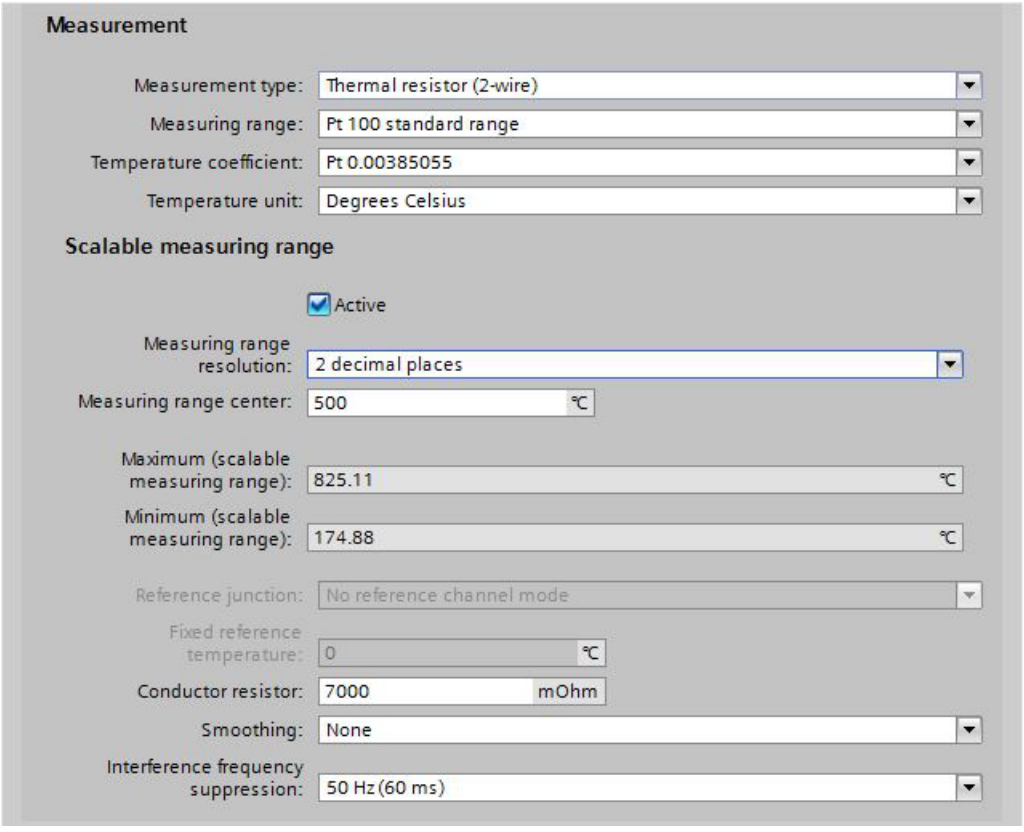
- **Position:** The scalable measuring range can be moved over the entire standard measuring range. This allows you to select the temperature range for which your application requires a higher resolution.
  Exception: The scalable measuring range cannot be moved to the extent that it enters the overflow or underflow of the standard measuring range (Clipping).
  You select the position of the scalable measuring range with the "Measuring range center" parameter (see figure below).
- **Resolution:** The following values can be set:
  - 2 decimal places (0.01 °C)
  - 3 decimal places (0.001 °C)

  You set the resolution with the "Measuring range resolution" parameter (figure below).

Example of a parameter assignment

The following figure shows a parameter assignment for the ET 200SP module "AI 8xRTD/TC 2-,3-,4-wire HF".

In STEP 7, you can find parameters in the properties box via General > AI 4 > Inputs > Channel 0 to channel 3.



Conductor resistor:

The "Conductor resistor" parameter in the parameter assignment above is enabled only if the "Thermal resistor (2-wire terminal)" measurement type was selected.

Here, enter the value for the resistance of the connecting cable of the thermal resistor: A 200 m long copper cable with 0.5 mm^2 wire cross-section, for example, has a resistance value of seven ohms.

Measuring range resolution:

In the parameter assignment above, a resolution of 0.01 °C was selected (measuring range resolution "2 decimal places").

Measuring range center:

The measuring range center is set to 500 °C.

With a resolution of 0.01 °C, this results in a scalable measuring range from 174.88 °C to 825.11 °C.

At a resolution of 0.01 °C, the scalable measuring range covers 650.23 °C.

Maximum (scalable measuring range):

This value represents the high limit of the scalable measuring range. In the example above, 825.11 °C.

The value is calculated by STEP 7 (at a resolution of 0.001 °C, the high limit is at 532.511 °C, see figure below).

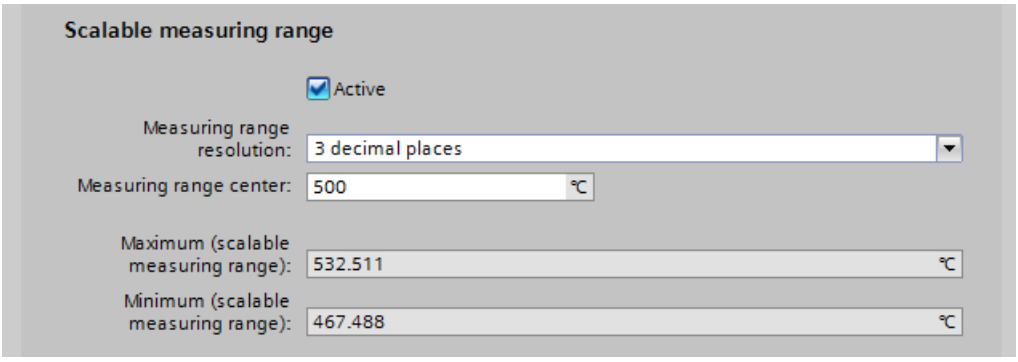
Minimum (scalable measuring range):

This value represents the low limit of the scalable measuring range. In the example above, 174.88 °C.

The value is calculated by STEP 7 (at a resolution of 0.001 °C, the low limit is at 467.488 °C; see figure below).

Higher resolution:

The following figure shows a parameter assignment with a resolution of 0.001 °C (otherwise the same example as in the figure above):



At a resolution of 0.001 °C, the scalable measuring range is between 467.488 and 532.511 °C and covers 65.023 °C (a tenth of the measuring range at a resolution of 0.01 °C).

Standard measuring range with 0.1 °C resolution

The following table shows the standard measuring range for thermal resistors of the type "Pt 100", values in degrees Celsius.

Pt 100 standard in °C (1 digit = 0.1 °C)	Decimal values	Hexadecimal values	Ranges
> 1000.0	32767	7FFF	Overflow
1000.0 : 850.1	10000 : 8501	2710 : 2135	Over range
850.0 : -200.0	8500 : -2000	2134 : F830	Nominal range
-200.1 : -243.0	-2001 : -2430	F82F : F682	Under range
< -243.0	-32768	8000	Underflow

The standard measuring range is the basis for the scalable measuring range.

You can set the measuring range center within the nominal range (-200 °C to 850 °C, see table above).

For temperatures below and above the set measuring range center, you then obtain measured values with a higher resolution.

The width of this range around the measured value center depends on the selected resolution.

Scalable measuring range 0.01 °C and 0.001 °C resolution

The scalable measuring range is identified by the following value ranges:

Scalable measuring range	Measuring range resolution (values in °C)		Hexadecimal values
	2 decimal places	3 decimal places	
Overflow	> 325.11	> 32.511	7FFF
High limit	325.11	32.511	7EFF
Measuring range center	0	0	0
Low limit	325.11	-32.511	8100
Underflow	< -325.11	< -32.511	8000

The maximum and minimum of the scalable measuring range depend on the selected resolution:

- 2 decimal places, resolution of 0.01 °C:
  The high limit is 325.11 °C above the measuring range center you have set.
  The low limit is 325.11 °C below the measuring range center you have set.
  This means that the scalable measuring range is 650.22 °C around the measuring range center.
- 3 decimal places, resolution of 0.001 °C:
  The high limit is 32.511 °C above the measuring range center you have set.
  The low limit is 32.511 °C below the measuring range center you have set.
  This means that the scalable measuring range is 65.022 °C around the measuring range center.

Calculation of the temperature

You calculate the temperature value by adding the value you receive from the module to the measuring range center.

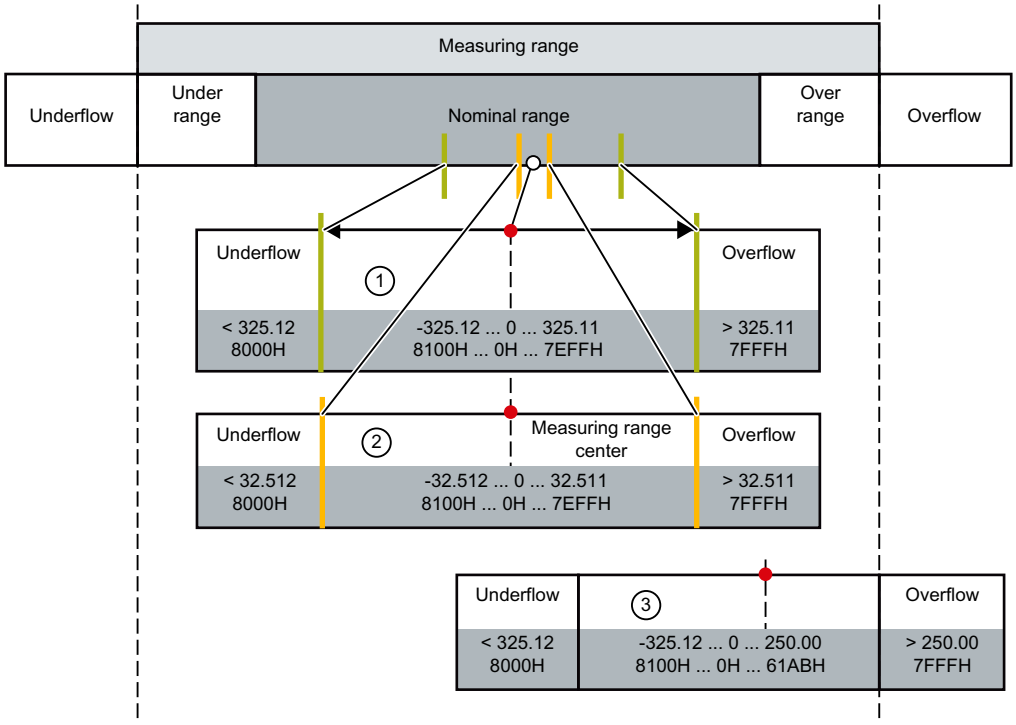
Example:

- You have set the measuring range center 500 °C (see example in the section "Example of a parameter assignment"). For the resolution, you selected "2 decimal places".
- From the module, you receive the hexadecimal value "0100" in S7 format:

Bit 15	Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Bit 9	Bit 8	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

- The hexadecimal value "0100" corresponds to the decimal value 256.
- Since you have selected a resolution of 0.**01** °C, the number 256 corresponds to the temperature value "2.**56** °C".
- You now add 500 °C and 2.56 °C and obtain the measured value 502.56 °C.

Scalable measuring range in the standard measuring range



① Scalable measuring range with 2 decimal places, temperature values in S7 format.

② Scalable measuring range with 3 decimal places, temperature values in S7 format.

③ Scalable measuring range cut off at the overflow of the standard measuring range ("Clipping").

The sum of the measuring range center (for example 750 °C) and the measured value returned by the module must not extend into the overflow of the standard measuring range. For this reason, in the example above, the maximum value that the module can return is limited to 250 °C

Clipping

STEP 7 limits the maximum of the scalable measuring range so that the sum of the measured value center and the maximum measured value that the module can return is not located in the overflow of the standard measuring range. In the same way, STEP 7 restricts the minimum of the scalable measuring range.

ET 200AL

ET 200AL distributed I/O system

SIMATIC ET 200AL

The SIMATIC ET 200AL distributed I/O system is a scalable and highly flexible, distributed I/O system for connecting process signals to a superordinate control with a field bus.

Properties

- Connection to PROFINET, PROFIBUS or integration in ET 200SP
- Up to 32 modules on an ET 200AL
- Integration in ET 200SP: Up to 16 AT modules can be connected to an ET 200AL
- Connection of modules via ET-Connection
- Spatially separated mounting possible
- Module widths of 30 and 45 millimeters
- Degree of protection IP65/IP67
- Suitable for temperatures from -25 to +55 °C and accelerations up to 5 g.
- Installation in all positions
- Color coding of the cables and connections
- CA-compliant labeling of the interfaces
- PROFIenergy integrated
- Configuration control
- Connection of sensors and actuators using M8 and M12 connection system

Area of application

The SIMATIC ET 200AL distributed I/O system is especially well suited for use in tight spaces, moving applications and for assembly and handling technique. Thanks to its scalable construction, you have the option precisely customize its configuration to your on site needs.

The SIMATIC ET 200AL distributed I/O system features protection type IP65/IP67 and is suited for distributed use on a machine or assembly line.

Structure

The SIMATIC ET 200AL distributed I/O system is made up of the following components:

- Interface modules (PROFINET/PROFIBUS)
- Digital and analog I/O modules
- Communications module

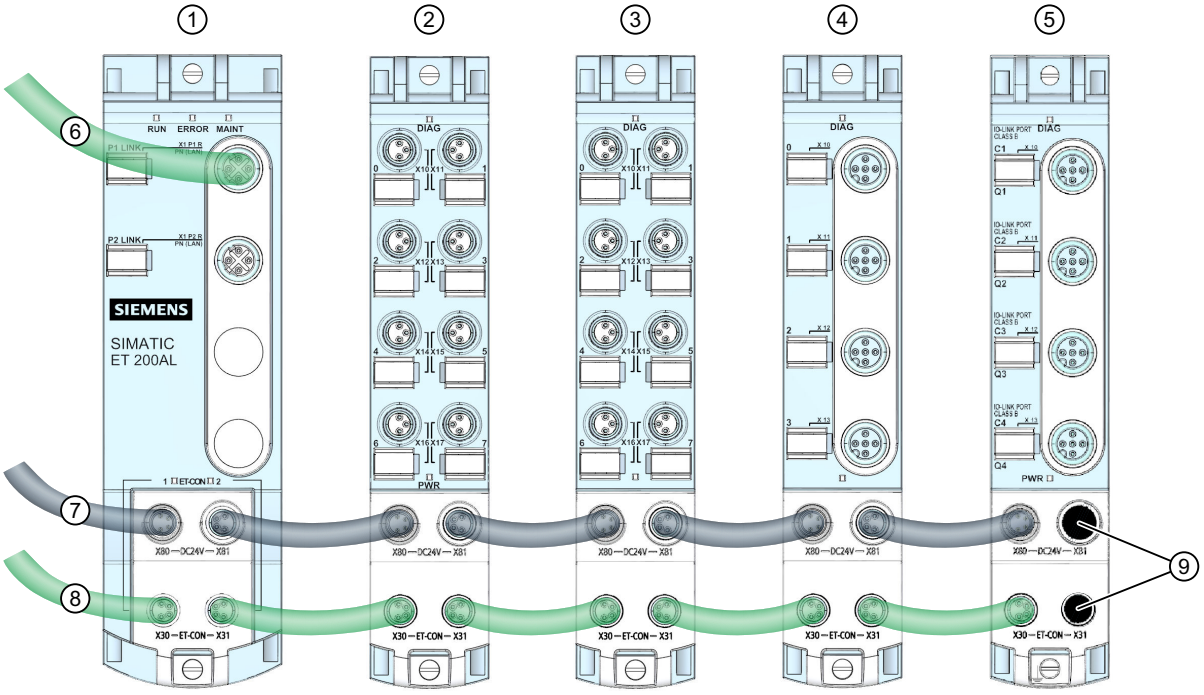
After an interface module you can configure 2 lines (ET-Connection), each with 16 modules.

Alternatively, you can configure a line with 16 I/O modules on the SIMATIC ET 200SP distributed I/O system with BaseUnit BU-Send and the BusAdapter BA-Send 1xFC.

The ET-Connection backplane bus is designed as a cable. This allows you to create spatial distances of up to 10 m between the modules.

Configuration example

The figure below shows a configuration example of the SIMATIC ET 200AL distributed I/O system with a PROFINET interface module.



① Interface module (PROFINET)
② Digital input/Digital output module
③ Digital input module
④ Analog input module
⑤ Communications module
⑥ PROFINET cable
⑦ Power supply cable
⑧ ET-Connection line
⑨ Sealing caps

Figure 10-7 Example configuration of the ET 200AL

Configuring ET 200AL

Introduction

ET 200AL is a distributed I/O system with an IP65/67 degree of protection. It is therefore designed for use on site, for example right beside a machine (no control cabinet required).

The system includes interface and communications modules as well as input and output modules.

There are two use cases for the ET 200AL:

1. As I/O device or DP slave: The system interface module is connected to a field bus (PROFINET or PROFIBUS) and connected to the PN or DP interface of a CPU.
2. As an ET 200SP expansion: The ET 200AL modules are connected to the ET 200SP over the "BA Send 1xFC" module ("mixed mode").

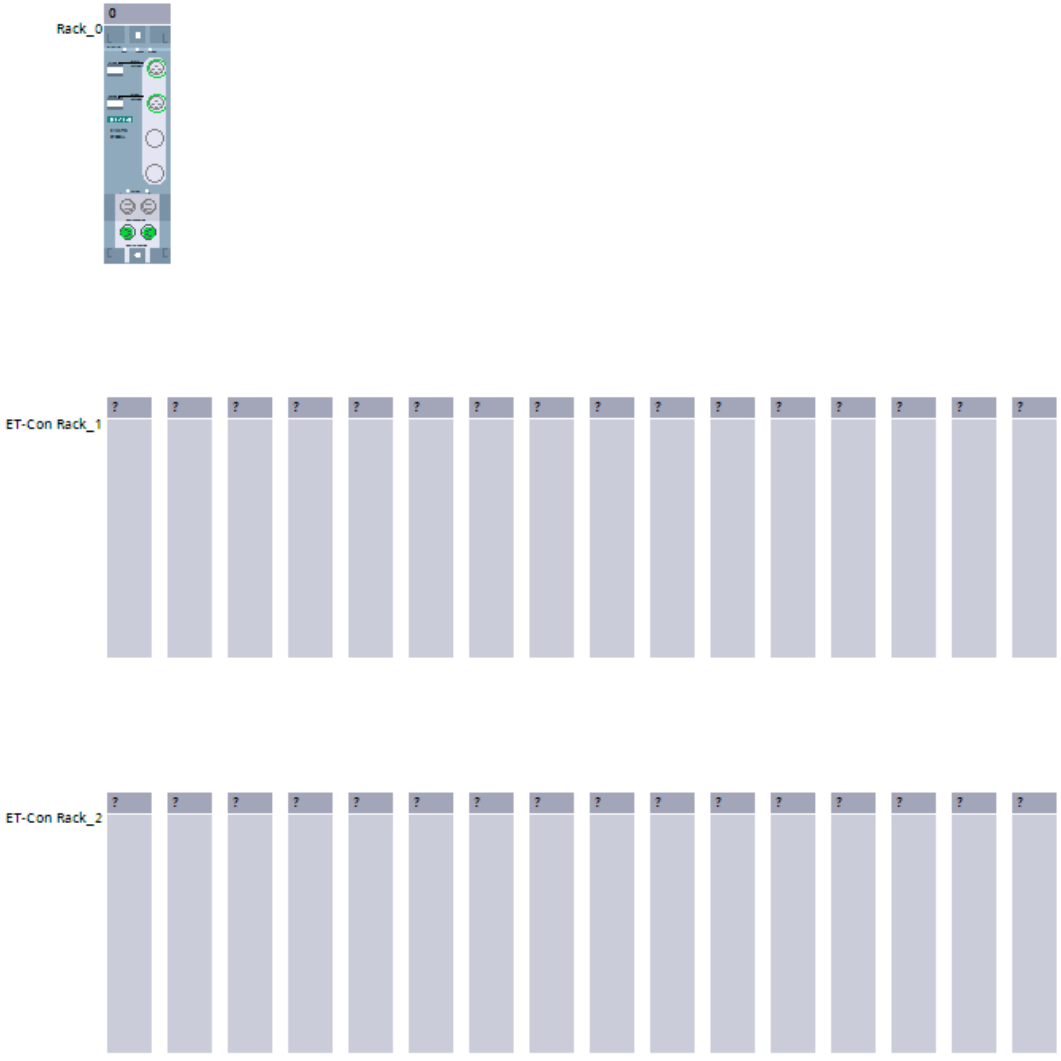
The following sections describe how to configure an ET 200AL as I/O device or DP slave (use case 1).

For use case 2, see the link under "See also".

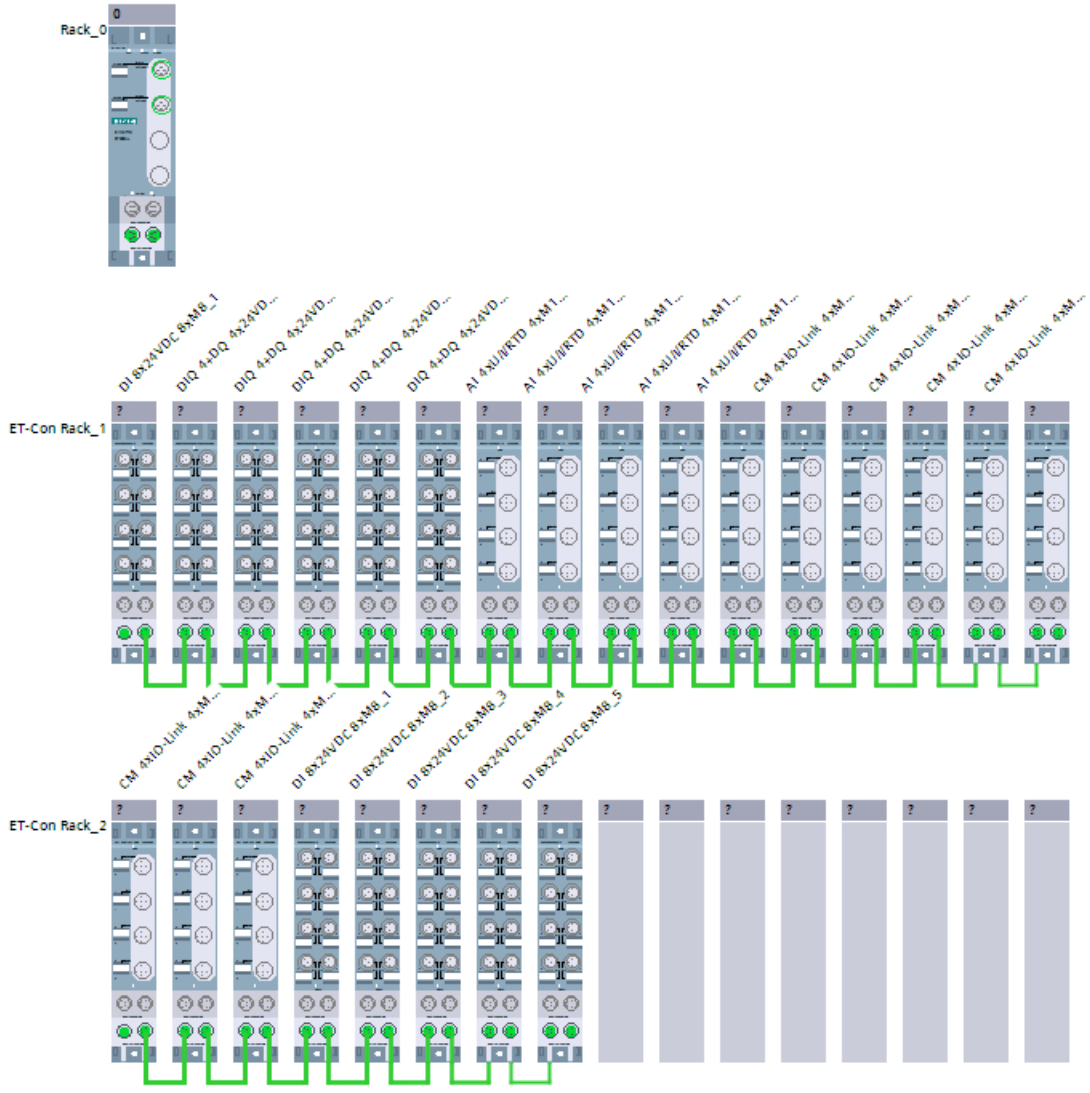
Procedure

Follow the steps below to configure an ET 200AL in STEP 7:

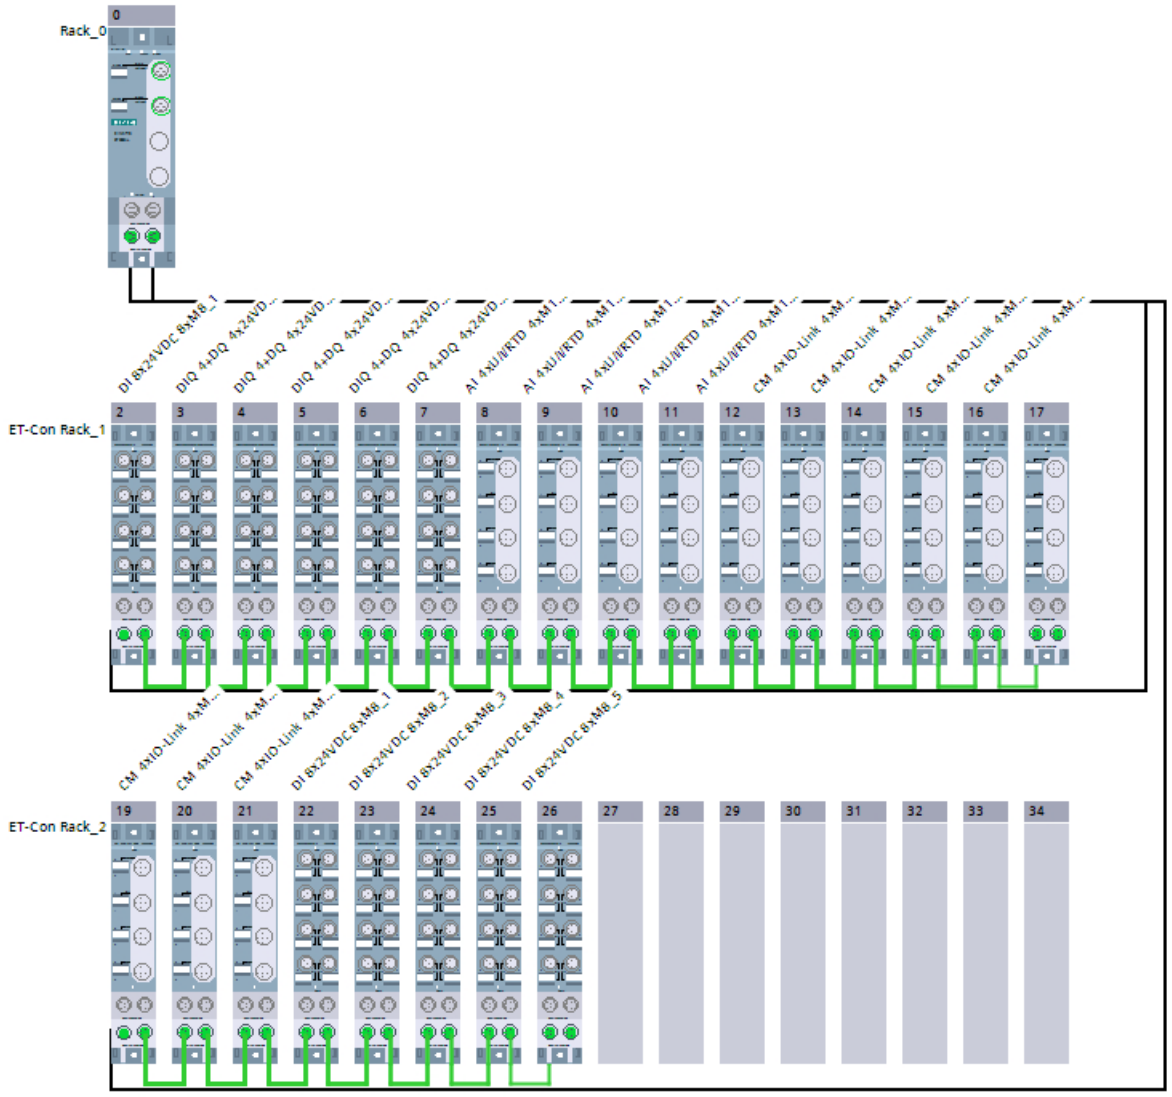
1. Copy an interface module (PROFINET or PROFIBUS) from the ET 200SP series to the network view (drag-and-drop operation from the hardware catalog).
2. Go to the device view. Double-click on the interface module you have just inserted.
   The interface module and two ET-Connection racks are displayed in the device view (figure below).
   There are no slot numbers assigned yet, which is why question marks are displayed above the slots.



3. Now select the modules (input, output and communication modules) from the hardware catalog (ET 200AL folder) and drag them to the free slots (outlined in blue; not shown). You can place up to 16 ET 200AL modules in each ET-Connection rack (figure below). An ET-Connection rack is a virtual rack that sets the order of the connected ET 200AL modules.



4. Now connect the interface module to the two ET-Connection racks.
   First click on an ET-Connection interface of the interface module, then hold and drag a line to the left-hand ET connection of the first module in one of the two ET-Connection racks.
   Repeat this step for the second ET-Connection interface of the interface module and the second ET-Connection rack (if used).



5. Double-click on a module to access the module properties and set the module parameters.

Rules

- The ET 200AL modules must be configured with no gaps.
- The first module in an ET-Connection rack must be connected to the interface module.

ET 200AL distributed I/O system (Page 1309)

Configuration control with ET 200AL

Operating principle

With configuration control, you can change the original configuration of an ET 200AL (created by configuring with STEP 7) with a user program and operate the ET 200AL in this modified configuration. STEP 7 is no longer required for this configuration: You use your user program to signal to the ET 200AL the slot in which a configured module is actually inserted.

You use control data record 196 for this. In this data record, you code which modules are missing or located in different slots in the real configuration compared to the configuration with STEP 7. The configuration control has no effect on the parameter assignment of the modules (for example, the enabling of diagnostic alarms).

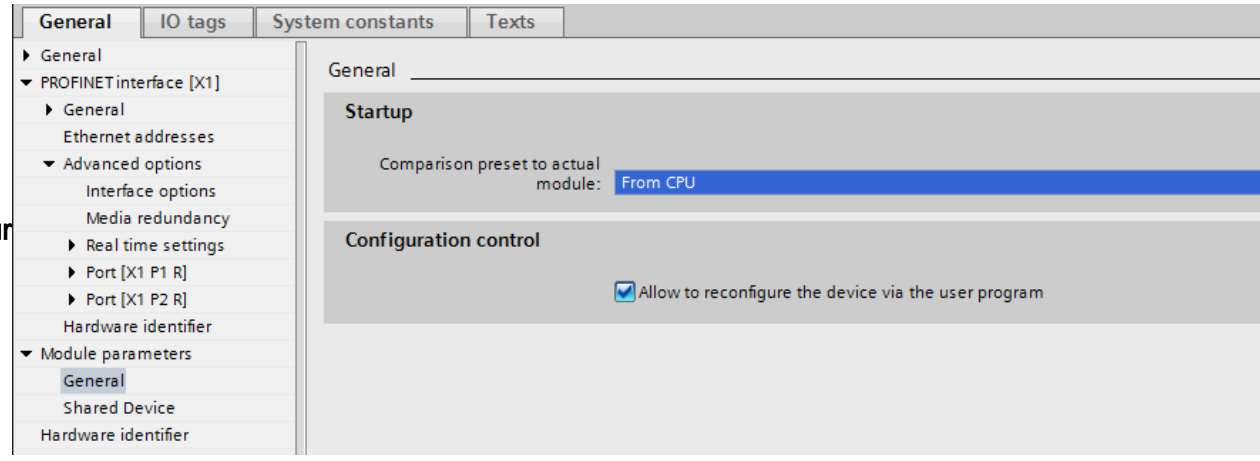
You then call the "WRREC" instruction and use it to write the data record to the interface module of the ET 200AL.

Configuration control gives you the flexibility to vary the configuration of an ET 200AL as long as the real configuration can be derived from a preset maximum configuration (originally created with STEP 7).

The following sections describe how to enable configuration control and how to structure the required data record 196 for the ET 200AL.

Requirement

Enabling configur



Structure of control data record 196

The configuration of the data block corresponds to the original configuration of the ET 200AL with STEP 7.

There are two bytes in the data record for each module. The position of these two bytes in the data record codes a module in the original configuration with STEP 7.

- Bytes 4 and 5 in the data record correspond to the module in slot 1 in the original configuration.
- Bytes 6 and 7 in the data record correspond to the module in slot 2 in the original configuration.
- Bytes 8 and 9 in the data record correspond to the module in slot 3 in the original configuration.
- etc.

The current (real) slot is coded by the number that is assigned to the "Slot_x" byte (by its value): Examples:

- The value "2" in byte 6 means you are assigning the module originally inserted in slot 2 to slot 2 in the current configuration.
- The value "3" in byte 6 means you are assigning the module originally inserted in slot 2 to slot 3 in the current configuration.
- The value "4" in byte 6 means you are assigning the module originally inserted in slot 2 to slot 4 in the current configuration.
- etc.

Creating control data record 196

The figure below shows part of control data record 196 for configuration of an ET 200AL.

This configuration is given as an example:

- ET-Con1 is inserted in "slot_1" (fixed setting). The two ET-Connection submodules "ET-Con1" and "ET-Con2" are submodules of the interface module of the ET 200AL. They are integrated as fixed modules in the IM module. They cannot be inserted individually.
- ET-Con2 is inserted in "slot_18" (fixed setting).
- In this configuration, 16 AL modules are connected to ET-Con1 ("slot_2" to "slot_17" in the following data record). This is the maximum configuration.
- In this configuration, one AL module is connected to ET-Con2 ("slot_19"). However, a total of 16 AL electronic modules could be connected to ET-Con2 (as to ET-Con1).

The ET 200AL originally configured with STEP 7 is now to be reconfigured from the user program.

The new configuration has the following properties:

- ET-Con1 is inserted in "slot_1" (fixed setting).
- Module 2 is also operated in slot 2 in the modified configuration.
- Module 3 is not used.
- Module 4 is now inserted in slot 3.
- Module 5 is now inserted in slot 4.
- No other modules at ET-Con1 are used.

- ET-Con2 is inserted in "slot_18" (fixed setting)
- The module at ET-Con2 is used.

Record_196_ET_200AL

	Name	Data type	Default value

42	reserve_19	USInt	0

The components of control data record 196 (definition in section "Control data record 196" below):

- block_length: Note the length of the control data record here; in the example: 42 (bytes). The length of the control data block is calculated using the following formula: 2 x "number of modules" + 4.
- block_ID: Enter the figure 196 here. This number identifies the data record as the data record for configuration control.
- version: The ET 200AL uses version 2 of control data record 196.
- subversion: The ET 200AL uses subversion 1 of control data record 196.
- slot_1: The ET-Connection 1 submodule is always inserted in slot 1 of the ET 200AL.
- reserve_1: This byte is not used (value "0").
- slot_2: The configured module 2 is inserted in slot 2 (value "2").
- reserve_2: This byte is not used (value "0").
- slot_3: The configured module 3 is not present in the current configuration (value "0").
- reserve_3: This byte is not used (value "0").
- slot_4: The configured module 4 is inserted in slot 3 in the current configuration (value "3").
- reserve_4: This byte is not used (value "0").
- slot_5: The configured module 5 is inserted in slot 4 in the current configuration (value "4").
- reserve_5: This byte is not used (value "0").
- slot_6: The configured module 6 is not present in the current configuration (value "0").
- reserve_6: This byte is not used (value "0").
- slot_7: The configured module 7 is not present in the current configuration (value "0").
- reserve_7: This byte is not used (value "0").
- etc.
- slot_18: The ET-Connection 2 submodule is always inserted in slot 18 of the ET 200AL (value "18").
- reserve_18: This byte is not used (value "0").
- slot_19: The configured module 19 is inserted in slot 19 in the current configuration (value "19").
- reserve_19: This byte is not used. (value "0")

Control data record 196 for ET 200AL

A control data record 196 containing a slot assignment is defined for configuration control.

Byte	Element	Value	Description	
0	Block length in bytes	e.g. 14 for ET 200AL with 5 modules	The length of the data record is calculated using the formula: 4 + (number of modules x 2) bytes	Header
1	Block ID	196	ID for control data record 196	
2	Version	2	Version 2 of control data record 196	
3	Subversion	1	Subversion 1 of control data record 196	
4	Configured module 1 (ET-Connection 1)	1	ET-Connection 1 is always assigned to slot 1 (fixed). The value "1" must therefore always be entered in byte 4.	Assignment for configured module 1 (ET-Connection 1) to real slot 1
5	Reserve for configured module 1	0	Not used	
6	Configured module 2	Real slot of module 2 Possible values: 2 up to the number of modules (except 18) 0 (if the configured module 2 is not present)	The configured module 2 can be inserted in any slot from 2 to slot 34. Slot 18 is reserved for ET-Con 2. If the configured module is not used, this byte contains the value "0".	Assignment for the configured module 2 to a real slot
7	Reserve for configured module 2	0	Not used	
8	Configured module 3	Real slot of module 3 Possible values: 2 up to the number of modules (except 18) 0 (if the configured module 2 is not present)	The configured module 3 can be inserted in any slot from 2 to slot 34. Slot 18 is reserved for ET-Connection 2. If the configured module is not used, this byte contains the value "0".	Assignment for the configured module 3 to a real slot
9	Reserve for configured module 3	0	Not used	
:	:	:	:	:
39	Configured module 18 (ET-Connection 2)	18	ET-Connection 2 is always assigned to slot 18 if AT modules are connected at this submodule.	Assignment for configured module 18 (ET-Connection 2) to real slot 18
40	Reserve for configured module 18	0	Not used	
:	:	:	:	:

(Bytes 4 to 70, not byte 39)	Configured module x	Real slot of module x Possible values: 2 up to the number of modules (except 18) 0 (if there is no configured module x)	The configured module x can be inserted in any real slot from 2 to slot 34. Slot 18 is reserved for ET-Con 2 (bytes 39 and 40 in the control data record)	Assignment for configured module x to a real slot y
(Bytes 5 to 71, not byte 40)	Reserve for configured module x	0	Not used	

Rules

- The ET-Connection 1 and ET-Connection 2 submodules must be treated like real modules in configuration control. Restriction: ET-Connection 1 is always placed in slot 1 and ET-Connection 2 is always placed in slot 18 (fixed assignment).
- There are no reserve modules for the ET 200AL (unlike for the ET 200S or with BU cover modules for the ET 200SP). For this reason, bit 7 of "slot_x" must not be set (i.e. only the values 0 to 127 may be used).
- The value "0" of "slot_x" indicates that this module is not inserted in the current configuration.
- Gaps must not be left between the AL modules when configuring with STEP 7.
- If no modules are connected to ET-Con2 when STEP 7 is configured, ET-Con2 is not configured: This shortens data record 196.
- If fewer than 16 modules are connected to ET-Con1 during configuration with STEP 7 and there are also modules connected to ET-Con2, control data record 196 must contain all unassigned slots for ET-Con 1. They are assigned zero as the value for the real slot.

Writing a data record

Transfer the control data record to the ET 200AL module.

To do so, call the extended WRREC (Write data record) instruction, and transfer the control data record created.

If you do not transfer a control data record, the interface module uses the original configuration created with STEP 7. In this case, the following applies: Configured module x is inserted in real slot x.

Addressing the interface module using the HW identifier

To transfer data record 196 with the instruction WRREC, you must enter the HW identifier of the IM submodule with the extension "~Head" as the input parameter for the instruction. The system constant of this HW identifier is, for example, "IO-Device_2~Head". The system constants of a selected device are, for example, displayed in the network view in the "System constants" tab. Use the corresponding value for addressing.

Error messages

The following error messages are returned if an error occurs when writing control data record 196:

Table 10-99 Error messages

Error code	Meaning
16#80A2	DP protocol error on layer 2. Indicates that a data record has not been acknowledged due to the system.
16#80B1	Invalid length; the length information in data record 196 is not correct.
16#80B5	Configuration control parameters not assigned.
16#80B2	Invalid slot: The configured slot is not assigned.
16#80B8	Parameter error; module signals invalid parameters.
16#80C5	DP slave or module not available. Indicates that a data record has not been acknowledged due to the system.

Readback data record 197 for ET 200AL

Readback data record 197 is used to read the actual configuration of a station (in this case of an ET 200AL).

This data record allows you to check the real configuration of the ET 200AL (actual configuration). The readback data record for each configured module specifies whether or not it is actually available.

- The value "1" means that the correct module is inserted in the correct slot.
- The value "0" codes all other options (wrong module, empty slot, BU cover).

Example:

A module has been configured with STEP 7 for slot 4.

This module has then been moved to slot 3 in the current configuration using data record 196.

If this module is also really in slot 3, this is coded by the value "1" (status_slot_4 = 1).

Configuration details:

The configuration of the data block corresponds to the original configuration of the ET 200AL with STEP 7.

There are two bytes in the data record for each module. The position of these two bytes in the data record corresponds to the position of a module in the original configuration with STEP 7.

Sequence of bytes:

- "status_slot_1_ET_Con1" and "reserve_slot_1_ET-Con1" (bytes 4 and 5 in the data record) correspond to the module in slot 1 in the configuration,
- "status_slot_2" and "reserve_slot_2" (bytes 6 and 7) correspond to the module in slot 2 in the configuration
- "status_slot_3" and "reserve_slot_3" (bytes 8 and 9) correspond to the module in slot 3 in the configuration,
- etc.

Example

The following readback data record 197 is returned by the ET 200AL that was reconfigured with control data record 196 in the example above (section "Creating control data record 196").

Record_197_ET_200AL

	Name	Data type	Default value
1	block_length	USInt	42
2	block_ID	USInt	197
3	version	USInt	2
4	subversion	USInt	1
5	status_slot_1_ET_Con1	USInt	1
6	reserve_1_ET_Con1	USInt	0
7	status_slot_2	USInt	1
8	reserve_2	USInt	0
9	status_slot_3	USInt	0
10	reserve_3	USInt	0
11	status_slot_4	USInt	1
12	reserve_4	USInt	0
13	status_slot_5	USInt	1
14	reserve_5	USInt	0
15	status_slot_6	USInt	0
16	reserve_6	USInt	0
17	status_slot_7	USInt	0
18	reserve_7	USInt	0
19	status_slot_8	USInt	0
20	reserve_8	USInt	0
21	status_slot_9	USInt	0
22	reserve_9	USInt	0
23	status_slot_10	USInt	0
24	reserve_10	USInt	0
25	status_slot_11	USInt	0
26	reserve_11	USInt	0
27	status_slot_12	USInt	0
28	reserve_12	USInt	0
29	status_slot_13	USInt	0
30	reserve_13	USInt	0
31	status_slot_14	USInt	0
32	reserve_14	USInt	0
33	status_slot_15	USInt	0
34	reserve_15	USInt	0
35	status_slot_16	USInt	0
36	reserve_16	USInt	0
37	status_slot_17	USInt	0
38	reserve_17	USInt	0
39	status_slot_18 ET_Con2	USInt	1
40	reserve_18_ET_Con2	USInt	0
41	status_slot_19	USInt	1
42	reserve_19	USInt	0

Modules 2, 4 and 5 are actually connected to ET-Con1.

None of the other modules that were connected to ET-Con1 in the configuration with STEP 7 are present in the current configuration (in line with the control data record 196 settings from the example above).

A module is really connected to ET-Con2 as in the original configuration with STEP 7.

Reading readback data record 197

You can read readback data record 197 from the ET 200AL with the instruction RDREC. RDREC operates asynchronously. If you call RDREC in the startup OB, you must call the instruction multiple times using a loop until the "BUSY" or "DONE" output parameter indicates that the data record has been read.

To read data record 197 with the instruction RDREC, you must enter the HW identifier of the IM submodule with the extension "~Head" as the input parameter for the instruction. The system constant of this HW identifier is, for example, "IO-Device_2~Head". The system constants of a selected device are, for example, displayed in the network view in the "System constants" tab. Use the corresponding value for addressing.

Further information and examples

Further information on ET 200AL is available here (http://support.automation.siemens.com/WW/view/en/89254863).

Specific examples of configuration control can be found here in this application description (http://support.automation.siemens.com/WW/view/en/29430270).

ET 200MP

ET 200MP distributed I/O system

Definition

The ET 200MP distributed I/O system is a scalable and flexible distributed I/O system for connection of process signals to a central controller via a field bus.

Application area

The ET 200MP is a multi-functional distributed I/O system for various fields of application. The scalable design allows you to configure the system exactly to the specific requirements on location.

The ET 200MP complies with IP 20 degree of protection and is intended for installation in a control cabinet.

Structure

The ET 200MP is installed on a mounting rail and comprises:

- An interface module that communicates with all IO controllers conforming to the PROFINET standard IEC 61158
- Up to 30 modules (power supply modules and I/O modules from the S7-1500 I/O range) can be inserted to the right of the interface module.
- If you insert a power supply module to the left of the interface module, this yields a possible maximum configuration of 32 modules in total.
- The number of insertable I/O modules is limited by their power requirements.

Slot rules

- Slot 0: Power supply module (optional)
- Slot 1: Interface module
- Slot 2 to 31: I/O modules or power supply modules

Interface module parameters

Supply voltage L+ connected

Parameter "Supply voltage L+ connected"

This parameter influences the diagnostics and the checking of the power budget.

- Diagnostics of the ET 200MP:
  If the actual configuration does not match the preset configuration with regard to the supply voltage of the interface module, the interface module generates a diagnostic alarm.
  Example: You have deactivated the "Supply voltage L+ connected" option, but you have connected the supply voltage in the actual configuration.
- Power budget check during configuration:
  The power budget changes in accordance with the parameter setting: Either the interface module feeds power into the backplane bus or it draws power from the backplane bus.

The default ("Supply voltage L+ connected" option is **activated**) means that the front of the interface module is supplied with 24 V DC and the power is stored in the backplane bus.

If the "Supply voltage L+ connected" option is **deactivated**, the interface module may not be supplied with 24 V DC on the front.

In this case, insert a power supply unit (PS) on the left next to the interface module that supplies the interface module and the modules to the right of the interface module.

Note

We recommend that you always supply the interface module on the front side with 24 V DC. If a system power supply unit (PS) is inserted and connected additionally **before** or on the left next to the interface module, both the power from the system power supply unit (PS) as well as the power from the integrated power supply of the interface module are then available to the configuration.

In this case, you do not have to change the default setting of the parameter.

Configuration control with ET 200MP

Operating principle

Configuration control allows you to operate various real configurations (options) with a single configuration of the ET 200MP distributed I/O device.

Configuration control provides you with the option of configuring the ET 200MP distributed I/O device with its maximum configuration and still operating it with modules missing. If missing modules are retrofitted later, no new configuration is required and the hardware configuration does not have to be reloaded either.

Using control data record 196, which is transferred to the interface module in the user program, you define a current configuration. You transfer the control data record with the instruction WRREC.

Readback data record 197 is used to read the actual configuration of an ET 200MP.

Requirements

- STEP 7 Professional version V13 SP1 or higher
- The CPU startup parameter "Compare preset to actual configuration" is set to Startup even if mismatch (default setting). This setting is also selected for the startup parameters of the individual modules of the ET 200MP.

Enabling configuration control

In the properties of the interface module under Module parameters > General > Configuration control, select "Enable reconfiguration of device via user program". This activates configuration control.

Control data record 196 for ET 200MP

The figure below shows the start of control data record 196 for the configuration control of an ET 200MP.

The data block is 36 bytes long (maximum configuration with 32 modules). The value "36" therefore appears in the "block_length" element of the data record.

If you configure an ET 200MP in STEP 7 with fewer modules, the data block will be shorter: If there are only five modules, for example, the data record is reduced to 9 bytes (4 bytes for the header plus one byte for each module).

There is one byte in the data record for each module. The position of this byte in the data record codes a module in the original configuration with STEP 7:

- "slot_0 power supply" (byte 4 in the data record below) corresponds to the power supply module in slot 0 in the configuration with STEP 7.
- "slot_1 interface module" (byte 5 in the data record) corresponds to the interface module in slot 1 in the configuration.
- "slot_2" (byte 6 in the data record) corresponds to the module in slot 2 in the configuration.
- "slot_3" (byte 7 in the data record) corresponds to the module in slot 3 in the configuration.
- "slot_4" (byte 8) corresponds to the module in slot 4 in the configuration.
- etc.

Value in slot_x

The current slot is coded by the figure that is assigned to "slot_x" (by its value). Examples:

- The value "2" in slot_2 means you are assigning the module originally inserted in slot 2 to slot 2 in the current configuration (slot_2 = 2).
- The value "3" in slot_2 means you are assigning the module originally inserted in slot 2 to slot 3 in the current configuration (slot_2 = 3).
- The value "4" in slot_2 means you are assigning the module originally inserted in slot 2 to slot 4 in the current configuration (slot_2 = 4).
- etc.

Example for data record 196

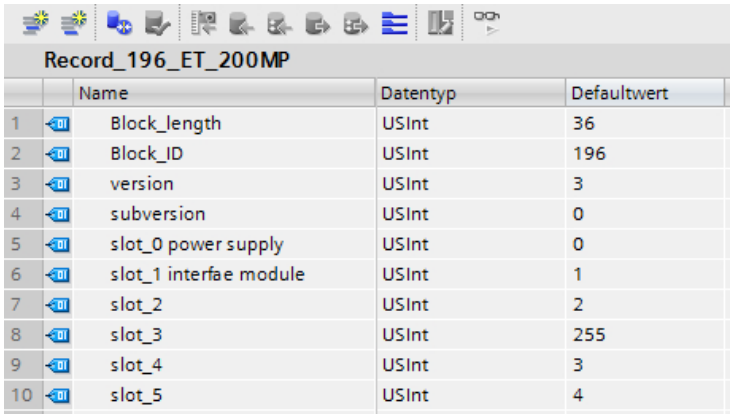
The following data record was created for a configuration that changes the original configuration with STEP 7.

The modified configuration has the following properties:

- The module inserted in slot 0 in the configuration (power supply module) is also inserted in slot 0 in the current configuration (specification).
- The module inserted in slot 1 in the configuration (interface module) is also inserted in slot 1 in the current configuration (specification).
- The module inserted in slot 2 in the configuration (module 2) is also inserted in slot 2 in the current configuration.
- The module inserted in slot 3 in the configuration (module 3) does not exist in the current configuration.
- The module inserted in slot 4 in the configuration (module 4) is inserted in slot 3 in the current configuration.

- The module inserted in slot 5 in the configuration (module 5) is inserted in slot 4 in the current configuration.
- etc.

The bytes "slot_6" to "slot_31" are not shown in the figure below.



Record_196_ET_200MP

	Name	Datentyp	Defaultwert
1	Block_length	USInt	36
2	Block_ID	USInt	196
3	version	USInt	3
4	subversion	USInt	0
5	slot_0 power supply	USInt	0
6	slot_1 interfae module	USInt	1
7	slot_2	USInt	2
8	slot_3	USInt	255
9	slot_4	USInt	3
10	slot_5	USInt	4

Rules

- If a module is not available in the current configuration, this is indicated by the value 255: "slot_x" = 255
- The power supply module is always in slot 0 ("slot_0 power supply" = 0).
- The interface module is always in slot 1 ("slot_1 interface module" = 1).

Addressing the interface module using the HW identifier

To transfer data record 196 with the instruction WRREC, you must enter the HW identifier of the IM submodule with the extension "~Head" as the input parameter for the instruction. The system constant of this HW identifier is, for example, "IO-Device_2~Head". The system constants of a selected device are, for example, displayed in the network view in the "System constants" tab. Use the corresponding value for addressing.

Readback data record 197 for ET 200MP

Readback data record 197 is used to read the actual configuration of a station (in this case, of an ET 200MP).

This data record allows you to check the real configuration of the ET 200MP (actual configuration). The readback data record for each configured module specifies whether or not it is actually available.

- The value "1" means that the correct module is inserted in the correct slot.
- The value "0" codes all other options (wrong module, empty slot, reserve module).

Example:

A module has been configured with STEP 7 for slot 4.

This module has then been moved to slot 3 in the current configuration using data record 196.

If this module is also really in slot 3, this is coded by the value "1" (status_slot_4 = 1).

Configuration details:

The configuration of the data block corresponds to the original configuration of the ET 200MP with STEP 7.

There is a byte in the data record for each module. The position of this bytes in the data record corresponds to the position of a module in the original configuration with STEP 7.

Sequence of bytes:

- "status_slot_0 power supply" (byte 4 in the data record below) corresponds to the power supply module in slot 0 in the configuration with STEP 7.
- "status_slot_1 interface module" (byte 5 in the data record) corresponds to the interface module in slot 1 in the configuration.
- "status_slot_2" (byte 6) corresponds to the module in slot 2 in the configuration.
- "status_slot_3" (byte 7) corresponds to the module in slot 3 in the configuration.
- etc.

You can choose any name for the components (for example "status_slot_2").

Meaning of "status_slot_x":

- The value "1" in status_slot_x means that module x is in the correct slot.
- The value "0" in status_slot_x codes all other options (wrong module, module does not exist).

Example:

The figure below shows readback data record 197 for the configuration of an ET 200MP in which there is no module 3 (the module in slot 3 in the configuration).

All other modules are available and correctly plugged.

The bytes "status_slot_6" to "status_slot_31" are not shown in the figure below.

Record_197_ET_200MP

	Name	Datentyp	Defaultwert
1	Block_length	USInt	36
2	Block_ID	USInt	197
3	version	USInt	3
4	subversion	USInt	0
5	status_slot_0 power supply	USInt	1
6	status_slot_1 interfae module	USInt	1
7	status_slot_2	USInt	1
8	status_slot_3	USInt	0
9	status_slot_4	USInt	1
10	status_slot_5	USInt	1

Reading readback data record 197

You can read readback data record 197 from the ET 200MP with the instruction RDREC. RDREC operates asynchronously. If you call RDREC in the startup OB, you must call the instruction multiple times using a loop until the "BUSY" or "DONE" output parameter indicates that the data record has been read.

To read data record 197 with the instruction RDREC, you must enter the HW identifier of the IM submodule with the extension "~Head" as the input parameter for the instruction. The system constant of this HW identifier is, for example, "IO-Device_2~Head". The system constants of a selected device are, for example, displayed in the network view in the "System constants" tab. Use the corresponding value for addressing.

Further information and examples

Further information on ET 200MP can be found in the manual for IM 155-5 PN (http://support.automation.siemens.com/WW/view/en/89261636).

Specific examples of configuration control can be found in this application description (http://support.automation.siemens.com/WW/view/en/29430270).

See also

Documentation on configuration control (http://support.automation.siemens.com/WW/view/en/67295970)

Input module parameters

Parameters of the analog input modules

Missing supply voltage L+

Enabling of the diagnostics for missing or insufficient supply voltage L+.

Wire break

Enabling of the diagnostics if the module has no current flow or the current is too weak for the measurement at the corresponding configured input or the applied voltage is too low.

Current limit for wire break diagnostics

Threshold at which a wire break is reported. The value can be set to 1.185 mA or 3.6 mA, depending on the sensor used.

Overflow

Enabling of the diagnostics if the measured value exceeds the overrange.

Underflow

Enabling of the diagnostics if the measured value undershoots the underrange.

Common mode error

Enable diagnostics if the valid common mode voltage is exceeded.

Reference channel error (only for AI 8xU/I/RTD/TC ST)

- Enable diagnostics on error at the temperature compensation channel, e.g. wire break.
- Dynamic reference temperature compensation type is configured and no reference temperature has been transferred to the module yet.

Temperature coefficient

The temperature coefficient depends on the chemical composition of the material. In Europe, only one value is used per sensor type (default value).

The correction factor for the temperature coefficient (α value) specifies how much the resistance of a certain material changes when the temperature is raised by 1 °C.

The further values facilitate a sensor-specific setting of the temperature coefficient and enhance accuracy.

Interference frequency suppression

At analog input modules, this suppresses interference caused by the frequency of AC mains.

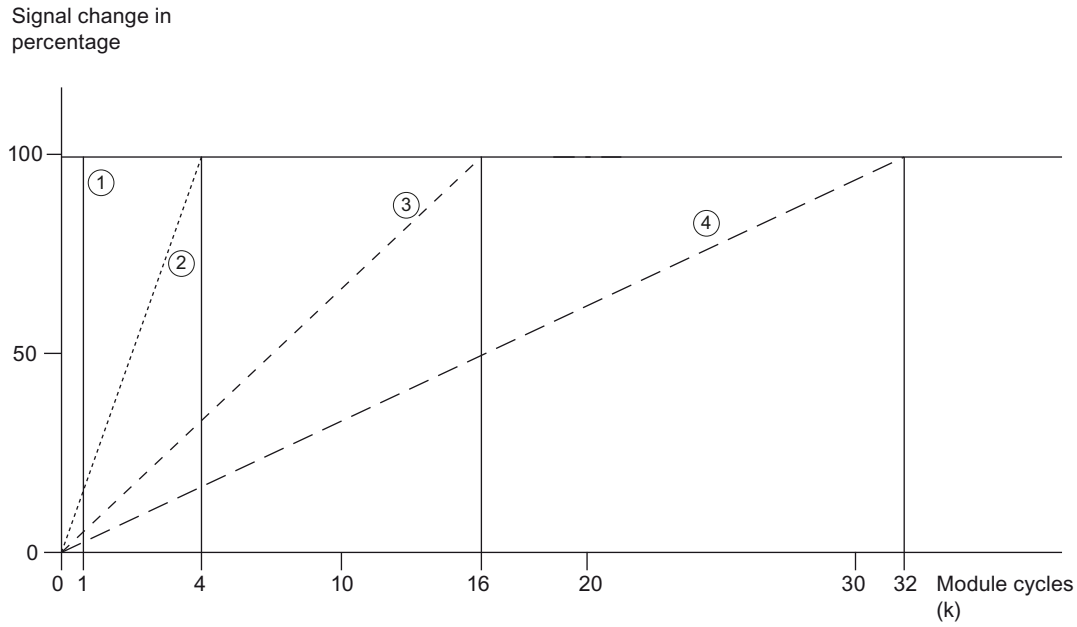
The frequency of the AC network may interfere with measured values, particularly for measurements within low voltage ranges and when thermocouples are being used. With this parameter, you define the mains frequency in your system.

Smoothing

The individual measured values are smoothed using filtering. Smoothing can be set in 4 stages for the analog input modules AI 8xU/I/RTD/TC ST and AI 8xU/I HS.

Smoothing time = number of module cycles (k) x cycle time of the module.

The figure below shows the number of module cycles after which the smoothed analog value is almost 100%, depending on the set smoothing. Is valid for each signal change at the analog input.



① None (k = 1)
② Weak (k = 4)
③ Medium (k = 16)
④ Strong (k = 32)

Reference junction (only for AI 8xU/I/RTD/TC ST)

The following settings can be configured for the reference junction parameter:

Table 10-100 Possible parameter assignments for the reference junction parameter

Setting	Description
Fixed reference temperature	The reference junction temperature is configured and stored in the module as a fixed value.
Dynamic reference temperature	The reference junction temperature is transferred in the user program from the CPU to the module by data records 192 to 199 using the WRREC (SFB 53) instruction.
Internal reference junction	The reference junction temperature is determined using an integrated sensor of the module.
Reference channel of the module	The reference junction temperature is determined using an external resistance thermometer (RTD) at the reference channel (COMP) of the module.

Note

Fixed reference temperature

During parameter assignment of a thermocouple Type B, only the setting "Fixed reference temperature" with a temperature of 0 °C is possible.

Enable hardware interrupt 1 or 2

Enable a hardware interrupt if high limit 1 or 2 is exceeded, or low limit 1 or 2 is violated.

Low limit 1 or 2

Specifies the low limit threshold that triggers hardware interrupt 1 or 2.

High limit 1 or 2

Specifies the high limit threshold that triggers hardware interrupt 1 or 2.

Temperature compensation for thermocouples

Introduction

You have several options of measuring the reference junction temperature in order to obtain an absolute temperature value as a function of the temperature difference between the reference junction and the measuring point.

You can use various compensation options depending on the required location of the reference junction.

Note

During parameter assignment of a thermocouple Type B, only the setting "Fixed reference temperature" with a temperature of 0 °C is possible.

Options of compensating for the reference junction temperature

Compensation options	Explanation	Application case
Internal reference junction	With this compensation, the reference junction temperature is determined using an integrated sensor of the module. **Procedure** Connect the thermocouple to the I/O module directly or with compensating lines.	• For the connection, you use compensating lines matching the thermocouple material. • If the reference junction temperature and the module temperature are identical in your system, you may also use lines made from a different material.
Reference channel of the module	The reference junction temperature is determined using an external resistance thermometer (RTD). **Procedure** Connect the thermocouple to the supply lines at the reference junction, either directly or with compensating lines. You connect the supply lines to the appropriate terminals of the module. Connect the resistance thermometer (RTD) to the reference channel of the module. The resistance thermometer (RTD) must be placed in the area of the reference junction.	• You want to measure the temperature directly at the reference junction. • The measured temperatures of all channels that you have configured for this compensation type is corrected automatically by the temperature value of the reference junction. • You can use inexpensive lines, e.g., copper lines, from the reference junction to the module.
Dynamic reference temperature	The temperature of the reference junction is determined via a module. This temperature value is transferred to other modules via a data record in the user program. **Procedure** Connect the resistance thermometer (RTD) for the reference junction to any channel. The reference junction temperature is communicated from the CPU to the module by data records 192 to 199 using the WRREC instruction.	• You use multiple modules at the reference junction and can therefore compensate all channels using a common temperature value. • You require only one resistance thermometer (RTD) to acquire the temperature value. • You can use inexpensive lines, e.g., copper lines, from the reference junction to the module.
Fixed reference temperature	The reference junction temperature is stored in the module as a fixed value. **Procedure** Connect the thermocouple to the supply lines at the reference junction, either directly or with compensating lines. You connect the supply lines to the appropriate terminals of the module. When configuring the module, specify a fixed temperature value for the reference junction (e.g. 20 °C).	• You keep the reference junction temperature constant and know the temperature value. • You can use inexpensive lines, e.g., copper lines, from the reference junction to the module.

Output module parameters

Parameters of the analog output modules

Missing supply voltage L+

Enabling of the diagnostics, with missing or too little supply voltage L+.

Short-circuit to ground

Enabling of the diagnostics if a short-circuit of the actuator supply to ground occurs.

Wire break

Enabling diagnostics if the line to the encoder is interrupted.

Overflow

Enabling of the diagnostics if the measured value exceeds the overflow range.

Underflow

Enabling of the diagnostics if the measured value falls below the underflow range.

Reaction to CPU STOP

Determines the reaction of the output to the CPU going into STOP state.

Substitute value

The substitute values are values that the outputs (the output) issue in the event of a CPU STOP.

ET 200M

Configuring an ET 200M

Introduction

For the ET 200M series, you can find a wide range of modules in the hardware catalog under "Distributed I/O".

Configuration and parameter assignment

Information on configuration and parameter assignment can be found in the following sections.

ET 200M configuration

Definition

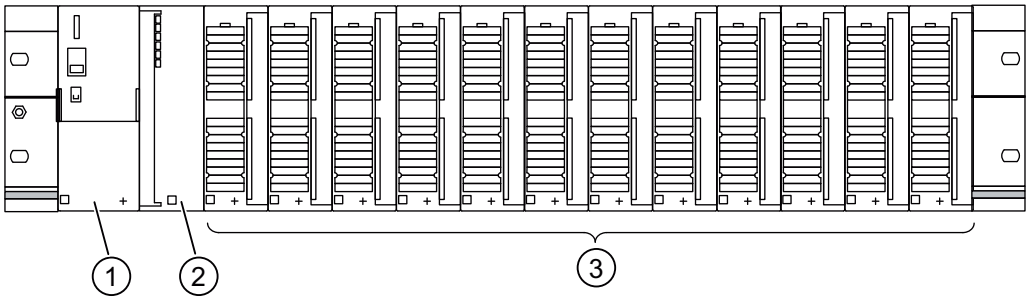
The distributed IO device, ET 200M, is a modular DP slave with an IP 20 degree of protection.

The ET 200M has the configuration technology of the S7-300 automation system and consists of an IM 153-x and I/O modules of the S7-300.

ET 200M supports communication with:

- all DP masters compliant with IEC 61784-1:2002 Ed1 CP 3/1
- all IO controllers compliant with IEC 61158

Configuration of the ET 200M (example)



① Power supply module PS 307
② Interface module IM 153-x
③ up to 12 I/O modules (SM / FM / CP)

Configuration of the 'Module replacement during operation' function

Introduction

The ET 200M supports the "Replace modules during operation" function and the associated pull/plug interrupt.

The "Replace modules during operation" function makes it possible for you to pull modules from or plug modules into the ET 200M rack during operation.

Requirement

You have configured an interface module that supports replacing modules during operation. (as of IM 153-1, article no. 153-1AA02-0XB0).

In addition, the configured CPU must also support the function, e.g. for PROFIBUS an S7-400 with DP interface.

You must use the active backplane bus (bus rail with slots) for the hardware configuration. The conventional profile rail with bus connectors between the modules does not support this function.

Configuring

If the configuration requirements have been met, the "Replace modules during operation" parameter is available for selection in the inspector window's "Module parameters" area. Below this parameter, a table for the configured modules is displayed, which shows the required active bus modules for the hardware configuration.

For a PROFIBUS configuration, the "Startup if preset configuration does not match actual configuration" option is displayed. This option is automatically enabled if "Replace modules during operation" is enabled.

Signal modules for process automation

Fundamentals

Introduction

Signal modules for the process automation are S7-300 models, such as SM 321; DI 16xNAMUR or SM 322; DO 16x24VDC/0.5A.

They are being operated in a DP slave (IM 153-2).

Unlike standard modules, they offer the following additional technical functions, such as pulse extension and chatter monitoring.

See also

Changeover contact (Page 1337)

Technological parameters (Page 1338)

Changeover contact

"Changeover contact" sensor type

If the digital inputs of a channel group are configured as "changeover contacts", the module runs diagnostics for the changeover contact sensor type for this channel group.

Changeover contact

A changeover contact is an auxiliary switch with only one moving switch element with one close setting each for closed and open switching device.

Remember the following rule:

- Always connect a normally open contact to the "even" channel
- Always connect a normally closed contact to the "odd" channel.

The tolerated switchover time between the two channels is fixed at 300 ms.

If the result of the check is negative, then

- the module identifies the value status of the normally open channel as "invalid"
- the module generates a diagnostic entry for the normally open channel
- triggers a diagnostic interrupt (if diagnostic interrupts have been enabled)

The digital input signal and the value status are updated only for the normally open channel. For the normally closed channel, the digital input signal is set permanently to "zero" and the value status to "invalid" since this channel is used only to check the sensor.

Diagnostics depends on the "Selection" parameter (of the sensor). You should also note the special features of diagnostics with the changeover contact sensor type in the "Signal Modules for Process Automation" manual.

See also

Documentation on modules for process automation (http://support.automation.siemens.com/WW/view/de/7215812/0/en)

Technological parameters

Pulse extension and flutter monitoring

Pulse extension is a function for changing a digital input signal. A pulse at a digital input is extended to at least the length set in the parameters. If the input pulse is already longer than the specified length, it is not changed.

If you want the pulse to be extended, click in the box to select the time. If you do not want the pulses to be extended, select the "---" entry.

Flutter monitoring is a process control function for digital input signals. It detects and reports signal changes that are unexpected in process control, for example when an input signal fluctuates too often between "0" and "1".

Flutter monitoring is possible only when group diagnostics has also been enabled for this input.

Monitoring window and number of signal changes

Flutter monitoring works with aid of the two parameters Monitoring window and Number of signal changes.

The first time the signal changes, the time set as the monitoring window is started. If the signal changes more often during this time than allowed by the number of signal changes parameter,

this is signaled as a flutter error. If no flutter error is detected during the monitoring window time, the monitoring window can be restarted at the next signal change.

Note

If you set pulse extension for an input channel, this also affects the flutter monitoring enabled for this channel. The "extended pulse" signal is the input signal for the flutter monitoring. You should therefore make sure that the values set for pulse extension and flutter monitoring are compatible with each other.

IQ Sense module

Properties of 8 IQ-SENSE

Properties

The 8 IQ-SENSE module has the following properties:

- Connection of sensors with IQ-SENSE®, photoelectric proximity switches: for example, reflex sensors, diffuse sensors, and laser sensors.
- It can be used centrally in an S7-300 or distributed in an ET 200M.
- You can connect up to 8 sensors to every module. Each sensor requires a two-wire cable.
- Function reserve that can be assigned parameters.
- Time functions, switching hysteresis, synchronous mode that can be assigned parameters
- Sensitivity and distance values can be specified (*IntelliTeach* using the "IQ-SENSE Opto" FB)
- Teach-in
- Sensors can be removed and inserted during operation (automatic reassignment of parameters)

Anti-interference group

Only for optical IQ Sense devices (IQ profile ID 1).

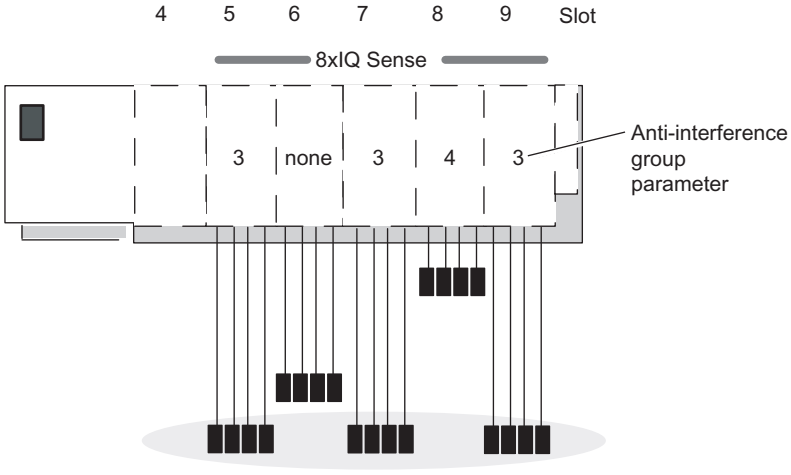
For IQ Sense devices with IQ profile ID 128 (ultrasound), see "Multiplex/synchronous mode" under the channel-specific parameters.

Prevention of interference (e.g., scattered light) by assigning an anti-interference group. This means:

- Anti-interference group: None (= default)
  Optical sensors on one or more modules can mutually influence each other when unfavorably arranged.
- Anti-interference group: 3 or 4
  Optical sensors on the same module with anti-interference group 3 or 4 cannot mutually influence each other. Similarly, optical sensors on different modules with anti-interference group 3 or 4 cannot mutually influence each other. You need not maintain minimum clearance between the IQ Sense devices and can, for example, align two retroreflective sensors on a single reflector.

Operating principle

The diagram below explains the functioning of the anti-interference group parameter:



Mutual interference is only possible between the optical sensors of the modules in slot 5, 6, 7 and 9 because they are in the same anti-interference group 3 or "None" is set.

Note

Sensors in the same anti-interference group must be installed to maintain the minimum clearance (see sensor package insert) and to prevent mutual interference.

Encoder type

This parameter is used to set the sensor type per channel:

- Reflex sensor or
- Diffuse sensor or
- Disabled

Diffuse sensor

Table 10-101 Diffuse sensor

Diffuse sensor	Object	
Transmitter Receiver		Circuit state 0: No object detected, which means the object is not in the beam. The receiver does not see any light.
Transmitter Receiver		Circuit state 1: Object detected, which means the object is in the beam. The receiver does not see any light.

Reflex sensor

Table 10-102 Reflex sensor

Reflex sensor	Object	
Transmitter Receiver		Circuit state 0: No object detected, which means the object is not in the beam. The receiver sees light.
Transmitter Receiver		Circuit state 1: Object detected, which means the object is in the beam. The receiver does not see any light.

Switching hysteresis

Faults with the diffuse sensor or in the production process can result in signal wobbles. The measured value then changes the switching threshold by 100 % (object detected - object not detected). You can prevent this switching threshold wobble using the switching hysteresis parameter. This will ensure a stable output signal on the sensor.

You can assigned parameters to 5 %/10 %/20 %/50 % for switching hysteresis.

Requirements

You can only set the switching hysteresis parameter for diffuse sensors with background fadeout.

Operating principle

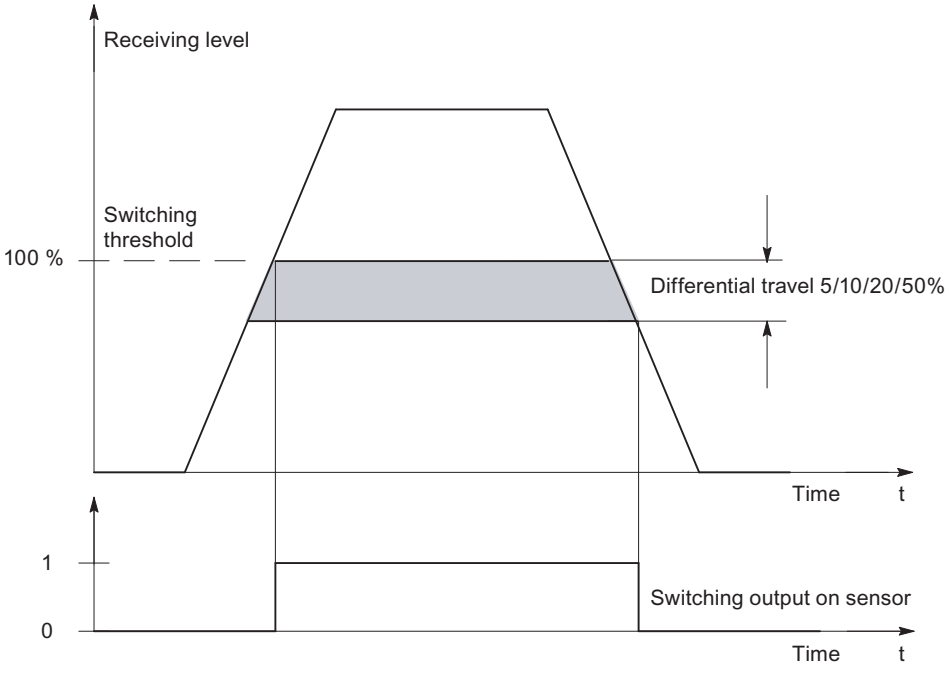


Figure 10-8 Switching hysteresis parameter

Time function,time value

These parameters can be used to set the electronic module for its specific application.

Operating principle

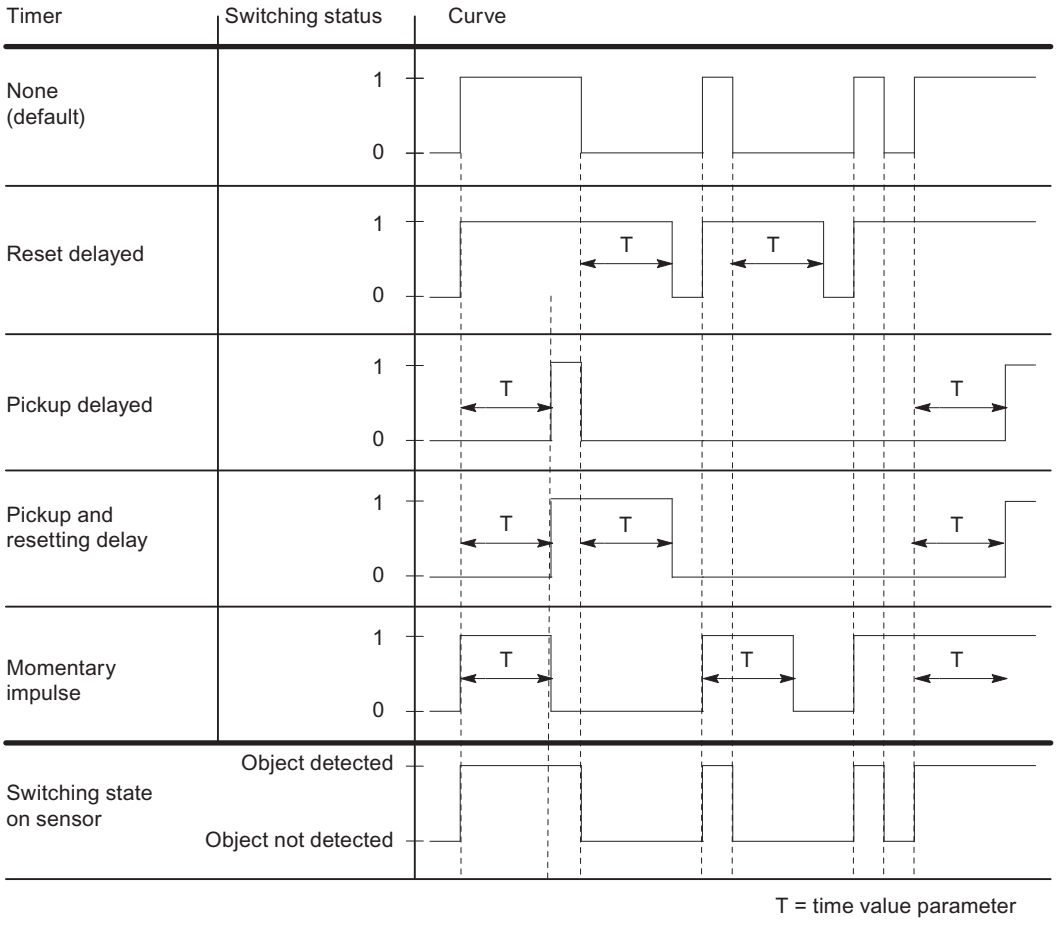

Figure 10-9 Time functions, time values parameters

Multiplex/synchronous mode

For the prevention of mutual influence between IQ Sense ultrasound devices in spatial proximity (devices with IQ profile ID 128), use the "Multiplex/synchronous operation" parameter.

Settings for the multiplex/synchronous mode parameter

Disabled: Mutual influence between IQ Sense ultrasound sensors in spatial proximity is possible (default). The cycle time is determined by the IQ Sense ultrasound sensor.

Multiplex: The IQ Sense ultrasound sensors determine the process value (distance) one after another, preventing them from affecting one another. The cycle time here is the sum of the configured synchronous cycle times of the IQ Sense ultrasound sensors that are to be multiplexed.

Synchronization: The IQ Sense ultrasound sensors determine the process value (distance) at exactly the same time, preventing them from affecting one another. The cycle time here corresponds to the greatest configured synchronous cycle time from among the IQ Sense ultrasound sensors that are to be synchronized.

You can, for example, use synchronous operation for a curtain function in which several IQ Sense ultrasound sensors aligned in parallel share a single extended detection area. The sensors simultaneously emit an ultrasound impulse. When an object enters the detection area, the sensor nearest to the object receives the echo most quickly. The object can therefore not only be detected, it can be located as well.

AFI value

Using the AFI value (application series identifier, as defined in the ISO 15693-3 international standard), transponders can be selected for different applications. Only transponders whose AFI value coincides with the value set on the sensor are processed. If a transponder has the AFI value "0", it can be identified and processed regardless of the AFI value of the sensor.

This parameter is only important if it is supported by the ident system, otherwise any value (normally "0") may be assigned.

Transponder type

Depending on the type of the transponder, you must configure whether it is an ISO transponder or a vendor-specific type.

For transponders in accordance with international standard ISO 15693, the value "1" should be selected; for all other types "0" is set. Based on this setting, one of the two possible air interface drivers is selected in the sensor.

This parameter is only important if it is supported by the ID system, otherwise any value (normally "0") may be assigned.

ET 200S

Configuring an ET 200S

Introduction

For the ET 200S series, you can find a wide range of modules in the hardware catalog under "Distributed I/O".

Assigning parameters

For information on configuration and parameter assignment, refer to "See also".

Frequency converters

Use of the frequency converter

Frequency converters

The frequency converter ICU24 and ICU24F (as fail-safe version) are modular design frequency converters that are completely embedded in the distributed I/O system ET 200S. For parameterization of both modules, please see the following.

Message frame

The message frame number and the operating mode of the module are only displayed and cannot be modified.

Application ID

You indicate the saved parameters in the frequency converter as a whole with the application ID. Enter an application ID from the value range 0 to 65535. During startup (or pull/plug), this ID is compared with the application ID stored on the converter.

Converters that work with identical applications are usually also identically parameterized and should be identified with the same application ID. Converters with the same application ID may be exchanged between each other. Copying of the complete parameterization of a converter to another converter, for example, via an MMC, is only accepted, if both have the same application ID.

Converters that work with different applications and are parameterized differently must be identified by different application IDs. This prevents a converter with unsuitable parameterization from starting on an incorrect slot, i.e. on the wrong application. This also prevents the parameterization that is saved in the converter from being accidently overwritten with any parameteriation that is stored on an MMC.

Enable diagnostic interrupt

You can enable the diagnostic interrupt for the frequency converter. If diagnostic interrupt is enabled, an OB 82 must be available in a CPU to process the diagnostic events.

See also

Documentation for the frequency converter (http://support.automation.siemens.com/WW/view/en/26291825/0/en)

ET 200pro

Configuration control with ET 200pro

Operating principle

Through the configuration control, it is possible to change the original configuration of an ET 200pro (created by configuring with STEP 7) and to operate the ET 200pro in this modified configuration. STEP 7 is no longer required for this configuration: You communicate to the ET 200pro the slot in which a configured module is actually inserted by means of your user program.

You use control data record 196 for this. In this data record, you code which modules are missing or located on different slots in the real configuration as compared to the preset configuration. The configuration control has no effect on the parameter assignment of the modules (for example, the enabling of diagnostic alarms).

You then call the "WRREC" instruction and use it to write the data record to the interface module of the ET 200pro.

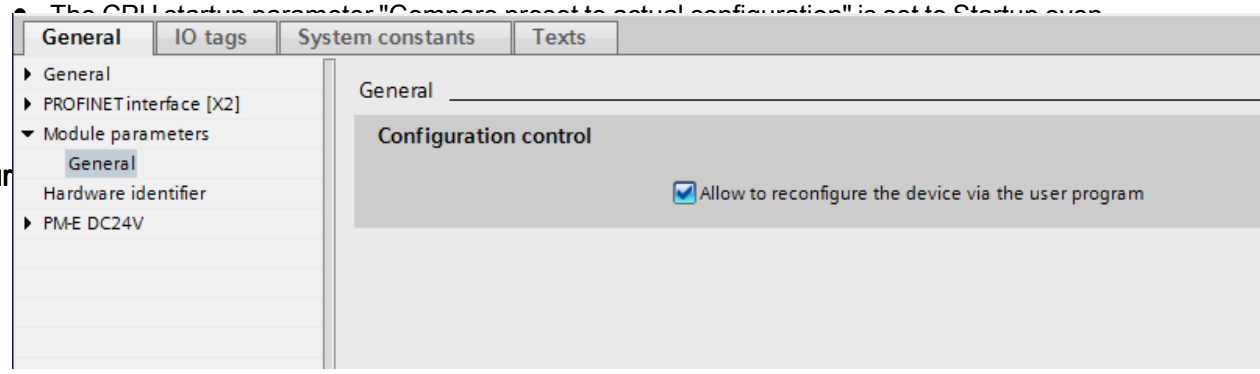
Configuration control gives you the flexibility to vary the configuration of an ET 200pro as long as the real configuration can be derived from a preset maximum configuration (originally created with STEP 7).

The following sections describe how to enable configuration control. They also outline how control data record 196 and readback data record 197 are structured.

Requirements

- STEP 7 Professional version V13 SP1 or higher
- The CPU startup parameter "Compare preset to actual configuration" is set to Startup even

Enabling configur



Configuration of control data record 196 for the ET 200pro

There is a byte in control data record 196 for each module.

The position of this byte in the data record codes one module in the original configuration with STEP 7:

- "slot_IM" (byte 4 in the data record, figure below) corresponds to the module in slot 1 in the configuration
- "slot_2" (byte 5) corresponds to the module in slot 2 in the configuration.
- "slot_3" (byte 6) corresponds to the module in slot 3 in the configuration.
- etc.

"slot_x" byte

The current slot is coded by the figure that is assigned to "slot_x" (by its value). Examples:

- The value "2" in byte 5 means you are assigning the module originally inserted in slot 2 to slot 2 in the current configuration (slot_2 = 2).
- The value "3" in byte 5 means you are assigning the module originally inserted in slot 2 to slot 3 in the current configuration (slot_2 = 3).
- The value "4" in byte 5 means you are assigning the module originally inserted in slot 2 to slot 4 in the current configuration (slot_2 = 4).
- etc.

There are no reserve modules for the ET 200pro (unlike for the ET 200S or with BU cover modules for the ET 200SP). For this reason, bit 7 of "slot_x" must not be set.

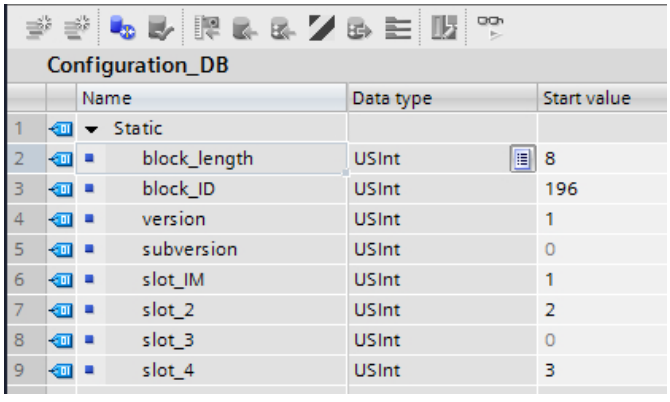
The value "0" in "slot_x" indicates that this module is not inserted in the current configuration.

Example of control data record 196

The figure below shows control data record 196 for a configuration of an ET 200pro with four modules.

This configuration is given as an example:

- The module originally configured with STEP 7 in slot 1 is also inserted in slot 1 in the current configuration.
- The module in slot 2 is in slot 2 in the current configuration.
- The module in slot 3 does not exist in the current configuration.
- The module in slot 4 is actually inserted in slot 3 in the current configuration.



Configuration_DB

		Name	Data type	Start value
1		Static		
2		block_length	USInt	8
3		block_ID	USInt	196
4		version	USInt	1
5		subversion	USInt	0
6		slot_IM	USInt	1
7		slot_2	USInt	2
8		slot_3	USInt	0
9		slot_4	USInt	3

The components of control data record 196 (figure above):

- block_length: Note here the length of the control data record; in the example: 8 (bytes). The length is calculated using the following formula: "Number of assigned slots" + 4.
- block_ID: Enter the figure 196 here.
- version: The ET 200pro uses Version 1 of control data record 196.
- subversion: The ET 200pro uses Subversion 0 of control data record 196.
- slot_IM: The IM module is always inserted in slot 0 of the ET 200pro. Slot 1 always contains the virtual power module that is integrated as a fixed module in the IM module. The "slot_IM" (name can be changed) can contain any values. This byte is not interpreted in the configuration control of the ET 200pro.
- slot_2: The configured module 2 is inserted in slot 2 (value "2").
- slot_3: The configured module 3 is not present in the current configuration (value "0").
- slot_4: The configured module 4 is inserted in slot 3 in the current configuration (value "3").

Definition of control data record 196

A control data record 196 containing a slot assignment is defined for configuration control.

Byte	Element	Value	Description
0	Block length	e.g., 8 for ET 200pro with four modules	The length of the data record is calculated using the formula: 4 + Number of modules in bytes
1	Block ID	196	ID for control data record 196
2	Version	1	Version 1 of control data record 196
3	Subversion	0	Subversion 0 of control data record 196
4	Slot_1	Any values are possible: For example "1"	This byte is not interpreted for the ET 200pro because the power module that is integrated as a fixed module in the IM module of the ET 200pro is always inserted in slot 1.
5	Slot_2	Coding of the actual slot: 2 = Slot 2 3 = Slot 3 4 = Slot 4 etc. Coding for missing module: 0 = No slot, module not present	Byte 5 indicates where the module originally configured with STEP 7 in slot 2 is actually inserted in the current configuration. Example: 2 The module originally configured with STEP 7 in slot 2 is also actually located in slot 2 in the current configuration (value "2").

6	Slot_3	Coding of the actual slot: 2 = Slot 2 3 = Slot 3 4 = Slot 4 etc. Coding for missing module: 0 = No slot, module not present	Byte 6 indicates where the module originally configured with STEP 7 in slot 3 is actually inserted in the current configuration. Example: 0 The module originally configured with STEP 7 in slot 3 is not present in the current configuration (value "0").
7	Slot_4	Coding of the actual slot: 2 = Slot 2 3 = Slot 3 4 = Slot 4 etc. Coding for missing module: 0 = No slot, module not present	Byte 7 indicates where the module originally configured with STEP 7 in slot 4 is actually inserted in the current configuration. Example: 3 The module originally configured with STEP 7 in slot 4 is actually located in slot 3 in the current configuration (value "3").
:	:	:	:

Writing a data record

Transfer the control data record to the ET 200pro module.

To do so, call the extended WRREC (Write data record) instruction, and transfer the control data record created.

If you do not transfer a control data record, the interface module uses the original configuration created with STEP 7. In this case, the following applies: Configured module x is inserted in real slot x.

Addressing the interface module using the HW identifier

To transfer data record 196 with the instruction WRREC, you must enter the HW identifier of the IM submodule with the extension "~Head" as the input parameter for the instruction. The system constant of this HW identifier is, for example, "IO-Device_2~Head". The system constants of a selected device are, for example, displayed in the network view in the "System constants" tab. Use the corresponding value for addressing.

Error messages

The following error messages are returned if an error occurs when writing control data record 196:

Table 10-103 Error messages

Error code	Meaning
16#80A2	DP protocol error on layer 2. Indicates that a data record has not been acknowledged due to the system.
16#80B1	Invalid length; the length information in data record 196 is not correct.
16#80B5	Configuration control parameters not assigned.
16#80B2	Invalid slot: The configured slot is not assigned.
16#80B8	Parameter error; module signals invalid parameters.
16#80C5	DP slave or module not available. Indicates that a data record has not been acknowledged due to the system.

Readback data record 197 for ET 200pro

Readback data record 197 is used to read the actual configuration of a station (in this case of an ET 200pro).

This data record allows you to check the real configuration of the ET 200pro (actual configuration). The readback data record for each configured module specifies whether or not it is actually available.

- The value "1" means that the correct module is inserted in the correct slot.
- The value "0" codes all other options (wrong module, empty slot).

Example:

A module has been configured with STEP 7 for slot 4.

This module has then been moved to slot 3 in the current configuration using data record 196.

If this module is also really in slot 3, this is coded by the value "1" (status_slot_4 = 1).

Configuration details:

The configuration of the data block corresponds to the original configuration of the ET 200pro with STEP 7.

There is a byte in the data record for each module. The position of this bytes in the data record corresponds to the position of a module in the original configuration with STEP 7.

Sequence of bytes:

- "status_slot_IM" (byte 4 in the data record) corresponds to the module in slot 1 in the configuration,
- "status_slot_2" (byte 5) corresponds to the module in slot 2 in the configuration
- "status_slot_3" (byte 6) corresponds to the module in slot 3 in the configuration,
- etc.

The following example is for a configuration with 4 modules. The value "8" therefore appears in the "block_length" element of the data record.

If you configure an ET 200pro in STEP 7 with fewer modules, the data block will be shorter.

You can choose any name for the components of the control data record (for example "status_slot_2").

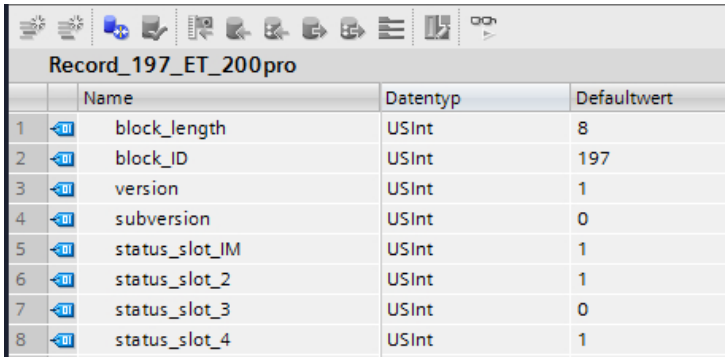
Meaning of "status_slot_x":

- The value "1" in status_slot_x means that module x is inserted in the correct slot
- The value "0" in status_slot_x codes all other options (wrong module, module does not exist).

Example:

The figure below shows readback data record 197 for an ET 200pro with four modules.

- There is no module 3 (this was assigned in control data record 196, see section "Example of control data record 196" above)
- The three other modules are actually inserted in the ET 200pro.



Record_197_ET_200pro

	Name	Datentyp	Defaultwert
1	block_length	USInt	8
2	block_ID	USInt	197
3	version	USInt	1
4	subversion	USInt	0
5	status_slot_IM	USInt	1
6	status_slot_2	USInt	1
7	status_slot_3	USInt	0
8	status_slot_4	USInt	1

Reading readback data record 197

You can read readback data record 197 from the ET 200pro with the instruction RDREC. RDREC operates asynchronously. If you call RDREC in the startup OB, you must call the instruction multiple times using a loop until the "BUSY" or "DONE" output parameter indicates that the data record has been read.

To read data record 197 with the instruction RDREC, you must enter the HW identifier of the IM submodule with the extension "~Head" as the input parameter for the instruction. The system constant of this HW identifier is, for example, "IO-Device_2~Head". The system constants of a selected device are, for example, displayed in the network view in the "System constants" tab. Use the corresponding value for addressing.

Further information and examples

Further information on the PN interface module of the ET 200pro is available here (http://support.automation.siemens.com/WW/view/en/98099372).

Specific examples of configuration control can be found here in this application description (http://support.automation.siemens.com/WW/view/en/29430270).

Configuration control with ET 200SP (Page 1274)

Use of the frequency converter

Frequency converters

The frequency converters ET 200pro FC and ET 200pro F-FC (as fail-safe version) are modularly design frequency converters that are completely embedded in the distributed I/O system ET 200pro. The following section describes how to configure the two modules.

Message frame

The message frame number and the operating mode of the module are only displayed and cannot be modified.

Application ID

You indicate the saved parameters in the frequency converter as a whole with the application ID. Enter an application ID from the value range 0 to 65535. During startup (or pull/plug), this ID is compared with the application ID stored on the converter.

Converters that work with identical applications are usually also identically configured and should be identified with the same application ID. Converters with the same application ID may be exchanged between each other. Copying of the complete configuration of a converter to another converter, for example, via an MMC, is only applied, if both have the same application ID.

Converters that work with different applications and are configured differently must be identified by different application IDs. This prevents a converter with unsuitable configuration from starting on an incorrect slot, in other words on the wrong application. This also prevents the configuration that is saved in the converter from being accidently overwritten with any configuration that is stored on an MMC.

Enable diagnostic interrupt

You can enable the diagnostic interrupt for the frequency converter. If diagnostic interrupt is enabled, an OB 82 must be available in a CPU to process the diagnostic events.

10.1.6.4 IPv6 configuration

IPv6 protocol

The Internet Protocol version 6 - called IPv6 below - extends the Internet Protocol version 4 (IPv4) that is used predominantly at the current time.

Address format IPv6: Notation

IPv6 addresses consist of 8 fields each with four-character hexadecimal numbers (128 bits in total). The fields are separated by a colon.

Example:

fd00:ffff:ffff:ffff:ffff:ffff:2f33:8f21

Rules / simplifications:

- Leading zeros within a field can be omitted.
  Example: fd01:0:ffff::2d12:7d23
- If one or more fields have the value 0, a shortened notation is possible.
  The address fd00:0:0:0:0:0:0:8f21 can also be shortened and written as follows:
  fd00::8f21
  To ensure uniqueness, this shortened form can only be used once within the entire address.
- Decimal notation with periods
  The last 2 fields or 4 bytes can be written in the normal decimal notation with periods.
  Example: The IPv6 address fd00::ffff.125.1.0.1 is equivalent to fd00::ffff:7d01:1

Entry and appearance

The entry of IPv6 addresses is possible in the notations described above. IPv6 addresses are always shown in the same notation in which they were entered.

IPv6 with the CP 1543-1 (Page 1353)

IPv6 with the CP 1543-1

Use of IPv6 with the CP 1543-1

The CP supports the Internet Protocol version 4 (IPv4) for all IP services

The additional specification of addresses in IPv6 format can be used with the CP for the following services and applications:

- FETCH/WRITE
  Direct write/read access by PC stations, SIMATIC S5 or third-party devices
- FTP client
  FTP access from the S7-1500 CPU to an FTP server with the program block FTP_CMD
- FTP server
  FTP access from an FTP client to data areas of the S7-1500 CPU
- SNMP
  Data query using MIB objects according to SNMP
- E-mail
  Data transfer from the S7-1500 CPU using the program block T_Mail

10.2 Device and network diagnostics

10.2.1 Hardware diagnostics

10.2.1.1 Overview of hardware diagnostics

Principal methods of hardware diagnostics

Principal methods of hardware diagnostics

Hardware diagnostics can be performed as follows:

- Using the Online and Diagnostics view
- Using the "Online Tools" task card
- Using the "Diagnostics > Device Info" area of the Inspector window
- Using diagnostics icons, for example, in the device view and the project tree

Structure of the Online and Diagnostics view

The Online and Diagnostics view consists of two windows alongside each other:

- The left window shows a tree structure with folders and - when you open the folder - groups.
- The right window contains detailed information on the selected folder or selected group.

The "Online access" group and the "Diagnostics" and "Functions" folders are located here:

- "Online access" group: Displays whether or not there is currently an online connection with the associated target. In addition, you can establish or disconnect the online connection.
- "Diagnostics": Contains several diagnostics groups for the selected module.
- "Functions": Contains several groups, in which you can make settings for the selected module or issue commands to the module.

Function and structure of the "Online Tools" task card

For modules with their own operating mode (such as CPUs), the "Online tools" task card allows you to read current diagnostics information and commands to the module.

If you selected a module without its own operating mode or if you selected several modules before activation of the "Online Tools" task card, the task card relates to the relevant CPU.

The "Online Tools" task card consists of the following panes:

- CPU control panel
- Cycle time
- Memory

Note

A pane is filled with content only if the module controls the associated functions and an online connection exists.

If there is no online connection to the respective module, the display "No online connection" appears in blue in each pane. If an existing online connection was disconnected, then "This target is not available" will be displayed.

Structure or the "Diagnostics" tab of the Inspector window

The "Diagnostics" tab of the Inspector window itself consists of several tabs. Of these tabs, the following is relevant for the hardware diagnostics.

- Device information
  This tab relates to all online devices (e.g. CPUs) to which an online connection has been established and to the devices that are assigned to these online devices (such as PROFINET devices and PROFIBUS slaves). Alarms related to the faulty online devices and the faulty devices are output here.

Note

What is displayed when a module is faulty?

If a module within a device is faulty, only the associated device or its proxy (e.g. head module) are shown, but not the module itself.

The faulty devices are displayed "at the top level" and not in a hierarchical view below their online device (as is the case in the project tree).

See also

Basics on task cards (Page 326)

Inspector window (Page 324)

Determination of which of the devices that are connected online are defective

Overview of the defective devices

In the "Diagnostics > Device Info" area of the Inspector window you will obtain an overview of the defective devices that are or were connected online.

The "Diagnostics> Device Info" area of the Inspector window consists of the following elements:

- Header line with the number of defective devices
- Table with detailed information on each defective device

If you originate the establishment of an online connection to a device which is not reachable or reports one or more faults or is not in RUN mode, it will rank as defective.

Structure of the table with detailed information on the defective devices

The table consists of the following columns:

- Online status: Contains the online status as a diagnostic symbol and in words
- Operating mode: Contains the operating mode as a symbol and in words
- Device / module: Name of the affected device or the affected module
- Message: explains the entry of the previous column
- Details: The link opens the online and diagnostics view for the device, and places it in the foreground. If an online connection does not exist any longer, the link will open the connection establishment dialog.
- Help: The link supplies further information on the defect that has occurred.

Displaying diagnostics status and comparison status using icons (Page 1356)

Displaying diagnostics status and comparison status using icons

Determining diagnostics status online and displaying using icons

When the online connection to a device is established, the diagnostics status of the device and, if applicable, its lower-level components is determined. The operating state of the device is also determined, where applicable.

The following is a description of which icons are displayed in specific views.

- Device view
  - The associated diagnostic icon is displayed for every hardware component (except the signal board on the CPU).
    To start the Online and Diagnostics view (if available), double-click the diagnostic icon.
  - For a hardware component with lower-level components, if there is a hardware error in at least one lower-level component, the diagnostic icon appears as follows: The hardware component's diagnostic icon has a pale appearance and the diagnostic icon "Hardware error in lower-level component" is also shown in the lower right corner.
  - For hardware components with their own operating state, the operating state icon is also displayed to the left of or above the diagnostic icon.
  - The following applies to modules or submodules of a shared device with an S7-1500 CPU: No diagnostic icons are displayed (due to the configuration as GSDML device).
- Device overview
  - The associated diagnostic icon is displayed for every hardware component.
    To start the Online and Diagnostics view (if available), double-click the diagnostic icon.
  - For a hardware component with lower-level components, if there is a hardware error in at least one lower-level component, the diagnostic icon appears as follows: The hardware component's diagnostic icon has a pale appearance and the diagnostic icon "Hardware error in lower-level component" is also shown in the lower right corner.
  - The following applies to modules or submodules of a shared device with an S7-1500 CPU: For modules assigned to the CPU, the associated diagnostic icon is displayed (modules that are not assigned do not receive a diagnostic icon). The associated diagnostic icon is displayed for plug-in submodules of an assigned module (submodules that are not pluggable are not visible and therefore do not receive a diagnostic icon).
- Network view
  - The associated diagnostic icon is displayed for every device.
    To start the Online and Diagnostics view (if available), double-click the diagnostic icon.
  - For a hardware component with lower-level components, if there is a hardware error in at least one lower-level component, the diagnostic icon appears as follows: The hardware component's diagnostic icon has a pale appearance and the diagnostic icon "Hardware error in lower-level component" is also shown in the lower right corner.
  - The following applies to modules or submodules of a shared device with an S7-1500 CPU: A diagnostic icon is displayed. It belongs to that part of the station that is assigned to the CPU.

- Network overview
  - The associated diagnostic icon is displayed for every hardware component.
    To start the Online and Diagnostics view (if available), double-click the diagnostic icon.
  - For a hardware component with lower-level components, if there is a hardware error in at least one lower-level component, the diagnostic icon appears as follows: The hardware component's diagnostic icon has a pale appearance and the diagnostic icon "Hardware error in lower-level component" is also shown in the lower right corner.
  - The following applies to modules or submodules of a shared device with an S7-1500 CPU: A diagnostic icon is displayed. It belongs to that part of the station that is assigned to the CPU.
- Topology view
  - The associated diagnostic icon is displayed for every device.
    To start the Online and Diagnostics view (if available), double-click the diagnostic icon.
  - For a hardware component with lower-level components, if there is a hardware error in at least one lower-level component, the diagnostic icon appears as follows: The hardware component's diagnostic icon has a pale appearance and the diagnostic icon "Hardware error in lower-level component" is also shown in the lower right corner.
  - The associated diagnostic icon is displayed for every port. The meaning of the individual colors is described further below.
  - Each cable between two online ports is assigned the color associated with its diagnostics status.
    The color of the cable between two ports depends on the status of the individual ports:

Color of the first port	Color of the second port	Color of the connecting cable
light green	light green	light green
light green	dark green	dark green
green	gray	gray
green	red	red
gray	red	red

  - The following applies to modules or submodules of a shared device with an S7-1500 CPU: A diagnostic icon is displayed. It belongs to that part of the station that is assigned to the CPU.
- Topological overview
  - The associated diagnostic icon is displayed for every hardware component.
    To start the Online and Diagnostics view (if available), double-click the diagnostic icon.
  - For a hardware component with lower-level components, if there is a hardware error in at least one lower-level component, the diagnostic icon appears as follows: The hardware component's diagnostic icon has a pale appearance and the diagnostic icon "Hardware error in lower-level component" is also shown in the lower right corner.
  - The following applies to modules or submodules of a shared device with an S7-1500 CPU: A diagnostic icon is displayed. It belongs to that part of the station that is assigned to the CPU.

- Project tree
  - The associated diagnostic icon is displayed behind every hardware component.
  - For a hardware component with lower-level components (e.g., distributed I/O, Slave_1), if there is a hardware error in at least one lower-level component, the diagnostic icon appears as follows: The hardware component's diagnostic icon has a pale appearance and the diagnostic icon "Hardware error in lower-level component" is also shown in the lower right corner.
  - For hardware components with their own operating state, the operating state icon is also displayed in the top right corner of the diagnostic icon.
  - If forcing is active on a CPU, a red F is displayed at the left margin of the diagnostic icon.
  - The diagnostic icon "Hardware error in lower-level component" is displayed behind the "Local modules" folder when there is a hardware error in at least one of the associated modules.
  - The diagnostic icon "Hardware error in lower-level component" is displayed behind the "Distributed I/O" folder when there is a hardware error in at least one of the associated modules.
  - The diagnostic icon "Hardware error in lower-level component" is displayed behind the project folder when the "Hardware error in lower-level component" diagnostic icon is displayed behind at least one of the "Local modules" or "Distributed I/O" folders.
  - The following applies to modules or submodules of a shared device with an S7-1500 CPU: The associated diagnostic icon is displayed for modules assigned to the CPU (modules that are not assigned are grayed out and do not receive a diagnostic icon). The associated diagnostic icon is displayed for plug-in submodules of an assigned module (submodules that are not pluggable are not visible and therefore do not receive a diagnostic icon).

Note

If the diagnostic for a hardware component is "not reachable from the CPU", the diagnostic icon "Hardware error in lower-level component" is not additionally shown.

Diagnostic icons for modules and devices

The following table shows the available icons and their respective meaning.

Icon	Meaning
	The connection with a CPU is currently being established.
	The CPU is not reachable at the set address.
	The configured CPU and the CPU actually present are of incompatible types.
	On establishment of the online connection to a protected CPU, the password dialog was terminated without specification of the correct password.
	No fault

Icon	Meaning
	Maintenance required
	Maintenance demanded
	Error
	The module or device is deactivated.
	The module or the device cannot be reached from the CPU (valid for modules and devices below a CPU).
	No input or output data are available, because the (sub)module has blocked its input or output channels.
	Diagnostics data are not available because the current online configuration data differ from the offline configuration data.
	The configured module or device and the module or device actually present are incompatible (valid for modules or devices under a CPU).
	The configured module does not support display of the diagnostics status (valid for modules under a CPU).
	The connection is established, but the module status has not yet been determined or is unknown.
	The configured module does not support display of the diagnostics status.
	Hardware error in lower-level component: A hardware error is present in at least one lower-level hardware component. (occurs as a separate icon only in the project tree)

Note

Some modules, for example, the FM 450-1, are only indicated as having a problem in the case of an error if you have enabled the diagnostic interrupt when assigning the module property parameters.

Icons for the comparison status

The diagnostic icons can be combined at the bottom right with additional smaller icons that indicate the result of the online/offline comparison. The following table shows the available comparison icons and their meaning.

Icon	Meaning
	Hardware error in lower-level component: The online and offline versions differ (only in the project tree) in at least one lower-level hardware component.
	Software error in lower-level component: The online and offline versions differ (only in the project tree) in at least one lower-level software component.
	Online and offline versions of the object are different
	Object only exists online
	Object only exists offline
	Online and offline versions of the object are the same

Note

If both a comparison icon and the "Error in lower-level component" diagnostic icon are to be displayed at the bottom right in the device view, the following rule applies: The diagnostic icon for the lower-level hardware component has a higher priority than the comparison icon. This means that a comparison icon is only displayed if the lower-level hardware components have no errors.

Display of software errors in the project tree

- The associated comparison icon is shown behind each block.
- Behind each folder, under which exclusively blocks are contained, the diagnostic icon "Software error in lower-level component" is displayed when there is a software error in at least one of the associated blocks.
- For a hardware component with lower-level software components, if there is no hardware error and there is an error in at least one lower-level software component, the diagnostic icon appears as follows: The hardware component's diagnostic icon has a pale appearance and the diagnostic icon "Software error in lower-level component" is also shown in the lower right corner.

Combined diagnostics and comparison icons

The following table shows examples of icons that are displayed in the diagnostics icon.

Icon	Meaning
	Folder contains objects whose online and offline versions differ (only in the project tree)
	Object only exists online

Operating state icons for CPUs and CPs

The following table shows the available icons and their respective operating states.

Icon	Operating state
	RUN
	STOP
	STARTUP
	HOLD
	DEFECTIVE

Icon	Operating state
	Unknown operating state
	The configured module does not support display of the operating state.

Note

If forcing is active on a CPU, a red F is displayed on a pink background at the bottom right of the operating state icon.

Color marking of ports and Ethernet cables

The following table shows the available colors and their respective meaning.

Color	Meaning
	No fault or maintenance required
	Offline
	Maintenance demanded
	Communication error or topological error
	no diagnostic capability

Start online and diagnostics view

Overview of possible ways of starting the Online and Diagnostics view

You can start the Online and Diagnostics view of a module to be diagnosed at the following locations:

- Overview
- Project tree
- Device view
- Device overview
- Network view
- Network overview
- Topology view
- Topological overview

In the following, examples are used to show how to proceed.

Requirement

The project with the module to be diagnosed is open.

Note

This requirement does not apply if you call the online and diagnostics view from the project tree after you have identified the accessible devices.

Procedure

To start the online and diagnostics view of a module, follow these steps:

1. In the project tree, open the respective device folder.
2. Double click on "Online & Diagnostics".

Or:

1. In the project tree, select the respective device folder.
2. Select the "Online & Diagnostics" command in the shortcut menu or the "Online" main menu.

Or:

1. In the project tree, open the "Online access" folder.
2. Open the folder for the interface with which you want to establish the online connection.
3. Double click on "Show/Update accessible devices".
4. Select the module to be diagnosed.
5. Select the "Online & Diagnostics" command in the shortcut menu or the "Online" main menu.

Or:

1. In the project tree, open the "Local modules" folder.
2. Select the respective device or the module that is to be diagnosed.
3. Select the "Online & Diagnostics" command in the shortcut menu or the main menu.

Or:

1. Open the device view in the device configuration.
2. Select the module to be diagnosed.
3. Select the "Online & Diagnostics" command in the shortcut menu or the "Online" main menu.

Or:

1. Open the device view in the device configuration.
2. Establish an online connection to the module to be diagnosed.
3. Double-click on the diagnostics icon above the module.

Or:

1. Open the network view in the device configuration.
2. Select the station with the module to be diagnosed.
3. Select the "Online & Diagnostics" command in the shortcut menu or the "Online" main menu.

Or:

1. Open the topology view in the device configuration.
2. Establish an online connection to the module to be diagnosed.
3. In the topology view, double-click the diagnostic icon associated with the module.

Result

The online and diagnostics view of the module to be diagnosed will be started. If an online connection to the associated CPU had previously been created, the header bar of the Online and Diagnostics view will now have an orange background.

Note

If no online connection exists when the online and diagnostics view is started, no online information is displayed and the display fields remain empty.

Activation of the "Online Tools" task card

Activation of the "Online Tools" task card

You can activate this task card as follows:

1. Start the online and diagnostics view.
2. Click on the "Online Tools" task card.

Or:

1. Start the device view.
2. Click on the "Online Tools" task card.

Or:

1. Start the network view.
2. Click on the "Online Tools" task card.

10.2.1.2 Showing non-editable and current values of configurable module properties

Showing general properties and system-relevant information for a module

Where do I find the information I need?

The general properties and system-relevant information for a module can be found in the "General" group in the "Diagnostics" folder in the online and diagnostics view of the module to be diagnosed.

Structure of the "General" group

The "General" group consists of the following areas:

- Module
- Module information
- Vendor information

"Module" area

This area shows the following data of the module:

- Short designation, for example, CPU 1214C DC/DC/DC
- Article no.
- Hardware
- Firmware
- Racks
- Slot

"Module information" area

This area shows the following data of the module that you configured during hardware configuration:

- Module name
- Installation date (not displayed for all modules)
- Additional information (not displayed for all modules)

"Manufacturer information" area

This area shows the following data of the module:

- Manufacturer
- Serial number

- Profile: Profile ID as hexadecimal number

  Note

  You will find the corresponding profile name in the profile ID table for PROFIBUS International (see "www.profibus.com").

- Profile details: Profile-specific type as hexadecimal number

  Note

  You will find the corresponding profile-specific type name in the profile-specific type table for PROFIBUS International (see "www.profibus.com").

Display configured cycle times

Where do I find the information I need?

The required information can be found in the following places:

- In the "Cycle time" group of the "Diagnostics" folder in the Online and Diagnostics view of the module to be diagnosed.
- In the "Cycle time" pane of the "Online Tools" task card

Structure of the "Cycle time" group in the "Diagnostics" folder of the Online and Diagnostics view

The "Cycle time" group consists of the following areas:

- Cycle time diagram (graphical display of the assigned and measured cycle times)
- Cycle time configured (display of the assigned cycle times as absolute values)
- Cycle times measured (display of the measured cycle times as absolute values)

Structure of the "Cycle time" pane of the "Online Tools" task card

The "Cycle time" pane displays the cycle time diagram and below it the measured cycle times as absolute values.

Assigned cycle times

The following assigned cycle times are displayed in the cycle time diagram and in the "Cycle time configured" area.

- Minimum cycle time
- Maximum cycle time

In the cycle time diagram, the minimum cycle time and the maximum cycle time correspond to the two markings on the time axis.

In the "Cycle time configured" area, the assigned cycle times are displayed as absolute values.

Show interfaces and interface properties of a module

Where do I find the information I need?

The interfaces and interface properties of a module can be found in the "Diagnostics" folder in the online and diagnostics view of the module to be diagnosed in the following group:

- PROFINET interface

"PROFINET interface" group

This group is divided into the following areas:

- "Ethernet address" with the "Network connection" and "IP Parameters" subareas
- "Ports"

"Network connection" subarea of the "Ethernet address" area

This subarea shows the following data for the module:

- MAC Address:
  MAC address of the interface.
  The MAC address consists of two parts. The first part ("Basic MAC address") identifies the manufacturer (Siemens, 3COM, ...). The second part of the MAC address differentiates between the various Ethernet devices. Each Ethernet module is assigned a unique MAC address.

"IP Parameters" subarea of the "Ethernet address" area

This subarea shows the following data for the module:

- IP address:
  Internet protocol address of the device on the bus (TCP/IP)
- Subnet mask:
  The subnet mask shows which part of the IP address determines the membership of a particular sub-network.
- Default router:
  If the subnet is connected via a router to other subnets, the IP address of the default router must be known. This is the only way a datagram can be forwarded with a non-matching subnet address.
- IP settings:
  Identifier for the path by which the device has obtained its IP settings (IP address, subnet mask, default router).

Identifier	Meaning
0	IP address is not initialized
1	By configuration (i.e., by the configuration loaded to the device from the device or network view)
2	Via the "Assign IP address" group of the online and diagnostics view

Identifier	Meaning
3	Via the DHCP server (i.e., the IP parameters are obtained by a special service from a DHCP server (Dynamic Host Configuration Protocol) and assigned for a limited time)
4	IP address is set by a user program
5	Source of IP address unknown

- IP setting time:
  Time stamp of the last change to the IP address directly through the Ethernet connection of the module

"Ports" area

This area shows the following data for the module:

- Ethernet ports
  Physical properties of the PROFINET interface

Properties of the PROFINET interface	Meaning
Port no.	Port number The short description of interface (X + interface no.) and port (P + port no.) is specified in parentheses. An "R" in the short description of a port means that it is a ring port.
Status	Displays the status of the port LINK LED. • Status "OK" means another device (such as a switch) is connected to the port and the physical connection is available. • Status "disconnected" means no other device is connected to the port. • Status "deactivated" means that access to the port is blocked.
Settings	• "Automatic" for automatic network settings of the device • Network settings for speed and transmission method for manual network settings of the device
Operating mode	Network settings for speed and transmission method

If you select a line in the port table, additional help information will be provided for the corresponding port.

Displaying IO controllers that access modules of a Shared Device

Where do I find the information I need?

The display of those IO controllers that access the modules of a Shared Device can be found in the Online and Diagnostics view of the interface module of the Shared Device in the "Diagnostics" folder in the following area of the "PROFINET interface" group:

- IO controller

Displaying sync domain properties of a PROFINET device

Where do I find the information I need?

The sync domain properties of a PROFINET device can be found in the following area of the "PROFINET interface" group in the "Diagnostics" folder of the Online and Diagnostics view of the device to be diagnosed:

- Domain

"Domain" area

This area is divided into the following subareas:

- Sync domain
- MRP domain

What is a sync domain?

A sync domain is a group of PROFINET devices that are synchronized to a common clock. Exactly one device has the role of the sync master (clock generator); all other devices assume the role of a sync slave. The sync master is usually an IO controller or a switch.

Non-synchronized PROFINET devices are not part of a sync domain.

"Sync domain" subarea of the "Domain" area

This subarea shows the following properties of the sync domain:

- Name:
  Name of sync domain
- Role:
  Role of the PROFINET device in the sync domain. The following roles are possible:
  - Sync master
  - Sync slave
- Synchronization interval:
  Interval at which the synchronization is performed
- Send clock
  Smallest possible send interval for the data exchange
- Jitter accuracy of the send clock
- Reserved bandwidth for cyclic communication

Displaying MRP domain properties of a PROFINET device

Where do I find the information I need?

The MRP domain properties of a PROFINET device can be found in the following area of the "PROFINET interface" group in the "Diagnostics" folder of the Online and Diagnostics view of the device to be diagnosed:

- Domain

"Domain" area

This area is divided into the following subareas:

- Sync domain
- MRP domain

What is an MRP domain?

The Media Redundancy Protocol (MRP) enables redundant networks to be structured. Redundant transmission paths (ring topology) ensure that, if one transmission path fails, an alternative communication path is available. The PROFINET devices that are part of this redundant network form an MRP domain.

"MRP domain" subarea of the "Domain" area

This subarea shows the following properties of the MRP domain:

- Name:
  Name of MRP domain
- Role:
  Role of the PROFINET device in the MRP domain. The following roles are possible:
  - Manager
  - Manager (Auto)
  - Client
  - Not a device of the ring
- Ring port 1:
  The port of the PROFINET device that has the "Ring port 1" property
- Ring port 2:
  The port of the PROFINET device that has the "Ring port 2" property
- Status of the MRP ring:
  Indicates whether the ring is interrupted ("open" status) or not ("closed" status).

Displaying current firmware of a module

Displaying firmware

You can display the currently installed firmware of a module.

Requirements

- The module supports a firmware update.
- The module is connected online.

Procedure

To display the current firmware, follow these steps:

1. Open the module in the Online and Diagnostics view.
2. Select the "Firmware update" group in the "Functions" folder.
3. You read off the current firmware in the "Online data" area under "Firmware".

10.2.1.3 Showing the current values of dynamic modules properties

Display measured cycle times

Where do I find the information I need?

The measured cycle times can be found at each of the following places:

- In the "Cycle time" group of the "Diagnostics" folder in the Online and Diagnostics view of the module to be diagnosed.
- In the "Cycle time" pane of the "Online Tools" task card

Structure of the "Cycle time" group in the "Diagnostics" folder of the Online and Diagnostics view

The "Cycle time" group consists of the following areas:

- Cycle time diagram (graphical display of the assigned and measured cycle times)
- Cycle time configured (display of the assigned cycle times as absolute values)
- Cycle times measured (display of the measured cycle times as absolute values)

Structure of the "Cycle time" pane of the "Online Tools" task card

The "Cycle time" pane displays the cycle time diagram and below it the measured cycle times as absolute values.

Graphical display of the measured cycle times

The following measured cycle times are displayed in the cycle time diagram:

- Shortest cycle time: Duration of the shortest cycle since the last transition from STOP to RUN
  This corresponds to the dashed gray arrow on the left in the diagram.
- Current / last cycle time: Duration of the last cycle
  This corresponds to the green arrow in the diagram. If the current / last cycle time exceeds the maximum cycle time, the arrow will turn red.

  Note

  If the duration of the last cycle comes close to the maximum cycle time, it may be possible that it will be exceeded. Depending on the CPU type, parameter assignment and your user program, the CPU can switch to STOP mode. If for instance you are monitoring the tags in your program, this will increase the cycle time.

  If the cycle lasts longer than double the maximum cycle time, and you do not restart the maximum cycle time in the user program (by calling the extended RE_TRIGR) instruction, the CPU will switch to STOP mode.
- Longest cycle time: Duration of the longest cycle since the last transition from STOP to RUN.
  This corresponds to the dashed blue arrow on the right in the diagram.

A blue band extends between the two dashed lines; this band corresponds to the entire range of the measured cycle times. If a measured cycle time is greater than the maximum cycle time, the portion of the band that lies outside the assigned limits will be colored red.

Display of the measured cycle times as absolute values

The following measured times are displayed in the "Cycle times measured" area and in the "Cycle time" pane.

- Shortest cycle time since the last transition from STOP to RUN.
- Current/last cycle time:
- Longest cycle time since the last transition from STOP to RUN.

Showing the current status of the LEDs of a CPU

Where do I find the information I need?

The current status of the LEDs of a CPU can be found in the display area of the "CPU control panel" pane of the "Online tools" task card.

Display area of the "CPU control panel" pane of the "Online Tools" task card

This area contains the following displays:

- Station name and CPU type (short designation)
- RUN / STOP (corresponds to the "RUN / STOP" LED of the CPU)
- ERROR (corresponds to the "ERROR" LED on the CPU)
- MAINT (corresponds to the "MAINT" LED on the CPU)

Showing fill levels of all types of memory on a CPU

Where do I find the information I need?

The fill levels of all types of memory on a CPU can be found on the following two pages:

- In the display area of the "Memory" group in the "Diagnostics" folder in the online and diagnostics view of the module to be diagnosed
- In the display area of the "Memory" pane on the "Online Tools" task card

Display area of the "Memory" group in the "Diagnostics" folder of the online and diagnostics view

This area contains the current memory utilization of the associated module and details of the individual memory areas.

The memory utilization is shown both as a bar diagram and as a numerical value (percentage).

The following memory utilizations are shown:

- Load memory
  If no memory card is inserted, the internal load memory is displayed.
  If a memory card is inserted, the operating system only uses the inserted load memory as the load memory. This is displayed here.
- Work memory
- Retentive memory

Display area of the "Memory" pane of the "Online Tools" task card

This area contains the current memory utilization of the associated module. The available memory is shown both as a bar diagram and as a numerical value (percentage). The numerical value is rounded to an integer value.

Note

If less than 1% of a memory area is utilized, the available portion of this memory area is shown as "99%".

The following memory utilizations are shown:

- Load memory
  If no memory card is inserted, the internal load memory is displayed.
  If a memory card is inserted, the operating system only uses the inserted load memory as the load memory. This is displayed here.
- Work memory
- Retentive memory

Displaying fill level of all types of memory of an S7-1500 CPU

Where do I find the information I need?

The fill levels of all types of memory of an S7-1500 CPU can be found at the following two places:

- In the display area of the "Memory" group in the "Diagnostics" folder in the online and diagnostics view of the module to be diagnosed
- In the display area of the "Memory" pane on the "Online Tools" task card

Display area of the "Memory" group in the "Diagnostics" folder of the online and diagnostics view

This area contains the current memory utilization of the associated module and details of the individual memory areas.

The memory utilization is shown both as a bar diagram and as a numerical value (percentage).

The following memory utilizations are shown:

- Load memory

  Note

  The load memory is located on the SIMATIC memory card.

- Code work memory: work memory for program code
- Data work memory: work memory for data blocks
- Retentive memory

Display area of the "Memory" pane of the "Online Tools" task card

  Note

  The load memory is located on the SIMATIC memory card.

- Code work memory: work memory for program code
- Data work memory: work memory for data blocks
- Retentive memory

10.2.1.4 Checking a module for defects

Determining the diagnostic status of a module

Where is the diagnostics status of a module displayed?

The diagnostic status of a module is displayed in the "Diagnostic status" group in the "Diagnostics" folder in the online and diagnostics view of the module to be diagnosed.

The "Diagnostics status" group consists of the following areas:

- Status
- Standard diagnostics (for S7-300 and S7-400 only for non-CPU modules)

"Status" area

The following status information is displayed in this area:

- Status of the module as viewed by the CPU, for example:
  - Module available and OK.
  - Module defective.
    If the module experiences a fault and you have enabled the diagnostic error interrupt during configuration, the "Module defective" status is displayed.
  - Module configured, but not available.
    Example: Diagnostics data is not available because the current online configuration differs from the offline configuration.
- Detected differences between the configured and the inserted module. Provided it can be ascertained, the article number will be displayed for the set and actual type.

The scope of the displayed information depends on the selected module.

"Standard diagnostics" area

The following diagnostics information for non-CPU modules is displayed in this area:

- Internal and external faults that relate to the overall module
- Associated diagnostics events

Examples of such diagnostics information are:

- Entire backup failed
- Module defective

Note

Diagnostic interrupts

A diagnostic interrupt can be reported to the CPU only if the module has diagnostic interrupt capability and the diagnostic interrupt has been enabled.

The display of the diagnostic interrupt is a snapshot. Sporadic module defects can be identified in the diagnostics buffer of the respective CPU.

Reading out the diagnostics buffer of a CPU

Where do you read out the diagnostics buffer of a CPU?

You read out the diagnostics buffer of a CPU in the "Diagnostics buffer" group in the "Diagnostics" folder in the Online and Diagnostics view.

Structure of the "Diagnostics buffer" group

The "Diagnostics buffer" group consists of the following areas:

- "Events"
- "Settings"

Diagnostics buffer

The diagnostics buffer is used as a log file for the diagnostics events that occurred on the CPU and the modules assigned to it. These are entered in the order of their occurrence, with the latest event shown at the top.

"Events" area

The "Events" area consists of the following elements:

- Check box "CPU time stamp takes into account local PG/PC time"
- Event table
- "Freeze display" or "Cancel freeze" button
- Details of the event: Event no., event ID, description, time stamp, incoming/outgoing information
- "Help on event", "Open in editor", "Save as ..." buttons

Check box "CPU time stamp takes into account local PG/PC time"

If you have not activated the check box, the diagnostics buffer entries are shown with the module time.

If you have activated the check box, the diagnostics buffer entries are shown with the time given by the following formula:

Displayed time = module time + time zone offset on your programming device / PC

This requires the module time to be identical to UTC.

You should use this setting if you wish to see the times of the diagnostics buffer entries for the module expressed in the local time of your programming device / PC.

Selecting or clearing the check box immediately changes the times displayed for the diagnostics buffer entries.

Note

If you use the "WR_SYS_T" instruction in your program or if you set the real-time clock of the CPU using an HMI device instead of using UTC, we recommend that you clear the "CPU time stamp takes into account local PG/PC time" check box. In this case, the module time is the sole time of concern.

Event table

The following information is displayed in the table for each diagnostics event:

- Sequential number of the entry
  The first entry contains the latest event.
- Date and time of the diagnostics event
  If no date and time are shown, the module has no integral clock.
- Short name of the event and, if applicable, the reaction of the CPU

  Note

  If an individual parameter of a text cannot be determined, the character string "###" is shown in its place.

  If no display text is yet available for new modules or new events, the numbers of the events and the individual parameters are stated as hexadecimal values.

- Icon for information related to incoming/outgoing status
  The following table shows the available icons and their respective meaning.

Icon	Meaning
	Incoming event
	Outgoing event
	Incoming event to which there is no independent outgoing event
	User-defined diagnostics event

- Only for S7-1200 and S7-1500 CPUs: Icon for the severity of the event
  The following table shows the available icons and their respective meaning.

Icon	Meaning
	No maintenance and/or no fault
	Maintenance required
	Maintenance demanded
	Error

You can change the order of the columns, adjust the column widths and remove and add individual columns in the event table. In addition, you can sort as follows: by sequential number, by "Date and time" and by "Event".

"Freeze display" or "Cancel freeze" button

The "Freeze display" or "Cancel freeze" button is only enabled when there is an online connection to the CPU.

The default setting is "Freeze display".

The following happens when you click the "Freeze display" button:

- The current display of the diagnostics buffer entries is frozen.
- The labeling of the button changes to "Cancel freeze".

If an error has occurred in your system, diagnostics events can occur very quickly in succession. This produces a high update rate on the display. Freezing the display allows you to calmly examine the situation in more detail.

If the display is frozen and you click the "Cancel freeze" button, the following happens:

- The display of the diagnostics buffer entries is updated again.
- The labeling of the button changes to "Freeze display".

Note

If you freeze the diagnostics buffer display, the CPU continues to enter events in the diagnostics buffer.

Details of the event

If you select a line in the list of events, you obtain detailed information on the respective event:

- Sequential number of the event in the diagnostics buffer
- Event ID
- Description of the event with event-dependent additional information. Examples of this additional information:
  - Command that caused the event
  - Operating mode switch caused by the diagnostics event
- Time stamp
- Only for S7-1200 and S7-1500 CPUs: Associated I&M data (module and, if required, station and/or device name, rack/slot, plant designation, location designation)
- Priority of the event
- Information on whether the event is an incoming or outgoing event

"Help on event" button

If you click on this button, the selected event is explained in more detail and any remedies given.

Note

For a small number of events, the "Help on event" button is grayed out.

"Open in editor" button

The following table shows if the "Open block" button is active and which function it conceals.

When is the "Open in editor" button enabled?	What happens when you click this button?
If the diagnostics event references the relative address of a block. This is the address of the command that caused the event.	The "Open in editor" function opens the referenced block in the offline view at the programming instruction that causes the error. This allows you to check and, if necessary, change the source code of the block at the specified place and then download it again to the CPU.
If the diagnostics event was triggered by a module.	The "Open in editor" function opens the Device view of the module involved.

"Save as ..." button

If you click this button, the content of the diagnostics buffer is saved in a text file. "Diagnostics", depending on the language, with the extension ".txt" is suggested as the file name. You can however change this name.

"Settings" area

The "Settings" area consists of the following elements:

- "Display events" list
- "Apply settings as default" button
- "Output event information in hexadecimal format" check box

List "Display events:"

There is an check box in this list for every event class (default setting: all check boxes are selected). If you clear a check box, the events of that event class is no longer displayed in the "Events" area. Reselecting the check box displays the associated events once again.

"Apply settings as default" button

If you click this button, the settings are also applied to future occasions when the "Events" tab is opened.

"Output event information in hexadecimal format" check box

If you select the check box, the event IDs in the Events list of the "Events" area is displayed in hexadecimal format. If you clear the check box, the event information is given in text form.

Basic information on the diagnostics buffer (Page 1398)

Saving service data

Purpose

In the event of servicing it may be possible that the SIEMENS Customer Support requires very special information about the state of a module of your system for diagnostic purposes.

If such a case occurs in your system, you will be asked by Customer Support to save the service data of the module and send the resulting file to them.

Where do you carry out the saving of service data of a module?

You carry out the saving of service data of a module in its online and diagnostics view at the following points: In the "Functions" folder in the "Save service data" group"

The "Save service data" group consists of the following areas:

- Online data
- Saving service data

"Online data" area

This area shows the following data of the module:

- Article number
- Firmware version
- Module name (you configured this while configuring the hardware.)
- Rack
- Slot

"Save service data" area

Proceed as follows to create and save a file with special service data:

1. Select the point in the file system at which you want to save the file:
   - You use the path preset in the "Path" field.
   - Click the three-dot (browse) button. In the dialog that opens specify the desired path and enter the file name.
2. Click the "Save data" button.

10.2.1.5 Changing the properties of a module or the programming device/PC

Changing the mode of a CPU

Requirement

There is an online connection to the CPU whose mode you want to change.

Procedure

To change the mode of the CPU, follow these steps:

1. Enable the "Online tools" task card of the CPU.
2. Click the "RUN" button in the "CPU control panel" pane if you want to change the CPU to RUN mode or the "STOP" button if you want to change the CPU to STOP mode.

   Note

   The only button active is the one that can be selected in the current operating mode of the CPU.

3. Acknowledge the confirmation prompt with "OK".

Or:

1. Open the "Online" menu.
2. Choose the "Start CPU" menu command if you want to set the CPU to RUN mode and "Stop CPU" if you want to set the CPU to STOP mode.

   Note

   The only button that is active is the one that can be chosen in the current operating mode of the CPU.

3. Acknowledge the confirmation prompt with "OK".

Or:

1. Click the "Start CPU" button in the toolbar if you want to set the CPU to RUN mode and the "Stop CPU" button if you want to set the CPU to STOP mode.

   Note

   The only button that is active is the one that can be chosen in the current operating mode of the CPU.

2. Acknowledge the confirmation prompt with "OK".

Result

The CPU will be switched to the required operating mode.

Performing a memory reset

Requirement

- There is an online connection to the CPU on which the memory reset is to be performed.
- The CPU is in STOP mode.

Note

If the CPU is still in RUN mode and you start the memory reset, you can place it in STOP mode after acknowledging a confirmation prompt.

Procedure

To perform a memory reset on a CPU, follow these steps:

1. Enable the "Online Tools" task card of the CPU.
2. Click the "MRES" button in the "CPU control panel" pane.
3. Acknowledge the confirmation prompt with "OK".

Result

The CPU is switched to STOP mode, if necessary, and the memory reset is performed on the CPU.

See also

Basics of a memory reset (Page 1169)

Determining and setting the time of day on a CPU

Where do I find the functions I need?

You determine and change the time of day on a CPU in the "Set time of day" group in the "Functions" folder of the Online and Diagnostics view. This requires an online connection.

Structure of the "Set time of day" group

The "Set time of day" group consists of the following areas:

- Area for reading out and setting the time of day
- Time system (This area does not exist for S7-1200 and will not be examined here.)

Structure of the area for reading out and setting the time of day

This area consists of the following parts:

- Programming device / PC time
  Here the time zone setting, the current date and the current time setting of your programming device / PC are displayed.
- Module time
  Here the date and time values currently read from the module (for example the CPU), are converted to local time and date and displayed.
  If the "Take from PG/PC" check box is selected, when you click the "Apply" button, the date and the PG/PC time converted to UTC are transferred to the module.
  If the "Take from PG/PC" check box is not selected, you can assign the date and time for the integrated clock of the module. After clicking the "Apply" button, the date and the time recalculated to UTC time are transferred to the module.

Updating the firmware of a module

Performing a firmware update

Using firmware files, you can update the firmware of a module.

Requirements

- The module is connected online.
- The module supports a firmware update.
- For those modules that require a supply voltage to perform the firmware update correctly: The supply voltage of the module is secured. For details, see the documentation of the module.

Procedure

To perform a firmware update, follow these steps:

1. Open the module in the Online and Diagnostics view.
2. Select the "Firmware update" group in the "Functions" folder.

   Note

   For S7-1500-CPUs, this group is subdivided into "PLC" and "Display".

3. Click the "Browse" button in the "Firmware update" area in order to select the path to the firmware update files.
4. Select one of these files. The table then lists all modules for which an update is possible with the selected firmware file.

5. Optional: Select the "Run firmware after update" check box to reset the module after the load operation and to start the new firmware.
6. Click the "Start update" button. If the selected file can be interpreted by the module, it is downloaded to the module. If the mode of the CPU needs to be changed, you will be prompted to do this in dialogs.

Warning

Invalid plant states possible

An S7-1500 CPU immediately goes to STOP mode when you start the firmware update, which can have an effect on the operation of an online process or a machine.
Unexpected operation of a process or a machine can result in severe or fatal injuries and/or damage to property.

Note

After you have run a firmware update, you will need to replace the module involved with the same module with the current firmware version in the hardware configuration of your project. The engineering configuration then matches the actual physical configuration again.

"Run firmware after update" check box

If you have not selected the "Run firmware after update" check box, the previous firmware remains active until the module is reset (for example by cycling power). The new firmware only becomes active after the module has been reset.

If you have selected the check box, the module is automatically reset after the firmware has been downloaded and it then continues with the new firmware.

Activating the firmware following the update has the following consequences:

- A station executes a restart. This means that all modules in the station become unavailable.
- If the corresponding CPU is in RUN, activating the firmware can lead to access errors or other problems in the user program and might even mean that the CPU remains permanently in STOP.

  Note

  For some CPUs, the "Run firmware after update" check box is grayed out and deactivated. In this case, you must restart the CPU manually.

  For S7-1500 CPUs, the "Run firmware after update" check box is grayed out and selected. In this case, the new firmware is activated immediately after the download operation.

Replacing a hardware component (Page 574)

Resetting an S7-1200 CPU to factory settings

Requirement

- There is no memory card inserted in the CPU.
- There is an online connection to the CPU that you want to reset to the factory settings.
- The CPU is in STOP mode.

Note

If the CPU is still in RUN mode and you start the reset operation, you can place it in STOP mode by answering the security prompt with yes.

Procedure

To reset an S7-1200 CPU to factory settings, follow these steps:

1. Open the Online and Diagnostics view of the CPU.
2. Select the "Reset to factory settings" group in the "Functions" folder.
3. Select the "Keep IP address" check box if you want to keep the IP address or the "Delete IP address" check box if you want to delete the IP address.

   Note

   The two check boxes mentioned are only available if the module to be reset is able to choose whether to retain or delete the IP address.

4. Click the "Reset" button.
5. Acknowledge the confirmation prompt with "OK".

Result

The module is switched to STOP mode if necessary and the settings are then reset to factory settings. This means:

- The work memory and the internal load memory and all operand areas are cleared.
- All parameters are reset to their defaults.
- The diagnostic buffer is cleared.
- The time is reset.
- The IP address is kept or deleted depending on which setting you made.

Resetting an S7-1500 CPU to factory settings

Requirement

- If you start a reset to factory settings from the project context, an online connection to the relevant CPU must exist.
- The relevant CPU is in STOP mode.

Note

If the CPU is still in RUN mode and you start the reset operation, you can place it in STOP mode after acknowledging a confirmation prompt.

Procedure

To reset an S7-1500 CPU to factory settings, follow these steps:

1. Open the Online and Diagnostics view of the CPU (either from the project context or via "Accessible devices").
2. Select the "Reset to factory settings" group in the "Functions" folder.
3. Select the "Keep IP address" check box if you want to keep the IP address or the "Delete IP address" check box if you want to delete the IP address.

   Note

   With "Delete IP address", all IP addresses are deleted. This applies regardless of how you created the online connection.

   If a memory card is inserted, selecting the "Delete IP address" option causes the following: The IP addresses are deleted and the CPU is reset to factory settings. Then, the configuration (including IP addresses) that is stored on the memory card is transferred into the CPU (see below). If the memory card was formatted before resetting to factory settings or if it is empty, no IP address is transferred into the CPU.

4. Click the "Reset" button.
5. Acknowledge the confirmation prompt with "OK".

Result

The module is switched to STOP mode if necessary and the settings are then reset to factory settings. This means:

- The work memory and the internal retentive system memory and all operand areas are cleared.
- All parameters are reset to their defaults.
- The diagnostic buffer is cleared.
- The time of day is reset.
- The I&M data are deleted except for I&M0 data.
- The runtime meters are reset.

- The IP address is kept or deleted depending on which setting you made.
- If a memory card was inserted prior to the reset to factory settings, the configuration contained on the memory card (hardware and software) is downloaded to the CPU.

Formatting an S7-1500 memory card

Requirement

- If you start the formatting of the memory card from the project context, an online connection to the relevant CPU must exist.
- The relevant CPU is in STOP mode.

Note

If the CPU is still in RUN mode and you start a formatting operation, you can place it in STOP mode after acknowledging a confirmation prompt.

Procedure

To format an S7-1500 memory card, follow these steps:

1. Open the Online and Diagnostics view of the CPU (either from the project context or via "Accessible devices").
2. Select the "Format memory card" group in the "Functions" folder.
3. Click the "Format" button.
4. Answer the safety prompt with "Yes".

Result

- The memory card is formatted.
- The CPU is temporarily unavailable.
- The project data on the CPU are deleted with the exception of the IP address.
- If you start the formatting of the memory card from the project context, the Online and Diagnostics view remains open. If formatting is started via "Accessible devices", the Online and Diagnostics view will close.

Assigning an IP address to a PROFINET IO device

Basic information on assigning an IP address to a PROFINET IO device

Overview

All PROFINET IO devices work with the TCP/IP protocol and therefore require an IP address for operation on Industrial Ethernet. Once an IP address has been assigned to an IO device, it can be accessed via this address. You can then download configuration data or perform diagnostics, for example.

Requirement

- The Ethernet LAN connection must already be established.
- The Ethernet interface of your programming device or PC must be accessible.
- The IO device that is to be assigned an IP address must be in the same IP band as the programming device or PC.

Starting the address assignment via "Accessible devices"

Requirement

- The devices accessible via the associated interface of the PG/PC are displayed in the project tree (to display these, either double-click "Update accessible devices" in the project tree or select the "Accessible devices..." command in the "Online" menu.).
- You have double-clicked "Online access" -> <Selected interface> -> <PROFINET IO device> -> "Online & Diagnostics" in the project tree to open the Online and Diagnostics view.

Procedure

1. Open the "Functions" folder and the "Assign IP address" group inside this folder. The "MAC address" field displays the MAC address of the PROFINET IO device. The "Accessible devices" button is grayed out.
2. Enter the desired IP address.
3. Enter the subnet mask.
4. If a router is to be used, select the "Use router" check box and enter its IP address.
5. Click the "Assign IP address" button.

Result

The IP address is permanently assigned to the IO device or to the relevant PROFINET interface of the IO device. It is retained even through a startup or a power failure.

Note

For an S7-1500 CPU, you can also use the above-described method to change the IP address of a PROFINET interface, if a project has already been downloaded to the CPU via this interface. This overwrites the IP address downloaded via the project.

See also

Retentivity of IP address parameters and device names (Page 1124)

Starting the address assignment from the project context

Requirement

- An online connection to the PROFINET IO device exists.
- You have opened the Online and Diagnostics view of the PROFINET IO device from the project context.
- The PROFINET IO device is not assigned to any IO controller.

Procedure

1. Open the "Functions" folder and the "Assign IP address" group inside this folder.
2. Click the "Accessible devices" button in order to identify the devices that can be accessed. Note: For an S7-1500 CPU, there are two entries here because it has two PROFINET interfaces.
3. Select the IO device. The "IP address" field, "Subnet mask" field, "Use router" check box and "Router address" field are grayed out and contain the node properties you used to establish the current online access.
4. Click the "Assign IP address" button.

Result

The IP address is permanently assigned to the IO device or to the relevant PROFINET interface of the IO device. It is retained even through a startup or a power failure.

See also

Retentivity of IP address parameters and device names (Page 1124)

Assigning a PROFINET device name

Basic information on assigning a name to a PROFINET IO device

Device name

Before an IO device can be addressed by an IO controller, it must have a device name. This procedure was chosen for PROFINET because names are easier to handle than complex IP addresses.

Assigning a device name to a PROFINET IO device is comparable to setting the PROFIBUS address for a DP slave.

An IO device has no device name in its delivery state. For an IO controller to address an IO device, it must first be assigned a device name using the programming device or PC. It is now ready to transfer the configuration information including the IP address during startup or exchange user data in cyclic operation.

Rules for the device name

The device name is subject to the following limitations:

- Restricted to a total of 240 characters (lower case letters, numbers, dash, or dot)
- A name component within the device name, which is a character string between two dots, must not exceed 63 characters.
- No special characters such as umlauts, brackets, underscore, slash, blank space, etc. The only special character permitted is the dash.
- The device name must not begin or end with the "-" character.
- The device name must not begin with a number.
- The device name form n.n.n.n (n = 0, ... 999) is not permitted.
- The device name must not begin with the string "port-xyz" or "port-xyz-abcde" (a, b, c, d, e, x, y, z = 0, ... 9).

Where do I find the function I am seeking?

You can assign the name of a PROFINET IO device at the following places:

- In the online and diagnostics view of the device in the "Assign name" group of the "Functions" folder. The user interface for this group differs depending on how you open the online and diagnostics view:
  - Open via "Accessible devices"
  - Open from the project context
- In the "Assign PROFINET device name" dialog

See also

Assigning a name in the online and diagnostics view opened via "Accessible devices" (Page 1392)

Assigning a name in the online and diagnostics view opened from the project context (Page 1392)

Assigning a name in the "Assign PROFINET device name" dialog (Page 1393)

Assigning a name in the online and diagnostics view opened via "Accessible devices"

Requirement

- You have opened the online and diagnostics view of the PROFINET IO device using "Update accessible devices" (in the project tree) or "Accessible devices..." ("Online" menu).

Procedure

1. Open the "Functions" folder and the "Assign name" group inside this folder. The "Type" field displays the module type of the PROFINET IO device.
2. Enter the required device name in the "PROFINET device name" input box.
3. Optional: Select the "Flash LED" check box in order to run an LED flash test on the PROFINET IO device. In this way, you verify that you are naming the desired IO device.

   Note

   The LED flash test is not supported by all PROFINET IO devices.

   The LED flash test runs until you cancel it. This is done, for example, by clearing the "Flash LED" check box or by closing the online and diagnostics view.
4. Click "Assign name".

Result

The entered name is assigned to the PROFINET IO device.

Assigning a name in the online and diagnostics view opened from the project context

Requirement

- You have opened the online and diagnostics view of the PROFINET IO device from the project context.
- The PROFINET IO device can be accessed using at least one PG/PC interface.

Procedure

1. Open the "Functions" folder and the "Assign name" group inside this folder. The "PROFINET device name" drop-down list displays the current name in the offline project, and the "Type" box shows the module type of the PROFINET IO device.

   Note

   For CPUs with several PROFINET interfaces, the names of all existing PROFINET interfaces are displayed in the offline project.

2. Choose a different name from the drop-down list, if necessary.

   Note

   In steps 3 to 5, you determine the IO devices that are present in the PROFINET subnet.

3. In the "PG/PC interface for assignment" drop-down list, select the PG/PC interface you want to use to establish the online connection.
4. Optional: Use the three check boxes to make a selection from all IO devices available online.
5. Click the icon for determining the IO devices present in the PROFINET subnet. The table is then updated.
6. Select the desired IO device in the table.
7. Optional: Select the "Flash LED" check box in order to run an LED flash test on the PROFINET IO device. In this way, you verify that you are naming the desired IO device.

   Note

   The LED flash test is not supported by all PROFINET IO devices.

   The LED flash test runs until you cancel it. This is done, for example, by clearing the "Flash LED" check box, by selecting another IO device in the table, or by closing the online and diagnostics view.
8. Click "Assign name".

Result

The selected name is assigned to the PROFINET IO device or one of its PROFINET interfaces.

Assigning a name in the "Assign PROFINET device name" dialog

Requirement

- You have opened the "Assign PROFINET device name" dialog from the network view (from the shortcut menu of a PN/IE connection).
- The PROFINET IO device can be accessed using at least one PG/PC interface.

Procedure

1. The following is displayed in the "PROFINET device name" drop-down list:
   - the name of the interface that was used to open the project in the current offline project
   - the names of those IO devices that are connected by means of this interface

   The "Type" field displays the module type of the PROFINET IO device.
   Choose a different name from the drop-down list, if necessary.

   Note

   In steps 2 to 4, you determine the IO devices that are present in the PROFINET subnet.

2. In the "PG/PC interface for assignment" drop-down list, select the PG/PC interface you want to use to establish the online connection.
3. Optional: Use the three check boxes to make a selection from all IO devices available online.
4. Click the icon for determining the IO devices present in the PROFINET subnet. The table is then updated.
5. Select the desired IO device in the table.
6. Optional: Select the "Flash LED" check box in order to run an LED flash test on the PROFINET IO device. In this way, you verify that you are naming the desired IO device.

   Note

   The LED flash test is not supported by all PROFINET IO devices.

   The LED flash test runs until you cancel it. This is done, for example, by clearing the "Flash LED" check box or by selecting another IO device in the table.
7. Click "Assign name".

Result

The selected name is assigned to the PROFINET IO device or the interface that was used to open the dialog.

Calibrating an S7-1500 analog module

Calibrating an S7-1500 analog module - Overview

Where do you calibrate an S7-1500 analog module?

You calibrate an S7-1500 analog module in its Online and Diagnostics view in the "Calibrate" group of the "Functions" folder.

Overview of the function scope of the calibrating function

You can perform the following functions for an S7-1500 analog module in the "Calibrate" group:

- Specifying the current calibration of all channels
- Calibrating a channel
- Canceling a running calibration
- Resetting the calibration of a channel to the factory settings

Requirement for the calibrating function described below

The following is required for the calibrating function described below:

- You have opened the Online and Diagnostics view from the project context (thus not from the project tree or via the "Online" menu).
- There is an online connection to the analog module that is to be calibrated.
- Offline and online configuration are identical.

Calibrating an S7-1500 analog module

Overview of the calibration of a channel of an S7-1500 analog module

The calibration of a channel of an S7-1500 analog module consists of the following steps:

1. Start calibration
2. Perform the second step up to the next to last step of the calibration
3. Complete calibration

These steps are described in more detail in the following section.

Requirement

- You have opened the Online and Diagnostic view of the S7-1500 analog module from the project context and are in the "Calibrate" group of the "Functions" folder.
- The associated CPU is online.
- No calibration is currently running on the analog module (if you want to start the calibration) or the last step initiated has been performed successfully (if you want to resume or complete the calibration).

Procedure for starting the calibration

To start the calibration, follow these steps:

1. In the overview table, select the line that belongs to the channel to be calibrated.
2. Click the "Start manual calibration" button.

The user interface then changes as follows:

- The overview table and the "Start manual calibration" button and "Set to factory settings" buttons become inactive.
- The step display is activated and displays the numbers of the current and last steps.
- The "Command" field becomes active and indicates what the user must do in the next calibration step.
- The "Status" field becomes active and shows the current status of the calibration, e.g., "Calibration successfully started".
- The "Measured value" field becomes active. For an input module a value is displayed here; you must enter a value here for an output module.
- The "Cancel" button becomes active.
- The "Next" button becomes active. This button can be used to advance to the next step of the calibration.

Procedure for the second to the next to last step of the calibration

Follow these steps:

1. Click the "Next" button.

The fields of the user interface described above are then updated.

Procedure for the last step of the calibration

Follow these steps:

1. Click the "Next" button.

The user interface then changes as follows:

- The overview table becomes active.
- The calibration display of the calibrated channel is updated.
- The "Start manual calibration" button and "Set to factory settings" buttons become active.
- The step display is deactivated and the numbers of the current step and last steps are empty.
- The "Command" field becomes inactive and is empty.
- The "Status" field becomes inactive and shows the last status of the calibration, e.g., "Calibration successfully finished".
- The "Measured value" field becomes inactive and is empty.
- The "Cancel" button becomes inactive.
- The "Next" button becomes inactive.

Error occurrence

If an error occurs during the calibration, the module cancels the calibration. Afterwards, the channel that was to be calibrated has the same settings as before the start of the calibration.

Except for the "Status" field, the user interface appears the same after the occurrence of an error as before the calibration. The "Status" field displays the error that the module detected during the calibration.

Canceling a running calibration of an S7-1500 analog module

Requirement

- You have opened the Online and Diagnostic view of the S7-1500 analog module from the project context and are in the "Calibrate" group of the "Functions" folder.
- The associated CPU is online.
- A calibration is currently running on the analog module.

Procedure

To cancel a running calibration, follow these steps:

1. Click the "Cancel" button.

Result

The running calibration is canceled, and afterwards the channel to be calibrated has the same settings as before the calibration.

All operator controls in the user interface are deactivated until the cancelation is complete. Except for the "Status" field, the user interface appears the same afterwards as before the calibration. The "Status" field displays the result of the cancelation.

Resetting an S7-1500 analog module to factory settings

Requirement

- You have opened the Online and Diagnostic view of the S7-1500 analog module from the project context and are in the "Calibrate" group of the "Functions" folder.
- The associated CPU is online.

Procedure

To reset a channel of an S7-1500 analog module to factory settings, follow these steps:

1. Select the line associated with the channel to be reset in the overview table.
2. Click the "Set to factory settings" button.

Result

All operator controls in the user interface are deactivated until the reset operation is complete. Except for the "Status" field, the user interface appears the same afterwards as before the reset operation. The "Status" field displays the result of the reset operation.

10.2.1.6 Diagnostics in STOP mode

Basic information on the diagnostics buffer

Function

The operating system of the CPU enters the errors detected by the CPU and the diagnostics-capable modules into the diagnostics buffer in the order in which they occurred. This includes the following events:

- Every mode change of the CPU (POWER UP, change to STOP mode, change to RUN mode)
- Every hardware and diagnostic error interrupt

The top entry contains the most recent event. The entries in the diagnostics buffer are stored permanently. They are retained even if the power supply fails and can only be deleted by resetting the CPU to factory settings.

A diagnostics buffer entry contains the following elements:

- Time stamp
- Error ID
- Additional information specific to the error ID

Advantages of the diagnostics buffer

The diagnostics buffer offers the following advantages:

- After the CPU has changed to STOP mode, you can evaluate the last events prior to the STOP so that you can locate and identify the cause of the STOP.
- You can detect and eliminate the causes of errors more quickly and thus increase the availability of the system.
- You can evaluate and optimize the dynamic system response.

Organization of the diagnostics buffer

The diagnostics buffer is a ring buffer. The maximum number of entries for the S7-1200 CPUs is 50. When the diagnostics buffer is full and a further entry needs to be made, all existing entries are shifted by one position (which means that the oldest entry is deleted) and the new entry is made at the top position that is now free (FIFO principle: first in, first out).

Evaluation of the diagnostics buffer

The contents of the diagnostics buffer can be accessed as follows:

- Using the Online and Diagnostics view

The evaluation of events occurring prior to the error event (e.g., transition to STOP mode) allows you to obtain a picture of the possible causes or to zero in more closely or specify in more detail the possible causes (depending on the error type).

Read the detailed information about the events carefully and use the "Help on event" button to obtain additional information and possible causes of individual entries.

Note

To make the best use of the time stamp information on the diagnostics buffer entries in time-critical systems, it is advisable to check and correct the date and time of day on the CPU occasionally.

Alternatively, it is possible to perform a time-of-day synchronization using an NTP time server.

See also

Resetting an S7-1200 CPU to factory settings (Page 1386)

Determining the cause of a STOP of a CPU (Page 1399)

Determining and setting the time of day on a CPU (Page 1383)

Assigning the clock parameters (Page 1193)

Determining the cause of a STOP of a CPU

Requirement

The CPU you want to analyze is in STOP mode.

Procedure

To find out the reason why a CPU changed to STOP, follow these steps:

1. Open the online and diagnostics view of the CPU.
2. Select the "Diagnostics buffer" group from the "Diagnostics" folder.
3. Evaluate the events occurring prior to the transition to STOP mode. Use this to obtain a picture of the possible causes or to zero in on or specify in more detail the possible causes (depending on the error type).
   Read the detailed information about the events carefully and use the "Help on event" button to obtain additional information and possible causes of individual entries.

Result

You were able to zero in on or determine in more detail the cause of the CPU STOP.

Note

If the analysis does not enable you to overcome the problem, contact Customer Support. In this case, use the "Save as" button to back up the content of the diagnostics data to a text file and submit it to Customer Support.

Reading out the diagnostics buffer of a CPU (Page 1376)

10.2.1.7 Online accesses in the Online and Diagnostics view

Displaying status of the online connection

Requirement

- The associated device can be accessed using at least one PG/PC interface.

Procedure

1. Open the online and diagnostics view for the device whose online connection status you want to display.
2. Select the "Online access" group.

   Note

   The "Online access" group exists only for CPUs and some CPs. However, if you have opened the online and diagnostics view using the "Show/update accessible devices" function, it is not displayed.

Result

The status of the online connection is displayed in the "Status" area both graphically and in text form.

Specifying a PG/PC interface, going online

Requirement

- The associated device can be accessed using at least one PG/PC interface.
- There is currently no online connection to the relevant device.

Procedure

1. Open the Online and Diagnostics view of the device to which you want to establish an online connection.
2. Choose the "Online access" group and the "Online access" area within this group.

   Note

   The "Online access" group exists only for CPUs and some CPs. If you have opened the Online and Diagnostics view using the "Show/update accessible devices" function, it is not displayed.

3. If an online connection was established previously for the device, the associated data for this online connection is preset in the drop-down lists. In this case, you can immediately continue with the last step of this operating instruction, provided you have not changed the IP address in the meantime using the Online and Diagnostics view.
4. Choose the interface type in the "Type of PG/PC interface" drop-down list.
   The "PG/PC interface for online access" drop-down list then shows only the interfaces of the programming device or PC that match the selected interface type.
5. In the "PG/PC interface for online access" drop-down list, select the programming device or PC interface via which you want to establish the online connection.
6. Optional: Click the "Properties" button to change the properties of the associated CP.
7. In the "Connection to subnet" drop-down list, select the subnet via which the device is connected to the PG/PC interface.

   Note

   The PG/PC interface is connected to an interface of a device.

   If you only want to access this device, select the setting "Directly at slot <interface name>" in the drop-down list.

   If, however, you want to access another device by means of routing, create a subnet at this interface in the device configuration and then select this subnet in the drop-down list.

8. If the device is accessible via a gateway, select the gateway that connects the two subnets involved in the "1st gateway" drop-down list.
9. In the "Device address" entry field, enter the IP address of the device to which you want to establish an online connection, if necessary.

   Note

   For CPUs with multiple IP addresses, select the IP address of the PROFINET interface you want to use to establish an online connection from the "Device address" drop-down list.

10. Alternatively: Click the "Show accessible devices" button and choose the device from the list of accessible devices to which you want to establish an online connection.
11. Click the "Go online" button.

Result

The online connection to the desired device is established.

Going offline

Requirement

- There is currently an online connection to the relevant device.

Procedure

1. Open the online and diagnostics view of the device for which you want to disconnect the online connection.
2. Choose the "Online access" group and the "Online access" area within this group.

   Note

   The "Online access" group exists only for CPUs and some CPs. However, if you have opened the online and diagnostics view using the "Show/update accessible devices" function, it is not displayed.

3. Click the "Go offline" button.

Result

The online connection to the desired device will be disconnected.

Performing the flash test for a device with an online connection

Requirement

- There is currently an online connection to the relevant device.
- The FORCE function is not active.

Procedure

1. Open the online and diagnostics view of the device for which you want to perform a flash test.
2. Choose the "Online access" group and the "Status" area within this group.

   Note

   The "Online access" group exists only for CPUs and some CPs. However, if you have opened the online and diagnostics view using the "Show/update accessible devices" function, it is not displayed.

3. Select the "LED flash test" check box.

Result

- On an S7-1200 CPU, the RUN/STOP, ERROR and MAINT LEDs flash.
- On an S7-1500 CPU, the RUN/STOP, ERROR, and MAINT LEDs flash.
- On an S7-300 or S7-400 CPU, the FRCE LED flashes.

The LEDs flash until you cancel the flash test. This is done, for example, by clearing the "LED flash test" check box, by changing to another group of the online and diagnostics view, or by changing settings in the "Online access" area.

10.2.1.8 Checking PROFIBUS DP subnets for faults

Basic information on the diagnostic repeater

What is the diagnostic repeater?

The diagnostic repeater is a repeater that can monitor a segment of an RS 485 PROFIBUS subnet (copper cable) during operation and signal line errors to the DP master via a diagnostics message frame.

The diagnostic repeater detects, localizes and visualizes line errors during operation at an early stage. As a result, problems in the system are identified early and production downtimes will be minimized.

Function of the diagnostic repeater

The diagnostic repeater can perform line diagnostics on the DP2 and DP3 segments because it has a measuring circuit for these segments.

The line diagnostics run in two steps:

- Step 1: Topology determination
  You start the topology determination by calling the "DP_TOPOL" instruction in your program. The diagnostic repeater then determines the PROFIBUS addresses and the distance of the devices and creates a topology table.
- Step 2: Error localization
  The diagnostic repeater checks the lines during operation. It determines the distance to the point of the error and the reason for the error; it then issues a diagnostics alarm with relative information on the error location.

Display of detailed information on the determined error location

You receive detailed information on the determined error location in the Online and Diagnostics view of the diagnostic repeater.

- By means of icons
- By means of a display with graphics and text

See also

Displaying the status of the segment diagnostics using icons (Page 1404)

Displaying the status of the segment diagnostics using graphics and text (Page 1404)

Displaying the status of the segment diagnostics using icons

Where do I find the information I need?

The icons for the status of the segment diagnostics are available:

- In the expanded "Segment diagnostics" folder in the navigation pane of the Online and Diagnostics view of the relevant diagnostic repeater.

The diagnostics icon associated with the segment will be displayed behind the segment designation. It must be noted here that line errors will be displayed for the DP2 and DP3 segments only. The DP1 and programming device segments do not display errors in the form of a diagnostics icon; rather, they signal only a few bus errors.

Diagnostics icons

The following table shows the available icons and their meaning.

Icon	Meaning
	Segment is error-free
	Segment contains errors
	Segment is deactivated

Displaying the status of the segment diagnostics using graphics and text

Where is the status of the segment diagnostics displayed with graphics and text?

The status of the segment diagnostics will be displayed using graphics and text in the "DP1", "DP2", "DP3", and "PG" groups of the "Segment diagnostics" folder in the Online and Diagnostics view of the relevant diagnostic repeater.

Structure of the "DP1", "DP2" "DP3", and "PG" groups

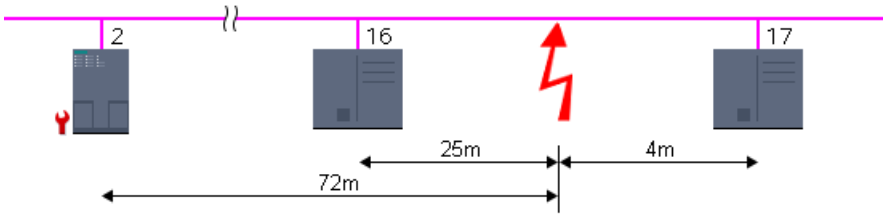
The "DP1", "DP2", "DP3", and "PG" groups consist of the following elements:

- "Error location" field
- "Error" field
- "Resolution" field
- "Help on event" button
- "Freeze display" or "Cancel freeze" button

"Error location" field

This field displays the error location graphically, provided the diagnostic repeater can determine the location.

The following picture shows an example for a line error occurring in the DP2 segment.



In this example, the diagnostic repeater has the PROFIBUS address 2, and a line error has occurred between the devices with PROFIBUS addresses 16 and 17. This line error is located 25 m from device 16, 4 m from device 17, and 72 m from the diagnostic repeater.

"Error" field

The error is explained in plain text in this field.

"Resolution" field

Here, you will find actions for resolving the error.

"Help on event" button

Click this button to obtain a more detailed explanation of the error and additional details on resolving the error, if applicable.

"Freeze display" or "Cancel freeze" button

The "Freeze display" or "Cancel freeze" button is only enabled when there is an online connection to the diagnostic repeater.

The default setting is "Freeze display".

The following happens when you click the "Freeze display" button:

- The current display of the segment diagnostics is frozen.
- The labeling of the button changes to "Cancel freeze".

If the display is frozen and you click the "Cancel freeze" button, the following happens:

- The display of the segment diagnostics is updated again.
- The labeling of the button changes to "Freeze display".

10.2.2 Connection diagnostics

10.2.2.1 Overview of connection diagnostics

Basics

Connection diagnostics, as described below, refers to the diagnostics of communication connections.

The connection diagnostics is started each time an online connection is established to a module (CPU or CP) that participates in one or more communication services. The connection status is updated automatically in the background.

In the case of one-way connections, an online connection must exist to the communication partner that has established the communication connection.

On connections configured at both ends, a distinction between the following two situations must be made:

- If there is an online connection to only one connection endpoint, only the part of the connection belonging to this connection endpoint can be diagnosed.
- If there is an online connection to both connection endpoints, both parts of the connection (and therefore the entire connection) can be diagnosed.

Basic connections diagnostics options

Connection diagnostics can be performed as follows:

- Using icons on the connection status display
  This display is generated in the connection table.
- Through detailed connection diagnostics
  This step is available in the "Diagnostics > Connection information" area of the Inspector window.

Requirement for the connection diagnostics described below

You can display the details of either all the communication connections created in the project (default) or selected communication connections in the connection table.

The connection diagnostics described in the following assume that you display the details of selected communication connections. To do this, clear the "Show all connections" option in the shortcut menu.

10.2.2.2 Displaying the connection status using icons

Content of connection table without an online connection

- For a CPU or CP, the connection table lists the communication connections (including properties) configured offline, if an online connection is not established.

Content of connection table with an online connection

After the online connection has been established, the properties of the communication connections listed offline will be expanded to include diagnostics icons for the connection status ("Online status" column).

In addition, entries for all communication connections that exist online only (e.g., connections for the instructions for Open User Communication, programming device and OP connections, connections for web server access) will now be added to the connection table.

For connections that exist online or offline only, the diagnostics icon at the bottom right is combined with a smaller additional comparison status icon.

Diagnostics icons for communication connections

The following table shows the diagnostics icons for communication connections.

Icon	Meaning
	Connection setup
	Connection not setup / is being setup
	Connection not available

Diagnostics icons for the comparison status

The diagnostic icons for communication connections can be combined at the bottom right with additional smaller icons that indicate the result of the online/offline comparison. The following table shows the available comparison icons and their meaning.

Icon	Meaning
	Connection exists online only
	Connection exists offline only

10.2.2.3 Detailed connection diagnostics

Detailed connection diagnostics - overview

Where do I perform detailed connection diagnostics?

To perform detailed connection diagnostics, go to the "Diagnostics > Connection" information of the Inspector window.

How do I open the "Diagnostics > Connection information" area of the Inspector window?

The following options are available for opening the "Connection information" tab of the Inspector window.

- Select the line of the relevant connection in the connection table. Click the "Diagnostics" and "Connection information" tabs one after the other in the Inspector window.
- Double-click the diagnostics icon of the relevant connection in the connection table.
- This step takes you to the programming editor for a S7 communication instruction or open user communication instruction. Double-click the diagnostic icon of the instruction (stethoscope).

Structure or the "Diagnostics > Connection information" area of the Inspector window

Requirements: the content of the "Connection information" tab has been filled, and an online connection to at least one end point of the relevant connection has been established.

If a module has been selected (network view), the tab will contain the following group:

- Connection resources (for S7-1200 and S7-1500)

If a connection has been selected (connection table), it will contain the following groups:

- Connection details
- Address details of the connection (for S7-1200 and S7-1500)

Determining online connection resources for S7-1200

Where do you determine the online connection resources?

The online connection resources are obtained in the "Connection resources" group. This group is located in the "Diagnostics > Connection information" area of the Inspector window. It is displayed only if you have selected a module in the network view to which an online connection exists.

Number of connection resources

- Maximum number: Specifies the maximum number of available connection resources of the module.
- Not assigned: Indicates how many connection resources are not yet assigned. If connection resources are already reserved for certain types of communication, then the unreserved connection resources cannot always be used for the various connection types.

Reserved and currently assigned connection resources

For the communication types indicated below, the connection resources that are reserved and currently assigned by the module will be displayed.

Communication type	Meaning
PG communication	Resources for connections between the module and programming devices (for example, for the establishment of a connection from the project tree, for online diagnostics, etc.)
HMI communication	Resources for connections between the module and HMI devices
Open User Communication	Resources for connection of open user communication instructions
S7 communication	Resources for configured S7 connections, through which data can be exchanged by calling instructions in the user program.
Other communication	Specifies other assigned connection resources for which connection resources are not reserved.

Determining online connection resources for S7-1500

Where do you determine the online connection resources?

The online connection resources are obtained in the "Connection resources" group. This group is located in the "Diagnostics > Connection information" area of the Inspector window. It is displayed only if you have selected a module in the network view to which an online connection exists.

Description of the detailed display of the connection resources

The detailed display of the connection resources includes:

- Number of available connection resources
- Number of configured connection resources
- Number of connection resources still available

For a description of these, go to here .

Determining connection details

Where do I determine the connection details?

The connection details are obtained in the "Connection details" group. This group is located in the "Diagnostics > Connection information" area of the Inspector window.

When is the "Connection details" group filled in?

The following requirements must be met to fill in the "Connection details" group on the "Connection information" tab:

- An online connection to the end point of the relevant connection must exist.
- You have selected a line in the connection table.

Structure of the "Connection details" group

The "Connection details" group consists of the following elements:

- Local ID (hex)
- Connection type (for S7-1200 and S7-1500)
- Protocol
- Connection status: icon and description
- Details
- Last status change (for S7-300 and S7-400 only)

Determining the address details of a connection

Where do I determine the address details of a connection?

The address details of a connection are obtained in the "Connection address details" group. This group is located in the "Diagnostics > Connection information" area of the Inspector window.

For which CPUs is the "Connection address details" group available?

The "Connection address details" group of the "Connection information" tab is available for S7-1200 and S7-1500 CPUs.

When is the "Connection address details" group filled in?

The following requirements must be met to fill in the "Connection address details" group on the "Connection information" tab:

- An online connection to the end points of the relevant connection must exist.
- You have selected a line in the connection table.

Structure of the "Connection address details" group

The address details relevant to the connection type are specified for the two communication partners.

Programming the PLC 11

11.1 Creating the user program

11.1.1 Programming basics

11.1.1.1 Operating system and user program

Operating system

Function

The operating system is contained in every CPU and organizes all CPU functions and sequences that are not associated with a specific control task.

The tasks of the operating system, for example, include the following:

- Processing a warm restart
- Updating the process image of the inputs and outputs
- Calling the user program
- Detecting interrupts and calling interrupt OBs
- Detecting and handling errors
- Managing memory areas

The operating system is a component of the CPU and is already installed there upon delivery.

See also

User program (Page 1411)

User program

Function

The user program contains all functions that are necessary for processing your specific automation task.

The tasks of the user program include:

- Checking the requirements for a (warm) restart using startup OBs, for example, limit switch in correct position or safety relay active.
- Processing process data, e.g. linking binary signals, reading in and evaluating analog values, defining binary signals for output, and outputting analog values
- Reaction to interrupts, for example, diagnostic error interrupt if the limit value of an analog expansion module is overshot.
- Error handling in normal program execution

You write the user program and load it into the CPU.

See also

Operating system (Page 1411)

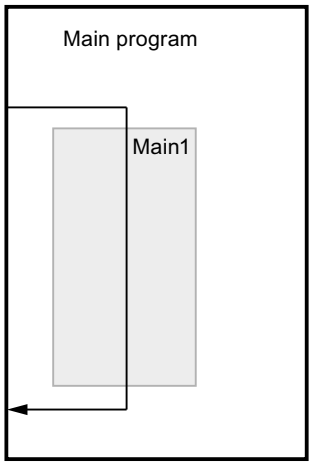
11.1.1.2 Blocks in the user program

Linear and structured programming

Linear programming

Solutions for small automation tasks can be programmed linearly in a program cycle OB. This is only recommended for simple programs.

The following figure shows a linear program schematically: The "Main1" program cycle OB contains the complete user program.



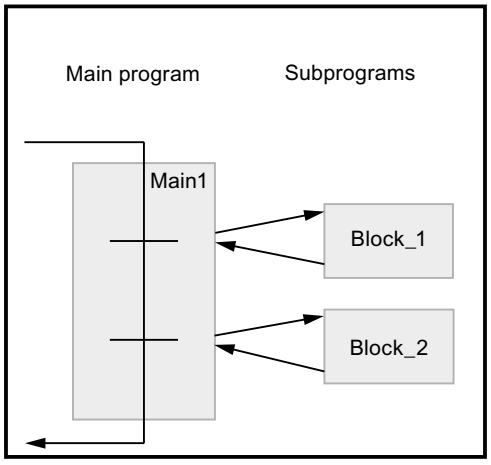
Structured programming

Complex automation tasks can be more easily handled and managed by dividing them into smaller sub-tasks that correspond to the technological functions of the process or that can be reused. These sub-tasks are represented in the user program by blocks. Each block is then an independent section of the user program.

Structuring the program offers the following advantages:

- Extensive programs are easier to program through the structure.
- Individual program sections can be standardized and used repeatedly with changing parameters.
- Program organization is simplified.
- Changes to the program can be made more easily.
- Debugging is simplified since separate sections can be tested.
- Commissioning is simplified.

The following figure shows a structured program schematically: The "Main1" program cycle OB calls subprograms one after the other that execute defined subtasks.



Overview of the block types

Block types

Different BLOCK types are available to perform tasks within an automation system. The following table shows the available block types:

Block type	Brief description
Organization blocks (Page 1414) (OB)	Organization blocks define the structure of the user program.
Functions (Page 1414) (FC)	Functions contain program routines for recurring tasks. They have no "memory".
Function blocks (Page 1415) (FB)	Function blocks are code blocks that store their values permanently in instance data blocks, so that they remain available even after the block has been executed.

Block type	Brief description
Instance data blocks (Page 1417)	Instance data blocks are assigned to a function block when it is is called for the purpose of storing program data.
Global data blocks (Page 1416)	Global data blocks are data areas for storing data that can be used by any blocks.

Organization blocks (OB)

Definition

Organization blocks (OBs) form the interface between the operating system and the user program. They are called by the operating system and control, for example, the following operations:

- Startup characteristics of the automation system
- Cyclic program processing
- Interrupt-driven program execution
- Error handling

You can program the organization blocks and at the same time determine the behavior of the CPU. Various organization blocks are available to you depending on the CPU used.

For more information on organization blocks, refer to the descriptions of the modes of operation of CPUs in the "Additional information on configurations" chapter in "Configuring Hardware and Networks".

Start information of organization blocks

When certain organization blocks are started, the operating system provides information that can be evaluated in the user program. Refer to the descriptions of the organization blocks to find out which information is provided, if any.

See also

Creating organization blocks (Page 1506)

Functions (FCs)

Definition

Functions (FCs) are code blocks without memory. You have no data memory in which values of block parameters can be stored. Therefore, when a function is called, all formal parameters must be assigned actual parameters.
Functions can use global data blocks to store data permanently.

Application

A function contains a program that is executed when the function is called by another code block. Functions can be used, for example, for the following purposes:

- To return function values to the calling block, e.g. for mathematical functions
- To execute technological functions, e.g. individual controls using bit logic operations

A function can also be called several times at different points in a program. As a result, they simplify programming of frequently recurring functions.

Note

Parameter transfer when calling functions

To avoid errors when working with functions, observe the information in chapter "Auto-Hotspot".

See also

Creating functions and function blocks (Page 1507)

Function blocks (FB)

Definition

Function blocks are code blocks that store their input, output and in-out parameters permanently in instance data blocks, so that they remain available even after the block has been executed. Therefore they are also referred to as blocks "with memory".

Function blocks can also operate with temporary tags. Temporary tags are will not be stored in the instance DB, but are available for one cycle only.

Application

Function blocks contain subroutines that are always executed when a function block is called by another code block. A function block can also be called several times at different points in a program. As a result, they simplify programming of frequently recurring functions.

Instances of function blocks

A call of a function block is referred to as an instance. An instance data block is required for each instance of a function block; it contains instance-specific values for the formal parameters declared in the function block.

The function block can store its instance-specific data in its own instance data block or in the instance data block of the calling block.

Access modes

S7-1200 and S7-1500 offer two different access options for the instance data blocks, which can be assigned to a function block when this is called:

- Data blocks with optimized access
  Data blocks with optimized access have no firmly defined memory structure. The data elements contain only a symbolic name in the declaration, no fixed address within the block.
- Data blocks with standard access (compatible with S7-300/400)
  Data blocks with standard access have a fixed memory structure. The declaration elements contain both a symbolic name in the declaration and a fixed address within the block.

Note

To avoid errors when working with function blocks, refer to the section "Auto-Hotspot".

Basics of block access (Page 1419)

Global data blocks (DB)

Definition

Data blocks are used to store program data. Data blocks thus contain variable data that is used by the user program. Global data blocks store data that can be used by all other blocks.

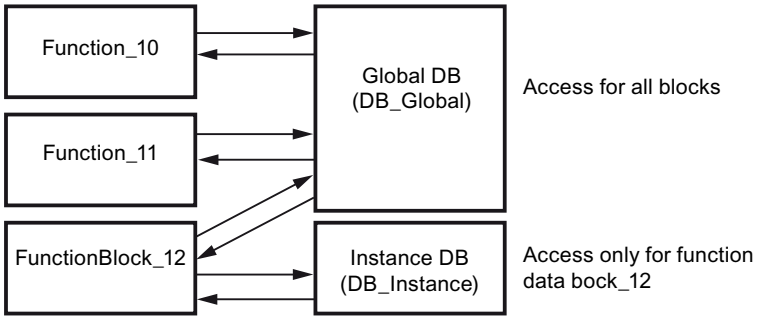
The maximum size of data blocks varies depending on the CPU. You can define the structure of global data blocks anyway you please.

You also have the option of using PLC data types (UDT) as a template for creating global data blocks.

Global data blocks in the user program

Every function block, function, or organization block can read the data from a global data block or can itself write data to a global data block. This data remains in the data block even after the data block is exited. A global data block and an instance data block can be open at the same time.

The following figure shows the different accesses to data blocks:



Access modes

S7-1200 and S7-1500 offer two different access options for global data blocks:

- Data blocks with optimized access
  Data blocks with optimized access have no fixed defined structure. In the declaration, the data elements are assigned only a symbolic name and no fixed address within the block.
- Data blocks with standard access (compatible with S7-300/400)
  Data blocks with standard access have a fixed structure. In the declaration, the data elements are assigned both a symbolic name and a fixed address within the block.

ARRAY data blocks (S7-1500)

ARRAY data blocks are a particular type of global data block. These consist of an ARRAY of any data type. For example, an ARRAY of a PLC data type (UDT) is possible. The DB contains no other elements besides the ARRAY. Because of their flat structure, ARRAY data blocks facilitate access to the ARRAY elements and their transfer to called blocks.

The "Optimized block access" attribute is always enabled for ARRAY data blocks. ARRAY data blocks with standard access are not possible.

The "Move operations" section of the "Instructions" task card offers options for addressing of ARRAY DBs.

Creating data blocks (Page 1508)

Basics of block access (Page 1419)

Instance data blocks

Definition

The call of a function block is referred to as an instance. The data with which the instance works is stored in an instance data block.

The maximum size of instance data blocks varies depending on the CPU. The tags declared in the function block determine the structure of the instance data block.

Access modes

S7-1200 and S7-1500 offer two different access options for the instance data blocks, which can be assigned to a function block when this is called:

- Data blocks with optimized access
  Data blocks with optimized access have no firmly defined structure. The declaration elements contain only one symbolic name in the declaration, and no fixed address within the block.
- Data blocks with standard access (compatible with S7-300/400)
  Data blocks with standard access have a fixed structure. The declaration elements contain both a symbolic name in the declaration and a fixed address within the block.

Creating data blocks (Page 1508)

Basics of block access (Page 1419)

CPU data blocks

Definition

CPU data blocks are generated by the CPU at runtime. To this purpose, insert the "CREATE_DB" instruction into your user program. You can use the data block that is generated at runtime to save your data.

CPU data blocks are indicated by means of a small CPU icon in the "Program blocks" folder of an available node. You can monitor the values of the variables of a CPU data block in online mode, similar to those of a different data block type.

You cannot create CPU data blocks in your offline project.

Loading CPU data blocks

The CPU data block that the user program has generated by means of the "CREATE_DB" instruction is initially only available on the device in online mode. All CPU data blocks will be included with the other blocks the next time you perform a complete download from the device to the project. The CPU data blocks are marked with a small CPU icon in the process. However, you cannot upload these CPU data blocks to your device again.

Restrictions on CPU data blocks in the project

Once the CPU data blocks have been loaded into your offline project, you can open and view their content. However, note that the CPU data blocks in the project are write-protected. The CPU data blocks in the project are therefore subject to the following restrictions:

- You cannot edit CPU data blocks, or convert these into a different data block type.
- CPU data blocks cannot be assigned a know-how protection.
- You cannot change the programming language of a CPU data block.
- CPU data blocks cannot be compiled or downloaded to a device.

Comparing CPU data blocks

Once the CPU data blocks have been loaded into your offline project, you can run an online/offline comparison for the CPU DBs loaded. The comparison editor provides you with a corresponding overview of the differences. It is possible to synchronize the online and off-line version of CPU data blocks if differences are found, but not by downloading the offline version to the device.

Deleting CPU data blocks

You can delete CPU data blocks both from the project and from the CPU.

Deleting CPU data blocks (Page 1528)

Blocks with optimized access

Basics of block access

Introduction

STEP 7 offers data blocks with different access options:

- Data blocks with optimized access (S7-1200/S7-1500)
- Data blocks with standard access (S7-300 / S7-400 / S7-1200 / S7-1500)

Within one program you can combine the two types of blocks.

Data blocks with optimized access

Data blocks with optimized access have no fixed defined structure. In the declaration, the data elements are assigned only a symbolic name and no fixed address within the block. The elements are saved automatically in the available memory area of the block so that there are no gaps in the memory. This makes for optimal use of the memory capacity.

Tags are identified by their symbolic names in these data blocks. To address the tag, enter its symbolic name. For example, you access the "Fill Level" tag in the "Data" DB as follows:
`"Data".Fill Level`

Blocks with optimized access offers the following advantages:

- You can create data blocks with any structure without paying attention to the physical arrangement of the individual data elements.
- Quick access to the optimized data is always available because the data storage is optimized and managed by the system.
- Access errors, as with indirect addressing or from the HMI, for example, are not possible.
- You can define specific individual tags as retentive.
- Optimized blocks are equipped with a memory reserve by default which lets you expand the interfaces of function blocks or data blocks during operation. You can download the modified blocks without setting the CPU to STOP and without affecting the values of already loaded tags.

Note

The "Optimized block access" attribute is always enabled for the following blocks and cannot be deselected.

- GRAPH blocks
- ARRAY data blocks

Data blocks with standard access

Data blocks with standard access have a fixed structure. In the declaration, the data elements are assigned both a symbolic name and a fixed address within the block. The address is shown in the "Offset" column.

Tags in these data blocks can be addressed in both symbolic and absolute form.
`"Data".Fill Level`
`DB1.DBW2`

Setting Retentivity for Optimized Access or Standard Access

If you define data as retentive, its values are retained even after a power failure or a network off. A retentive tag is not initialized after the hot restart but retains the value it had prior to the power failure. If a DB tag is defined as retentive, it is stored in the retentive memory area of the data block.

The options for setting the retentivity depend on the access type of the block.

- In data blocks with standard access, you cannot set the retentive behavior of individual tags. The retentivity setting is valid for all tags of the data block.
- In data blocks with optimized access you can define the retentive behavior of individual tags.
  For structured data type tags, the retentivity setting always applies to the entire structure. You cannot make any individual retentivity setting for separate elements within the data type.

Setting Addressing Options for Optimized Access or Standard Access

Blocks with optimized access permit only "type-safe" access. Type-safe access addresses tags by their symbolic name only. This means even changes to the block or the block interface will not result in inconsistencies in the program or access errors.

The following table shows the permitted addressing options for optimized data:

Addressing	Block with standard access	Block with optimized access
Symbolic addressing	x	x
Indexed addressing of ARRAYs		x
Slice access	x	x
Overlapping with AT	x	-
Absolute addressing	x	-
Indirect addressing via ANY	x	-
Indirect addressing via POINTER and VARIANT	x	with symbolic notation only

Setting up block access (Page 1421)

Setting up block access

Introduction

Block access is set up automatically when you create a block:

- Blocks created on CPUs of the S7-1200/1500 product range provide optimized access by means of a default setting.
- New blocks created on CPUs of the S7-300/S7-400 product range provide standard access by means of a default setting.

Access to a block that you copy or migrate to a CPU of a different product range is not converted automatically. However, in certain situations it may be useful to change block access in manual mode, e.g., in order to utilize the full functional scope of the CPU.

In most cases, you will have to recompile and load the program after block access has been converted.

Notice

Optimized block access for GRAPH blocks

The "Optimized block access" attribute is always enabled for GRAPH blocks in S7-1500 and cannot be deselected.

Procedure

To set the block access, proceed as follows:

1. Open the "Program blocks" folder in the project tree.
2. Right-click on the block whose block access you want to change.
3. Select the "Properties" command in the shortcut menu.
   The properties dialog box of the block opens.
4. Click "Attributes" in the area navigation.
5. Enable or disable the "Optimized block access" option.
6. Confirm your entries with "OK".

Restrictions and special features

As a matter of principle, you can only convert block access on CPUs of the S7-1200/1500 product range, as only these support the "optimized" access mode.

The following restrictions or special features apply in this context:

- Instance data blocks
  The block access of instance data blocks is always determined by the assigned function block and cannot be changed in manual mode. If you change the access mode on a function block, you also need to update the assigned instance data blocks. This update procedure adapts the access mode of the instance data block.
- System blocks and know-how protected blocks
  You cannot manually edit the block access for system blocks and know-how protected blocks.
- Organization blocks
  The start information of an OB with standard access is always stored in the first 20 bytes of the "Temp" section in the block interface. By contrast, the start information of an OB with optimized access is always written to the "Input" section. For this reason, the block interface of OBs will also change whenever you convert block access. Additional information is provided in the following sections.

Converting block access from "standard" to "optimized".

A block copied from the CPU of the S7-300/400 product range to a CPU of the S7-1200/1500 product range will initially retain the "standard" access mode. However, you can significantly increase the performance of program execution by using blocks with optimized access, which is why it may be useful to modify the access mode manually.

The blocks are adapted as follows in the course of conversion:

- Function blocks
  All interface parameters are assigned the "Non-retain" retentivity setting.
- Global data blocks
  The retentivity setting that was assigned centrally to the entire data block is transferred to the individual interface parameters. It is now possible to manipulate the retentivity setting of the various parameters.
  However, the following rule will still apply: For structured data type tags, the retentivity setting always applies to the entire structure. You cannot assign separate retentivity settings to the various elements within a structured data type. It therefore follows that you cannot assign individual retentivity settings to the tags of data blocks that are based on PLC data types.
- Organization blocks
  All interface parameters that are stored in the first 20 bytes of the "Temp" section will be deleted. New CPU-specific start information is entered in the "Input" section. Naming conflicts with user-defined interface parameters occurring in the process are resolved by renaming the user-defined interface parameters.

Caution

The conversion of the block access has the following consequences:

- Absolute addressing of the interface parameters of the block is no longer possible after conversion of block access to the "optimized mode.
  Example: `#L0.1` is no longer valid.
- Since conversion to the "optimized" block access mode of organization blocks also modifies the OB interface,

you may possibly have to adapt, recompile and load the program again due to these changes.

See also: Auto-Hotspot

Converting block access from "optimized" to "standard".

If you want to copy or move a block from the CPU of the S7-300/400 product range to a CPU of the S7-1200/1500 product range, you first need to set the "standard" access mode.

The blocks are adapted as follows in the course of conversion:

- Function blocks and global data blocks.
  You can no longer set a retentivity in the function block. The corresponding setting is made in the instance data block.
  All interface parameters in the instance DB or global DB are assigned the same retentivity setting. The conversion is subject to the following rule:
  - If all interface parameters in the original block were retentive, the entire block will be retentive after conversion.
  - If all interface parameters in the original block were non-retentive, the entire block will be non-retentive after conversion.
  - If the interface parameters in the original block had different retentivity settings, the entire block will be non-retentive after conversion.
- Organization blocks
  All interface parameters stored in the "Input" section will be deleted. New CPU-specific start information is entered in the "Temp" section. This data is written to the first 20 bytes. Naming conflicts with user-defined interface parameters occurring in the process are resolved by renaming the user-defined interface parameters.

Caution

The conversion of the block access has the following consequences:

Since a conversion to "standard" block access mode might change the retentivity settings of the interface parameters, you may possibly have to adapt, recompile and load the program again due to these changes.

11.1.1.3 Block calls

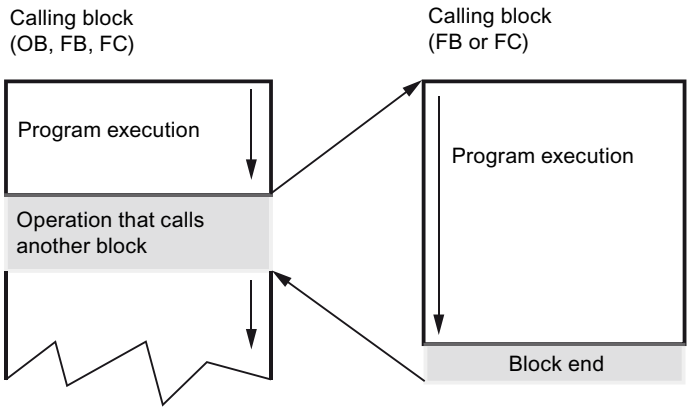
Principles of block calls

Function of block calls

For your blocks to be executed in the user program, they need to be called from another block.

When one block calls another block, the instructions of the called block are executed. Only when execution of the called block has been completed does execution of the calling block resume. The execution is continued with the instruction that follows on the block call.

The following figure shows the sequence of a block call within a user program:



Parameter transfer

When a block is called, you must assign values to the parameters in the block interface. By providing input parameters you specify the data with which the block is executed. By providing the output parameters you specify where the execution results are saved.

See also

Call hierarchy (Page 1425)

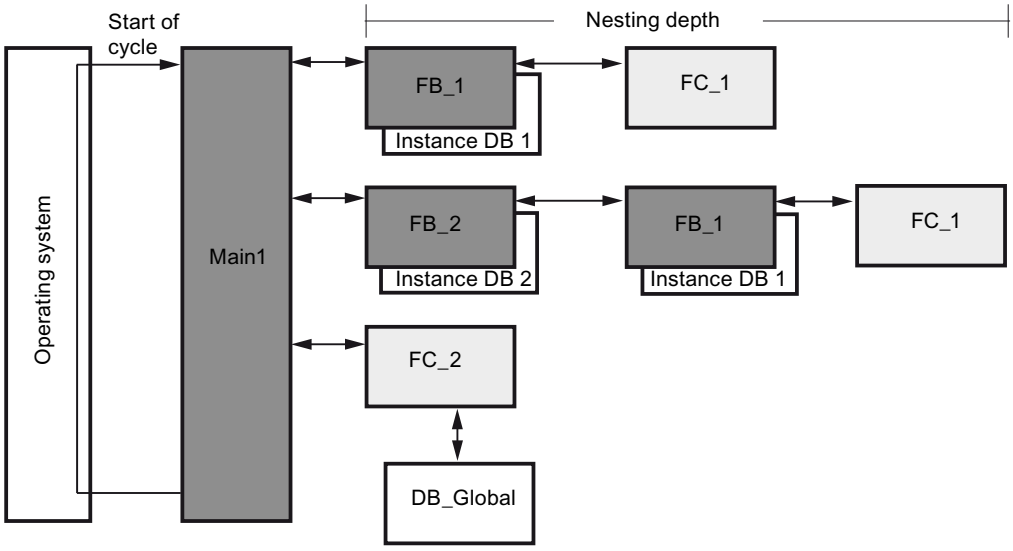
Principles for single instances and multi-instances (Page 1426)

Call hierarchy

Definition

The order and nesting of block calls is referred to as the call hierarchy. The permissible nesting depth depends on the CPU.

The following figure shows an example of the order and nesting of block calls within an execution cycle:



See also

Principles for single instances and multi-instances (Page 1426)

Principles of block calls (Page 1424)

Call function blocks as single or multi-instances

Principles for single instances and multi-instances

Use of single instances and multiple instances

Function blocks (FBs) store their data in instance data blocks. Instance data blocks store the values of the block parameters and the static local data of the function blocks.

You can assign instance data blocks as follows:

- Single instance:
  One instance data block for each instance of a function block
- Multiple instance:
  An instance data block for the instance of a function block and all instances of function blocks called in it.

See also

Principles of block calls (Page 1424)

Multi-instances (Page 1427)

Single instances (Page 1427)

Call hierarchy (Page 1425)

Single instances

Definition

The call of a function block, which is assigned its own instance data block, is called a single instance data block.

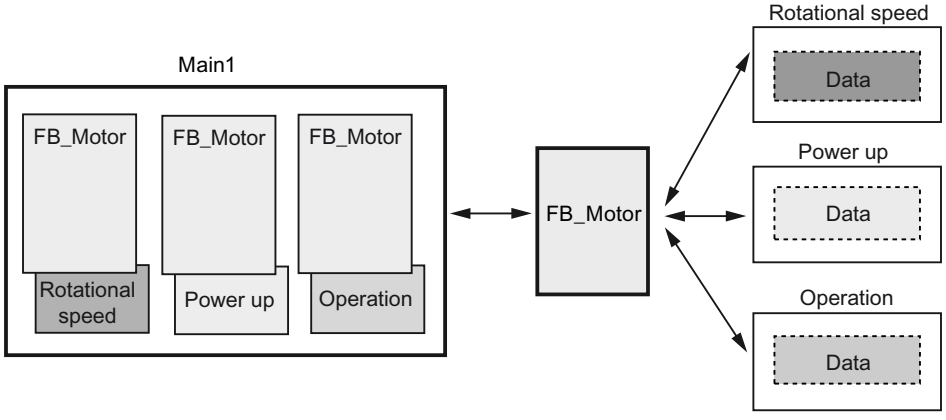
By assignment of the instance data block, you specify where the instance data of the FB is to be stored. By assigning a different instance data block to each call, you can use the same FBs several times with different instance data in each case.

Example of a single instance

You can control several motors using one function block. For this purpose, you assign a different instance data block for each function block call for motor control.

The different data for the various motors, such as speed, ramp-up time, total operating time, are saved in the different instance data blocks. A different motor will be controlled, depending on the instance data block assigned.

The following figure shows the control of three motors using one function block and three different data blocks:



See also

Principles for single instances and multi-instances (Page 1426)

Multi-instances (Page 1427)

Multi-instances

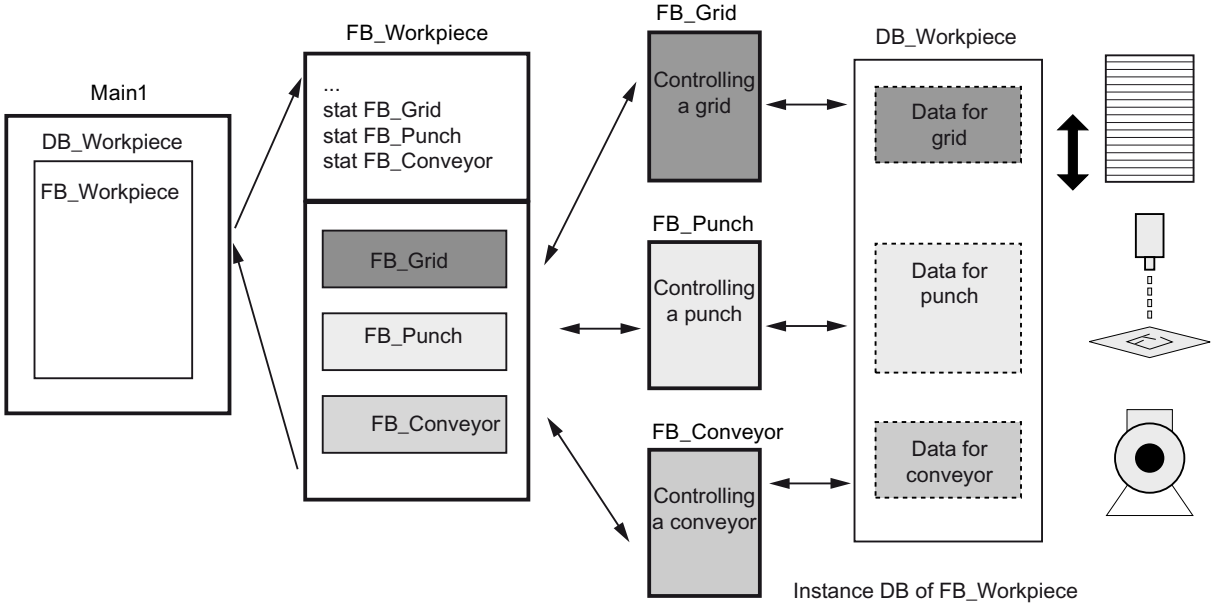
Definition

Multi-instances enable a called function block to store its data in the instance data block of the calling function block.

This allows you to concentrate the instance data in one instance data block and thus make better use of the number of instance data blocks available.

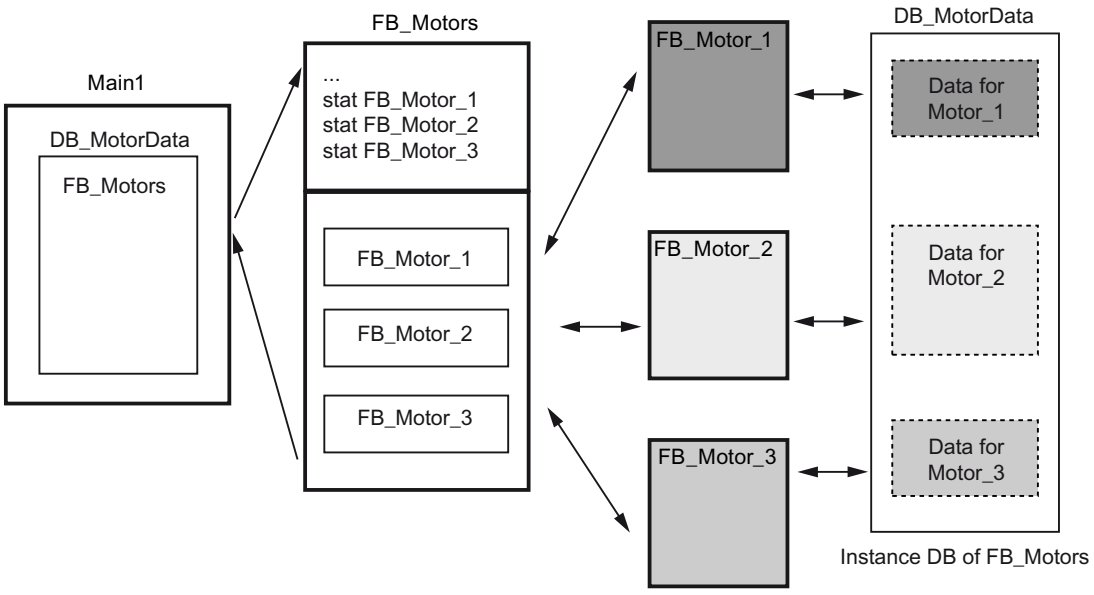
One instance data block for the instances of different function blocks

The following figure shows how multiple different function blocks store their data in a calling block. The FB_Workpiece calls the following on after the other: FB_Grid, FB_Punch and FB_Conveyor. The called blocks store their data in the DB_Workpiece, the instance data block of the calling block.



One instance data block for multi-instances of a function block

The following figure shows how a function block that is called in multi-instances stores the data for all the instances in one instance data block.



The function block FB_Motors calls three instances of the FB_Motor. The instances are "Motor_1", "Motor_2" and "Motor_3". Each call uses different instance data. However, all instance data are located in a single instance data block, DB_MotorData.

Principles for single instances and multi-instances (Page 1426)

Single instances (Page 1427)

Parameter transfer at block call

Basics of block parameters

Introduction

The calling block gives the called block the values with which it is to work. These values are referred to as block parameters. The input parameters provide the called block with the values that it has to process. The block returns the results via the output parameters.

Block parameters are therefore the interface between the calling and the call block.

You use input parameters when you want to only query or read values, and output parameters when you want to set or write these values. If block parameters are read and written you have to create these as in-out parameters.

Formal and actual parameters

The block parameters are defined in the interface of the called block. These parameters are referred to as formal parameters. They are placeholders for the parameters that are transferred to the block when it is called. The parameters transferred to the block when it is called are referred to as actual parameters.

Rules for using the block parameters

The following rules apply to the use of block parameters within the block:

- Input parameters may only be read.
- Output parameters may only be written.
- In/out parameters may be read and written.

Keywords (Page 1442)

Supplying block parameters during call

General rules for assigning parameters

Introduction

When you call a block with block parameters, assign actual parameters to its formal parameters. The rules described below apply here.

Compatible data types

The data types of actual and formal parameters must be identical or convertible according to the rules of data type conversion.

Transferring ARRAYs

You can transfer ARRAYs as parameters. If a block has an input parameter of ARRAY type, you must transfer as actual parameter an ARRAY with identical structure. This means the data type, the number of dimensions and the number of field components must be identical. You can also transfer individual elements of an ARRAY as actual parameter if the element corresponds to the data type of the formal parameter.

Transferring PLC data types

You can also transfer tags that are declared as PLC data type as actual parameters. If the formal parameter is declared as PLC data type in the tag declaration, you must transfer a tag that has the same PLC data type as actual parameter.

An element of a tag declared by means of PLC data type can also be transferred as actual parameter at block call, provided that the data type of the element of the tag matches the data type of the formal parameter.

Transferring structures (STRUCT)

You can transfer structures as parameters. If a block has an input parameter of the STRUCT type, you must transfer as actual parameter a STRUCT with identical structure. This means that the names and data types of all structure components have to be identical.

You can also transfer individual elements of an STRUCT as actual parameter if the element corresponds to the data type of the formal parameter.

Note

We recommend programming structures as PLC data types. PLC data types make programming easier, since they can be used multiple times and modified centrally.

See also

Parameter assignment to function blocks (Page 1433)

Parameter assignment to functions (Page 1431)

Basics of block parameters (Page 1429)

PLC data types (Page 1954)

Parameter assignment to functions

Parameters of functions (FC)

Functions have no data memory in which values of block parameters can be stored. Therefore, when a function is called, all formal parameters must be assigned actual parameters.

Input parameters (Input)

Input parameters are read only once per cycle, namely before the block call. Therefore, the rule is that writing an input parameter within the block does not affect the actual parameter. Only the formal parameter is written.

Output parameters (Output)

Output parameters are read only once per cycle, namely after the block call. Therefore, the rule is that output parameters should not be read within the block. If you nevertheless read an output parameter, please note that only the value of the formal parameter is read. The value of the actual parameter cannot be read within the block.

If an output parameter of a function is not written in this function, the value that is predefined for the specified data type is used. For example, the value "false" is predefined for BOOL. However, structured output parameters are not pre-assigned with a value.

To prevent unintentional further processing of the predefined value or an undefined value, note the following when programming the block:

- Make sure that the output parameters are written with values for all possible program paths within the block. In doing so, note that jump commands may skip instruction sequences in which outputs are set, for example.
- Note that the set and reset commands are dependent on the result of the logic operation. If the value of an output parameter is determined with these commands and RLO = 0, a value will not be generated.
- If possible, assign a default value for the output parameters of functions.

In/out parameters (InOut)

In/out parameters are read before the block call and written after the block call. If you read or write the parameter within the block, you only access its formal parameter.

An exception is in/out parameters with a structured data type. Structured data types consist of several data elements, for example ARRAY or STRUCT. These are passed to the called block through a POINTER. You therefore always access the actual parameter when you read or write a structured in/out parameter within a block.

When an in/out parameter of a function is not written to this function, the old output value or the input value is used as a value. Nevertheless, you should observe the information provided above for output parameters so that old values are not inadvertently processed further.

Temporary local data (Temp)

Temporary local data is only available within a cycle. It is treated differently depending on the block type:

- Standard access
  The following rule applies to code blocks with standard access as well as to all tags with retentivity setting "Set in IDB":
  If you are using temporary local data, you must ensure that the values are initialized prior to use. Otherwise, the values will be random. Temporary data of the STRING of WSTRING data type is an exception: They are automatically pre-assigned the maximum length of 254 characters and the actual length 0.
- Optimized access
  The following rule applies to code blocks with optimized access:
  If a temporary tag is not written within a function, the value that is predefined for the specified data type is used. For example, the value "false" is predefined for BOOL. Elements of the PLC data types are pre-assigned with the default value that is specified in the declaration of the PLC data type (UDT). ARRAY elements are pre-assigned with the value "0", even if they are used within a PLC data type. STRINGs and WSTRINGs are automatically pre-assigned the maximum length of 254 characters and the actual length 0.

Function value (Return)

Functions normally calculate a function value. This function value can be returned to the calling block via the RET_VAL output parameter. For this, the RET_VAL output parameter must be declared in the interface of the function. RET_VAL is always the first output parameter of a function. All data types are permitted for the RET_VAL parameter except ARRAY and STRUCT, as well as parameter types TIMER and COUNTER.

In the SCL programming language functions can be call directly in an expression. The result of the expression is then formed with the calculated function value. Therefore, the data type ANY is not permitted in SCL for the function value.

Parameter assignment to function blocks (Page 1433)

Basics of block parameters (Page 1429)

General rules for assigning parameters (Page 1430)

Calling functions (Page 1685)

Examples for calling functions in SCL (Page 1688)

Parameter assignment to function blocks

Supplying parameters of function blocks (FB)

In the case of function blocks the parameter values will be stored in the instance data.

If the input, output, or in-out parameters of a function block were not assigned with values, the stored values are used.

In some cases, it is mandatory to specify an actual parameter.

The following table shows which parameters of a function block must be assigned actual parameters:

Parameter	Elementary data type	Structured data type	Parameter type
Input (Input)	optional	optional	required
Output (Output)	optional	optional	required
In-out (InOut)	optional	required	Permitted with S7-1200 only, parameter assignment required
Temporary (Temp)	required S7-1500: Optional with optimized block access	required S7-1500: Optional with optimized block access	required

Basics of block parameters (Page 1429)

General rules for assigning parameters (Page 1430)

Parameter assignment to functions (Page 1431)

Parameter types (Page 1953)

Transfer parameter as copy or as pointer

Introduction

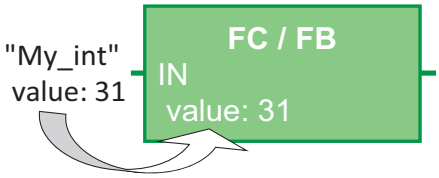
When a block is called, you transfer data to the parameters in the block interface. At the input parameters, you transfer the data with which the block is to work. At the output parameters, you specify where the results of the processing are saved. In/out parameters are used to transfer data to the called block as well as to return results.

Internally, STEP 7 recognizes two different methods of parameter transfer: The data is transferred either as pointer or as copy, depending on the transfer range and data type of the parameter.

Transfer as copy (Call by value)

During a block call, the value of the operand is copied to the input parameter of the called block. With function blocks, the copy is stored in the instance DB; with functions, it is stored in the block stack. Additional storage space is required for the copy.

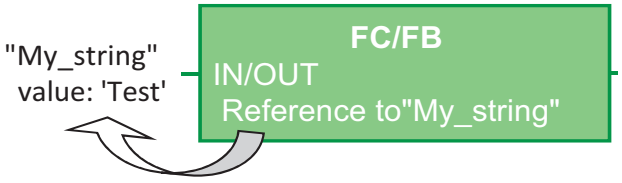
This means that the called block always works with the value that the specified operand had at the time of the block call. It cannot access the operand directly. Write access modifies only the copy, but not the actual value of the specified operand. Read access reads only the copy that was created at the time of the block call.



Transfer as pointer (Call by reference)

The parameters are referenced via a pointer during the block call.

This means that the called block can directly access the memory address of the operand that is specified as parameter: Write access directly results in the changing of the specified operand. Read access reads the value of the operand directly at the time of access. As no copy is created, no additional memory is required.



Note

Declare structured data types in the "InOut" area

If possible, use the "InOut" area in the block interface for structured tags (e.g., of data type ARRAY, STRUCT, STRING, …). As structured in/out parameters are always transferred as pointer, the required data memory is not increased more than necessary.

Parameter transfer with S7-1200/1500

The following table shows how block parameters with elementary or structured data type are transferred in S7-1200/1500. Elementary data types are, for example, BOOL, INT or BYTE. Structured data types are, for example, ARRAY, STRUCT or STRING.

		Elementary data types	Structured data types
FC	Input	Copy	Pointer
	Output	Copy	Pointer
	InOut	Copy	Pointer
FB	Input	Copy	Copy
	Output	Copy	Copy
	InOut	Copy	Pointer

Note

Parameter transfer between blocks with optimized access and blocks with standard access

When optimized data is transferred to a block with the property "Standard access", it is always transferred as copy. If the block contains numerous structured parameters, this can quickly lead to the temporary memory area (local data stack) overflowing.

You can avoid this by setting the same access type for both blocks.

See also: Auto-Hotspot

Parameter transfer with S7-300/400

The following table shows how block parameters with elementary or structured data type are transferred in S7-300/400.

		Elementary data types	Structured data types
FC	Input	Copy*	Pointer
	Output	Copy*	Pointer
	InOut	Copy*	Pointer
FB	Input	Copy	Copy
	Output	Copy	Copy
	InOut	Copy	Pointer

* Exception: Operands from the memory areas I, Q, M, P, L and partly qualified DB addresses (for example, "DW 2") are transferred as pointer.

Note

Special aspects of transfer as pointer in S7-300/400

In cases in which the parameters are transferred via a pointer, it is not possible to forward output parameters or in/out parameters from the calling block to the input parameters of the called block.

Forwarding of block parameters

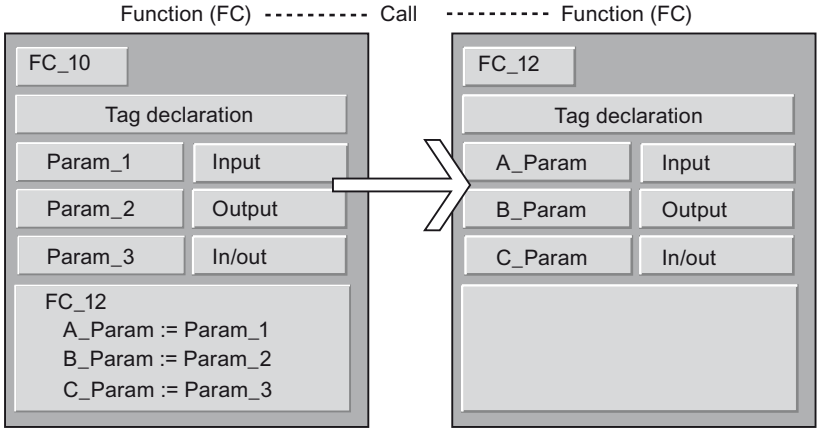
Basic information on forwarding block parameters

Introduction

Definition

The "Forwarding" of block parameters is a special type of parameter use. In this case the block parameters of the calling block are forwarded to the parameters of the called block. The called block uses the values that are currently present at the block parameters of the calling block as the actual parameters.

The following figure shows how the parameters of the function FC_10 are forwarded to the function FC_12:



Rules for LAD/FBD

The following general rules apply in LAD and FBD:

- Input parameters can only be forwarded to input parameters.
- Output parameters can only be forwarded to output parameters.
- In/out parameters can be forwarded to all parameter types.
- In S7-300/400, the two block parameters must have the same data type.
- In S7-1200/1500, the parameters can also be converted according to the rules of implicit conversion.

Rules for STL

The following general rules apply in STL:

- Input parameters can only be forwarded to input parameters.
- Output parameters can only be forwarded to output parameters.

- In/out parameters can be forwarded to all parameter types.
- Both block parameters must have the same data type. In STL, this rule applies to all CPU families.

Rules for SCL

The rules for SCL are less stringent. So that programs from previous SCL versions can be taken over more easily, additional parameter transfer options are permissible, but subject to warning. You can, for example, forward an in/out parameter to an input parameter, but a warning is output as the transferred in/out parameter cannot be written by the program.

Additional rules are described in detail in the following chapters.

11.1.1.4 Using and addressing operands

Basic information about operands

Introduction

When you program instructions you must specify which data values the instruction should process. These values are referred to as operands. You can, for example, use the following elements as operands:

- PLC tags
- Constants
- Tags in instance data blocks
- Tags in global data blocks

Absolute address and symbolic name

Operands are identified by means of an absolute address and a symbolic name. You define the names and addresses in the PLC tag table or in the tag declaration of the blocks.

Data blocks with optimized access (S7-1200, S7-1500)

Data elements in data blocks with optimized access only receive a symbolic name and no absolute address in the declaration. For more information on this, refer to "See also".

See also

Basics of block access (Page 1419)

Keywords

SIMATIC recognizes a range of key words whose definitions are fixed and which have a certain meaning in the program. You should not use these keywords as names for tags or constants.

Table of keywords

The following table shows all keywords.

Keywords German mnemonics	Keywords English mnemonics	Description
&	&	And logical operation of logical expressions
A	Q	Output, bit
A1	CC1	Condition code bit
A0	CC0	Condition code bit
AB	QB	Output, byte
AD	QD	Output, double word
AND	AND	And logical operation of logical expressions
ANY	ANY	Data type, pointer
AR1	AR1	Address Register 1
AR2	AR2	Address Register 2
ARRAY	ARRAY	Introduces the specification of an array and is followed by the index list between "[" and "]"
AT	AT	Overlaying tag declaration
AUTHOR	AUTHOR	Name of the author, company name, department name, or other name (max. 8 characters, no spaces)
AW	QW	Output, word
B	B	Byte
BEGIN	BEGIN	Introduces the instruction part for code blocks or initialization part for a data block
BIE	BR	Binary result

Keywords German mnemonics	Keywords English mnemonics	Description
BLOCK_FB	BLOCK_FB	Parameter type for specification of an FB
BLOCK_FC	BLOCK_FC	Parameter type for specification of an FC
BLOCK_SDB	BLOCK_SDB	Parameter type for specification of an SDB
BOOL	BOOL	Data type
BY	BY	Increment of the FOR loop
BYTE	BYTE	Data type
CALL	CALL	Call
CASE	CASE	Introduction to the CASE statement
CHAR	CHAR	Elementary data type
CODE_VERSION1	CODE_VERSION1	Label, whether an FB is multiple instance capable or not. If you want to declare multiple instances, the FB must not have this characteristic.
CONST	CONST	Start of the constant declaration
CONTINUE	CONTINUE	Instruction to exit a loop in SCL
COUNTER	COUNTER	Parameter type for specification of a counter
DATA_BLOCK	DATA_BLOCK	Introduces the data block
DATE	DATE	Data type
DATE_AND_TIME	DATE_AND_TIME	Data type
DB	DB	Data block
DB_ANY	DB_ANY	Data type
DBB	DBB	Data block, data byte
DBD	DBD	Data block, data double word
DBLG	DBLG	Data block length
DBNO	DBNO	Data block number
DBW	DBW	Data block, data word
DBX	DBX	Data block, data bit
DI	DI	Instance data block
DIB	DIB	Instance data block, data byte
DID	DID	Instance data block, data double word
DILG	DILG	Instance data block length
DINO	DINO	Instance data block number
DINT	DINT	Data type
DIW	DIW	Instance data block, data word
DIX	DIX	Instance data block, data bit
DO	DO	Introduction of the instruction part in FOR and WHILE instruction

Keywords German mnemonics	Keywords English mnemonics	Description
DT	DT	Data type
DTL	DTL	Data type
DWORD	DWORD	Data type
E	I	Input (via process image), bit
EB	IB	Input (via process image), byte
ED	ID	Input (via process image), double word
ELSE	ELSE	Alternative branch in IF and CASE statement
ELSIF	ELSIF	Alternative condition of the IF instruction
EN	EN	System operand of the EN/ENO mechanism
ENO	ENO	System operand of the EN/ENO mechanism
END_CASE	END_CASE	End of the CASE statement
END_DATA_BLOCK	END_DATA_BLOCK	Ends the data block
END_FOR	END_FOR	End of the FOR statement
END_FUNCTION	END_FUNCTION	Ends the function
END_FUNCTION_BLOCK	END_FUNCTION_BLOCK	Ends the function block
END_IF	END_IF	End of the IF instruction
END_ORGANIZATION_BLOCK	END_ORGANIZATION_BLOCK	Ends the organization block
END_REPEAT	END_REPEAT	End of the REPEAT statement
END_STRUCT	END_STRUCT	Ends the specification of a structure
END_SYSTEM_FUNCTION	END_SYSTEM_FUNCTION	Ends the system function
END_SYSTEM_FUNCTION_BLOCK	END_SYSTEM_FUNCTION_BLOCK	Ends the system function block
END_TYPE	END_TYPE	Ends the PLC data type
END_VAR	END_VAR	Ends a declaration block
END_WHILE	END_WHILE	End of the WHILE instruction
EW	IW	Input (via process image), word
EXIT	EXIT	Instruction to exit a loop in SCL
FALSE	FALSE	Predefined Boolean constant: Logical condition false, value equal to 0
FAMILY	FAMILY	Block family name: e.g. controller
FB	FB	Function block
FC	FC	Function
FOR	FOR	Introduction of the FOR statement
FUNCTION	FUNCTION	Introduces the function
FUNCTION_BLOCK	FUNCTION_BLOCK	Introduces the function block

Keywords German mnemonics	Keywords English mnemonics	Description
GOTO	GOTO	Introduction of the GOTO statement
IF	IF	Introduction of the IF instruction
INSTANCE	INSTANCE	Data type
INT	INT	Data type
KNOW_HOW_PROTECT	KNOW_HOW_PROTECT	Block protection
L	L	Local data bit
LB	LB	Local data byte
LD	LD	Local data double word
LDT	LDT	Data type
LINT	LINT	Data type
LTIME	LTIME	Data type
LTOD	LTOD	Data type
LW	LW	Local data word
LWORD	LWORD	Data type
M	M	Memory bit
MB	MB	Memory byte
MD	MD	Memory double word
MOD	MOD	Modulo operator
MW	MW	Memory word
NAME	NAME	Block name
NETWORK	NETWORK	Network
NOT	NOT	Logic inversion
NULL	NULL	Zero pointer
OB	OB	Organization block
OF	OF	Introduction of the data type specification / Introduction of the instruction part of the CASE statement
OR	OR	Or logical operation of logical expressions
ORGANIZATION_BLOCK	ORGANIZATION_BLOCK	Introduces the organization block
OS	OS	Save overflow
OV	OV	Overflow
PA	PQ	Output (direct peripherals), bit
PAB	PQB	Output (direct peripherals), byte
PAD	PQD	Output (direct peripherals), double word
PAW	PQW	Output (direct peripherals), word
PE	PI	Input (direct peripherals), bit
PEB	PIB	Input (direct peripherals), byte
PED	PID	Input (direct peripherals), double word

Keywords German mnemonics	Keywords English mnemonics	Description
PEW	PIW	Input (direct peripherals), word
POINTER	POINTER	Data type
READ_ONLY	READ_ONLY	Write protection for data blocks
REAL	REAL	Data type
REPEAT	REPEAT	Introduction of the REPEAT statement
RET_VAL	RET_VAL	Return value
RETURN	RETURN	RETURN statement in SCL
S5T	S5T	Syntax for data type S5TIME
S5TIME	S5TIME	Data type
S7_	S7_	Keywords for system attributes
SDB	SDB	System data block
SFB	SFB	System function block
SFC	SFC	System function
SINT	SINT	Data type
STRING	STRING	Data type
STRUCT	STRUCT	Introduces the specification of a structure and is followed by a list of components
STW	STW	Status word
SYSTEM_FUNCTION	SYSTEM_FUNCTION	System function
SYSTEM_FUNCTION_BLOCK	SYSTEM_FUNCTION_BLOCK	System function block
T	T	Time element (timer)
THEN	THEN	Introduction of the instruction part of an IF instruction
THIS	THIS	Syntax for access to an ARRAY data block
TIME	TIME	Elementary data type for time information
TIME_OF_DAY	TIME_OF_DAY	Data type
TIMER	TIMER	Parameter type for specification of a timer
TITLE	TITLE	Optional block title or network title
TO	TO	Definition of the full-scale value of a FOR statement
TOD	TOD	Data type
TRUE	TRUE	Predefined Boolean constant: Logical condition true, value not equal to 0
TYPE	TYPE	Introduction of the PLC data type
UDT	UDT	Global or PLC data type
UDINT	UDINT	Data type
UINT	UINT	Data type

Keywords German mnemonics	Keywords English mnemonics	Description
ULINT	ULINT	Data type
UNLINKED	UNLINKED	Marking 'non runtime-related'
UNTIL	UNTIL	End of the instruction part of a REPEAT statement
USINT	USINT	Data type
UO	UO	Query after (Q1=1) AND (Q0=1)
VAR	VAR	Introduces a declaration block
VAR_IN_OUT	VAR_IN_OUT	Introduces a declaration block
VAR_INPUT	VAR_INPUT	Introduces a declaration block
VAR_OUTPUT	VAR_OUTPUT	Introduces a declaration block
VAR_TEMP	VAR_TEMP	Introduces a declaration block
VARIANT	VARIANT	Data type
VERSION	VERSION	Version number of the block
VOID	VOID	Function has no return value
WCHAR	WCHAR	Data type
WSTRING	WSTRING	Data type
WHILE	WHILE	Introduction of a WHILE instruction
WORD	WORD	Data type
XOR	XOR	Logic operation
Z	C	Counter

Using tags within the program

Definition

A variable is a placeholder for a data value that can be changed in the program. The format of the data value is defined. The use of variables makes your program more flexible. For example, you can assign different values to variables that you have declared in the block interface for each block call. As a result, you can reuse a block you have already programmed for various purposes.

A variable consists of the following elements:

- Name
- Data type
- Absolute address
  - PLC tags and DB tags in blocks with standard access have an absolute address.
  - DB variables in blocks with optimized access have no absolute address.
- Value (optional)

Declaring Variables

You can define variables with different scopes for your program:

- PLC tags that apply in all areas of the CPU
- DB variables in global data block that can be used by all blocks throughout the CPU.
- DB tags in instance data blocks that are predominantly used within the block in which they are declared.

The following table shows the difference between the variable types:

	PLC tags	Variables in instance DBs	Variables in global DBs
Range of application	• Are valid throughout the entire CPU. • Can be used by all blocks on the CPU. • The name is unique within the CPU.	• Are predominantly used in the block in which they are defined. • The name is unique within the instance DB.	• Can be used by all blocks on the CPU. • The name is unique within the global DB.
Permissible characters	• Letters, numbers, special characters • Quotation marks are not permitted. • Reserved keywords are not permitted.	• Letters, numbers, special characters • Reserved keywords are not permitted.	• Letters, numbers, special characters • Reserved keywords are not permitted.
Use	• I/O signals (I, IB, IW, ID, Q, QB, QW, QD) • Bit memory (M, MB, MW, MD)	• Block parameters (input, output and in-out parameters), • Static data of a block	• Static data
Location of definition	PLC tag table	Block interface	Declaration table of the global DB

Constants

Basics of constants

Definition

Constants are data with a fixed value that you cannot change during program runtime. Constants can be read by various program elements during the execution of the program but cannot be overwritten. There are defined notations for the value of a constant, depending on the data type and data format. A distinction is made between the typed and non-typed notation.

Non-typed constants

In the non-typed notation, you only enter the value of the constant without a data type. Non-typed constants do not receive their data type until the first arithmetic or logical operation in which they are used.

The example below shows the non-typed notation:

```
SCL
#My_Int1 := #My_Int2 + 12345        (*The data type of the constant "12345"
                                    results from the addition with My_Int 2. "12345"
                                    receives the data type INT.*)
#My_Real1 := #My_Real2 + 12345      (*The data type of the constant "12345" results
                                    from the addition with My_Real2. "12345" re-
                                    ceives the data type REAL.*)
```

Typed constants

In the typed notation, you specify a data type in addition to the value of the constant.

The example below shows the typed notation:

```
SCL
#My_Int1 :=  INT#12345                    (*The data type of the constant is always
                                          INT.*)
```

Note

Constants of BOOL type in LAD/FBD

Constants of the BOOL type may not be used as inputs of instructions in S7-300/400.

Constants of the BOOL type may be used as inputs of instructions which are a system-internal function block (FB) in S7-1200/1500. These instructions are identified by the fact that the "Call options" dialog opens when you insert the instruction into a network. Boolean constants may not be used as inputs for all other instructions.

Additional information

Additional information on the data types of constants, their input formats and value ranges:

Data types (Page 1908)

Calculating with constants in SCL (Page 295)

See also

Layout of the block interface (Page 1551)

Declaration of symbolic names for constants

Symbolic constants

You have the option of declaring symbolic names for constants and thus making constant values available under a name in the program. This makes a program more readable and easier to maintain when changing constant values.

A symbolic constant consists of the following elements:

- Name
- Data type
  Symbolic constants always have a data type; non-typed notation is not possible for symbolic constants.
- Constant value
  You can select any value from the value range of the specified data type as constant value. For information on the value ranges, refer to the "Data types" chapter.

Declaration of constants

You can define constants with different scopes of validity:

- Global constants that apply to all areas of the CPU
- Local constants that only apply within a block

The table below shows the difference between the constant types:

	Global constants	Local constants
Scope of validity	• Are valid throughout the entire CPU • The name is unique within the CPU.	• Are valid only in the block in which they were declared. • The name is unique within the block.
Permitted characters	• The permitted characters in constant names are letters, digits and special characters.	• The permitted characters in constant names are letters, digits and special characters.

	Global constants	Local constants
Location of definition	"Constants" tab from the PLC tag table	Block interface
Representation	In quotation marks, for example.: `"Glob_Const"`	Prefixed with a number sign, for example: `#Loc_Const`

Note

Downloading constant declarations (S7-300/400)

Local and global constant declarations are not downloaded into the CPU. If you download a program from a device, the constant declarations may no longer be available.

Additional information

Additional information on the procedure for declaring constants:

Overview of the valid data types (Page 1908)

Auto-Hotspot

Auto-Hotspot

Calculating with constants in SCL (Page 295)

Data types of constants

Permitted data types

For constants, all basic data types as well as all derived data types are permitted:

- Binary numbers
- Bit strings
- Integers
- Floating-point numbers
- Timers
- Date and time
- Character strings

All general rules for explicit and implicit type conversion apply.

Data types of non-typed constants

Non-typed constants do not contain an explicit type specification. They do not receive their data type until the first arithmetic or logical operation in which they are used.

The example below shows how non-typed constants are used:

```
SCL
#My_Int1 := #My_Int2 + 12345        (*The data type of the constant "12345"
                                    results from the addition with My_Int 2. "12345"
                                    receives the data type INT.*)
#My_Real1 := #My_Real2 + 12345      (*The data type of the constant "12345" results
                                    from the addition with My_Real2. "12345" re-
                                    ceives the data type REAL.*)
```

Note

STEP 7 always uses the data type with the highest possible precision

Unless the data type of a constant can be clearly defined in an expression, the data type with the highest precision available on the current CPU is used.

Example:

```
#My_Real := #My_Int / 3.5
```

In this expression an integer tag is combined with a non-typed floating point constant. In S7-300/400 the right part of the assignment is calculated in the REAL format. In S7-1200/1500, calculation is performed using the highest possible precision, which in this case means LREAL. As a result, the assignment to a REAL tag is invalid or generates a warning.

To precisely define the data type of a constant, use the typed notation.

Example:

```
#My_Real := #My_Int / REAL#3.5
```

Additional information

Additional information on the data types of constants, their input formats and value ranges:

Data types (Page 1908)

Calculating with constants in SCL (Page 295)

Examples of using constants

Use in instructions, assignments and expressions

Constants can be used in place of tags in instructions or assignments. You can also use constants in expressions in SCL. But because constants cannot be written, they may only be used as inputs.

The example below shows possible uses of constants:

```
SCL
#My_Int :=   3;
```

```
SCL
#My_Real1 := #My_Real2 * 3;
#My_Real1 := #My_Real2 * #My_local_const;
#My_Real1 := #My_Real2 * "My_global_const";
```

Use as a default value

You can use constants as the default value of a tag. To do so, enter either the value or the symbolic name of the constant in the "Default value" column of the block interface. The data type of the constant must match the data type of the tag or be convertible with it according to the implicit conversion with IEC check.

Name conflicts can occur if you have declared a local and a global constant with the same symbolic name and have used this doubly specified name as the default value of a tag. In this case, the local constant is automatically used.

Use as an ARRAY limit

You can use local or global constants of data type INT or DINT as ARRAY limits.

The example below shows the use of constants as ARRAY limits:

```
SCL
Array[#My_local_const1..#My_local_const2] of REAL
Array["My_global_const1".."My_global_const1"] of REAL
```

Note

Constants as ARRAY limits

- Constants which are used as ARRAY limits cannot be changed if the memory reserve of the block is activated. This applies to both local and global constants. To change these constants, you must first disable the memory reserve.
- Changes to global constants result in inconsistencies in the blocks which use them as ARRAY limits. The inconsistencies are marked in red in the block used. To remedy these inconsistencies, the data blocks have to be updated.
  See also: Updating data blocks (Page 1708)

Additional information

Additional information on the data types of constants, their input formats and value ranges:

Data types

Calculating with constants in SCL (Page 295)

See also

Overview of the valid data types (Page 1908)

Addressing operands

Addressing global variables

Addressing global variables

To address a global PLC variable, you can use the absolute address or the symbolic name.

Note

The LWORD, LINT, ULINT, LREAL, LTIME, LTOD and LDT data types can only be addressed by means of their symbolic name.

Addressing global variables in symbolic form

When you use addressing in symbolic form, you enter the variable name from the PLC tag table. The symbolic name of global variables are automatically enclosed in quotation marks.

You address structured tags that are based on a PLC data type with the symbolic name of the PLC tag. You can also indicate the names of the individual components separated by a dot.

Addressing global variables in absolute form

When you use addressing in absolute form, you enter the address of the variables from the PLC tag table. The absolute address uses numerical addresses starting with zero for each operand range. The address identifier % is set automatically as prefix for the absolute address of global tags.

Examples

The following examples show applications of symbolic and absolute addressing:

Addressing	Description
%Q1.0	Absolute address: Output 1.0
%I16.4	Absolute address: Input 16.4
%IW4	Absolute address: Input word 4
"Motor"	Symbolic address "Motor"
"Value"	Symbolic address "Value"
"Structured_Tag"	Symbolic address of a tag that is based on a PLC data type
"Structured_Tag".Component	Symbolic address of the component of a structured tag.

See also

Displaying symbolic and absolute addresses (Page 1539)

Accessing I/O devices (Page 1455)

Accessing I/O devices

Description

The process image of the CPU is updated once in a cycle. In time-critical applications, however, it can be that the current state of a digital input or output has to be read or transferred more often than once per cycle. For this purpose you can use a suffix for I/O access identifiers on the operand to directly access the I/O.

If you want to read the input directly from the peripherals, use the peripheral inputs memory area (PI) instead of the process input image (I). The peripherals memory area can be read as a bit, byte, word, or double word.

If you want to write directly to the output, use the peripheral output (PQ) memory area instead of the process output image (Q). The peripheral output memory area can be written as a bit, byte, word, or double word.

To read or write a signal directly from a peripheral input, you can add the suffix for I/O access ":P", to the operand.

Components of structured PLC tags can also be addressed with ":P". However, access to the higher-level tag with ":P" is not possible.

Warning
Direct writing of the I/O

Immediate writing to the I/O can lead to hazardous states, for example when writing multiple times to an output in one program cycle.

Syntax

```
<Operand>:P
```

Example

The following example shows applications of I/O access identifiers:

Addressing	Description
"Motor"	Addresses the "Motor" tag in the process image.
"Motor":P	Addresses the "Motor" tag in the I/O memory area (PI or PQ).
"Structured_Tag".Component	Addresses the component of a structured PLC tag in the process image.

Addressing	Description
"Structured_Tag".Component:P	Addresses the component of a structured PLC tag in the I/O memory area (PI or PQ).

Addressing global variables (Page 1454)

Addressing variables in data blocks

Addressing variables in global data blocks

Description

Tags in global data blocks can be addressed in symbolic or absolute form. For symbolic addressing, you use the name of the data block and the name of the tag, separated by a dot. The name of the data block is enclosed in quotation marks.

For absolute addressing, you use the number of the data block and the absolute address of the tags in the data block, separated by a dot. The address identifier % is set automatically as prefix for the absolute address.

The S7-1200/1500 provides you with an option of accessing a data block that is not yet known during programming. For this purpose, create a block parameter of data type DB_ANY in the block interface of the accessing block. The data block name or data block number is transferred to this parameter during runtime. In order to access the internal tags of the data block, use the name of the block parameter of data type DB_ANY and the absolute address of the tag, separated by a dot.

Note

Transfer DB with memory reserve to the parameter DB_ANY.

It is not possible to transfer a DB with memory reserve to a block parameter of data type "DB_ANY".

Note

Addressing DB tags in absolute form

Absolute addressing is not possible for the following tags:

- Tags in blocks with optimized access.
- Tags of data type LWORD, LINT, ULINT, LREAL, LTIME, LTOD and LDT.

Best practice is to use the more convenient symbolic addressing for these tags.

ARRAY data blocks

ARRAY data blocks are a particular type of global data block. These consist of an ARRAY of any data type. For example, an ARRAY of a PLC data type (UDT) is possible.

You address elements in ARRAY data blocks with the help of the keyword "THIS". The index is then specified in square brackets. The index can be a constant as well as a tag. Integers with a width of up to 32 bits are permitted as tags for the index.
Extended options for addressing ARRAY DBs are available in the "Move" section of the "Instructions" task card. These instructions give you the option, for example, to also address the DB name indirectly.

Syntax

```
"<DBname>".TagName
%<DBnumber>.absoluteAddress
#<DBAny_name>.%absoluteAddress
"<ArrayDBname".THIS[#i].<Component>.<ComponentElement>
```

SCL:
```
"<ArrayDBname"."THIS"[#i].<Component>.<ComponentElement>
```

The following table show the possible absolute addresses of tags in data blocks:

Data type	Absolute address	Example	Description
BOOL	%DBn.DBXx.y	%DB1.DBX1.0	Data bit 1.0 in DB1
BYTE, CHAR, SINT, USINT	%DBn.DBBy	%DB1.DBB1	Data bit 1 in DB1
WORD, INT, UINT	%DBn. DBWy	%DB1.DBW1	Data word 1 in DB1
DWORD, DINT, UDINT, REAL, TIME	%DBn.DBDy	%DB1.DBD1	Data double word 1 in DB1

Example

The following examples show the addressing of tags in global data blocks:

Addressing	Description
"Motor".Value	Symbolic addressing of the "Value" tag in the "Motor" global data block.
%DB1.DBX1.0	Absolute addressing of the "DBX1.0" tags in the "DB1" global data block.
#MyDBAny.%DBX30.0	Absolute addressing of the "DBX30.0" tag in the global data block that is transferred at runtime at the "MyDBany" parameter.
"MyARRAY_DB".THIS[#MyIndex].MyComponent.MyComponentElement	Addressing an ARRAY data block. The ARRAY index is specified with the "MyIndex" tag. The ARRAY element has two additional substructures: "MyComponent" and "MyComponentElement".

Using the DB_ANY data type (Page 275)

Addressing structured variables (Page 1459)

Addressing areas of a tag with slice access (Page 1461)

Basics of indirect addressing (Page 1465)

Addressing instance data (Page 1458)

Addressing instance data

Description

You can address data elements from the interface of the current block. These tags are stored in the instance data block.

Note

Tags in blocks with optimized access can only be addressed in symbolic form.

To address a tag from the interface of the current block, enter the character # followed by the symbolic tag name.

You can also access the tags of a multiple instance block. Within the multiple instance block, also use the character # followed by the tag name to address the data. You access the data of the multiple instance block from the calling block using #<Multiple instanceName.TagName>.

Syntax

Use the following syntax for addressing tags in instance data blocks:

```
#<TagName>
#<Multiple instanceName.TagName>
```

Examples

The following examples show the addressing of tags in instance data blocks:

Addressing	Description
#Value	Addressing the "Value" tag in the instance data block.
#On	Addressing the "On" tag within the multiple instance block
#Multi.On	Addressing the "On" tag of the multiple instance block from the calling block

See also

Addressing variables in global data blocks (Page 1456)

Addressing areas of a tag with slice access (Page 1461)

Basics of indirect addressing (Page 1465)

Addressing structured variables

Addressing data elements of an ARRAY

You access an element in an ARRAY using the syntax `ArrayName[i,j,k...]`.

The index of the element is specified in square brackets. The index includes an integer value (-2147483648 ... 2147483647) for each ARRAY dimension.

Access errors result when you access an element during runtime which is located outside the declared ARRAY limits. The various CPU families react differently to violations of the ARRAY limits:

- S7-300/400
  - The CPU changes to "STOP" mode.
  - You can program the program execution error OB (OB 85) to prevent this.
  - In SCL, you also have the option of enabling the attribute "Check ARRAY limits" in the block properties. This causes the enable output ENO to be set to FALSE in the case of ARRAY access errors.
- S7-1200
  - The CPU generates a diagnostic buffer entry and remains in "RUN" mode.
- S7-1500
  - The CPU changes to "STOP" mode.
  - You can program the programming error OB (OB 121) to prevent this.
  - You also have the option of programming the local error handling with the instructions "GET_ERROR: Get error locally" or "GET_ERROR_ID: Get error ID locally".

Note

Monitoring ARRAY access errors with ENO

The enable output ENO is not set to the signal state FALSE if the ARRAY limits are violated during execution of an instruction. The only exception is SCL blocks on CPUs of the S7-300/400 series for which the block property "Check ARRAY limits" is set.

See also:

Array (Page 1941)

Indirect indexing of ARRAY components (Page 1467)

Addressing ARRAY data blocks

ARRAY data blocks are a particular form of the ARRAY. ARRAY data blocks are global data blocks that consist of exactly one ARRAY. You address elements in ARRAY data blocks using the following syntax:

```
"<GlobArrayDBname".THIS[#i].<componentname>."<elementname>"
```

SCL:

```
"<GlobArrayDBname"."THIS"[#i].<componentname>."<elementname>".
```

The "Move" section of the "Instructions" task card offers extended options for addressing ARRAY DBs. These instructions give you the option, for example, to also address the DB name indirectly.

Addressing data elements in structures

You access individual elements in a structure using `StructureName.ElementName`.

See also:

Structures (Page 1945)

Addressing data elements of an PLC data type

The syntax `PLCDataTypeName.ElementName` is used to access elements of a PLC data type.

See also:

Auto-Hotspot

Addressing individual characters of a STRING or WSTRING (S7-1200/1500)

Use the syntax `StringName[i]` to access an individual character of a STRING or WSTRING tag. The counting index "i" begins with "1". Thus, you access the first character of the string with StringName[1].

You cannot access individual characters of a STRING or WSTRING constant.

Errors result when you access a character during runtime which is located outside the STRING length. On read access to the STRING, you receive the character '$00' or '$0000'; write access to the STRING is not executed. If the instruction has the enable output ENO, ENO is set to the signal state FALSE. The CPU does not change to STOP.

See also:

Character strings (Page 1936)

Examples:

The following examples show the addressing of structured data type tags:

Addressing	Description
`Motor.Value_1x3[2]`	Addressing of a one-dimensional array
`Motor.Value_2x4[2,4]`	Addressing of a two-dimensional array

Addressing	Description
Motor.Value_4x7[2,4,1,3]	Addressing of a four-dimensional array
Batch_1.Temperature	Addressing of the element "Temperature" in the structure "Batch_1"
Values.Temperature	Addressing of the "Temperature" element in the "Values" tag, which is based on a PLC data type.
STRING[3]	Addresses the third character of the STRING.
WSTRING[3]	Addresses the third character of the WSTRING.

Basics of indirect addressing (Page 1465)

Addressing areas of a tag with slice access

Description

You have the option to specifically address areas within declared tags. You can access areas of the 1-bit, 8-bit, 16-bit, or 32-bit width. The type of access is referred to as "slice access".

Structures, constants and tags overlaying AT cannot be addressed with slice access.

Syntax

The following syntax is used for addressing:

```
<Tag>.X<Bit number>
<Tag>.B<BYTE number>
<Tag>.W<WORD number>
<Tag>.D<DWORD number>
```

The syntax has the following components:

Part	Description
<Tag>	Tag that you access. The tag must be of the "Bit string" data type. In the case of deactivated IEC check, access to tags of the "Integer" data type is also possible.
X	ID for the access width "Bit (1Bit)"
B	ID for the access width "Byte (8 Bit)"
W	ID for the access width "Word (16 Bit)"
D	ID for access width "DWord (32-bit)"
<BIT number>	Bit number within <tag> that is accessed. Number 0 accesses the least significant BIT.
<BYTE number>	Byte number within <tag> that is accessed. The number 0 accesses the least significant BYTE.

Part	Description
<WORD number>	Word number within <tag> that is accessed. The number 0 accesses the least significant WORD.
<DWORD number>	DWord number within <tag> that is accessed. The number 0 accesses the least significant DWORD.

Examples

The following examples show the addressing of individual bits:

Addressing	Description
"Engine".Motor.X0 "Engine".Motor.X7	"Motor" is a tag of the BYTE, WORD, DWORD or LWORD data type in the global data block "Engine". X0 addresses the bit address 0, X7 the bit address 7 within "Motor".
"Engine".Speed.B0 "Engine".Speed.B1	"Speed" is a tag of the WORD, DWORD or LWORD data type in the global data block "Engine". B0 addresses the byte address 0, B1 the byte address 1 within "Speed".
"Engine".Fuel.W0 "Engine".Fuel.W1	"FUEL" is a tag of the DWORD or LWORD data type in the global data block "Engine". W0 addresses the word address 0, W1 the word address 1 within "Fuel".
"Engine".Data.D0 "Engine".Data.D1	"Data" is a tag of the LWORD data type in the global data block "Engine". D0 addresses the double word address 0, D1 the double word address 1 within "Data".

See also

Addressing with Slice access (Page 250)

Overlaying tags with AT

Description

To access data areas within a declared tag, you can overlay the declared tags with an additional declaration. This provides you with the option of addressing an already declared tag with a different data type. You can, for example, address the individual bits of a tag of WORD data type with an ARRAY of BOOL.

Rules

The following general rules are valid for tag overlaying:

- Overlaying is possible in S7-1200 and S7-1500 in STL, LAD, FBD and GRAPH.
- SCL supports overlaying in all CPU families.

- Overlaying of tags is possible in the following blocks:
  - In code blocks with standard access
  - In code blocks with optimized access for tags with the retain setting "Set in IDB"
- The data width of the overlaying tag must be equal to or less than that of the overlaid tag.
- It is not possible to overlay tags of the VARIANT and INSTANCE data types.
- Blocks from libraries which are declared as parameters in the interface cannot be overlaid.
- Structured PLC tags that are declared as parameters in the interface cannot be overlaid.
- You cannot address overlaying tags with slice access.

Note

S7-1200/1500: Using AT in FCs

The data widths of the overlaying tag and the overlaid tag must be identical for FCs in S7-1200/1500. If this is not possible in your program, check to see if you can use slice access instead of the AT construct.

See also: Addressing areas of a tag with slice access (Page 1461)

The following combination rules are also valid:

		Overlaying tag	Overlaid tag			
Elementary	Structured *	Any/Pointer	DB_ANY			
FB	Input	Elementary	x	x		x
		Structured *	x	x	x	x
		Any/Pointer		x		
	Temp	Elementary	x	x		
		Structured	x	x	x	
		Any/Pointer		x		
	Static, Output	Elementary	x	x		x
		Structured	x	x		x
		Any/Pointer				
	InOut	Elementary	x			x
		Structured		x		
		Any/Pointer				
FC	Temp	Elementary	x	x		
		Structured	x	x	x	
		Any/Pointer		x		
	Input, Output, InOut	Elementary (both tags must have the same bit width)	x			x
		Structured		x	x	
		Any/Pointer				

		Overlaying tag	Overlaid tag			
OB	Temp	Elementary	x	x		
		Structured	x	x	x	
		Any/Pointer		x		

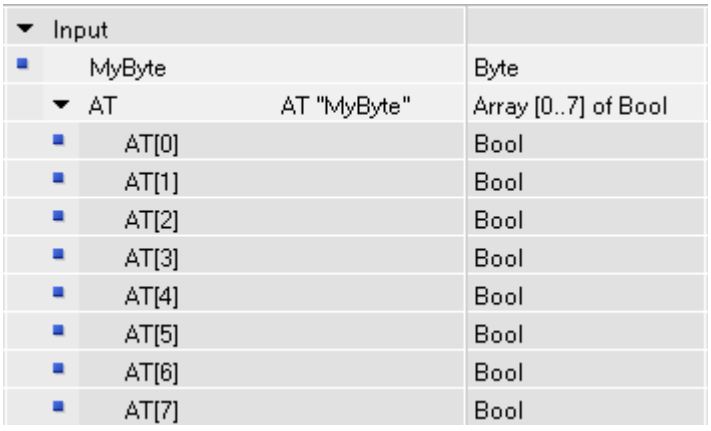
* Structured data types consist of several data elements, e.g. ARRAY or STRUCT.

Declaration

To overlay a tag, declare an additional tag directly after the tag that is to be overlaid and identify it with the keyword "AT".

Example

The following figure shows the declaration of an overlaid tag in the interface of a FB:



Input		
MyByte		Byte
AT	AT "MyByte"	Array [0..7] of Bool
AT[0]		Bool
AT[1]		Bool
AT[2]		Bool
AT[3]		Bool
AT[4]		Bool
AT[5]		Bool
AT[6]		Bool
AT[7]		Bool

When a block is called with the shown tag declaration, the "MyByte" tag is assigned. Within the block there are now two options for interpreting the data:

- as a byte
- As one-dimensional ARRAY of BOOL

Addressing operands indirectly

Basics of indirect addressing

Introduction

Indirect addressing offers the option of addressing operands whose address is not calculated until during runtime. With indirect addressing, program sections can be executed several times and a different operand can be used during each run.

Warning

Risk of access errors

Since operands are only calculated during runtime with indirect addressing, there is a risk that access errors may occur and that the program will operate with incorrect values. In addition, memory areas may inadvertently be overwritten with incorrect values. The automation system can then react in unexpected manner.

Therefore, use indirect addressing only with caution.

Indirect addressing

Basics of indirect addressing

General indirect addressing options in S7-1200 and S7-1500

The following indirect addressing options are available in all programming languages:

- Indirect addressing via pointer
- Indirect indexing of ARRAY components
- Indirect addressing of a data block via DB_ANY data type.

Language-specific options of indirect addressing

The following specific addressing options are also available in the various programming languages:

- In STL, you can address operands indirectly via the address register.
- In SCL, you can read or write a variable memory area with the following instructions:
  - POKE - Write memory address
  - POKE_BOOL - Write memory bit
  - PEEK - Read memory address
  - PEEK_BOOL - Read memory bit
  - POKE_BLK - Write memory area

For a detailed description of these addressing options, refer to "See also".

POKE_BLK: Write memory area (Page 2855)
Indirect addressing via pointer (Page 1466)
Indirect indexing of ARRAY components (Page 1467)
Indirect addressing in STL (Page 1471)

Indirect addressing via pointer

Description

For indirect addressing, a special data format is required that contains the address and possibly also the range and the data type of an operand. This data format is referred to as pointer. The following types of pointers are available to you:

- POINTER (S7-1500)
- ANY (S7-1500, only for blocks with standard access)
- VARIANT (S7-1200/1500)

For more information on the pointer data types, refer to "See also".

Note

In SCL the use of the POINTER is restricted. The only option available is to forward it to the called block.

Example

The following example shows an indirect addressing with an area-internal pointer:

Addressing in STL	Explanation
L P#10.0	// Load pointer (P#10.0) in accumulator 1
T MD20	// Transfer pointer to the operand MD20
L MW [MD20]	// Load MW10 in accumulator 1
....	// Any program
L MD [MD20]	// Load MD10 in accumulator 1
....	// Any program
= M [MD20]	// If RLO=1, set the memory bit M10.0

The pointer P#10.0 is transferred to the operand MD20. If the operand MD20 in square brackets is programmed, this will be replaced in runtime by the address that is contained in the pointer.

See also

Basics of indirect addressing (Page 1465)

Pointer (Page 1946)

Indirect indexing of ARRAY components

Description

For addressing the components of an ARRAY, you can specify tags of the integer data type as well as constants as the index. Integers with a length of up to 32 bits are allowed here. When tags are used, the index is calculated during runtime. You can, for example, use a different index for each cycle in program loops.

Note

When you call a block and transfer an indirectly indexed ARRAY component ("<Data block>".<ARRAY>["i"]) to it as in/out parameter (InOut), you cannot change the value of the index tag [i] while the block is being executed. The value is therefore always written back to the same ARRAY component from which it was read.

Syntax

The following syntax is used for the indirect indexing of a ARRAY:

```
"<Data block>".<ARRAY>["i"] // one-dimensional ARRAY
"<Data block>".<ARRAY>["i"] // one-dimensional ARRAY of STRUCT
"<Data block>".<ARRAY>["i"] // multidimensional ARRAY
"<Data block>".<ARRAY>["i"] // multidimensional ARRAY of STRUCT
```

The syntax has the following components:

Part	Description
Data block	Name of the data block in which the ARRAY is located
ARRAY	Tag of the ARRAY data type
i, j	PLC tags of the integer data type that are used as pointers
a	Additional partial tag of the structure

Examples

The following example shows indirect array indexing of an ARRAY component in STL:

Several axes traverse at different angles. The values for axis number and angle are stored in the two-dimensional ARRAY "control_axis".

You can use the "SEL" instruction to select the components of the "control_axis" ARRAY to be written at the "#out" output parameter.

The axis number is defined by the constants "Constant_Axis_NoX" and "Constant_Axis_NoY"; the angle is defined by the "#Angle" tag.

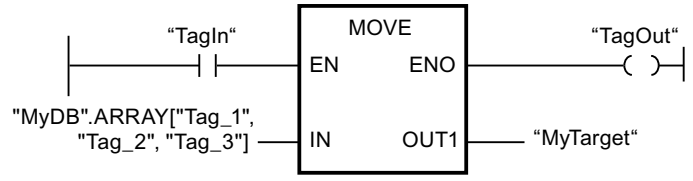
Addressing in STL

```
CALL  SEL
    value_type:=Int
    G   :="Select"
    IN0 :=#control_axis["Constant_Axis_NoX", #Angle]
    IN1 :=#control_axis["Constant_Axis_NoY", #Angle]
    OUT :=#out
```

The following examples are based on SCL and demonstrate indirect indexing of an ARRAY component. "MOTOR" is a one-dimensional ARRAY_of_INT with three rows. "VALUES" is a PLC tag of data type "Integer".

Addressing in SCL	Explanation
`MOTOR[2] := VALUES;`	`(*Direct addressing: Assignment of VALUES to the second row of the ARRAY MOTOR*)`
`MOTOR["Tag_1"] := VALUES;`	`(*Indirect addressing: Assignment of VALUES to the rows of ARRAY MOTOR*) specified by "Tag_1"`
`#MOTOR["Tag_2"+"Tag_3"] := #Values;`	`(*Indirect addressing: Assignment of VALUES to the row of the MOTOR*) ARRAY specified by the expression "Tag_2"+"Tag_3"`

The following example shows the indirect indexing of an ARRAY component as an example of LAD. "ARRAY" is a three-dimensional ARRAY. "Tag_1", " "Tag_2" and ""Tag_3" are PLC tags of the "Integer" data type. Depending on their values, one of the "ARRAY" components will be copied to the "MyTarget" tag.



Indexing ARRAY components using the "FieldRead" and "FieldWrite" instructions

You may also use the following instructions for indirect indexing of ARRAY components in LAD and FBD:

- FieldWrite - Write field
- FieldRead - Read field
  For more information on these instructions, refer to the "References" chapter.

Additional information

For more information on the ARRAY data type, refer to "See also".

Basics of indirect addressing (Page 1465)

Array (Page 1941)

Addressing structured variables (Page 1459)

Indirect addressing of individual characters of a STRING

Description

For addressing the individual characters of a STRING or WSTRING, you can specify constants and also tags as the index. The tags must be of the Integer data type. When tags are used, the index is calculated during runtime. You can, for example, use a different index for each cycle in program loops.

If you transfer a STRING or WSTRING with variable index to an in/out parameter during a block call, please note that: The index tag [i] is read once at the start of the block call and cannot be changed by the called block while it is being executed.

Note

Monitoring STRING access in runtime

When a STRING or WSTRING that exceeds the defined length is written in runtime, unwanted reactions may occur in the program. Violation of the STRING or WSTRING length is monitored in S7-1200/1500. On read access to the STRING, you receive the character '$00' or '$0000'; write access to the STRING is not executed. If the instruction has the enable output ENO, ENO is set to the signal state FALSE. The CPU does not change to STOP.

Syntax

The following syntax is used for the indirect indexing of a STRING or WSTRING:

```
"<Data block>".<STRING>["i"]
"<Data block>".<WSTRING>["i"]
```

Example

The example below shows indirect indexing of a STRING using SCL as an example. "STRING", "WSTRING", "CHAR" and "WCHAR" are tags. "Tag_1" is a PLC tag of the "Integer" data type.

Addressing in SCL	Description
`STRING["Tag_1"] := CHAR;`	`(*Indirect addressing: Assignment of "CHAR" to the character of the STRING*) specified by "Tag_1"`

Addressing in SCL	Description
`WSTRING["Tag_1"] := WCHAR;`	`(*Indirect addressing: Assignment of "WCHAR" to the character of the WSTRING*) specified by "Tag_1"`
`WCHAR := WSTRING["Tag_1"];`	`(*Indirect addressing: Assignment of the WSTRING character specified by "Tag_1" to WCHAR*)`

Additional information

You can find additional information on the STRING and WSTRING data types under "See also".

STRING (Page 1937)

WSTRING (Page 1939)

Indirect addressing in STL

Basic information about address registers

Introduction

Two address registers are available for the indirect addressing of operands: address register 1 (AR1), and address register 2 (AR2). The address registers are equal and are 32 bits in length. You can store area-internal and cross-area pointers in the address registers. To define the address of an operand, you can call the stored data in the program.

Data is exchanged between the registers and the other available memory areas with the assistance of load and transfer instructions.

Note

In S7-1500, special rules apply to data exchange via address register and data block register:

- The values in the registers do not remain in existence beyond the block limits.
- The registers are reset when the language is changed within a block.
- You can only reference data in blocks with optimized access if these have the retain setting "Set in IDB".
- It is not possible to reference local data in blocks with optimized access with the help of the address registers (across areas).

Additional information

For more information on the statements that address registers use and on indirect addressing, refer to "See also".

See also

Indirect addressing in STL (Page 1471)

Addressing areas of a tag with slice access (Page 1461)

Indirect addressing in STL

In STL, the following options are available for indirect addressing:

- Memory-indirect addressing
- Register-indirect area-internal addressing
- Register-indirect cross-area addressing

Memory-indirect addressing

In the case of memory-indirect addressing, you store the address in a tag. The tag can be of WORD or DWORD data type. The tag can be located in the memory areas "Data" (DB or DI), "Bit memory" (M) or "Temporary local data" (L). In S7-1500, FB parameters can also be used to store the address. If the tag is located in a data block, it must be a data black with standard access.

The following example shows applications of memory-indirect addressing:

Addressing in STL	Explanation
`U E [MD 2]`	`// Execute an AND logic operation with a variable input bit. The address of the input bit is located in the memory double word MD2.`
`= DIX [DBD 2]`	`// Assign the RLO to a variable data bit. The address of the data bit is located in the data double word DBD2.`
`L EB [DID 4]`	`// Load a variable input byte to ACCU 1. The address of the input byte is located in the instance double word DID4.`
`AUF DB [LW 2]`	`// Open a variable data block. The number of the data block is located in the local data word LW2.`

Register-indirect area-internal addressing

Register-indirect addressing uses one of the address registers (AR1 or AR2) to pick up the address of the operand.

In the case of register-indirect, area-internal addressing, you index only the bit address and the byte address via the address register (e.g. `P#10.0`). You do not enter the memory area for which the address in the address register is to apply until during programming of the instruction. The address in the address register then moves to the memory area specified in the instruction.

Possible memory areas are "Inputs" (I), "Outputs" (Q), "I/O" (PI or PQ), "Bit memory" (M), "Temporary local data" (L) and "Data" (DB or DI). If the operand is located in a data block, it must be a data black with standard access.

When you enter register-indirect, area-internal addressing, specify an offset after the specification of the address register. This offset is added to the contents of the address register without changing the address register. This offset also has the format of a pointer. The specification of a pointer is mandatory and must be entered as constant (e.g. `P#0.0` or `P#2.0`).

The following example shows an application of register-indirect area-internal addressing:

STL	**Explanation**
`LAR1 P#10.0`	`// Load pointer (P#10.0) to address register 1`
`L IW [AR1, P#2.0]`	`// Increase contents of address register 1 (P#10.0) by offset P#2.0.`
	`// Load contents of input word IW12 into accumulator 1`
`L IW [AR1, P#0.0]`	`// Increase contents of address register 1 (P#10.0) by offset P#0.0.`
	`// Load contents of input word IW10 into accumulator 1`

Register-indirect cross-area addressing

In the case of register-indirect, cross-area addressing, use the address register to index the entire address of the operand, in other words, the bit address and byte address, as well as the memory area. Possible memory areas are "Inputs" (I), "Outputs" (Q), "I/O" (P), "Bit memory" (M), "Temporary local data" (L) and "Data" (DB or DI). If the operand is located in a data block, it must be a data black with standard access or the operand must have the retain setting "Set in IDB".

In the instruction, program only the operand width. Possible operand widths are bit, byte, word, and double word.

The following example shows an application of register-indirect cross-area addressing:

`LAR1 P#M10.0`	`// Load cross-area pointer (P#M10.0) to address register 1`
`L W [AR1, P#2.0]`	`// Increase contents of address register 1 (P#M10.0) by offset P#2.0.`
	`// Load contents of memory word "MW12" into accumulator 1`
`LAR1 P#A10.0`	`// Load cross-area pointer (P#A10.0) to address register 1`
`L W [AR1, P#2.0]`	`// Add contents of address register 1 (P#A10.0) by offset P#2.0`
	`// Load contents of output word QW12.0 into accumulator 1`

Note

Special features in S7-1500

In S7-1500, special rules apply to data exchange via address register and data block register:

- The values in the registers do not remain in existence beyond the block limits. The registers are also reset when the language is changed within a block.
- If you access an operand of the BYTE, WORD or DWORD type using register-indirect addressing, the address must begin at a byte limit.
  Examples:
  LAR1 P#0.0
  L MW [AR1, P#0.0] // P#0.0 + P#0.0 = P#0.0 - The addressing is allowed, because P#0.0 points to a byte limit.
  L MW [AR1, P#2.1] // P#0.0 + P#2.1 = P#2.1 - The addressing is not allowed, because P#2.1 does not point to a byte limit.

11.1.1.5 Program flow control

EN/ENO mechanism

Basics of the EN/ENO mechanism

Introduction

Runtime errors that require a program abort can occur during the processing of instructions. You can use the EN/ENO mechanism to avoid such program aborts. This mechanism can be used at two levels:

- EN/ENO mechanism for individual instructions
- EN/ENO mechanism for block calls

EN/ENO mechanism for instructions in LAD/FBD

In LAD and FBD, certain instructions have an enable input EN and an enable output ENO.

You can use the enable input EN to make the execution of the instruction dependent on conditions. The instructions are only executed if the signal state is "1" at the enable input EN.

You can use the enable output ENO to query runtime errors in instructions and react to these.

The enable output ENO returns the signal state "1" if one of the following conditions applies:

- No error occurred during processing.

The enable output ENO returns signal state "0" if one of the following conditions applies:

- The EN input has signal state "0".
- An error occurred during processing.

The EN/ENO mechanism is used for the following basic instructions:

- Mathematical functions
- Move operations
- Conversion operations
- Word logic operations
- Shift + rotate

In LAD and FBD, you can switch the evaluation of the enable output ENO on and off by means of the shortcut menu specifically for certain instructions.

EN/ENO mechanism for block calls in LAD/FBD

All blocks that you call in LAD or FBD are provided with an enable input EN and an enable output ENO when called. This applies to all called blocks, regardless of the programming language in which they were created.

You can use the enable input EN to call the block depending on conditions. The block is only executed if the signal state is "1" at the enable input EN.

You can query the error status of the block with the enable output ENO. It has signal "1" as soon as the execution of the block starts. If you do not explicitly set the output ENO to "0" in the program code, it retains signal "1".
However, you can explicitly set it to "0" to return an error statement to the called block. In LAD or FBD, the output ENO is set with the instruction "RET: Return".

See also:

Example of the use of the EN/ENO mechanism in LAD (Page 1476)

Example of the use of the EN/ENO mechanism in FBD (Page 1476)

EN/ENO mechanism for STL

In STL, the EN/ENO mechanism is not required for individual instructions. This function is mapped by language-specific instruction sequences.

Blocks that you call from an STL block are not provided with the EN and ENO parameters. Regardless of the programming language in which they were created, you can transfer an error statement to the calling STL block using the BR bit of the status word.

In STL, you can evaluate the error status of the called block by linking the BR bit of the status word with the RLO. It has signal "1" as soon as the execution of the block starts. If you do not explicitly set it to "0" in the program code, it retains signal "1".
However, you can explicitly set it to "0" to return an error statement to the calling block. In STL, the error statement is set with the instructions "SAVE" or "JNB".

See also: Example of the simulation of the EN/ENO mechanism in STL (Page 1478)

EN/ENO mechanism in SCL

With SCL, the use of the EN/ENO mechanism for instructions is optional. You can activate it with the block property "Set ENO automatically". If the property is active, all blocks implicitly receive an error handling.

You can implement a conditional block call with the enable input EN. Use the enable input EN in the parameter list as a normal input parameter. If EN has signal "1" or when EN is not used, the block is called. If EN has signal "0", the block is not called.

Note

When you call functions in SCL, you cannot use the release mechanism via EN. Use an IF statement instead to call functions conditionally.

You can query the error status of the block with the enable output ENO. If the ENO has signal "1", the block was processed without errors. If the ENO has signal "0", an error occurred during processing. To query the state of the enable output, insert an additional output parameter with the name ENO in the parameter list during a block call.

See also: Example of the use of the EN/ENO mechanism in SCL (Page 1477)

ENO in GRAPH (S7-1500)

In GRAPH, you can use the ENO operand to evaluate whether an action has been completed successfully. You can select the "Set ENO automatically" option for this.

- Select the option in the program properties in order for it to be used as the default setting for new GRAPH blocks.
- Select the option in the block properties in order for it to be used for specific blocks.

If this option is selected, the ENO operand is displayed when testing with program status. This operand has the value "TRUE" if the action was successful and "FALSE" if the action failed.

The ENO operand can be used in the following cases:

- When blocks are called that have the enable output ENO.
- For instructions in which errors can occur, e.g., conversions or mathematical functions.

EN/ENO mechanism for memory and I/O access errors

You cannot evaluate memory and I/O access errors with the EN/ENO mechanism. You do this either with the global troubleshooting via OBs (S7-300/400 and S7-1200/1500) or local troubleshooting using the "GetError" instruction (S7-1200/1500 only). If a memory access error occurred for an instruction, you can evaluate the associated ENO.

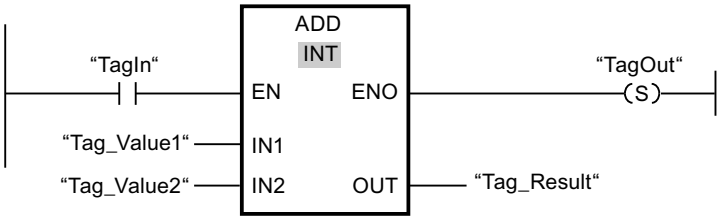
See also

Enabling and disabling the EN/ENO mechanism (Page 1608)

Example of the use of the EN/ENO mechanism in LAD

Description

The following figure shows an ADD instruction with EN and ENO protective circuit:



After the normally open contact, the RLO contains the previous result of logic operation:

- If "TagIn" signal is "0", the addition is not executed. EN and ENO both lead to the signal state "0".
- If "TagIn" signal is "1", EN is also "1" and the addition is executed. If no errors occur during the processing of the instruction, the output ENO also has the signal state "1" and the output ""TagOut"" is set.

See also

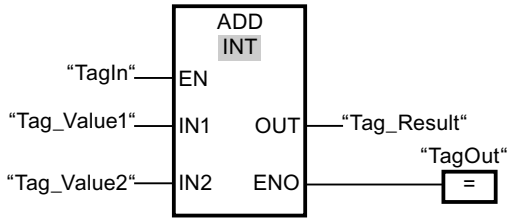
Basics of the EN/ENO mechanism (Page 1473)

ADD: Add (Page 2303)

Example of the use of the EN/ENO mechanism in FBD

Description

The following figure shows an ADD instruction with EN and ENO protective circuit:



- If "TagIn" signal is "1", EN is also "1" and the addition is executed. If no errors occur during the processing of the instruction, the output ENO also has the signal state "1" and the output ""TagOut"" is set.
- If "TagIn" signal is "0", the addition is not executed. EN and ENO both lead to the signal state "0".

See also

Basics of the EN/ENO mechanism (Page 1473)

Example of the use of the EN/ENO mechanism in SCL

Example of the EN/ENO mechanism for basic instructions

To use the EN/ENO mechanism for instructions in SCL, you have to activate the block property "Set ENO automatically". The following example shows the use of the enable output ENO for the "a/b" instruction.

SCL

```
"MyoutputREAL" :=a/b;
IF ENO
    THEN "MyOutputBool":=1;
    ELSE "MyOutputBool":=0;
END_IF;
```

If the "a/b" instruction is executed error-free, MyOutputBool has signal "1".

Example of the use of the EN/ENO mechanism in block calls

The following example shows the use of the enable output ENO for a block call.

SCL

```
"MyDB"."MyFB"(EN:="MyTag1">"MyTag2",
              in1:="MyInputBool1",
              in2:="MyInputBool1",
              EN0=>"MyOutputBool");
```

If MyTag1 is not greater than MyTag2 the block call is not processed. EN and ENO both lead to the signal state "0".

If MyTag1 is greater than MyTag2, EN has signal "1" and the block call is executed.

If all instructions within MyFB are executed error-free, MyOutputBool has signal "1".

See also

Basics of the EN/ENO mechanism (Page 1473)

Example of the simulation of the EN/ENO mechanism in STL

Description

The following example shows an program section for adding values with EN and ENO connected:

STL	Description
A"Tag_Input_1"	// Query whether the signal state of the operand is "1" and AND with current RLO
JNBMyLABEL	// Evaluation of the EN input
	// If RLO="0" jump to jump label "MyLABEL" and save the current RLO in the BR
	// Execute next instruction if RLO="1"
L"Tag_Input_2"	// Load first value of addition
L"Tag_Input_3"	// Load second value of addition
+I	// Add values
T "Tag_Result"	// Transfer sum to the operand "Tag_Result"
AN OV	// Query if errors occurred
SAVE	// Transfer signal state of the RLO to the BR bit
CLR	// Reset RLO to "0"
MyLABEL: U BR	// Jump label "MyLABEL"
	// Query BR and AND with RLO
= "Tag_Output"	// Assign signal state of the RLO to the operand "Tag_Output"

The query of the operand "U" Tag_Input_1"" provides the result of the preceding logic operation (RLO). The instruction "Jump at RLO = 0 and save RLO (SPBNB)" saves the RLO to the BR. The instruction "Jump if RLO = 0 and save RL0" also evaluates the RLO and executes one of the following actions depending on the evaluation:

- If the RLO is "0", the processing of the program is continued at the jump label "MyLABEL" with the query of the BR. The addition is not executed. Assign the current RLO to the operand "Tag_Output".
- If the RLO is "1", the addition is executed. A query of the overflow bit (OV) shows if an error occurred during the addition. The query result is saved in the BR. The operation "CLR" resets the RLO to "0". The BR is then queried for "1" and AND'd with the current RLO. The result is assigned to the operand "Tag_Output". The signal state of the BR and of the operand "Tag_Output" shows if the addition was carried out with any error

11.1.2 Declaring PLC tags

11.1.2.1 Overview of PLC tag tables

Introduction

PLC tag tables contain the definitions of the PLC tags and symbolic constants that are valid throughout the CPU. A PLC tag table is created automatically for each CPU used in the project. You can create additional tag tables and use these to sort and group tags and constants.

In the project tree there is a "PLC tags" folder for each CPU of the project. The following tables are included:

- "All tags" table
- Standard tag table
- Optional: Other user-defined tag tables

All tags

The "All tags" table gives an overview of all PLC tags, user constants and system constants of the CPU. This table cannot be deleted or moved.

Standard tag table

There is one standard tag table for each CPU of the project. It cannot be deleted, renamed or moved. The default tag table contains PLC tags, user constants and system constants. You can declare all PLC tags in the default tag table, or create additional user-defined tag tables as you want.

User-defined tag tables

You can create multiple user-defined tag tables for each CPU to group tags according to your requirements. You can rename, gather into groups, or delete user-defined tag tables. User-defined tag tables can contain PLC tags and user constants.

See also

Structure of the PLC tag tables (Page 1480)

Using tags within the program (Page 1447)

Basics of constants (Page 1449)

11.1.2.2 Structure of the PLC tag tables

Introduction

Each PLC tag table contains a tab for tags and a tab for user constants. The default tag table and the "All tags" table also have a "System constants" tab.

Structure of the "PLC tags" tab

In the "Tags" tab you declare the global PLC tags that you require in the program. The following figure shows the tab structure. The number of columns shown may vary.

	Name	Data type	Address	Retain	Visible in HMI	Accessible from HMI	Comment
	Motor1	Bool	%Q3.1	☐	☑	☑	
	Motor2	Bool	%Q3.2	☐	☑	☑	
	Control	Bool	%I3.3	☐	☑	☑	

The following table shows the meaning of the individual columns. The number of columns shown may vary. You can show or hide the columns as required.

Column	Description
	Symbol you can click on to drag-and-drop a tag to a program for use as an operand.
Name	Unique name for the constants throughout the CPU.
Data type	Data type of the tags.
Address	Tag address.
Retain	Marks the tag as retentive. The values of retentive tags are retained even after the power supply is switched off.
Accessible from HMI	Shows whether HMI can access this tag during runtime.
Visible in HMI	Shows whether the tag is visible by default in the operand selection of HMI.
Monitor value	Current data value in the CPU. This column only appears if an online connection is established and you select the "Monitor all" button.
Tag table	Shows which tag table includes the tag declaration. This column is only available in the "All tags" table.
Comment	Comment to document the tags.

Structure of the "User constants" and "System constants" tabs

In the "User constants" you define symbolic constants that are valid throughout the CPU. The constants required by the system are shown in the "Systems constants" tab. System constants can be hardware IDs, for example, which can be used for identification of modules.

The following figure shows the structure of both tabs. The number of columns shown may vary.

	Name	Data type	Value	Comment
	Const_1	Bool	true	
	Const_2	Byte	12	
	Const_3	Bool	false	
	Const_4	Real	1.0	

The following table shows the meaning of the individual columns. You can show or hide the columns as required.

Column	Description
	Symbol you can click to move a tag into a network via a drag-and-drop operation for use as an operand.
Name	Unique name for the constants throughout the CPU.
Data type	Data type of the constants
Value	Value of the constants
Tag table	Shows which tag table includes the constant declaration. This column is only available in the "All tags" table.
Comment	Comments to document the tags.

11.1.2.3 Rules for PLC tags

Valid names of PLC tags

Permissible characters

The following rules apply to the use of names for PLC tags:

- Letters, numbers, special characters are permitted.
- Quotation marks are not permitted.

Unique tag names

The names of the PLC tags must be unique throughout the CPU, even if the tags are located in different tag tables of a CPU. A name that is already used for a block, another PLC tag or a constant within the CPU, cannot be used for a new PLC tag. The uniqueness check does not differentiate between use of small and capital letters.

If you enter an already assigned name another time, a sequential number is automatically appended to the second name entered. For example, if you enter the name "Motor" a second time, the second entry is changed to "Motor(1)".

Unique table names

The names of the PLC tag tables must also be unique throughout the CPU. A unique name is automatically suggested when user-defined PLC tag tables are being created.

See also

Using tags within the program (Page 1447)

Permissible addresses and data types of PLC tags (Page 1482)

Keywords (Page 1442)

Permissible addresses and data types of PLC tags

The addresses of PLC tags are made up of the particulars of the operand area and the address within this area.

The addresses must be unique throughout the CPU. If you enter an address that is already assigned to another tag, the address will be highlighted at both places in yellow and an error message will be issued.

Operand areas

The following table shows the possible operand areas. The available data types depend on the CPU you use:

Operand area		Description	Data type	Format	Address area:		
International mnemonics	German mnemonics				S7-1200	S7-300/400	S7-1500
I	E	Input bit	BOOL	I x.y E x.y	0.0..1023.7	0.0..65535.7	0.0..32767.7
I	E	Input (64-bit)	LWORD, LINT, ULINT, LTIME, LTOD, LDT, LREAL, PLC data type	I x.0 E x.0	-	-	0.0..32760.0

Operand area		Description	Data type	Format	Address area:		
Interna-tional mnemon-ics	German mnemon-ics				S7-1200	S7-300/400	S7-1500
IB	EB	Input byte	BYTE, CHAR, SINT, USINT, PLC data type	IB x EB y	0..1023	0..65535	0..32767
IW	EW	Input word	WORD, INT, UINT, DATE, S5TIME, PLC data type	IW x EW y	0..1022	0..65534	0..32766
ID	ED	Input double word	DWORD, DINT, UDINT, RE-AL, TIME, TOD, PLC da-ta type	ID x ED y	0..1020	0..65532	0..32764
Q	A	Output bit	BOOL	Q x.y A x.y	0.0..1023.7	0.0..65535.7	0.0..32767.7
Q	A	Output (64-bit)	LWORD, LINT, ULINT, LTIME, LTOD, LDT, LREAL, PLC data type	Q x.0 A x.0	-	-	0.0..32760.0
QB	AB	Output byte	BYTE, CHAR, SINT, USINT, PLC data type	QB x AB y	0..1023	0..65535	0..32767
QW	AW	Output word	WORD, INT, UINT, DATE, S5TIME, PLC data type	QW x AW y	0..1022	0..65534	0..32766
QD	AD	Output dou-ble word	DWORD, DINT, UDINT, RE-AL, TIME, TOD, PLC da-ta type	QD x AD y	0..1020	0..65532	0..32764
M	M	Memory bit	BOOL	M x.y	0.0..8191.7	0.0..65535.7	0.0..16383.7
M	M	Bit memory (64-bit)	LREAL	M x.0	0.0..8184.0	-	0.0..16376.0
M	M	Bit memory (64-bit)	LWORD, LINT, ULINT, LTIME, LTOD, LDT	M x.0	-	-	0.0..16376.0
MB	MB	Memory byte	BYTE, CHAR, SINT, USINT	MB x	0..8191	0..65535	0..16383

Operand area		Description	Data type	Format	Address area:		
Interna-tional mnemon-ics	German mnemon-ics				S7-1200	S7-300/400	S7-1500
MW	MW	Memory word	WORD, INT, UINT, DATE, S5TIME	MW x	0..8190	0..65534	0..16382
MD	MD	Memory dou-ble word	DWORD, DINT, UDINT, RE-AL, TIME, TOD	MD x	0..8188	0..65532	0..16380
T	T	Time function (for S7-300/400 only)	Timer	T n	-	0..65535	0..2047
C	Z	Counter func-tion (for S7-300/400 only)	Counter	Z n C n	-	0..65535	0..2047

Addresses

The following table shows the possible addresses of tags:

Data type	Address	Example
BOOL	Tags with BOOL data type are addressed with a byte number and a bit number. The numbering of the bytes begins for each operand area at 0. The numbering of the bits goes from 0 to 7.	A 1.0
BYTE, CHAR, SINT, USINT	Tags with BYTE, CHAR, SINT, and USINT data type are addressed with a byte number.	MB 1
WORD, INT, UINT, DATE, S5TIME	Tags with WORD, INT, UINT, DATE, S5TIME data type consist of two bytes. They are addressed with the number of the lowest byte.	IW 1
DWORD, DINT, UDINT, RE-AL, TIME, TOD	Tags with DWORD, DINT, UDINT, REAL, TIME, TOD data type con-sist of four bytes. They are addressed with the number of the lowest byte.	AD 1
LWORD, LINT, ULINT, LTIME, LTOD, LDT, LREAL	Tags of data type LWORD, LINT, ULINT, LTIME, LTOD, LDT, and LREAL consist of eight bytes. They are addressed with it number 0 and the number of the lower byte.	I 1.0

Mnemonics used

The addresses that you enter in the PLC tag table are automatically adapted to the set mnemonics.

See also

Setting the mnemonics (Page 1539)

Using tags within the program (Page 1447)

Valid names of PLC tags (Page 1481)

Overview of the valid data types (Page 1908)

11.1.2.4 Creating and managing PLC tag tables

Creating a PLC tag table

You can created multiple user-defined PLC tag tables in a CPU. Each tag table must have have a unique name throughout the CPU.

Requirement

The project view is open.

Procedure

To created a new PLC tag table, follow these steps:

1. Open the "PLC tags" folder under the CPU in the project tree.
2. Double-click the "Add new tag table" entry.
   A new PLC tag table with the default name "TagTable_x" is created.
3. Select the PLC tag table in the project tree.
4. Select the "Rename" command in the shortcut menu.
5. Type in a name that is unique throughout the CPU.

Result

A new PLC tag table is created. You can now declare tag and constants in this table.

See also

Overview of PLC tag tables (Page 1479)

Structure of the PLC tag tables (Page 1480)

Grouping PLC tag tables

You can gather the user-defined tag tables of the CPU into groups. You cannot, however, move the standard tag table and the "All tags" table into a group.

Requirement

Multiple user-defined tag tables are contained in the "PLC tags" folder of the CPU.

Procedure

To gather multiple PLC tag tables into a group, follow these steps:

1. Select the "PLC tags" folder under the CPU in the project tree.
2. Select the "Insert > Group" menu command.
   A new group with the standard name "Group_x" is inserted.
3. Select the newly inserted group in the project tree.
4. Select the "Rename" command in the shortcut menu.
5. Assign the new group a unique name throughout the CPU.
6. Drag to the new group the tables you want to group together.

Result

The tag tables are gathered in the new group.

See also

Overview of PLC tag tables (Page 1479)

Structure of the PLC tag tables (Page 1480)

Opening the PLC tag table

Procedure

To open the PLC tag table in a CPU, proceed as follows:

1. Open the "PLC tags" folder under the CPU in the project tree.
2. Double-click the PLC tag table in the folder.
3. Select the desired tab in the upper corner.

Result

The PLC tag table associated with the CPU opens. You can declare the required tags and constants.

See also

Overview of PLC tag tables (Page 1479)

Structure of the PLC tag tables (Page 1480)

11.1.2.5 Declaring PLC tags

Entering a PLC tag declaration

Declaring tags in the PLC tag table

Requirements

The "Tags" tab of the PLC tag table is open.

Procedure

To define PLC tags, follow these steps:

1. Enter a tag name in the "Name" column.
2. Enter the required data type in the "Data type" column. You will be supported by autocompletion during input.
   An address corresponding to the data type is automatically appended.
3. Optional: Click on the arrow key in the "Address" column and enter an operand identifier, an operand type, an address and a bit number in the dialog which then opens.
4. Optional: Enter a comment in the "Comments" column.
5. Repeat steps 1 to 4 for all the tags you require.

See also: Permissible addresses and data types of PLC tags (Page 1482)

Syntax check

A syntax check is performed automatically after each entry, and any errors found are displayed in red. You do not have to correct these errors immediately - you can continue editing and make any corrections later. As long as the tag declaration contains syntax errors and the tag is used in the program, you will not be able to compile the program.

See also

Valid names of PLC tags (Page 1481)

Declaring PLC tags in the program editor (Page 1487)

Structure of the PLC tag tables (Page 1480)

Editing tables (Page 347)

Declaring PLC tags in the program editor

Requirement

- The program editor is open.

Procedure

To declare operands as global PLC tags, follow these steps:

1. Insert an instruction in your program.
   The "<???>", "<??.?>" or "..." strings represent operand placeholders.
2. Replace an operand placeholder with the name of the PLC tag to be created.
3. Select the tag name.
   If you want to declare multiple PLC tags, select the names of all the tags to be declared.
4. Select the "Define tag" command in the shortcut menu.
   The "Define tag" dialog box opens. This dialog displays a declaration table in which the name of the tag is already entered.
5. Click the arrow key in the "Section" column and select one of the following entries:
   - Global Memory
   - Global Input
   - Global Output
6. In the other columns, enter the address, data type, and comments.
   See also: Permissible addresses and data types of PLC tags (Page 1482)
7. If the CPU contains multiple PLC tag tables, you can use an entry in the "PLC tag table" column to indicate in which table the tag is to be inserted. If you make no entry in the column, the new tag will be inserted in the default tag table.
8. Click the "Define" button to complete your entry.

Result

The tag declaration is written to the PLC tag table and is valid for all blocks in the CPU.

See also

Valid names of PLC tags (Page 1481)

Editing tables (Page 347)

Declaring tags in the PLC tag table (Page 1487)

Setting the retentivity of PLC tags

Retentive behavior of PLC tags

Retentive PLC tags

Each CPU has a memory area whose content remains available even after the supply voltage has been switched off. This area is referred to as retentive memory area.

To avoid data loss during power failure, you can save specific PLC tags to this memory area. You specify the retain setting of PLC tags in the PLC tag table.

Depending on the CPU family, the retentive memory area can accommodate various type of PLC tags. The following table provides an overview of the options of the various CPUs:

CPU type	Retentive bit memories	Retentive SIMATIC timers	Retentive SIMATIC counters
S7-300/400 series	✓	-	-
S7-1200 series	✓	-	-
S7-1500 series	✓	✓	✓

See also

Setting the retentive behavior of PLC tags (Page 1489)

Setting the retentive behavior of PLC tags

Introduction

In the PLC tag table you can specify the width of the retentive memory area for PLC tags. All tags with addresses in this memory area are then designated as retentive. You can recognize the retentivity setting of a tag by the check mark set in the "Retain" column of the PLC tag table.

Requirement

The "PLC tags" tab of the PLC tag table is open.

Procedure

To define the width of the retentive memory area for PLC tags, follow these steps:

1. On the toolbar, click the "Retain" button.
   The "Retain memory" dialog will open.
2. Specify the width of the retentive memory area by entering the number of retentive bytes, timers or counters in the input field.
3. Click the "OK" button.

Result

The width if the retentive memory area is defined. In the "Retain" column of the tag table a check mark is automatically set for all tags that are located within the retentive memory area.

Retentive behavior of PLC tags (Page 1488)

Editing tables (Page 347)

11.1.2.6 Grouping PLC tags for inputs and outputs in structures

Other useful information regarding structured PLC tags

Use of structured PLC tags (S7-1200 V4 and higher/S7-1500)

To make your program easier to view, you can group several input or output addresses in a higher-level PLC tag. The higher-level PLC tag represents a structure that contains several logically related inputs or outputs. When the block is called, you transfer the higher-level tag and thus need only an input or output parameter for all associated inputs or outputs.

Principle of operation

To create a structured PLC tag, you initially define a PLC data type (UDT). In it you declare the necessary data elements and specify their names and data types.

Then, you switch to the PLC tag table and specify the higher-level PLC tag there. As a data type for the tag, you select your PLC data types. The system now reserves a certain number of input or output addresses starting from the start address of the higher-level tag. The number of reserved addresses depends on the length of your PLC data type.

If you call a block that requires the reserved inputs or outputs for program execution, you transfer the higher-level tag as a block parameter.

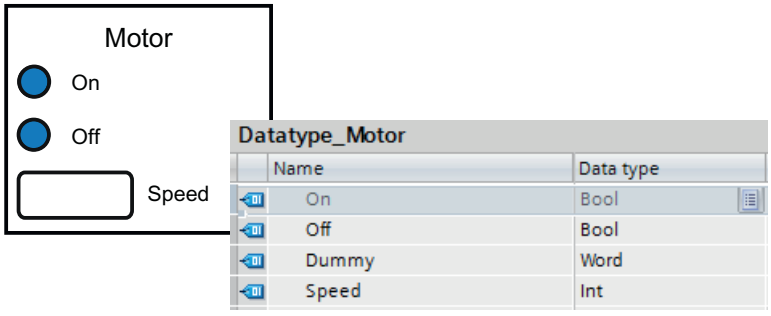
You can address the individual PLC tags like structure elements in the program code.

A detailed description of the individual handling steps can be found in the following chapters.

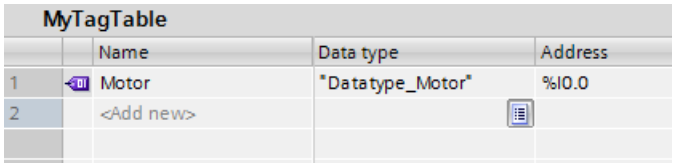
Application example

You can use structured PLC tags in order to group the inputs or outputs of a function module. The following figure shows the schematic representation of a motor: A component was created in the "Datatype_Motor" PLC data type for each of the three inputs.

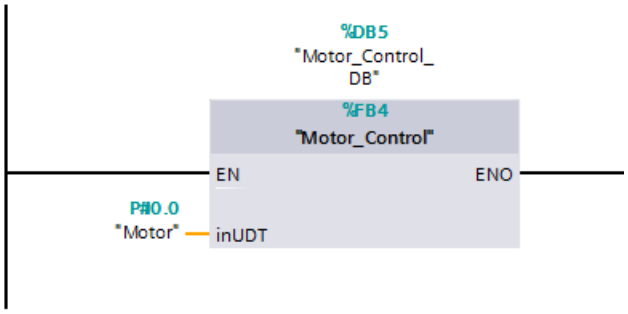
The memory areas of the declared tags must not overlap. In the example, you see that the "Speed" component has the data type "Integer" and therefore must start at a word address. For this reason, the first input word has been filled with the "Dummy" fill tag. This means that "Speed" is located on the second input word.



The following figure shows the higher-level "Motor" PLC tag that is based on the "Data type_Motor" data type. With the declaration of "Motor", the addresses IW0 and IW1 are reserved on the input module.



The following figure shows the transfer of the "Motor" PLC tag as an input parameter of the "Motor_Control" block.



You can address the individual components of the tag in the "Motor_Control" block.

Addressing	Description
"Motor"	Addressing the higher-level PLC tag.
"Motor".On	Addressing a component of a structured PLC tag.
"Motor".On:P	Addressing an I/O input or output (PI or PQ).

Rules for use of structured PLC tags

Note the following rules when creating and using structured PLC tags.

- Structured PLC tags can be used in the "Inputs" and "Outputs" operand areas.
- Structured tags are not permitted in the bit memory address area.
- Structured PLC tags cannot be addressed from HMI.

Observe the following rules when creating the PLC data type that is to serve as the basis for a PLC tag:

- The memory areas of the individual elements must not overlap.
  See also: Permissible addresses and data types of PLC tags (Page 1482)
- Do not group inputs and outputs in one PLC data type but create different PLC data types for inputs and outputs.

- Do not group inputs or outputs from different modules in a PLC data type because it is not guaranteed that the process images of the modules are updated synchronously.
- In the lower-level PLC data types, all data types are permitted except for "STRING" and "WSTRING".

See also

Creating structured PLC tags (Page 1492)

Creating structured PLC tags

Rules

Note the following rules when creating structured PLC tags:

- Use separate PLC data types for the "Inputs" and "Outputs" operand areas.
- Structured tags are not permitted in the bit memory address area.
- Do not group inputs or outputs from different modules in a PLC data type because it is not guaranteed that the process images of the modules are updated synchronously.

Procedure

To create a structured PLC tag, follow these steps:

1. Double-click the "Add new data type" command in the "PLC data types" folder in the project tree.
   A new declaration table for creating a PLC data type will be created and opened.
2. Declare all the necessary components in the PLC type. All data types except for "STRING" and "WSTRING" are permitted.
3. Select the PLC data type in the project tree and select the "Compile > Software (only changes)" command from the shortcut menu.
   The PLC data type is compiled and can then be used in the PLC tag table.
   Even when you make changes to existing PLC data types, you must recompile the program. This updates all locations of use of the PLC data type.
4. Open a PLC tag table within the same CPU.
5. Declare a new tag or select an existing tag.
6. In the "Data type" column, select the PLC data type and assign it to the PLC tag.
   The PLC tag receives the structure of the PLC data type. A suitable address is assigned automatically. Structured PLC tags always start at word addresses.
   The highest structure element is displayed without its subelements in the table.

Note

Assignment rules and default values

- For the declaration of the PLC data type, note that the memory areas of the individual tags must not overlap. For example, tags of data type "Integer" must start at a word limit. If necessary, insert "fill tags" to prevent overlaps.
  See also: Permissible addresses and data types of PLC tags (Page 1482)
- It is not possible to assign default values for the individual components. Values that you enter in the "Default value" column are not evaluated. Tags of data types "DT" and "DTL" may therefore contain invalid values.

11.1.2.7 Declaring global constants

Rules for global user constants

Permitted characters

Names of global constants may consist of the following characters:

- Letters, numbers, special characters are permitted.
- Quotation marks are not permitted.

Unique constant names

The names of global constants must be unique throughout the CPU, even if the constants are located in different tag tables of a CPU. A name that is already used for a block, a PLC tag or another constant within the CPU, cannot be used for new constant. The uniqueness check does not differentiate between use of small and capital letters.

If you enter an already assigned name another time, a sequential number is automatically appended to the second name entered. For example, if you enter the name "Motor" a second time, the second entry is changed to "Motor(1)".

Permitted data types

For constants, all data types supported by the CPU are permitted, with the exception of structured data types.

Permitted values

You can select any value from the value range of the specified data type as constant value. For information on the value ranges, refer to the "Data types" chapter.

See also: Auto-Hotspot

See also

Basics of constants (Page 1449)

Declaring global constants (Page 1495)

Rules for global system constants

Definition

System constants are global constants, unique throughout the CPU, that are required and automatically created by the system. System constants can, for example, be used to address and identify hardware objects.

Rules

System constants are assigned automatically when components are inserted in the device or network view, and entered in the default tag table ("System constants" tab). A system constant is created for each module, but also for each submodule. An integrated counter, for example, therefore receives a system constant as well. System constants consist of a symbolic name and a numeric HW identifier and cannot be changed.

Names of system constants

The names of the system constants are structured hierarchically. They consist of a maximum of four hierarchical levels, each of which is separated by a tilde "~". Based on the name, you can therefore recognize the "path" to the relevant hardware module.

Example

A system constant with the name "`Local~PROFINET_interface_1~Port_1`" designates Port 1 of the PROFINET interface 1 of the local CPU.

Auto-Hotspot

Auto-Hotspot

Instructions for address conversion (Page 3358)

Declaring global constants

Introduction

You declare constants in the "User constants" tab of a PLC tag table. During declaration you have to to enter a symbolic name, a data type and a fixed value for each constant. You can select any value from the value range of the specified data type as constant value. For information on the value ranges, refer to the "Data types" chapter.

See also: Auto-Hotspot

Procedure

To declare constants, follow these steps:

1. Open a PLC tag table.
2. Open the "User constants" tab.
   The constants table opens.
3. Enter a constant name in the "Name" column.
4. Enter the required data type in the "Data type" column. You will be supported by autocompletion during input.
5. Enter a constant value in the "Value" column; this constant value must be valid for the selected data type.
6. If you want, enter comments on the constants in the "Comments" column. The entry of a comment is optional.
7. If you want to declare additional constants, place the cursor in the next row and repeat steps 3 to 6.

Syntax check

A syntax check is performed automatically after each entry, and any errors found are displayed in red. You do not have to correct these errors immediately - you can continue editing and make any corrections later. As long as the tag declaration contains syntax errors and the constant is used in the program, you will not be able to compile the program.

11.1.2.8 Editing properties

Editing the properties of PLC tags

Properties of PLC tags

Overview

The following table provides an overview of the properties of PLC tags. The display of properties may vary depending on the CPU type.

Group	Property	Description
General	Name	A unique name within the CPU.
	Data type	Data type of the tags.
	Address	Tag address.
	Retain	Shows whether the tag is in the retentive memory area.
	Comment	Comment on the tag.
History	Date created	Time when the tag was created (cannot be changed).
	Last modified	Time when the tag was last changed (cannot be changed).
Usage	Visible in HMI	Shows whether the tag is visible by default in the HMI selection list.
	Accessible from HMI	Shows whether HMI can access this tag during runtime.

Editing the properties of PLC tags (Page 1496)

Editing the properties of PLC tags

Editing properties in a PLC tag table

To edit the properties of one or more tags, follow these steps:

1. In the project tree, double-click the PLC tag table that contains the tags.
   The PLC tag table opens.
2. Change the entries in the columns.

Editing addresses in the program editor

To edit the address of a tag in the program editor, follow these steps:

1. Select the tag name.
2. Select the "Rewire tag" command in the shortcut menu.
   The "Rewire tag" dialog will open. The dialog shows a declaration table.

3. Enter the new address in the "Address" column.
4. Click the "Change" button to confirm the input.

Editing names in the program editor

To edit the name of a tag in the program editor, follow these steps:

1. Select the tag name.
2. Select the "Rename tag" command in the shortcut menu.
   The "Rename tag" dialog opens. The dialog shows a declaration table.
3. Enter the new name in the "Name" column.
4. Click the "Change" button to confirm the input.

Effect in the program

In the case of a change of the tag's name, data type or address, each location of use of the tag is automatically updated in the program.

Properties of global constants

Overview

The following table gives an overview of the properties of constants:

Group	Property	Description
General	Name	A unique name within the table
	Data type	Data type of the constants
	Value	Value that you defined for the constants. This value must be compatible with the declared data type. See also: Auto-Hotspot
	Comment	Comment on the constants
History	Date created	Time when the constant was created (cannot be changed)
	Last modified	Time when the constant was last changed (cannot be changed)

Editing properties of global constants

Editing properties in a PLC tag table

To edit the properties of one or more constants, follow these steps:

1. In the project tree, double-click the PLC tag table that contains the constants.
   The PLC tag table opens.
2. Open the "User constants" tab.
3. Change the entries in the "Name", "Data type", "Value", or "Comments" column.

Effect in the program

In the case of a change of a constant's name, data type or value, each location of use of the constant is automatically updated in the program.

11.1.2.9 Monitoring of PLC tags

Monitoring of PLC tags

You can monitor the current data values of the tags on the CPU directly in the PLC tag table.

Requirement

An online connection to the CPU exists or is possible.

Procedure

To monitor the data values, proceed as follows:

1. Open a PLC tag table.
2. Start monitoring by clicking the "Monitor all" button.
   - If no online connection to the CPU exists, this is established.
   - Monitoring is started with the trigger setting "Permanent".
   - The additional "Monitor value" column is displayed in the table. This shows the current data values.
   - The symbol for the forcing of tags is displayed if a tag is currently being forced.
3. End the monitoring by clicking the "Monitor all" button again.

Note

Editing PLC tags during the monitoring of tags

If the editing of tags is started and the PLC tag table is edited, for example by adding new tags, the monitoring is re-started after editing is complete.

Note

You also have the option of copying PLC tags to a monitor or force table so that you can monitor, control or force them in the table.

See also

11.1.2.10 Editing PLC tag tables

Inserting a table row in the PLC tag table

Procedure

Proceed as follows to insert a row above the selected row:

1. Select the row in front of which you want to insert a new row.
2. Click the "Insert row" button on the toolbar of the table.

Result

A new row is inserted above the selected row.

See also

Editing tables (Page 347)

Copying entries in the PLC tag table

You can copy PLC tags within a table or to other tables.

Procedure

To copy a tag, follow these steps:

1. Select the tags you want to copy.
   You can also select several tags by clicking on them one after the other while holding down the <Ctrl> key or by pressing and holding down <Shift> and clicking on the first and last tag.
2. Select "Copy" in the shortcut menu.
3. Position the insertion pointer at the location where you want to insert the tags.
4. Select "Paste" in the shortcut menu.

Or

1. Select the tag.
2. Hold down the left mouse button.
3. At the same time, press <Ctrl>.
4. Drag the tag to the destination.

Result

- The tag is copied to the destination.
- If there is a name conflict, a number is automatically appended to the tag name. For example, "Tag" becomes "Tag(1)".
- All other properties of the tag remain unchanged.

Editing tables (Page 347)

Deleting entries in the PLC tag table

Procedure

Follow the steps below to delete elements:

1. Select the row with the element to be deleted. You can also select several rows by clicking on them one after the other while holding down the <Ctrl> key or by pressing and holding down <Shift> and clicking on the first and last row.
2. Select the "Delete" command in the shortcut menu.

See also

Editing tables (Page 347)

Sorting rows in the PLC tag tables

You can sort the rows in the tables alphanumerically by name, data type, or address.

Procedure

To sort the table rows, follow these steps:

1. Select the column by which you want to sort.
2. Click the column header.
   The column will be sorted in order of increasing values.
   An up arrow shows the sort sequence.
3. In order to change the sort sequence, click the arrow.
   The column will be sorted in order of decreasing values. A down arrow shows the sort sequence.
4. To restore the original sequence, click a third time on the column header.

See also

Editing tables (Page 347)

Automatically filling in cells in the PLC tag table

You can load the contents of one or several table cells into the cells below, automatically filling in the successive cells.

If you automatically fill in cells in the "Name" column, a consecutive number will be appended to each name. For example, "Motor" will become "Motor_1".

If you fill the cells in the column "Address" automatically, the addresses will be increased depending on the indicated data type.

Procedure

To automatically fill in successive cells, follow these steps:

1. Select the cells to be loaded.
2. Click the "Fill" symbol in the bottom right corner of the cell.
   The mouse pointer is transformed into a crosshair.
3. Keep the mouse button pressed and drag the mouse pointer downwards over the cells that you want to fill in automatically.
4. Release the mouse button.
   The cells are filled in automatically. If entries are already present in the cells that are to be automatically updated, a dialog appears in which you can indicate whether you want to overwrite the existing entries or whether you want to insert new rows for the new tags.

See also

Editing tables (Page 347)

Show and hide table columns

You can show or hide the columns in a table as needed.

Procedure

To show or hide table columns, follow these steps:

1. Click a column header.
2. Select the "Show/Hide" command in the shortcut menu.
   The selection of available columns is displayed.
3. To show a column, select the column's check box.
4. To hide a column, clear the column's check box.
5. To hide or show several columns, click "More" and activate or deactivate the check box of the corresponding columns in the "Show/Hide" dialog.

Editing PLC tags with external editors

Basics for importing and exporting

Introduction

You can export PLC tag tables to a standardized XLSX format for editing with external table editors. Similarly, you can import PLC tag tables created with external table editors to the TIA Portal.

Overwriting existing PLC tags and constants during import

Existing entries of the same name will be overwritten during import if they have the same name as the entries that will be imported.

Link to existing objects

References to PLC tags or constants that already exist in the project are updated automatically during import. The update is executed based on the name of the PLC tags and constants.

See also

Format of the export file (Page 1503)

Exporting PLC tags (Page 1503)

Importing PLC tags (Page 1504)

Format of the export file

Introduction

During the export of PLC tag tables, a standardized XSLX format will be generated that you can edit with external table editors.

This format is also expected during the import of tables.

Format of the export file

The sheet is always named "PLCTags". This sheet can contain the displayed columns. The sorting order of columns can vary. The sheet does not necessarily have to include all columns. During import, the following values will be identified by a <no value> entry.

The names of the column headers are also clearly defined and are always expected in English.

The following table specifies the contents expected for the individual columns:

Element	Description
Name	Name of the tags
Path	Group and name of the PLC tag table
Data Type	The notation of the data type corresponds to the notation used in the PLC tag table.
Logical Address	The address can be specified with German or international mnemonics.
Comment	Free-form comments
Hmi Visible	The value TRUE or FALSE is expected.
Hmi Accessible	The value TRUE or FALSE is expected.

Exporting PLC tags (Page 1503)

Importing PLC tags (Page 1504)

Exporting PLC tags

Requirement

A PLC tag table is open.

Procedure

To export PLC tags and constants, follow these steps:

1. In the PLC tag table, click the "Export" button.
   The "Export to Excel" dialog opens.
2. Select the path to which you want to save the export file.
3. Select whether to export tags and/or constants.
4. Click the "OK" button.

Result

The export file will be generated. Errors and warnings generated during export are indicated in the "Info" tab of the Inspector window.

See also

Basics for importing and exporting (Page 1502)

Format of the export file (Page 1503)

Importing PLC tags (Page 1504)

Importing PLC tags

Requirement

A table exists and it conforms to format specifications.

Procedure

To import a PLC tag table, follow these steps:

1. Open the "All tags" table.
2. Click the "Import" button.
   The "Import from Excel" dialog opens.
3. Select whether to import PLC tags and/or constants.
4. Select the table you want to import.
5. Click the "OK" button.

Result

The PLC tag table will be imported.

Errors and warnings generated during export are indicated in the "Info" tab of the Inspector window.

See also

Basics for importing and exporting (Page 1502)

Format of the export file (Page 1503)

Exporting PLC tags (Page 1503)

Editing individual PLC tags with external editors

To edit individual PLC tags in external editors outside the TIA portal, you can export or import these tags using copy and paste. However, you cannot copy structured tags to an editor.

Requirement

A PLC tag table and an external editor are opened.

Procedure

To export and import individual PLC tags, follow these steps:

1. Select one or more PLC tags.
2. Select "Copy" in the shortcut menu.
3. Switch to the external editor and paste the copied tags.
4. Edit the tags as required.
5. Copy the tags in the external editor.
6. Switch back to the PLC tag table.
7. Select "Paste" in the shortcut menu.

Note

You also have the option of export or importing PLC tags as mass data.

11.1.3 Creating and managing blocks

11.1.3.1 Creating blocks

Block folder

Function

You can find a "Program blocks" folder in the project tree, in which you can create and manage the following blocks:

- Organization blocks (OB)
- Function blocks (FB)
- Functions (FCs)
- Data blocks (DB)

A "System blocks" subfolder containing another subfolder, "Program resources", is also created in the "Program blocks" folder the first time you drag an instruction to your program which is an internal system function block. The instance data block of the internal system function block is also pasted to the "Program resources" folder. You can move or copy such instance data blocks from the "Program resources" folder to any other folder and rename or delete them. You can also move your blocks into the "Program resources" folder. Blocks in the "Program resources" folder that are not required to run the user program are removed during the next compilation. If the "Program resources" folder contains no more blocks then it is also deleted with the "System blocks" folder.

A program cycle OB is automatically generated for each device and inserted in the "Program blocks" folder.

Creating functions and function blocks (Page 1507)

Creating data blocks (Page 1508)

Creating organization blocks (Page 1506)

Using blocks from libraries (Page 1510)

Creating organization blocks

Requirement

The "Program blocks" folder in the project tree is open.

Procedure

To create an organization block, follow these steps:

1. Double-click the "Add new block" command.
   The "Add new block" dialog box opens.
2. Click the "Organization block (OB)" button.
3. Select the type of new organization block.
4. Enter a name for the new organization block.
5. Enter the properties of the new organization block.
6. To enter additional properties for the new organization block, click "Additional information".
   An area with further input fields is displayed.
7. Enter all the properties you require.
8. Activate the "Add new and open" check box if the organization block does not open as soon as it is created.
9. Confirm your entries with "OK".

Result

The new organization block is created. You can find the organization block in the project tree in the "Program blocks" folder. You can assign additional parameters to some organization blocks in the inspector window or device view after they have been created. The organization block description will state whether the newly created organization block has additional parameters.

Entering a block comment (Page 1516)

Creating functions and function blocks

Requirement

The "Program blocks" folder in the project tree is open.

Procedure

To create a function (FC) or a function block (FB), follow these steps:

1. Double-click the "Add new block" command.
   The "Add new block" dialog box opens.
2. Click the "Function block (FB)" or "Function (FC)" button.
3. Enter a name for the new block.
4. Enter the properties of the new block.
5. To enter additional properties for the new block, click "Additional information".
   An area with further input fields is displayed.
6. Enter all the properties you require.
7. Activate the "Add new and open" check box if the block does not open as soon as it is created.
8. Confirm your entries with "OK".

Result

The new block is created. You can find the block in the project tree in the "Program blocks" folder.

Entering a block comment (Page 1516)

Creating data blocks

Requirement

The "Program blocks" folder in the project tree is open.

Procedure

To create a data block, follow these steps:

1. Double-click the "Add new block" command.
   The "Add new block" dialog box opens.
2. Click the "Data block (DB)" button.
3. Select the type of the data block. You have the following options available to you:
   - To create a global data block, select the list entry "Global DB".
   - To create an ARRAY data block, select the "ARRAY DB" entry in the list.
   - To create an instance data block, select the function block to which you want to assign the instance data block from the list. The list contains only the function blocks that were previously created for the CPU.
   - To create a data block based on a PLC data type, select the PLC data type from the list. The list contains only the PLC data types that were previously created for the CPU.
   - To create a data block based on a system data type, select the system data type from the list. The list contains only those system data types that have already been inserted to program blocks in the CPU.
4. Enter a name for the data block.
5. Enter the properties of the new data block.
6. If you have selected an ARRAY DB as the data block type, enter the ARRAY data type and the high limit for the ARRAY.
   You can change the high limit for the ARRAY at any time in the property window of the created block. The ARRAY data type cannot be changed subsequently.
7. To enter additional properties of the new data block, click "Additional information".
   An area with further input fields is displayed.
8. Enter all the properties you require.
9. Activate the "Add new and open" check box if the block does not open as soon as it is created.
10. Confirm your entry with "OK".

Result

The new data block is created. You can find the data block in the project tree in the "Program blocks" folder.

See also

Global data blocks (DB) (Page 1416)

Instance data blocks (Page 1417)

Block folder (Page 1506)

Using blocks from libraries (Page 1510)

Basics of block access (Page 1419)

System data types (Page 1955)

Using blocks from libraries

You can save blocks in the project library or in a global library, so that you can use them more than once within a user program. You can insert the blocks as master copies or as types.

See also: Library basics (Page 470)

Requirement

- The "Libraries" task card is displayed.
- No write protection is set for global libraries.

Adding blocks as master copies to the project library or to a global library

To add new blocks as master copies to the project library or to a global library, follow these steps:

1. Maximize the project library or the global library.
2. Use drag-and-drop to move the block you wish to add to the library to the "Master copies" folder or any one of the "Master copies" subfolders in the project library or a global library. Do not release the left mouse button until a small plus sign appears underneath the mouse pointer.

Or:

1. Copy the element you want to add as master copy.
2. Maximize the project library or the global library.
3. Right-click the "Master copies" folder or any of its subfolders.
4. Select "Paste" in the shortcut menu.

Adding blocks as types to the project library or to a global library

To add new blocks as types to the project library or to a global library, follow these steps:

1. Maximize the project library or the global library.
2. Drag-and-drop the element you want to add as a type into the "Types" folder or any of its subfolders in the project library or a global library. Do not release the left mouse button until a small plus sign appears underneath the mouse pointer.

Or:

1. Copy the element you want to add as a type.
2. Maximize the project library or the global library.

3. Right-click the "Types" folder or any of its subfolders.
4. Select "Paste" in the shortcut menu.

Using blocks of the project library or a global library

To use a block from the project library or a global library in your project, follow these steps:

1. Maximize the project library or the global library so that you can see the block you wish to use.
2. Use a drag-and-drop operation to move the block to the CPU block folder. If the selected insertion points is not allowed, the mouse pointer will appear as a circle with a slash.

Note

If you derive an instance from a type in a global library, the type is also inserted into the project library. The instance is then only linked to the type in the project library.

See also

Using libraries (Page 470)

Copying and pasting blocks

Basics of copying and pasting blocks

Function

You can also create new blocks by copying existing blocks and pasting the copy. Note the following principles when copying to CPUs of the same device family:

- You can copy organization blocks (OBs), functions (FCs), function blocks (FBs), and global data blocks (DBs) without restriction.
- You can copy instance data blocks only for the same function block, since the assignment to the function block cannot be changed afterwards. However, the assignment is canceled if you copy the instance data block to a different CPU. If a function block with the same name exists there, the instance data block will be assigned to this function block. If you copy the instance data block together with the function block into the other CPU, the instance data block is assigned to the copy of the function block.

The various device families sometimes support different blocks, especially in the case of organization blocks. However, function blocks and functions can also be programmed on the

various devices with different access types. Therefore, not all blocks are supported on all devices. Note the following principles when copying to a different device family:

- Copying to an S7-1200 CPU:
  - Organization blocks with "Optimized" access type can be copied to an S7-1200. If the copied OB type is supported by the S7-1200 CPU, the copied OB retains the properties of its event. You must, however, compile it again.
  - Although organization blocks with the "Standard" access type can be copied to an S7-1200, they are not supported by the CPU.
  - Function blocks (FBs), functions (FCs) and global data blocks (DBs) with "Optimized" access type can be copied to an S7-1200. However, they must be recompiled after this.
  - Although function blocks (FBs), functions (FCs) and global data blocks (DBs) with "Standard" access type can be copied to an S7-1200, they are not supported by the CPU.
  - Instance data blocks: If there is a function block in the target CPU with the name that was assigned to the instance data block in the source CPU, the instance data block is assigned to the function block in the target CPU. If you copy the instance data block together with the function block to which it was assigned in the source CPU into the target CPU, the instance data block is assigned to the copy of the function block.
- Copying to an S7-1500 CPU:
  - Organization blocks with "Optimized" access type can be copied to an S7-1500. If the copied OB type is supported by the S7-1500 CPU, the copied OB retains the properties of its event. You must, however, compile it again. OB types that are not supported receive a no parking symbol.
  - Organization blocks with "Standard" access type can be copied to an S7-1500. If the OB derives from an S7-300/400 CPU, it receives the standard event of the corresponding OB type. If the OB derives from an S7-1200/1500 CPU, it receives the properties of its event. However, it must be compiled again.
  - Function blocks (FBs), functions (FCs) and global data blocks (DBs) with "Optimized" access type can be copied to an S7-1500. However, they must be recompiled after this.
  - Although function blocks (FBs), functions (FCs) and global data blocks (DBs) with "Standard" access type can be copied to an S7-1500, they are not supported by the CPU.
  - Instance data blocks: If there is a function block in the target CPU with the name that was assigned to the instance data block in the source CPU, the instance data block is assigned to the function block in the target CPU. If you copy the instance data block together with the function block to which it was assigned in the source CPU into the target CPU, the instance data block is assigned to the copy of the function block.
- Copying to S7-300/400 CPUs:
  - Organization blocks can be copied as required between S7-300 and S7-400.
  - Although organization blocks from S7-1200/1500 CPUs can be copied to S7-300/400 CPUs, they are not supported by the target CPU.
  - Function blocks (FBs), functions (FCs) and global data blocks (DBs) can be copied as required between S7-300 and S7-400.

- Although function blocks (FBs), functions (FCs) and global data blocks (DBs) can be copied from S7-1200/1500 CPUs to S7-300/400 CPUs, they are not supported by the target CPU.
- Instance data blocks: If there is a function block in the target CPU with the name that was assigned to the instance data block in the source CPU, the instance data block is assigned to the function block in the target CPU. If you copy the instance data block together with the function block to which it was assigned in the source CPU into the target CPU, the instance data block is assigned to the copy of the function block.

In the project tree, blocks that are not supported are indicated by the no parking symbol. Blocks with a no parking symbol cannot be edited, but only used again as copy source.

Note

When blocks are copied between different device families, it is possible that the copied block needs to be recompiled. This applies also to the coping of blocks between CPUs and software controllers. If the block has know-how protection, re-compilation is only possible with the correct password.

Copying data

With paste, all the block data is copied and forwarded to the copy. This data includes:

- Block interface tags
- All networks
- Comments in all existing compilations
- Messages defined in the block
- The entire program code of the copied block including the call instructions contained in the block.
  However, called blocks and their associated instance data blocks are not copied.

Avoiding name conflicts during pasting

When pasting copied blocks with identical names to already existing blocks, the following mechanisms are used to avoid name conflicts:

- Pasting the copied block into the same CPU:
  The copy of the block gets a name that is extended by a number. For example, if block "A" is copied, a possible name for the copy is "A_1". Consecutive numbering is not used, but rather the smallest free number. The copy of block "A" can also get the name "A_25", if no lower number is available.
- Pasting the copied block into another CPU:
  A dialog box opens in which you can select whether the block with the same name will be replaced or the copied block will be pasted with a duplicate designation (Name_Number).

Note

Number conflicts

Number conflicts may occur, if the pasted block has the same block number as an existing block. The block number is not automatically changed during pasting. This double number may have an effect on block calls. When you copy blocks you should therefore check the block number carefully and correct duplicate block numbers manually or using the block properties. Duplicate block numbers lead to a compilation error.

Copying blocks (Page 1514)

Pasting blocks (Page 1514)

Copying blocks

Requirement

The "Program blocks" folder is opened in the project tree.

Procedure

To copy a block, follow these steps:

1. Right-click the block that you want to copy.
2. Select "Copy" in the shortcut menu.

Result

A copy of the block is now on the clipboard and can be pasted either into the same CPU or into another one.

See also

Basics of copying and pasting blocks (Page 1511)

Pasting blocks (Page 1514)

Pasting blocks

Requirement

You have copied a block.

Procedure

To paste a copied block and its data into a CPU, follow these steps:

1. In the project tree, open the folder structure for the CPU into which you want to paste the copied block.

   Note

   Please note that you can only paste the copied block into a CPU which supports the block programming language and type.

2. Right-click on the "Program blocks" folder.
3. Select "Paste" in the shortcut menu.
   - If you are pasting the block into the same CPU as the original block, "_<consecutive number>" will be appended to the name of the copy.
   - If you are pasting the block into a different CPU where a block of the same name already exists, the "Paste" dialog box opens. Select the required option and confirm with "OK".

Basics of copying and pasting blocks (Page 1511)

Copying blocks (Page 1514)

Entering a block title

The block title is the title of the block. It is not the same thing as the block name, which was assigned when the block was created. The length of the block title is restricted to one row. You can enter the block title for open and closed blocks.

Requirement

A code block is available.

Enter block title for open block

To insert the block title in an open block, follow these steps:

1. Click on the title bar of the block in the program editor.
2. Enter the block title.

Enter block title for closed blocks

To insert the block title in a closed block, follow these steps:

1. Right-click the block in the project tree.
2. Select the "Properties" command in the shortcut menu.
   The dialog with the properties of the block opens.

3. Select the entry "Information" in the area navigation.
4. Enter the block title in the "Title" input field.
5. Confirm your entry with "OK".

Creating organization blocks (Page 1506)

Creating functions and function blocks (Page 1507)

Entering a block comment (Page 1516)

Entering a block comment

You can use the block comment to document the entire code block. For example, you can indicate the purpose of the block or draw attention to special characteristics. You can enter the block comment for open and closed blocks.

Requirement

A code block is available.

Enter block comment for open blocks

To insert a block comment in an open block, proceed as follows:

1. Click the small arrow in front of the block title.
   The right arrow becomes a down arrow, and the comment area is displayed.
2. Click "Comment" in the comment area.
   The "Comment" text passage is selected.
3. Enter the block comment.

Enter block comments for closed blocks

To insert the block comment in a closed block, follow these steps:

1. Right-click the block in the project tree.
2. Select the "Properties" command in the shortcut menu.
   The dialog with the properties of the block opens.
3. Select the entry "Information" in the area navigation.
4. Enter the block comment in the "Comment" input field.
5. Confirm your entry with "OK".

11.1.3.2 Specifying block properties

Basics of block properties

Block properties

Each block has certain properties, which you can display and edit. These properties are used amongst other things to:

- Identify the block
- Display the memory requirements and the compilation status of the block
- Display the time stamp
- Display the reference information
- Specify the access protection

Setting the mnemonics (Page 1539)

Overview of block properties

Overview

The properties of the blocks are block and CPU-specific. Not all properties are therefore available for all blocks or in all CPU families. The following table gives an overview of block properties:

Group	Property	Description
General	Name	Unique block name within the station
	Constant name	Name of the constant pasted for the OB in the PLC tag table
	Type	Block type (cannot be changed)
	Number	Block number
	Event class	Event class of an OB (cannot be changed)
	Language	Programming language of the block
	Language in networks	Language used to program conditions in GRAPH blocks.
	Version	Version of the GRAPH block
	Process image partition number	Display of the process image partitions that are assigned to the organization block (cannot be changed)
	ARRAY data type	Data type of an ARRAY data block (cannot be changed)
	ARRAY limit	High limit of an ARRAY data block The "Move operations" section of the "Instructions" task card offers options for addressing of ARRAY data blocks.
Information	Title	Block title
	Comment	Block comment
	Version	Version number of the block
	Family	Block family name
	Author	Name of the author, company name, department name, or other names
	User-defined ID	ID created by the user
Time stamp	Block	Times of creation and time of change of the block (cannot be changed)
	Interface	Time of creation of the block interface (cannot be changed)
	Code	Code modification time (non-editable)
	Data	Data modification time (non-editable)
	Load-relevant	Time of the last load-relevant modification (cannot be changed)
Compilation	Status	Details of the last compilation run (cannot be changed)
	Lengths	Details of the block lengths (cannot be changed)
Protection	Protection	Setting up know-how protection and copy protection for the block See also: Protecting blocks

Group	Property	Description
Attributes	Optimized block access	The tag declaration for blocks with optimized access contains only the symbolic names of the data elements. The system automatically optimizes and manages the addresses. The CPU performance increases and access errors, for example, from SIMATIC HMI, are prevented. See also: Auto-Hotspot
	IEC check	The compatibility of the operands in comparison operations and arithmetic operations are tested according to IEC 61131. You have to explicitly convert non-compatible operands. See also: Overview of data type conversion (Page 2091)
	Local error handling within block	Troubleshooting inside the block with the GET_ERROR or GET_ERR_ID instruction (cannot be changed). See also: Auto-Hotspot
	Create extended status information	Allows you to monitor all tags in an SCL block. This option does, however, increase the program memory space required and the execution times.
	Check ARRAY limits	Checks whether array indexes are within the range declared for an ARRAY during the runtime of an SCL block. The block enable output ENO is set to "0" if an array index is outside of the permitted range.
	Set ENO automatically	Checks whether errors occur in the processing of certain instructions during the runtime of an SCL block. The block enable output ENO is set to "0" if a runtime error occurs.
	Create minimized DB	Creates instance data blocks for GRAPH blocks of the S7-300 and S7-400 in minimized format. This option reduces the GRAPH FB memory space required, however you will only receive limited program status information.
	Skip steps	If the transitions before and after a step become valid simultaneously in a GRAPH block, the step will not be activated and will be skipped.
	Acknowledge supervision alarms	Any supervision error which occurs during the operation of a GRAPH block must be acknowledged before the program can continue.
	Permanent processing of all interlocks in manual operation	Permanently monitors all interlock conditions in a GRAPH block in manual mode.
	Lock operating mode selection	Prevents a GRAPH block operating mode being selected.
	Data block write-protected in the device	Indicates whether the data block is read-only in the target system, and cannot be overwritten while the program is running (for data blocks only)
	Only store in load memory	On activation the data block is stored only in the load memory, occupies no space in the work memory, and is not linked into the program. The "Move operations" section of the "Instructions" task card offers options for transferring data blocks to the work memory (for data blocks only).
	Start information	Here you specify the structure of the start information of the OB for S7-1500 CPUs: either like for S7-300 and S7-400 CPUs or optimized start information.
	Priority	Shows the priority set for organization blocks. The CPU family used and the type of the organization block determine whether you can change the priority.

Group	Property	Description
	Parameter assignment by means of registers	Enables parameter input by means of registers in an STL block of S7-1500. This feature allows you to use the "Conditional call of blocks" (CC) and "Unconditional call of blocks" (UC) instructions in the block.
	Block can be used as know-how protected library item	Shows whether or not the block in the library can be used with know-how protection.
	Enable readback	Enables you to mark individual parameters of the block for readback. The "Tag readback" function is relevant if the block is used in a CFC chart.
	Block representation	Specifies how the block is represented in a CFC chart.
Time-of-day interrupt	Time-of-day interrupt	Parameters of the time-of-day interrupt OB: active (yes or no), execution, start date and time, local time or system time
Cyclic interrupt	Cyclic interrupt	Cycle time and phase shift of the cyclic interrupt OB
Triggers	Triggers	Display of start events of the hardware interrupt OB
Isochronous mode	Isochronous mode	Parameters of the isochronous mode interrupt OB: application cycles, automatic setting (yes or no), delay time. Also indicated is the PROFINET IO system or DP master system whose IO devices or DP slaves are assigned to the isochronous mode interrupt OB.
Download without reinitialization	Reserve in volatile memory	Defines the reserve in volatile memory that can be used for interface extensions. The number of currently available bytes is displayed in parentheses. This information is updated with each compilation.
	Activate download without reinitialization for retentive tags	Enables definition of a reserve in retentive memory.
	Reserve in retentive memory	Defines the reserve in retentive memory that can be used for interface extensions. The number of currently available bytes is displayed in parentheses. This information is updated with each compilation.

Block time stamps

Introduction

Blocks receive a number of different time stamps which show you when the block was created and when it was last changed. These time stamps are also used for automatic consistency checks before compilation.

Code block time stamps

The following time stamps are generated for code blocks (OBs, FBs, FCs):

- Block: Created on, Modified on
- Interface: Modified on
- Code/data: Modified on
- Load-relevant: Modified on

A time stamp conflict is displayed during compilation if the time stamp for the block calling is older than that of the interface for the block called.

Time stamps for code blocks are updated as follows:

- Block: The time stamp for the last block modification is always the same as the time stamp either of the interface or of the code depending on which area was modified last.
- Interface: The interface time stamp is updated each time the interface is modified. Even if you manually undo a change to the interface, for example change the name back, that is also a change which updates the time stamp. However, if you undo the change using the "Undo" function, the time stamp will be reset to the value it had before the undone change.
- Code/data: The code time stamp is updated each time the block code is changed. Even if you manually undo a change to the code, for example remove an instruction, that is also a change which will update the time stamp. However, if you undo the change using the "Undo" function, the time stamp will be reset to the value it had before the undone change.
- Load-relevant: The time stamp for "Load-relevant" is updated each time a code block is changed. These changes can affect the code, the data or the interface.

Global data block time stamps

The following time stamps are generated for global data blocks:

- Block: Created on, Modified on
- Interface: Modified on
- Data: Modified on
- Load-relevant: Modified on

Time stamp conflict is reported during compilation of a global data block based on a PLC data type if the time stamp of the global data block is older than the time stamp of the PLC data type used.

The time stamps for global data blocks are updated as follows:

- Block: The time stamp for the last change to a global data block is always the same as the time stamp for the interface and the data.
- Interface and data: The interface time stamps and the data are updated each time the global data block is changed. Even if you manually undo a change, for example remove a tag, that is also a change which will update the time stamp. However, if you undo the change using the "Undo" function, the time stamps will be reset to the value they had before the undone change.
- Load-relevant: The time stamp for "Load-relevant" is updated each time a global data block is changed. These changes can affect the data or the interface.

Instance data block time stamps

The following time stamps are generated for instance data blocks:

- Block: Created on, Modified on
- Interface: Modified on
- Data: Modified on
- Load-relevant: Modified on

A time stamp conflict will be reported during compilation of an instance data block if the interface time stamps of the instance data block are not identical to those of the function block.

The time stamps for instance data blocks are updated as follows:

- Block: The time stamp for the last change to an instance data block is always the same as the time stamp for the interface and the data.
- Interface and data: The interface time stamps and the data are updated each time the instance data block is changed. Even if you manually undo a change, for example cancel the tag retain setting, that is also a change which will update the time stamps. However, if you undo the change using the "Undo" function, the time stamps will be reset to the value they had before the undone change.
- Load-relevant: The time stamp for "Load-relevant" is updated each time an instance data block is changed. These changes can affect the data or the interface.

PLC data type time stamps

The following time stamps are generated for PLC data types:

- Block: Created on, Modified on
- Interface: Modified on
- Load-relevant: Modified on

The time stamps for PLC data types are updated as follows:

- Block: The time stamp for the last change to a PLC data type is always the same as the interface time stamp.
- Interface: The interface time stamp is updated each time the PLC data type is changed. Even if you manually undo a change, for example delete the content of a PLC data type, that is also a change which will update the time stamp. However, if you undo the change using the "Undo" function, the time stamp will be reset to the value it had before the undone change.
- Load-relevant: The time stamp for "Load-relevant" is updated each time a PLC data type is changed.

Basic information on compiling blocks (Page 1782)

Displaying and editing block properties

The properties of the blocks are block and CPU-specific. Not all properties are therefore available for all blocks or in all CPU families. Properties that can only be displayed are write-protected.

Displaying and editing properties of a closed block

To display and edit the properties of a closed block, follow these steps:

1. Open the "Program blocks" folder in the project tree.
2. Right-click the block whose properties you want to display or edit.
3. Select the "Properties" command in the shortcut menu.
   The properties dialog box of the block opens.
4. In the area navigation, click a group whose properties you want to display or edit.
5. Change the relevant property.
6. Confirm your entries with "OK".

Displaying and editing properties of an open block

To display or edit the properties of an open block, follow these steps:

1. Select the "Inspector window" check box in the "View" menu.
   The Inspector window opens.
2. Click the "Properties" tab.
   The properties of the block are shown in the "Properties" tab of the Inspector window.
3. In the area navigation, click a group whose properties you want to display or edit.
4. Change the relevant property.

Result

The properties of the block will be changed. The changes are not saved until the project is saved.

11.1.3.3 Managing blocks

Opening blocks

You can open both the blocks in the project (offline blocks) and also the blocks in the device (online blocks).

To open an offline block, you have the following options:

- Open offline block directly
  You can open a block directly if the corresponding block folder is open in the project tree or in the overview window.
- Find and open offline block
  You can look for blocks within a project, a device or the "Program blocks" folder and then open them.

Note the following special features when opening online blocks:

- You cannot edit online blocks.
- It is possible that another user can carry out a loading process on the selected CPU through joint parallel working on a CPU. Consequently, it can happen that the online block that you have open is deleted by the loading process if the block only exists in the device. In this case, the online block is closed and a message is displayed in the Inspector window.

Open offline block directly

To open an offline block directly, you have the following options:

1. Open the folder with the block you wish to open in the project tree or in the overview window.
2. Double-click on the block you wish to open.
   The block will open in the program editor.

Find and open offline block

To find an offline block and then open it, follow these steps:

1. Right-click on the project, a device, the "Program blocks" folder or a lower-level folder of "Program blocks" in the project tree.
2. In the shortcut menu select the "Open block/PLC data type" command or press the <F7> key.
   The "Open block/PLC data type" dialog box opens.
3. Enter the name, the address or the type of block you are looking for.
   The block list is filtered further with each letter entered. The block list is closed if there is no block that matches the input. You can show the complete block list at any time by clicking the button to the right of the text box. Keep in mind that there is no filtering in this case. If you want to filter for your inputs again, click the button once again.
4. In the block list, click the block you wish to open.
   The block is opened in the program editor and displayed as selection in the project tree.

Open online block

To open an online block directly, you have the following options:

1. Open the "Online access" folder in the project tree.
2. Click on the arrow symbol to the left of the interface to show all the objects that are arranged below the interface.
3. Double-click on the "Update accessible devices" command below the interface.
   All devices that are accessible via this interface are displayed.
4. Open the folder of the device that contains the block you want to open.
5. Open the "Program blocks" folder.
   All the device's blocks are displayed.
6. Double-click on the block you wish to open.
   The block will open in the program editor.

Deleting blocks online (Page 1527)

Opening know-how protected blocks (Page 1806)

Saving blocks

Blocks are always saved together with the project. Faulty blocks can also be saved. This allows the error to be resolved at a convenient time.

Procedure

To save a block, follow these steps:

1. Select the "Save" or "Save as" command in the "Project" menu.
   See also: Saving projects (Page 383)

See also

Opening blocks (Page 1524)

Deleting blocks offline (Page 1527)
Deleting blocks online (Page 1527)

Renaming blocks

Requirement

The "Program blocks" folder is opened in the project tree.

Procedure

To change the name of a block, follow these steps:

1. Right-click the block that you want to rename.
2. Select the "Rename" command in the shortcut menu.
   The block name in the project tree changes to an input field.
3. Input the new name for the block.
4. Confirm your entry with the Enter key.

Result

The name of the block is now changed at all points of use in the program.

Deleting blocks online (Page 1527)

Deleting blocks offline

Requirement

The "Program blocks" folder opens in the project tree.

Procedure

To delete a block that exists offline, proceed as follows:

1. In the project tree in the "Program blocks" folder, right-click on the block that you want to delete.
2. Select the "Delete" command in the shortcut menu.
3. Confirm the safety prompt with "Yes".
   The block is deleted offline from the project.

Note

If you are deleting organization blocks, note that events may be assigned to these blocks. If you delete such organization block the program cannot respond to parameterized events.

Deleting CPU data blocks

You may delete CPU data blocks both in offline and online mode.

Deleting CPU data blocks in offline mode

Proceed as follows to delete a CPU data block from the offline project:

1. Right-click the CPU data blocks that you want to delete in the project navigation, "Program blocks" folder.
2. Select the "Delete" command from the shortcut menu.
3. Confirm the safety prompt with "Yes".
   The CPU data block is deleted from the offline project.

Deleting CPU data blocks in online mode

Proceed as follows to delete a CPU data block from the online project:

1. Establish an online connection to the device containing the CPU data block that you want to delete.
2. Right-click the CPU data block that you want to delete from the device in the project navigation, "Program blocks" folder.
3. Select the "Delete" command from the shortcut menu.
   The "Delete" dialog opens.

4. Select the "Delete from device" check box.
5. Click "Yes".
   The CPU data block is deleted from the online device.

CPU data blocks (Page 1418)

11.1.4 Programming blocks

11.1.4.1 Program editor

Overview of the program editor

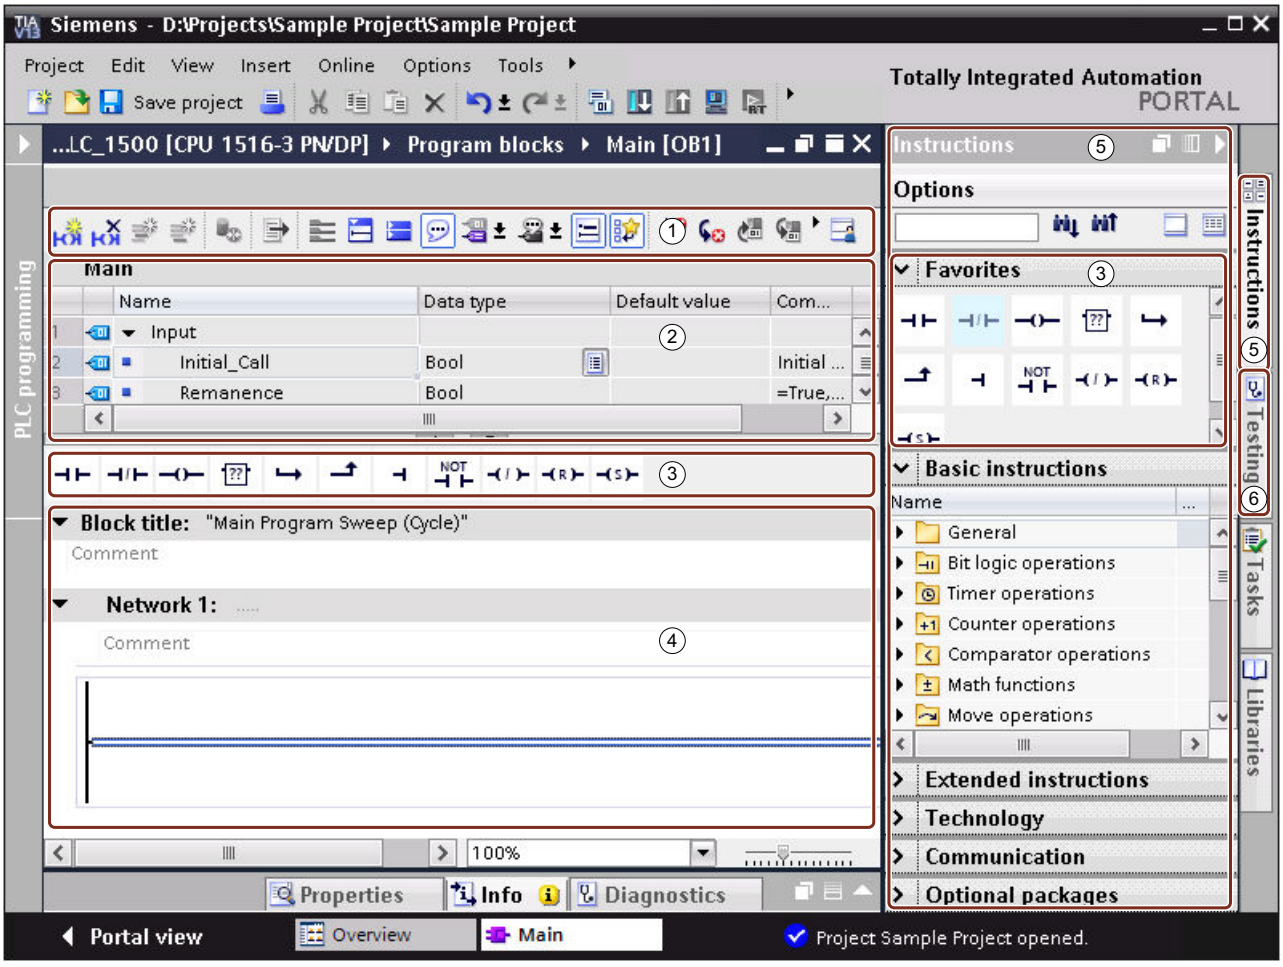
Function of the program editor

The program editor is the integrated development environment for programming functions, function blocks, and organization blocks. If offers comprehensive support for programming and troubleshooting.

The appearance and functionality of the program editor can vary depending on the CPU, programming language and block type used.

Structure of the program editor

Using LAD as an example, the following figure shows the components of the program editor:



① Toolbar
② Block interface
③ "Favorites" pane in the "Instructions" task card and favorites in the program editor
④ Programming window
⑤ "Instructions" task card
⑥ "Testing" task card

Toolbar

The toolbar allows you to access the principal functions of the program editor, such as:

- Show and hide absolute operands
- Showing and hiding favorites
- Skip to syntax errors

- Update block calls
- Show and hide program status

The functions available in the toolbar can vary depending on the programming language used.

Block interface

The block interface contains the declarations for local tags used solely within the block. The sections available depend on the block type.

Favorites

You can save frequently used instructions as favorites. These favorites are then displayed in the "Instructions" task card and the "Favorites" pane. You can also display favorites in the program editor using the program editor toolbar. This allows you to access your favorites even when the "Instructions" task card is not visible.

Programming window

The programming window is the work area of the program editor. You can enter the program code in this window. The appearance and functionality of the program window can vary depending on the programming language used.

"Instructions" task card

The "Instructions" task card offers you easy access to all instructions available for creating your program. The instructions are broken down by area into a number of different palettes. You can search the palettes for specific instructions.
See also: Find instructions (Page 1540)

You can show additional information on the instructions via the "Show column headers and additional columns" button in the task card toolbar. You can modify the arrangement of columns by clicking a column header and moving the column to the new position by means of drag-and-drop.

If an instruction profile is active, the offered instructions may vary.
See also: Using instruction profiles

"Testing" task card

You can set settings in the "Testing" task card for troubleshooting using the program status. The functions of the "Testing" task card are only available in online mode. It contains the following panes, which are displayed depending on the selected CPU and the configured programming language of the block:

- CPU operator panel
  The CPU operator panel allows you to switch the CPU operating mode.
- Breakpoints
  You can test blocks you created in the textual programming languages STL and SCL in single step mode. To do this, set breakpoints in the program code.
  In the "Breakpoints" pane, you can find all breakpoints that you have set and you can activate, delete, navigate to, or set the call environment for the individual breakpoints.
- PLC register
  This pane allows you to read off the values for the PLC registers and the accumulators.
- Sequence control
  In this pane you can set the operating mode for testing sequencers for GRAPH blocks.
- Test settings
  This pane allows you to specify the test settings for the GRAPH block.
- Call environment
  This pane allows you to specify the call environment for the block.
- Call hierarchy
  In this pane, you can trace the call hierarchy of the blocks. You only see the call hierarchy during block monitoring.

Using the keyboard in the program editor

Navigating in the editor

Function	Shortcut key
Open "Instructions" task card	<Ctrl+Shift+C>
Open "Testing" task card	<Ctrl+Shift+O>
Add new block	<Ctrl+N>
Expand all networks	<Alt+F11>
Collapse all networks	<Alt+F12>
Navigate to the next point of use of the selected block or operand	<Ctrl+Shift+F>
Navigate to the previous point of use of the selected block or operand	<Ctrl+Shift+G>

Function	Shortcut key
Navigate to the next read/write access	<Alt+F8>
Navigate to the previous read/write access	<Alt+F9>

Navigating in the program code (LAD/FBD)

Function	Selected object	Shortcut key
Navigating between objects in the network	Object in the network	Arrow keys
Navigate to the first element of the network	Object in the network	<Home>
Navigate to the last element of the network	Object in the network	<End>
Navigate to the next element of the network	Object in the network	<Tab>
Navigate to the previous element of the network	Object in the network	<Shift+Tab>
Insert network	Any	<Ctrl+R>

Navigating in the program code (STL/SCL)

Function	Position of the cursor	Shortcut key
Navigating in the program code	Line	Arrow keys
One word to the right/left	Line	<Ctrl+arrow keys>
Cursor to start of line	Line	<Home>
Cursor to end of line	Line	<End>
Cursor to start of code section	Line	<Ctrl+Home>
Cursor to end of code section	Line	<Ctrl+End>
To the next network (STL only)	Network title	<Down arrow>
To the next network (STL only)	Line	<Tab> Repeat the shortcut keys until the insertion point is in the next network.
To the previous network (STL only)	Network title	<Up arrow>
To the previous network (STL only)	Line	<Shift+Tab> Repeat the shortcut keys until the insertion point is in the previous network.
Insert network	Any	<Ctrl+R>

Inserting instructions (LAD)

Function	Selected object	Shortcut key
Insert normally open contact	Rung	<Shift+F2>
Insert normally closed contact	Rung	<Shift+F3>
Insert empty box	Rung	<Shift+F5>
Insert assignment	Rung	<Shift+F7>
"Insert "Open branch"	Rung	<Shift+F8>
"Insert "Close branch"	Rung	<Shift+F9>

Inserting instructions (FBD)

Function	Selected object	Shortcut key
Insert assignment	Network, input or output	<Shift+F7>
Insert empty box	Network	<Shift+F5>
"Insert "Open branch"	Connection line between two boxes	<Shift+F8>
Invert RLO	Network, input or output	<Ctrl+Shift+4>
Insert input	Network, input or output	<Ctrl+Shift+3>

Entering operands (LAD/FBD/GRAPH)

Function	Selected object	Shortcut key
Activate the input field for the first operand of the instruction	Instruction	<Return> Or <Any letters/numbers> An empty input field opens on <Return>, any letters or numbers will be entered in the input field.
Activate input field for the operand	Operand	<F2>
Delete operand	Operand	<Del>
Define tag	Operand	<Ctrl+Shift+I>
Rewire tag	Operand	<Ctrl+Shift+P>
Rename tag	Operand	<Ctrl+Shift+T>
Entering operands	Input field for operands	<Any letters/numbers>
Confirm entry of the operand	Input field for operands	<Return>
Open autocompletion	Input field for operands	<Ctrl+I>
Discard current change	Input field for operands	<Esc> The input field is deactivated and the previous contents restored.

Process instructions (STL/SCL)

Function	Selected object	Shortcut key
Indent line (SCL only)	Line	<Tab> or <Ctrl+R>
Outdent line (SCL only)	Line	<Shift+Tab> or <Ctrl+Shift+R>

Function	Selected object	Shortcut key
Automatically formatting selected text (SCL only)		<Ctrl+Shift+W>
Open "Call options" dialog	Cursor after block call	<Return>
Define tag	Operand	<Ctrl+Shift+I>
Rewire tag	Operand	<CtrlShift+P>
Rename tag	Operand	<Ctrl+Shift+T>
Expand/collapse parameter list (SCL only)	Operand	<Ctrl+Shift+Space>
Expand/collapse code section	Insertion mark within the code section	<Ctrl+Shift+Num+> <Ctrl+Shift+Num->
Expand/collapse all code sections	Any	<Ctrl+Shift+Num*> <Ctrl+Shift+Num/>
Open autocompletion	Any	<Ctrl+I> or <Ctrl+Spacebar>
Set/delete bookmarks		<Ctrl+Shift+M>
To the next bookmark		<Ctrl+Shift+6>
To the previous bookmark		<Ctrl+Shift+5>
Comment out selection	Line	<Ctrl+Shift+Y>
Remove comment	Line	<Ctrl+Shift+U>

Programming window of GRAPH

Function	Area	Shortcut key
Page Up/Down	Navigation view, single step view, sequence view, permanent instructions	<Page Up>/ <Page Down>
Navigate in the navigation view	Navigation view	<Up arrow> <Down arrow>
Expand/collapse object	Navigation view	<+> or <Right arrow> <-> or <Left arrow>
Switch between single step view and sequence view when a step or a transition is selected	Navigation view	<Return>
Switch between navigation view and work area	Navigation view, single step view, sequence view, permanent instructions	<ALT+F6>
Go to first element in a network	Single step view	<Home>
Go to last element in a network	Single step view	<End>
Switch to interlock	Single step view	<Ctrl+Home>
Switch to transition	Single step view	<Ctrl+End>
Navigate in the structure	Sequence view	Arrow keys
Go to first step	Sequence view	<Home> or <Ctrl+Home>
Go to last step	Sequence view	<End> or <Ctrl+End>
Open branch	Sequence view	<Shift+F8>

Function	Area	Shortcut key
Close branch	Sequence view	<Shift+F9>
Insert sequence end	Sequence view	<Shift+F7>
Insert jump	Sequence view	<Shift+F12>
Insert step and transition	Sequence view	<Shift+F5>
Delete element	Sequence view	<Del>
Go to first editable element	Permanent instructions	<Home>
Go to next editable element	Permanent instructions	<Tab>
Go to last editable element	Permanent instructions	<End>
Go to previous editable element	Permanent instructions	<Shift+Tab>
Jump to the start of the "Action" cell	Actions	<Home>
Jump to the end of the "Action" cell	Actions	<End>
Insert new action	Actions	<Return>

Monitor program

Function	Shortcut key
Set/remove breakpoint (STL, SCL)	<Ctrl+Shift+F9>
Step over breakpoint (STL, SCL)	<Ctrl+Shift+F10>
Jump to lower-level block (STL, SCL)	<Ctrl+Shift+F11>
Return to calling block (STL, SCL)	<Ctrl+Shift+F12>
Run program up to marker (cursor position) (STL, SCL)	<Ctrl+F3>
Display program status (SCL, STL)	<Ctrl+T>
Enable all breakpoints (STL, SCL)	<Ctrl+Shift+F2>
Disable all breakpoints (STL, SCL)	<Ctrl+Shift+F3>
Modify to 0 (LAD, FBD)	<Ctrl+Shift+9>
Modify to 1 (LAD, FBD)	<Ctrl+Shift+1>
Modify operand (LAD, FBD)	<Ctrl+Shift+2>

Text editing (Page 346)

Enlarging the programming window

Introduction

The programming window is relatively small when all components of the application are shown. If the program code is large, you may find you have to rearrange the work area constantly. To avoid this problem, you can hide or minimize the display of the following components of the application and of the program editor:

- Project tree
- Task cards
- Block interface
- Favorites
- Comments
- Networks

Note

You can also use the "Reduce automatically" option for the task cards, project tree, and Inspector window. These windows will then be minimized automatically when you do not need them.

See also: Maximizing and minimizing the work area

Hiding and showing the project tree

The project tree allows you to access all areas of the project. You can hide the project tree while you are creating a program so you have more space for the programming window.

To show and hide the project tree, follow these steps:

1. To hide the project tree, deselect the "Project tree" check box in the "View" menu, or click on "Collapse" on the project tree title bar.
2. To show the project tree, select the "Project tree" check box in the "View" menu or click on "Extend" on the project tree title bar.

Opening and closing task cards

The task cards are located at the right-hand edge of the programming window.

To open or close the task cards, follow these steps:

1. To close the task cards, deselect the "Task card" check box in the "View" menu or click "Collapse" on the task cards title bar.
2. To open the task cards, select the "Task card" check box in the "View" menu or click "Expand" on the task cards title bar.

Hiding and showing the block interface

The block interface is shown in the upper section of the program editor. During programming you can show and hide it as required.

To show and hide the block interface, follow these steps:

1. In the lower part of the interface within the window splitter, click on the Up arrow or Down arrow.

Showing and hiding favorites

To hide or show the favorites in the program editor, follow these steps:

1. Click the "Display favorites in the editor" button in the program editor toolbar.

Showing and hiding comments

Within a block you can enter a comment for the block or for each network. These two types of comments are shown and hidden differently.

To show or hide a block comment, follow these steps:

1. Click the the triangle at the start of the line with the block title.

To show or hide network comments, follow these steps:

1. Click "Network comments on/off" on the program editor toolbar.

Note

The comments available can vary depending on the programming language used.

Opening and closing networks

Some programming languages use networks. You can open or close these networks as required.

To open or close networks, follow these steps:

1. If you want to open a network, click the right arrow in front of the network title. If you want to close a network, click the down arrow in front of the network title.

To open and close all networks, follow these steps:

1. Click "Open all networks" or "Close all networks" in the program editor toolbar.

Note

Networks are not used in every programming language.

See also

Overview of the program editor (Page 1529)

Maximizing and minimizing the work area (Page 318)

Setting the mnemonics

You can program blocks using German or international mnemonics. When you open the TIA Portal for the first time, international mnemonics is set as default. You can change the mnemonics at any time.

Procedure

To set the mnemonics, follow these steps:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. Select the "General" group in the area navigation.
3. In the "General settings" group, select the mnemonics that you want to use.
   The mnemonics is changed in all blocks.

Displaying symbolic and absolute addresses

You have the following options for displaying operands in the program editor:

- Symbolic representation
  The symbolic operands are displayed in the program. The corresponding absolute addresses are shown in tooltips if you hold the mouse pointer over the operand.
- Absolute representation
  The absolute addresses are displayed in the program. The corresponding symbolic operands are displayed in tooltips.
- Symbolic and absolute representation
  Symbolic operands and absolute addresses are displayed in program.

Requirement

The program editor is open.

Procedure

To change the representation of the operands, follow these steps:

1. Click the "Absolute/symbolic operands" button in the program editor toolbar.
   Each time you click the button, the representation and the symbol on the button change.

Or:

1. Click the small arrow next to the "Absolute/symbolic operands" button in the program editor toolbar.
   A drop-down list is displayed.
2. Select the required representation from the drop-down list.
   The symbol on the button changes.

See also

Basic information about operands (Page 1441)

Find instructions

You have the option of finding specific instructions in the "Instructions" task card and then inserting them in your program. Note the following rules when entering search terms:

- No distinction is made between upper and lower case text.
- The search function considers parts of a search term.
- You cannot use placeholders, such as "*" and "?".
- If an instruction name includes underscores, the instruction is found even if you do not enter the underscore.
- The text in the columns "Name" and "Description" are taken into consideration in the search.

Requirement

- A block is open.
- Die "Instructions" task card is open.

Procedure

To search for a specific instruction in the "Instructions" task card, follow these steps:

1. Select a starting point for the search if you want to start the search at a specific point. If you do not select a starting point, the search starts either at the top or bottom in the task card, depending on the type of search you have selected.
2. Enter a search term in the text box of the task card toolbar.
3. Click "Search down" if you want to search the task card from top to bottom.
4. Click "Search up" if you want to search the task card from bottom to top.
   The first match with the search term found is displayed as the result. If you want to continue the search, click the "Search down" or "Search up" button again. If no matches are found, you will receive a corresponding message.

Overview of the program editor (Page 1529)

Use instruction versions

Basic information on instruction versions

The instructions available to you for programming the user program are managed in system libraries. If a new version of a system library is installed by an update, the newer versions of the instructions of this system library may also be installed.

If there are several versions for an instruction, these are listed in the "Instructions" task card after the respective instruction. If the instruction versions are not shown, you can show them via the "Show column headers and additional columns" button in the toolbar of the "Instructions" task card. You can then select the versions of the instructions to be used in the program from the dropdown-list box of the "Version" column. If you do not select any versions, the most recent versions are used.

Note

Please note the following:

- You can only ever use the same version of an instruction within a device.
- If you change the version of an instruction that other instructions depend on, the versions of the dependent instructions are also changed.
- If you select a version for an instruction that can not be run on the CPU used, the instruction is shaded out. This means that you cannot use this instruction in this version with your CPU.
- The system block in the project tree displays the block version number in its properties; it does not have to match the instruction version number of the associated instruction in the task card.
- If you change the version of an instruction in the task card, you must compile the associated system block in the project tree before you update its block version number.

Changes in the versions

New versions can be main versions or secondary versions. New versions, such as 2.0 or 3.0, have more substantial changes to them. New main versions may therefore result in changes to the block interface. New secondary versions, such as 1.3 or 1.4, contain lesser changes or remedies to errors.

Using instruction versions

You can decide within a device which version of an instruction you want to use. If you select another version for an instruction, the new version is specified for all locations of use of this instruction within your program. These instructions are identified in the program by a red frame. You must then download your program to the device to use the new instruction version.

Using instruction profiles

Basics of instruction profiles

Introduction

The TIA Portal provides you with numerous instructions that you can use to program the user program. However, you may filter out specific instructions that you do not want to use. To this end you can create instruction profiles in which you can explicitly specify the instructions to be listed in the "Instructions" task card. However, although you may create several instruction profiles in a project, only one of these profiles may be active at any given time. You can exchange instruction profiles with other users by means of shared libraries.

Note

Please note the following:

- The use of instructions that are not allowed in the active profile in a block will trigger the output of a block compilation error. Such a situation may be triggered if you drag-and-drop a block from the library to your program.
- Instructions of a profile that are not supported by the currently installed products are deleted from the profile the next time it is edited. If you transfer this profile to an engineering system in which these instructions are supported by the installed products, the instructions are again present in the profile but they are disabled. You can enable these instructions as required at any time.
- If you want to make changes to the active profile, you must recompile the blocks in the project. This is also necessary when you disable or delete the active profile or when you enable a profile.

See also

Creating new instruction profiles (Page 1542)

Opening and editing instruction profiles (Page 1544)

Activating and deactivating instruction profiles (Page 1545)

Deleting instruction profiles (Page 1546)

Creating new instruction profiles

Requirement

The "Common data > Instruction profiles" folder is open in the project navigation.

Procedure

Proceed as follows to create a new instruction profile:

1. Double-click the "Add new profile" command.
   The Instruction Profile Editor opens and displays the new instruction profile. All instructions are activated for the new instruction profile.
2. Edit the new instruction profile to suit your requirements.

If necessary, you can rename the new instruction profile. To do this, follow these steps:

1. Right-click on the new instruction profile.
2. Select the "Rename" command in the shortcut menu.
3. Enter a name for the new instruction profile.

Note

The first instruction profile that you create will be used as active profile. In this case, compile all blocks in the project. If other instruction profiles are already available you must explicitly activate the new one in order to use it as active profile. You can identify the active profile by its icon in the project navigation.

See also

Basics of instruction profiles (Page 1542)

Opening and editing instruction profiles (Page 1544)

Activating and deactivating instruction profiles (Page 1545)

Deleting instruction profiles (Page 1546)

Opening and editing instruction profiles

Once you have opened an instruction profile, you can edit it as follows:

- Activating and deactivating instructions
  You can explicitly specify the instructions to be allowed in the instruction profile.

  Note

  Note that dependencies exist between some instructions. As a result, it is possible that several instructions may be activated or deactivated by an action. The check box icon indicates the folders in which instructions are deactivated.

- Activating and deactivating instruction versions
  Certain instructions are available with different versions. You can explicitly specify the instruction versions to be allowed in the instruction profile.
- Renumbering blocks
  An instruction representing an internal function block (FB) or function (FC) in the system is assigned a specific block number by the system. You can replace this block number with your own block number. Within a version, there are several implementations for certain instructions. The block numbers in such instructions can only be changed for the specific implementation.

  Note

  If an instruction from the instruction profile is used in the program and the specified block number is already in use by a different block, the specified block number of the instruction will be replaced by a free block number.

Requirement

The "Common data > Instruction profiles" folder is open in the project navigation.

Opening instruction profiles

Proceed as follows to open an instruction profile:

1. Double-click the instruction profile that you want to edit.
   The instruction profile opens in the Instruction Profile Editor.

Editing instruction profiles

Proceed as follows to edit an instruction profile in the Instruction Profile Editor:

1. Select the device that you want to edit from the "Device family" drop-down list box.
2. Select the programming language for which you want to edit the instruction profile from the "Language" drop-down list box.
3. Deactivate the instructions or instruction versions that you want to exclude from the instruction profile. You can deactivate a folder to deactivate all subordinate instructions.

4. Activate the instructions or instruction versions that you want to allow in the instruction profile.
5. You may assign your own block numbers.

Note

You can assign the number up to 65535 for CPUs of the S7-1200/1500 series. For CPUs of the S7300/400 series you find the restrictions of the number ranges in the respective CPU manual.

Note

A new compilation process is required for all blocks in the project when you change the active profile.

See also

Basics of instruction profiles (Page 1542)

Activating and deactivating instruction profiles (Page 1545)

Deleting instruction profiles (Page 1546)

Use instruction versions (Page 1541)

Activating and deactivating instruction profiles

You first need to activate an instruction profile in order to include filtering of its instructions. You can always deactivate the instruction profile to reset the instructions task card to the default scope of instructions.

Note

A new compilation process is required for all blocks in the project.

Requirement

The "Common data > Instruction profiles" folder is open in the project navigation.

Activating instruction profiles

Proceed as follows to activate an instruction profile:

1. Right-click on the instruction profile that you want to activate.
2. Select the "Activate profile" command from the shortcut menu.
   The selected instruction profile is now active. Instructions can now only be used in accordance with the settings of this profile.

Deactivating instruction profiles

Proceed as follows to deactivate the instruction profile:

1. Right-click on the instruction profile that you want to deactivate.
2. Select the "Deactivate profile" command from the shortcut menu.
   No instruction profile is active and the "Instructions" task card once again shows all instructions that are available for use.

Basics of instruction profiles (Page 1542)

Creating new instruction profiles (Page 1542)

Opening and editing instruction profiles (Page 1544)

Deleting instruction profiles (Page 1546)

Deleting instruction profiles

Requirement

The "Common data > Instruction profiles" folder is open in the project tree.

Procedure

Proceed as follows to delete an instruction profile:

1. Right-click on the instruction profile that you want to delete.
2. Select the "Delete" command in the shortcut menu.

Note

A new compilation process is required for all blocks in the project when you delete the active profile.

Result

The selected instruction profile is deleted. If you deleted the active instruction profile, no more active profiles are available and the "Instructions" task card once again shows all instructions that are available for use.

Using autocompletion

Basics of autocompletion

Function

You can use autocompletion in the program window of the program editor as an easy way to access available tags or instructions during programming. Autocompletion means a context-specific list appears in a dialog from which you can select the tags or instructions you need.

See also

Using autocompletion in graphic programming languages (Page 1547)

Using autocompletion in textual programming languages (Page 1548)

Using autocompletion in graphic programming languages

Inserting tags using autocompletion

To insert tags in graphic programming languages using autocompletion, follow these steps:

1. Select an operand of the instruction to which you wish to assign a tag.
   The input field for the operand opens. The autocompletion button will appear beside the input field.
2. Either click the autocompletion button or use the shortcut <Ctrl+l>.
   Autocompletion opens. It contains only the local and global tags, data blocks and multiple instances which are admissible for the operand in the given context. You can exit autocompletion at any time by pressing <Esc>.

3. Select the required tag from the list. If necessary, you can also filter the list:
   - For example, enter the first few letters of the name of the tag or instruction you wish to insert. Autocompletion will be filtered further with each letter entered. If there is no tag or instruction starting with the letters entered, autocompletion will remain at the last match.
   - Enter # to access the local tags from the block interface.
   - Enter " to access the global tags.
   - Enter % to access absolute addresses.

   If the tag is a structured tag, a data block or a multiple instance, then an arrow is displayed at the end of the row. Click on the arrow to display the lower-level elements. You can navigate to the very last level in this way. If a structure is allowed as a data type for the operand, you can choose "None" from the list. This assigns the entire structure to the operand as a tag. Use the <Backspace> key to return to the previous level.
4. Press the <Return> key to apply the tag.

See also

Basics of autocompletion (Page 1547)

Using autocompletion in textual programming languages (Page 1548)

Using autocompletion in textual programming languages

Inserting tags and instructions using autocompletion

To insert tags and instructions in textual programming languages using autocompletion, follow these steps:

1. Enter the first few letters of the name of the tag or instruction you wish to insert. If necessary, you can directly filter the kind of tags:
   - Enter # to access the local tags from the block interface.
   - Enter " to access the global tags.
   - Enter % to access absolute addresses.

   Autocompletion opens. It contains only the local and global tags, data blocks, multiple instances and instructions which are admissible at the current position. You can exit autocompletion at any time by pressing <Esc>.
2. Enter more letters of the name of the tag or instruction you wish to insert. You can use <Enter> or <Tab> to apply the tag or instruction and close autocompletion. Autocompletion will be filtered further with each letter entered. If there is no tag or instruction starting with the letters entered, autocompletion only contains the previous matches.

3. Select the tag or instruction required from the list.
   If a tag is a structured tag, a data block or a multiple instance, first select the tag, the data block or multiple instance from the autocompletion and apply the selection with <Enter>.
   To select the additional components of the structure, data block, or multiple instance, enter a period. Autocompletion then reopens and you can select the next component.
4. Press the <Return> key to apply the tag.

General settings for the PLC programming

Overview of the general settings

Overview

The following table shows the general settings that you can make:

Group	Setting	Description
View	With comments	Network comments are shown.
	Tag information	Additional information for the tags used is displayed in the program editor. When you select the option "Tag information with hierarchy", the comments of the higher structure levels are also displayed for structured tags.
Compilation	Delete actual parameters on interface update	Actual parameters are deleted if the associated formal parameters were deleted in the called block, and you run the "Update block call" function or compile the block.
Default settings for new blocks	IEC check	The compatibility of operands in comparison operations and arithmetic operations are tested according to IEC rules. You have to explicitly convert non-compatible operands.
Additional settings	Set network title automatically	Sets the title of a network based on the comment of the output parameter of the first writing instruction in the network. See also: Inserting network title (Page 1583)
	Show autocompletion list	The autocompletion list is displayed.
	Mnemonics	German or international designation of operations and operands

Group	Setting	Description
Download without reinitialization	Memory reserve	Defines the size of reserve in volatile memory that can be used for interface extensions.
Block interface / data blocks	Set "HMI accessible" for new elements and ARRAY data blocks	Enables the option "HMI accessible" for new tags in the block interface and in data blocks. The use of this option makes sense especially when working with large amounts of data in ARRAY data blocks. See also: Basic principles for programming of data blocks (Page 1703)

See also

Layout of the block interface (Page 1551)

Permissible addresses and data types of PLC tags (Page 1482)

Overview of the print settings (Page 305)

Basics of block access (Page 1419)

Setting and canceling the IEC check (Page 2093)

Changing the settings

Procedure

To change the settings, follow these steps:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. In the area navigation, select the "PLC programming" group.
3. Change the settings.

Result

The change will be loaded directly, there is no need to save it explicitly.

See also

Overview of the general settings (Page 1549)

11.1.4.2 Programming code blocks

Declaring the block interface

Layout of the block interface

Introduction

The interface contains the declarations of local tags and constants that are used within the block. The tags are subdivided into two groups:

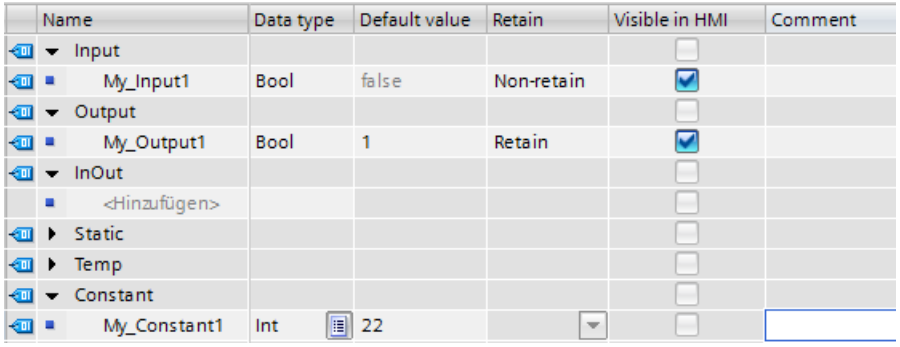
- Block parameters that form the block interface when it is called in the program.
- Local data that are used for storage of intermediate results.

You use the tag declaration to define the call interface of a block in the program and the names and data types of tags and constants that you want to use in the block.

The interface of function blocks also defines the structure of the instances that are assigned to the function block.

Layout of the block interface

The following figure shows the structure of the block interface. The number of columns and sections varies depending on the type of block.



Block parameters

The following table shows the types of block parameters:

Type	Section	Function	Available in
Input parameters	Input	Parameters whose values are read by the block.	Functions, function blocks and some types of organization blocks
Output parameters	Output	Parameters whose values are written by the block.	Functions and function blocks

Type	Section	Function	Available in
In/out parameters	InOut	Parameters whose values are read by the block when it is called, and whose values are written again by the block after execution.	Functions and function blocks
Return value	Return	Value that is returned to the calling block.	Functions

Depending on the type of block opened, additional sections may be displayed.

Local data

The following table shows the types of local data:

Type	Section	Function	Available in
Temporary local data	Temp	Tags that are used to store temporary intermediate results. Temporary local data are retained for only one cycle. If you use temporary local data, you have to make sure that the values are written within the cycle in which you want to read them. Otherwise the values will be random.	Functions, function blocks and organization blocks **Note**: Temporary local data is not shown in instance data blocks.
Static local data	Static	Tags that are used for storage of static intermediate results in the instance data block. Static data is retained until overwritten, which may be after several cycles. The names of the blocks, which are called in this code block as multiple instance, will also be stored in the static local data.	Function blocks
Constant	Constant	Constants with declared symbolic names that are used within the block.	Functions, function blocks and organization blocks **Note**: Local constants are not shown in instance data blocks.

Meaning of the columns

The following table shows the meaning of the individual columns. You can show or hide the columns as required. The number of columns displayed varies depending on the CPU series and the type of the open object.

Column	Description
	Symbol you can click on to drag-and-drop an element to a program for use as an operand.
Name	Name of the element.
Data type	Data type of the element.
Offset	Relative address of a tag. The column is only visible in blocks with standard access.

Column	Description
Default value	Value with which you can pre-assign specific tags in the interface of the code block, or the value of a local constant. Specification of the default value is optional for tags. If you do not specify any value the predefined value for the indicated data type is used. For example, the value "false" is predefined for BOOL. The default value of a tag is applied as the start value in the corresponding instance data block. You can replace these values with instance-specific start values in the instance data block. Constants always have the default value declared in the block interface. They are not shown in instance data blocks and cannot be assigned instance-specific values there.
Retentivity	Marks a tag as retentive. The values of retentive tags are retained even after the power supply is switched off. This column is only visible in the interface of the function block with optimized access.
Visible in HMI	Shows whether a tag is visible by default in the HMI selection list.
Accessible from HMI	Shows whether HMI can access this tag during runtime.
Setting value	Marks a tag as a setpoint. Setting values are the values that will probably have to be fine tuned during commissioning. The column is only available in the interface of function blocks.
Comment	Comments on documentation of the element.

Rules for declaring the block interface

General rules for declaring the block interface

Using POINTER

The following rules apply to the use of block parameters within the block:

- Input parameters may only be read.
- Output parameters may only be written.
- In/out parameters may be read and written.

Assigning default values to block parameters

You can assign default values to specific parameters in the function block interface. The possibility of the assignment depends on the declaration subsection and data type of the parameter.

The following table shows which parameters can be assigned a default value:

Parameter type	Section	Assignment of a default value is possible		
		Elementary data types	Structured data types	Parameter types
Input parameters	Input	X	X	-
Output parameters	Output	X	X	-
In/out parameters	InOut	X	- (1)	-
Static local data	Static	X	X	-
Temporary local data	Temp	-	-	-
Constants	Constant	X	-	-

(1) Exception: In blocks with optimized access, you have the option to use PLC data types as default values under certain conditions.

See also: Declaring PLC data types (UDT) as actual parameters for in-out parameters. (Page 1571)

Valid data types in the block interface

Valid data types in the block interface in S7-300/400

The following table shows which data types you can assign to the parameters in the individual sections of the interface.

Section	Standard Data types	ARRAY STRUCT STRING DT	Parameter types	VOID	POINTER	ANY
Organization block						
Temp	X	X	-	-	-	X
Constant	X	X(3)	-	-	-	-
Function block						
Input	X	X	X	-	X	X
Output	X	X	-	-	-	-
InOut	X	X (1)	-	-	X	X

Section	Standard Data types	ARRAY STRUCT STRING DT	Parameter types	VOID	POINTER	ANY
Static	X	X	-	-	-	-
Temp	X	X	-	-	-	X
Constant	X	X(3)	-	-	-	-
Function						
Input	X	X(1)	X	-	X	X
Output	X	X(1)	-	-	X	X
InOut	X	X(1)	-	-	X	X
Temp	X	X	-	-	-	X
Return	X	X	-	X	X	X(2)
Constant	X	X(3)	-	-	-	-

(1) STRING can only be defined in the standard length of 254 characters.

(2) In SCL, ANY is not permitted as a function value.

(3) Constants with the ARRAY or STRUCT data type are not permitted.

Valid data types in the block interface

Valid data types in the block interface in S7-1200

The following table shows which data types you can assign in the parameters in the individual sections of the interface.

Section	Standard Data types	ARRAY STRUCT STRING / WSTRING DT	VOID	VARIANT
Organization block				
Temp	X	X	-	X
Constant	X	X(2)	-	-
Function block				
Input	X	X	-	X
Output	X	X	-	-
InOut	X	X(1)	-	X
Static	X	X	-	-
Temp	X	X	-	X
Constant	X	X(2)	-	-
Function				
Input	X	X(1)	-	X
Output	X	X(1)	-	X
InOut	X	X(1)	-	X

Section	Standard Data types	ARRAY STRUCT STRING / WSTRING DT	VOID	VARIANT
Temp	X	X	-	X
Return	X	X	X	-
Constant	X	X(2)	-	-

(1) You cannot make length declarations for STRING and WSTRING in these sections. Here, STRINGs always have the standard length 254, WSTRINGs the standard length 16832. A declaration in the format MyString[3] would not be permitted. WSTRING is only permitted in blocks with optimized access in these sections.

(2) Constants with the ARRAY or STRUCT data type are not permitted.

Valid data types in the block interface in S7-1500

The following table shows which data types you can assign in the parameters in the individual sections of the interface.

Section	Standard Data types	ARRAY STRUCT STRING / WSTRING DT	Parame-ter types	VOID	DB_ANY	POINTER	ANY	VARIANT
Organization block								
Temp	X	X	-(4)	-	X	-	X(3)	X
Constant	X	X(5)	-	-	-	-	-	-
Function block								
Input	X	X	X	-	X	X	X	X
Output	X	X	-	-	X	-	-	-
InOut	X	X(1)	-(4)	-	X	X	X	X
Static	X	X	-	-	X	-	-	-
Temp	X	X	-(4)	-	-	-	X(3)	X
Constant	X	X(5)	-	-	-	-	-	-
Function								
Input	X	X(1)	X	-	X	X	X	X
Output	X	X(1)	-	-	X	X	X	X
InOut	X	X(1)	-(4)	-	X	X	X	X
Temp	X	X	-(4)	-	X	-	X(3)	X
Return	X	X	-	X	X	X	x(2)	-

Section	Standard Data types	ARRAY STRUCT STRING / WSTRING DT	Parame-ter types	VOID	DB_ANY	POINTER	ANY	VARIANT
Constant	X	X(5)	-	-	-	-	-	-

(1) You cannot make length declarations for STRING and WSTRING in these sections. Here, STRINGs always have the standard length 254, WSTRINGs the standard length 16832. A declaration in the format MyString[3] would not be permitted. WSTRING is only permitted in blocks with optimized access in these sections.

(2) In SCL, ANY is not permitted as a function value.

(3) ANY can only be used in blocks with standard access in the "Temp" section.

(4) The "INSTANCE" parameter type is the only exception permissible in the "TEMP" and "InOut" sections.

(5) Constants with the ARRAY or STRUCT data type are not permitted.

Declaring local tags and constants

Declaring local tags and constants in the block interface

Requirement

The block interface is open.

Procedure

To declare a tag or constant of the elementary data type, follow these steps:

1. Select the appropriate declaration section in the interface.
2. Enter a name for the element in the "Name" column.
3. Enter the required data type in the "Data type" column. You will be supported by autocompletion during input.
4. For constants, enter a value in the "Default value" column.
5. Optional: Change the properties that are displayed in the other columns of the block interface.

Result

The element is created.

Syntax check

A syntax check is performed after each entry, and any errors found are displayed in red. You do not have to correct these errors immediately - you can continue editing and make any corrections later. However, you will not be able to compile the program if the tag declaration contains syntax errors.

Note

If you change the interface of a block, the calls of the block in the program will possibly become inconsistent. The call locations are automatically updated, if possible.

If an automatic updating is not possible, the inconsistent blocks have to be updated manually.

Properties of local tags and constants (Page 1567)

Setting the retentivity of local tags (Page 1568)

Declaring a local tag in the program editor

Requirement

The program editor is open.

Procedure

To declare a local tag, follow these steps:

1. Insert an instruction in your program.
   The "<???>", "<??.?>" or "..." strings represent operand placeholders.
2. Replace an operand placeholder with the name of the tag to be created.
3. Select the name of the element.
   If you want to declare multiple elements, select the names of all the elements to be declared.
4. Select the "Define tag" command in the shortcut menu.
   The "Define tag" dialog box opens. It displays a declaration table in which the name of the element is already entered.

5. To declare a local tag, select one of the following sections:
   - Local In
   - Local Out
   - Local InOut
   - Local Static
   - Local Temp
6. In the other columns, enter data type and comments.
7. Click the "Define" button to complete your entry.

Result

The declaration is written directly into the block interface and is valid within the entire block.

Note

If you change the interface of a block, the calls of the block in the program will possibly become inconsistent. The call locations are automatically updated, if possible.

If an automatic updating is not possible, the inconsistent blocks have to be updated manually.

Setting the retentivity of local tags (Page 1568)

Declaring tags of the ARRAY data type

Requirement

The block interface is open.

Procedure

To declare a tag of the ARRAY data type, follow these steps:

1. Select the appropriate declaration section in the interface.
2. Enter a tag name in the "Name" column.
3. In the "Data type" column, click the button for the data type selection.
   A list of the permissible data types is opened.
4. Select the "Array" data type.
   The "Array" dialog opens.
5. In the "Data type" text box, specify the data type of the array elements.
6. In the "ARRAY limits" text box, specify the high and low limit for each dimension.
   Example of a one-dimensional ARRAY:
   `[0..3]`
   Example of a three-dimensional ARRAY:
   `[0..3, 0..15, 0..33]`
7. Confirm your entry.
8. Optional: Change the properties of the tags that are displayed in the other columns of the block interface.

Result

The tag of ARRAY data type is created.

Note

You cannot define specific default values for ARRAY elements. However, you can assign them start values in the instance.

See also

Array (Page 1941)

Editing tables (Page 347)

Declaring tags of STRUCT data type

Requirement

The block interface is open.

Procedure

To declare a tag of the STRUCT data type, follow these steps:

1. Select the appropriate declaration section in the interface.
2. Enter a tag name in the "Name" column.
3. Enter "Struct" in the "Data type" column. You will be supported by autocompletion during input.
   An empty, indented row is inserted after the new tag.
4. Insert the first structural element in the first empty row.
   An additional empty row is inserted after the element.
5. Select a data type for the structure element.
6. Optional: Change the properties of the structural element that is displayed in the other columns of the block interface.
7. Repeat the step 4 to 7 for all additional structure elements.
   It is not necessary to end the structure explicitly. The structure ends with the last element that is entered.
8. To insert a new tag after the structure, leave a blank row after the end of the structure and then start the new tag in the second empty row.

Result

The tag of STRUCT data type is created.

Note

S7-1500: A maximum of 252 structures in one data block

A maximum of 252 structures is permitted in one data block. If you need additional structures, you must restructure your program. You can, for example, create the structures in several global data blocks.

Editing tables (Page 347)

Declaring tags based on a PLC data type

Requirement

A PLC data type is declared in the current CPU.

Procedure

To declare a tag based on a PLC data type, follow these steps:

1. Select the appropriate declaration section in the interface:
2. Enter the PLC data type in the "Data type" column. You will be supported by Autocomplete during input.

Result

The tag is created.

Note

You define the default values of tags within a PLC data type when the PLC data type is created. You cannot change these values at the point of use of the PLC data type.

If you change or delete PLC data types that are used in the block interface, the interface becomes inconsistent. To remedy this inconsistency, the interface has to be updated.

Editing tables (Page 347)

Basics of PLC data types (Page 1734)

Declaring higher-level tags

Introduction

To access data areas within a declared tag, you can overlay the declared tags with an additional declaration. This provides you with the option of addressing an already declared tag with a different data type. You can, for example, address the individual bits of a tag of WORD data type with an ARRAY of BOOL.

Overlaying tags

To overlay a tag with a new data type, follow these steps:

1. Open the block interface.
2. In the interface, select the tag that you want to overlay with a new data type.
3. Click "Add row" in the toolbar.
   A row is inserted after the tag to be overlaid. The overlaying tag must be declared in the row directly after the tag that is to be overlaid.
4. Enter a tag name in the "Name" column.
5. Enter the "AT" entry in the "Data type" column. You will be supported by Autocomplete in this step.
   The following is added to the entry in the "Name" column.
   `"AT<Name of the higher-level tag>"`
6. Click the data type selection button again and select the data type for the new tag.
   The tag is created. It points to the same data as the higher-level tag, however interprets this data with the new data type.

Removing overlay

To remove the overlay of a tag, follow these steps:

1. Select the overlaid tag that you want to remove.
2. Select the "Delete" command in the shortcut menu.
3. The overlay is removed.

Editing tables (Page 347)

Overlaying tags with AT (Page 1462)

Declaring multi-instances

Requirement

- The function block to be called exists in project tree and is multi-instance capable.
- The block interface of the calling function block is open.

Procedure

To declare a function block to be called as a multi-instance, follow these steps:

1. In the "Name" column of the "Static" section, enter a designation for the block call.
2. In the "Data type" column, enter the symbolic name for the function block to be called.

Note

The program editor will declare the multi-instance automatically if you program a block call in a network and then specify in the "Call options" dialog that you want to call the block as a multiple instance.

See also

Updating the block interface (Page 1564)

Updating the block interface

Introduction

If you change or delete PLC data types or multiple instances that are used in the block interface, the interface will become inconsistent. To remedy this inconsistency, the interface has to be updated.

You have two options for updating the block interface:

- Explicit updating of the block interface.
  The used PLC data types and multiple instances will be updated. The instance data blocks that belong to the block are not implicitly updated during this process.
- Implicit updating during compilation.
  All used PLC data types and multiple instances as well as the related instance data blocks will be updated.

Explicit updating of the block interface

To explicitly update the block interface, follow these steps:

1. Open the block interface.
2. Select the "Update" command in the shortcut menu.

Implicit Updating during Compilation

Proceed as follows to implicitly update all uses of PLC data types and multiple instances as well as the instance data blocks during compilation:

1. Open the project tree.
2. Select the "Program blocks" folder.
3. Select the command "Compile > Software (rebuild all blocks)" in the shortcut menu.

Extending the block interface

Description

In order to enable the editing of PLC programs that have already been commissioned and that are running without error on a system, CPUs of the S7-1500 series and most CPUs of the S7-1200 V4 and higher series support the option of extending the interfaces of function blocks during runtime.

You can download the modified blocks without setting the CPU to STOP and without affecting the values of already loaded tags.

This is a simple means of implementing program changes. This load process (download without reinitialization) will not have a negative impact on the controlled process.

Principle of operation

Each function block is always assigned a default memory reserve. The memory reserve is not used initially. Activate the memory reserve if you decide on loading interface changes after having compiled and downloaded the block. All tags that you subsequently declare will be saved to the memory reserve. The subsequent download does not influence any tags that are already loaded or have a negative impact on runtime.

If you decide to review your program at a later time while the plant is not in operation, you are also provided an option of reworking the memory layout of individual or several blocks in a single pass. With this action, you move all tags from the reserve area to the regular area. The memory reserve is now cleared and made available for further interface extensions.

Requirements

This "Download without reinitialization" function is available if the following requirements are met:

- The project is in the "TIA Portal V12" format or a higher version.
- You are working with a CPU that supports "Download without reinitialization".
- The blocks were created in LAD, FBD, STL, or SCL.
- The blocks were created by the user, i.e. they are not included with the blocks delivered in your package.
- These blocks are assigned the optimized access attribute.

Basic steps

Perform the following steps if you want to extend the interface of a function block and then load the block without re-initialization.

1. All blocks have a default memory reserve of 100 bytes. You can adapt this memory reserve to suit your requirements.
2. Activate the memory reserve.
3. Extend the block interface.
4. Compile the block.
5. Download the block to the CPU as usual.

For more information on the various steps, refer to chapter "Loading blocks (S7-1200/1500) ".

Note

The full scope of the "Download without reinitialization" function is only available on CPUs of the S7-1500 and S7-1200 V4 series.

However, all CPU families support the option of extending the interface of function blocks and downloading newly declared tags without repercussion:

- You may add new tags in the "Temp" section and download these without influencing the process.
- You may create new tags of a structured data type in the "InOut" section and download these without influencing the process.

Editing the properties of local tags and constants

Properties of local tags and constants

Properties

The table below provides an overview of the properties of local tags and constants:

Group	Property	Description
General	Name	Name of the element.
	Data type	Data type of the element.
	Default value	Value with which you can pre-assign specific tags in the interface of the code block, or the value of a local constant. Specification of the default value is optional for tags. If you do not specify any value the predefined value for the indicated data type is used. For example, the value "false" is predefined for BOOL. The default value of a tag is applied as the start value in the corresponding instance. You can then replace these adopted values with instance-specific start values.
	Comment	Comment for the element.

Group	Property	Description
Attributes	Retain	Marks the tag as retentive. The values of retentive tags are retained even after the power supply is switched off. This attribute is only available in the interface of the function block with optimized access.
	Accessible from HMI	Indicates whether the tag can be used in HMI. When the attribute is set, you have read or write access to the tag from the HMI. When the attribute is not set, you cannot access the tag from the HMI. Please note, however, that you cannot implement general access protection for the tag with the "Accessible from HMI" attribute. Read or write access from other applications is possible even if the attribute is not enabled.
	Visible in HMI	Shows whether the tag is visible by default in the HMI selection list.
	Hidden parameter	Indicates whether the tag should be hidden for the block call. This is only possible if you have specified a valid predefined actual parameter beforehand.
	Predefined actual parameter	Defines a parameter that is to be used as actual parameter during the block call.
	Configurable	Indicates whether a parameter is configurable in CFC.
	For test	Indicates whether a parameter is registered for the CFC test mode.
	Visible	Indicates whether a parameter is visible in CFC.
	Interconnectable	Indicates whether a parameter is interconnectable in CFC.
	Enable tag readback	Indicates whether a parameter is relevant for the "Read back chart" function in CFC.
	Enumeration texts	Assigns a parameter to an enumeration in CFC.
	Engineering unit	Assigns a parameter to a unit in CFC.
	Low limit	Defines the low limit for the parameter in CFC.
	High limit	Defines the high limit for the parameter in CFC.

Setting the retentivity of local tags (Page 1568)

Changing properties of local tags and constants (Page 1569)

Keywords (Page 1442)

Setting the retentivity of local tags

Introduction

Function blocks store their data in an instance. To prevent data loss in the event of power failure, you can mark the data as retentive. This data is stored in a retentive memory area. The option of setting the retentivity depends on the set access type of the function block.

Retentive behavior in blocks with standard access

In blocks with standard access you cannot set the retentive behavior of individual tags. You can only define them as retentive in the assigned instance. All tags contained in the block are then considered as retentive.

Retentivity for optimized block access

In data blocks with optimized access you can define the retentive behavior of individual tags.

For structured data type tags, the retentivity setting always applies to the entire structure. You can make no individual retentivity setting for individual elements within the structure.

You cannot create retentive tags of the structured data type in the "InOut" section. In/out parameters with structured data type, for example ARRAY, STRUCT, or STRING, are always non-retentive.

The following settings are available:

- Retentive
  The values of the tags or the structure are available even after a power failure.
- Non-retentive
  The values of the tags or the structure are lost in the event of a power failure.
- Set in IDB
  The retentivity can be set in the instance data block. The setting that is made in the instance data block than applies, however, centrally to all tags that are selected with "Set in IDB".

Properties of local tags and constants (Page 1567)

Basics of block access (Page 1419)

Changing properties of local tags and constants

Editing properties of an element in the block interface

To edit the properties of an element in the block interface, follow these steps:

1. Open the block interface.
2. Select the required element in the table.
3. Change the entries in the columns.

Editing properties of several elements in the block interface

You can also simultaneously set or reset the "Retain", "Visible in HMI", "Accessible in HMI" and "Setpoint" columns for one or more selected elements.

To change one of these properties for several elements, follow these steps:

1. Open the block interface.
2. Hold down the CTRL key.
3. In the required column, select each of the table cells whose value you want to change.
4. Select the "Set <property>" or "Reset <property>" command in the shortcut menu.

Editing properties in the properties window

To edit the properties of an individual tag or constant, follow these steps:

1. Select an element in the table.
   The properties of the element are shown in the Inspector window.
2. Change the entries in the inspector window.

Renaming tags directly in the program editor

To rename one or more elements, follow these steps:

1. Select one or more elements in the program.
2. Select the "Rename tag" command in the shortcut menu.
   The "Rename tag" dialog opens. It displays a declaration table with the selected elements.
3. Change the entries in the "Name" column.
4. Confirm the input by clicking the "Change" button.

Editing the data type or comment in the program editor

Proceed as follows to edit the data type or tag comment in the program editor:

1. Select the name of the tag.
2. Select the "Rewire tag" command in the shortcut menu.
   The "Rewire tag" dialog will open. The dialog shows a declaration table.
3. Change the entry in the "Data type" or "Comment" columns.
4. Click the "Change" button to confirm the input.

Effect in the program

In case of a change of the name, data type or address of a tag or constant, each location of use of the tag is automatically updated in the program.

Note

If you change the interface of a block, the program may become inconsistent. The inconsistencies are automatically updated, if possible.

If an automatic updating is not possible, the inconsistent calls are marked in red. You than have to manually updated the inconsistencies.

Keywords (Page 1442)

Updating the block interface (Page 1564)

Declaring PLC data types (UDT) as actual parameters for in-out parameters.

Use of PLC data types as predefined actual parameters

In blocks with optimized access, you have the option to use PLC data types as actual parameters for in/out parameters (InOut) under certain conditions. This can be useful if you are using program blocks as library elements and want to store information about the actual parameters to be used along with the library element.

Additionally, you have the option of hiding in/out parameters that have a vaild predefined actual parameter when the block is called. Hidden parameters are not visible initially when the block is called but can be displayed via a small arrow at the bottom edge of the box.

Requirements

- The in/out parameter (InOut) is based on a PLC data type or a system data type.
- The in/out parameter has the retentivity setting "Retain" or "Non-retain". For in/out parameters with setting "Set in IDB", it is not possible to predefine actual parameters.
- The program block is a block with optimized access.

Procedure

To predefine the actual parameter of an in/out parameter, follow these steps:

1. Open the block interface.
2. Select an in/out parameter (InOut) in the block interface.
3. Open the "Properties" tab in the Inspector window.
4. Select the "Attributes" group in the area navigation.
5. Enter the required actual parameter in the "Predefined actual parameter" input box.
6. Select the "Hidden parameter" check box (optional).

Result

- An actual parameter is predefined. If you save the program block as a library element, it thus also contains information about the actual parameter to be used.
- If the library element is used in the program, a check is made to determine whether the actual parameter you have predefined can be addressed. If so, it is automatically used as the actual parameter.
- If the actual parameter is not found in the program, a syntax error is signaled. The parameter is not hidden and the parameter must be initialized manually.

Editing the block interface

Inserting table rows

Procedure

Proceed as follows to insert a row above the selected row:

1. Select the row in front of which you want to insert a new row.
2. Click the "Insert row" button on the toolbar of the table.

Result

A new row is inserted above the selected row.

Inserting table rows

Procedure

Proceed as follows to insert a row below the selected row:

1. Select the row below which you want to insert a new row.
2. Click the "Add row" button on the table toolbar.

Result

A new empty row will be inserted below the selected row.

Editing tables (Page 347)

Deleting tags

Procedure

Follow the steps below to delete elements:

1. Select the row with the element to be deleted. You can also select several rows by clicking on them one after the other while holding down the <Ctrl> key or by pressing and holding down <Shift> and clicking on the first and last row.
2. Select the "Delete" command in the shortcut menu.

Editing tables (Page 347)

Automatically filling in successive cells

You can load the contents of one or several table cells into the cells below, automatically filling in the successive cells.

If you automatically fill in cells in the "Name" column, a consecutive number will be appended to each name. For example, "Motor" will become "Motor_1".

You can define individual or more cells as well as entire rows as source area.

If less rows exist in the open table than you want to fill, then you will first have to insert additional empty rows.

Requirement

- The table is open.
- Sufficient declaration rows are available.

Procedure

To automatically fill in successive cells, follow these steps:

1. Select the cells to be loaded.
2. Click the "Fill" symbol in the bottom right corner of the cell.
   The mouse pointer is transformed into a crosshair.
3. Keep the mouse button pressed and drag the mouse pointer downwards over the cells that you want to fill in automatically.
4. Release the mouse button.
   The cells are filled in automatically.
5. If entries are already present in the cells that are to be automatically filled in, a dialog appears. In this dialog you can indicate whether you want to overwrite the existing entries or insert new rows for the new tags.

Editing tables (Page 347)

Show and hide table columns

You can show or hide the columns in a table as needed.

Procedure

To show or hide table columns, follow these steps:

1. Click a column header.
2. Select the "Show/Hide" command in the shortcut menu.
   The selection of available columns is displayed.
3. To show a column, select the column's check box.
4. To hide a column, clear the column's check box.
5. To hide or show several columns, click "More" and activate or deactivate the check box of the corresponding columns in the "Show/Hide" dialog.

Editing tags with external editors

To edit individual tags in external table editors, such as Excel, you can export or import these tags using copy and paste. However, you cannot copy structured tags to an editor.

Requirements

The block interface and an external editor are opened.

Procedure

To export individual tags to an external editor and import them again, follow these steps:

1. Select one or more tags.
2. Select "Copy" in the shortcut menu.
3. Switch to the external editor and paste the copied tags.
4. Edit the tags as required.
5. Copy the tags in the external editor.
6. Select the tags in the external editor.
7. Switch back to the block interface.
8. Select "Paste" in the shortcut menu.

Creating program code

Creating LAD programs

Basic information on LAD

LAD programming language

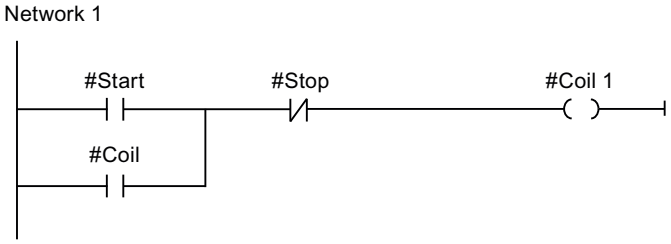
Overview of the Ladder Logic (LAD) programming language

LAD is a graphical programming language. The representation is based on circuit diagrams.

The program is mapped in one or more networks. A network contains a power rail on the left where the rungs originate. The binary signal scans are arranged in the form of contacts on the rungs. The serial arrangement of the elements on a rung creates a series connection; arrangement on simultaneous branches creates a parallel connection. Complex functions are represented by boxes.

Example of networks in LAD

The following figure shows a LAD network with two normally open contacts, one normally closed contact and one coil:



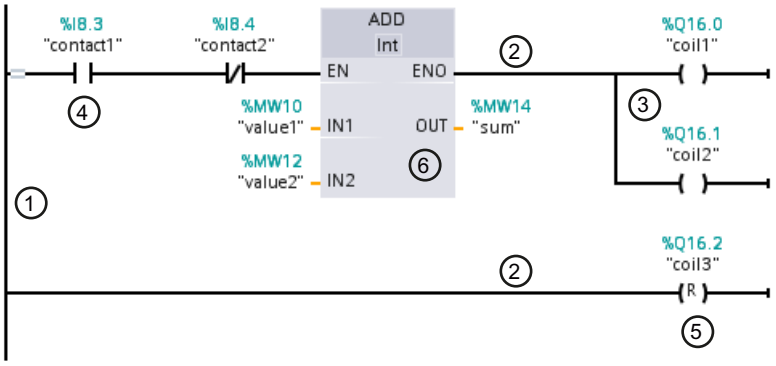
Overview of the LAD elements

LAD elements

A LAD program consists of separate elements that you can arrange in series or parallel on the power rail of a network. Most program elements must be supplied with tags.

There is at least one rung from the power rail. Network programming starts at the left edge of the rung. You can expand the power rail by several rungs and branches.

For example, the following figure shows elements of a LAD network:



1) Power rail

2) Rung

3) Branch

4) Contact

5) Coil

6) Box

Power rail

Each LAD network consists of a power rail that contains at least one rung. A network can be extended by adding additional rungs. You can use branches to program parallel connections in the specific rungs.

Contacts

You can use contacts to create or interrupt a current-carrying connection between two elements. The current is relayed from left to right. You can use contacts to query the signal state or the value of an operand and control it depending on the result of the current flow.

The following types of contact are available to you in a LAD program:

- Normally open contact:
  Normally open contacts forward the current if the signal state of a specified binary operand is "1".
- Normally closed contacts:
  Normally closed contacts forward the current if the signal state of a specified binary operand is "0".
- Contact with additional function:
  Contacts with additional function forward the current if a specific condition is met. With these contacts you can also execute an additional function, such as an RLO edge detection and a comparison.

Coils

You can use coils to control binary operands. Coils can set or reset a binary operand depending on the signal state of the result of logic operation.

The following types of coils are available to you in a LAD program:

- Standard coils:
  Standard coils set a binary operand if current flows in the coil. The "Assignment" instruction is an example of a standard coil.
- Coils with additional function:
  These coils have additional functions in addition to the evaluation of the logic operation result. Coils for RLO edge detection and program control are examples of coils with additional function.

Boxes

Boxes are LAD elements with complex functions. The empty box is an exception. You can use the empty box as a placeholder in which you can select the required instruction.

The following types of boxes are available to you in a LAD program:

- Boxes without EN/ENO mechanism:
  A box is executed depending on the signal state at the box inputs. The error status of the processing cannot be queried.
- Boxes with EN/ENO mechanism:
  A box is only executed if the enable input "EN" carries the signal state "1". If the box is processed correctly, the "ENO" enable output has signal state "1". If an error occurs during the processing, the "ENO" enable output is reset.

Calls of code block are also shown in the network as boxes with EN/ENO mechanism.

Rules for the use of LAD elements (Page 1586)

Settings for LAD

Overview of the settings for LAD

Overview

The following table shows the settings that you can make:

Group	Setting	Description
Font	Font size	Font size in program editor
View	Layout	Compact or wide Changes the vertical spacing between operands and other objects (such as operand and contact). The change becomes visible once the block is reopened.
	With absolute information	Additional display of the absolute addresses
Operand field	Maximum width	Maximum number of characters that can be entered horizontally in the operand field. This setting recalculates the layout of the networks.
	Maximum height	Maximum number of characters that can be entered vertically in the operand field. This setting recalculates the layout of the networks.

See also

Changing the settings (Page 1579)

Changing the settings

Procedure

To change the settings, follow these steps:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. In the area navigation, select the "PLC programming" group.
3. Change the settings.

Result

The change will be loaded directly, there is no need to save it explicitly.

See also

Overview of the settings for LAD (Page 1578)

Working with networks

Using networks

Function

The user program is created in the block within networks. For a code block to be programmed, it must contain at least one network. To achieve a better overview of the user program, you can also subdivide your program into several networks.

Inserting networks

Requirement

A block is open.

Procedure

To insert a new network, follow these steps:

1. Select the network after which you want to insert a new network.
2. Select the "Insert network" command in the shortcut menu.

Result

A new empty network is inserted into the block.

Selecting networks

Requirements

A network is available.

Selecting a network

To select a network, follow these steps:

1. Click the title bar of the network that you want to select.

Selecting several networks

Proceed as follows to select several individual networks:

1. Press and hold down the <Ctrl> key.
2. Click all the networks that you want to select.

To select several successive networks, follow these steps:

1. Press and hold down the <Shift> key.
2. Click the first network that you want to select.
3. Click the last network that you want to select.
   The first and last networks and all those in between are selected.

Copying and pasting networks

Copied networks can be pasted within the block or in another block. Networks that were created in LAD or FBD can also be inserted in blocks of the respective other programming language.

Requirement

A network is available.

Procedure

To copy and paste a network, follow these steps:

1. Select the network or networks to be copied.
2. Select "Copy" in the shortcut menu.
3. Select the network after which you want to paste in the copied network.
4. Select "Paste" in the shortcut menu.

Entering a network comment (Page 1584)

Navigating networks (Page 1585)

Inserting network title

The network title is the header of a network. The length of the network title is limited to one line. You can enter the title manually or set it automatically. When you set it automatically, you can do this for individual networks or use the settings to specify that the network title is always set automatically.

For automatic insertion of the network title, the comment of the operand in one of the following instructions in the network is evaluated:

- Assignment
- Set output
- Reset output

The instruction that is listed first in the network is used.

The network title is only inserted automatically when the following conditions are fulfilled:

- The network does not have a title yet.
- The operand of the instruction used for the comment has a comment.

Note

Note the following restrictions for automatic insertion of the network title:

- The network title is not adapted if you change the comment of the operand at a later time.
- The network title is not adapted if you change the operand of the instruction.
- The network title is only set by the writing instructions listed above.
- If the operand is of the data type array, the comment of the array is used and not the comments of the array elements.
- Comments of invalid operands are not taken into consideration.

Entering the network title manually

To enter a network title, follow these steps:

1. Click on the title bar of the network.
2. Enter the network title.

Setting the network title automatically

To specify that the network titles are always set automatically, follow these steps:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. In the area navigation, select the "PLC programming" group.
3. Select the "Set network title automatically" check box in the "Additional settings" group.
   The network titles are set automatically as of this time if the conditions listed above are fulfilled.

To set an individual network title automatically, follow these steps:

1. Right-click "Network <Number of the network>" in the title bar of a network.
2. Select the "Set network title automatically" command in the shortcut menu.
   The title of the selected network is set based on the comment of the operand if the conditions listed above are fulfilled.

Expanding and collapsing networks (Page 1582)

Entering a network comment (Page 1584)

Navigating networks (Page 1585)

Entering a network comment

You can use network comments to provide comments on the program contents of individual networks. For example, you can indicate the function of the network or draw attention to special characteristics.

Requirement

A network is available.

Procedure

To enter a network comment, follow these steps:

1. Click on the right arrow before the network title.
2. If the comment area is not visible, click "Network comments on/off" in the toolbar.
   The comment area is displayed.

3. Click "Comment" in the comment area.
   The "Comment" text passage is selected.
4. Enter the network comment.

Navigating networks (Page 1585)

Navigating networks

You can navigate straight to a specific position within a block.

Procedure

To navigate to a specific position within a block, follow these steps:

1. Right-click in the code area of the programming window.
2. Select the "Go to > Network/line" command in the shortcut menu.
   The "Go to" dialog will open.
3. Enter the network to which you want to navigate.
4. Enter the line number of the network to which you want to navigate.
5. Confirm your entry with "OK".

Result

The relevant line will be displayed if this is possible. If the network or line requested does not exist, the last existing network or the last existing line in the network requested will be displayed.

Inserting LAD elements

Rules for the use of LAD elements

Rules

Note the following rules when inserting LAD elements:

- Every LAD network must terminate with a coil or a box. However, the following LAD elements must not be used to terminate a network:
  - Comparator boxes
  - Instructions for positive and negative RLO edge detection
- The starting point of the branch for a box connection must always be the power rail. Logic operations or other boxes can be present in the branch before the box.
- Only contacts can be inserted into simultaneous branches with preceding logic operations. The contact for negating the result of logic operation (-|NOT|-) is an exception here. The contact for negating the result of logic operation, as well as coils and boxes, can be used in simultaneous branches if they originate directly from the power rail.
- Constants (e.g. TRUE or FALSE) cannot be assigned to normally closed or normally open contacts. Instead, use operands of the BOOL data type.
- Only one jump instruction can be inserted in each network.
- Only one jump label can be inserted in each network.
- Instructions with positive or negative edge detection may not be arranged directly at the left margin of the rung as they requires a prior logic operation.

Placement rules for S7-1200/1500 CPUs

The following table sets out the instructions that can only be positioned at the end of the network:

Instruction		Preceding logic operation required
Mnemonics	Name	
SET_BF	Set bit field	No
RESET_BF	Reset bit field	No
JMP	Jump if RLO = 1	No
JMPN	Jump if RLO = 0	Yes
JMP_LIST	Define jump list	No

Instruction		Preceding logic operation required
Mnemonics	Name	
SWITCH	Jump distributor	No
RET	Return	No

Placement rules for S7-300/400 CPUs

The following table sets out the instructions that can only be positioned at the end of the network:

Instruction		Preceding logic operation required
Mnemonics	Name	
S	Set output	Yes
R	Reset output	Yes
SP	Start pulse timer	Yes
SE	Start extended pulse timer	Yes
SD	Start on-delay timer	Yes
SS	Start retentive on-delay timer	Yes
SF	Start off-delay timer	Yes
SC	Set counter value	Yes
CU	Count up	Yes
CD	Count down	Yes
JMP	Jump if RLO = 1	No
JMPN	Jump if RLO = 0	Yes
RET	Return	No
OPN	Open global data block	No
OPNI	Open instance data block	No
CALL	Call block	No
SAVE	Save RLO in BR bit	No
MCRA	Enable MCR range	No
MCRD	Disable MCR range	No
MCR<	Open MCR ranges	No
MCR>	Close MCR ranges	No

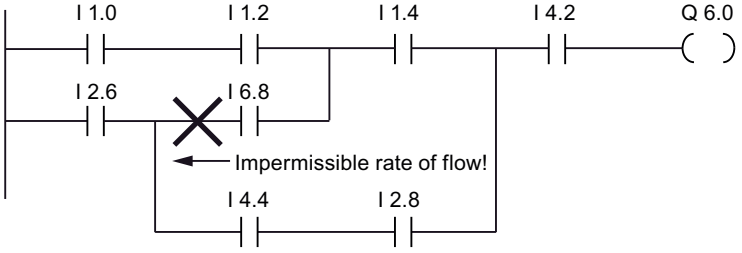
Prohibited interconnections in LAD (Page 1588)

Overview of the LAD elements (Page 1576)

Prohibited interconnections in LAD

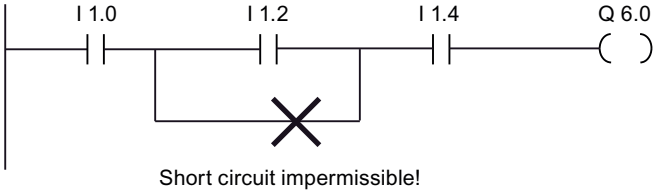
Power flow from right to left

No branches can be programmed that could result in a power flow in the reverse direction.



Short-circuit

No branches may be programmed that would cause a short-circuit.



Logic operations

The following rules apply to logic operations:

- Only Boolean inputs can be combined with preceding logic operations.
- Only the first Boolean output can be combined with a further logic operation.
- Only one complete logical path can exist per network. Paths that are not connected can be linked.

Rules for the use of LAD elements (Page 1586)

Inserting LAD elements using the "Instructions" task card

Requirement

A network is available.

Procedure

To insert a LAD element into a network using the "Instructions" task card, follow these steps:

1. Open the "Instructions" task card.
2. Navigate to the LAD element that you want to insert.
3. Use drag-and-drop to move the element to the desired place in the network.
   If the element is an internal system function block (FB), the "Call options" dialog opens. In this dialog you can create an instance data block of the single-instance or multiple-instance type for the function block in which the data of the inserted element will be saved. You will find the new instance data block created in the project tree in the "Program resources" folder under "Program blocks > System blocks". If you have selected "multiple instance", these are located in the block interface in the "Static" section.

Or:

1. Select the point in the network at which you want to insert the element.
2. Open the "Instructions" task card.
3. Double-click on the element you want to insert.
   If the element is an internal system function block (FB), the "Call options" dialog opens. In this dialog you can create an instance data block of the single-instance or multiple-instance type for the function block in which the data of the inserted element will be saved. You will find the new instance data block created in the project tree in the "Program resources" folder under "Program blocks > System blocks". If you have selected "multiple instance", these are located in the block interface in the "Static" section.

Result

The selected LAD element is inserted with placeholders for the parameters.

Inserting LAD elements using an empty box

Requirement

A network is available.

Procedure

To insert an LAD element into a network using an empty box, follow these steps:

1. Open the "Instructions" task card.
2. Navigate to "General > Empty box" in the "Basic instructions" palette.
3. Use a drag-and-drop operation to move the "Empty box" element to the desired place in the network.

4. Position the cursor over the triangle in the top right-hand corner of the empty box.
   A drop-down list is displayed.
5. Select the required LAD element from the drop-down list.
   If the element is an internal system function block (FB), the "Call option" dialog opens. In this dialog you can create an instance data block of the single-instance or multiple-instance type for the function block in which the data of the inserted element will be saved. You will find the new instance data block created in the project tree in the "Program resources" folder under "Program blocks > System blocks". If you have selected "multi-instance", these are located in the block interface in the "Static" section.

Result

The empty box is changed to the respective LAD element. Placeholders are inserted for the parameters.

Selecting the data type of a LAD element

Selecting a data type

Introduction

Some instructions can be executed with several different data types. If you use one of these instructions in the program, you have to specify a valid data type for the instruction at the specific point in the program. For some instructions, you have to select the data types for the inputs and outputs separately.

Note

The valid data type (BOOL) for the tags on the enable input EN and the enable output ENO is predefined by the system and cannot be changed.

The valid data types for an instruction are listed in the instruction drop-down list. You specify the data type of the instruction by selecting an entry from the drop-down list. If the data type of an operand differs from the data type of the instruction and cannot be converted implicitly, the operand is displayed in red and a rollout with the corresponding error message appears.

Data type selection of mathematical instructions

Some mathematical instructions provide you with the option of having the data type automatically set corresponding to the data types of the operand. In the drop-down list for data type selection, these instructions have the entry "Auto" in addition to the actual data types. If you select this entry and then allocate the first operand, the data type of the operand is selected as data type for the instruction. The entry in the drop-down list changes to "Auto (<Data type>)", e.g. "Auto (Real)". If you allocate additional operands, the automatically set data type of the instruction is adjusted according to the following criteria:

- You supply all other operands with tags of the same data type:
  The data type of the instruction is not changed.
- You supply all other operands with tags whose data type is smaller than the data type of the instruction:
  The data type of the instruction is not changed. For the operand with the smaller data type, an implicit conversion is conducted if necessary.
- You supply an additional operand with a tag whose data type is greater than the data type of the instruction:
  The data type of the instruction is changed to the larger data type. An implicit conversion is performed, if necessary, for operands that deviate from the newly set data type of the instruction.

Each change in the data type of an operand can result in a change of the data type of the instruction. Other operands may possibly be implicitly converted as a result. Operands for which an implicit conversion is performed are marked with a gray square.

Note

Please also observe the information on data type conversion for your device and, in particular, the notes on the IEC check.

Defining the data type of an instruction (Page 1591)

Defining the data type of an instruction

Introduction

Some instructions can be executed with several different data types. When you insert such instructions into your program, you must specify the data type for these instructions at the actual point in the program.

Specifying the data type by means of the drop-down list

To define the data type of an instruction using the drop-down list, follow these steps:

1. Insert the instruction at the required point in the program using drag-and-drop.
   The entry "???" (undefined) is displayed in the drop-down list of the inserted instruction.
2. Click the triangle in the upper corner of the drop-down list.
   The drop-down list will open to display the data types valid for the instruction.
3. Select a data type from the drop-down list.
   The selected data type is displayed.
4. If the instruction has two drop-down lists, select the data type for the instruction inputs in the left-hand drop-down list and the data type for the instruction outputs in the right-hand drop-down list.

Specifying data type by assigning tags

To define the data type of an instruction by assigning tags, follow these steps:

1. Insert the instruction at the required point in the program using drag-and-drop.
   The entry "???" (undefined) is displayed in the drop-down list of the inserted instruction.
2. At an input or output, specify a valid tag, the data type of which is to be applied as the instruction data type.
   The data type of the tag is displayed in the drop-down list.
3. Enter a valid tag at an input and a valid tag at an output if data types need to be defined for both the inputs and outputs of the instruction. The tag specified at the input determines the data type of the inputs; the tag specified at the output determines the data type of the outputs of the instruction.

Automatically specifying the data type of mathematical instructions

To automatically specify the data type for mathematical instructions, follow these steps:

1. Insert the mathematical instruction at the required point in the program using drag-and-drop.
   The entry "???" (undefined) is displayed in the drop-down list of the inserted instruction.
2. Select the "Auto" entry from the drop-down list.
3. Enter a valid tag at an input or output.
   The data type of the tag is applied as data type of the instruction. The entry in the drop-down list changes to "Auto (<Data type>)".

Using favorites in LAD

Adding LAD elements to Favorites

Requirement

- A block is open.
- The multipane mode is set for the "Instructions" task card or the Favorites are also displayed in the editor.

Procedure

To add SCL instructions to the Favorites, follow these steps:

1. Open the "Instructions" task card.
2. Maximize the "Basic instructions" pane.
3. Navigate in the "Basic instructions" pane to the instruction that you want to add to the Favorites.
4. Drag-and-drop the instruction into the "Favorites" pane or into the Favorites area in the program editor.

Note

To additionally display the Favorites in the program editor, click the "Display favorites in the editor" button in the program editor toolbar.

Insert block calls in LAD

Inserting block calls using a drag-and-drop operation

You can insert calls for existing functions (FC) and function blocks (FB) using a drag-and-drop operation from the project tree. If you call function blocks from other function blocks, you can either call them as single-instance or multi-instance blocks. If a function block is called as single instance, it will store its data in a data block of its own. If a function block is called as multi-instance, it will store its data in the instance data block of the calling function block.

Requirement

- A network is available.
- The block that is to be called is available.

Inserting a call of a function (FC)

To insert a call of a function (FC) into a network using a drag-and-drop operation, follow these steps:

1. Drag the function from the project tree to the required network.

Inserting a call for a function block (FB)

To insert a call for a function block (FB), follow these steps:

1. Drag the function block from the project tree to the required network.
   The "Call options" dialog opens.
2. Enter in the dialog whether you wish to call the block as single or multi-instance.
   - If you click on the "Single instance" button, you will have to enter a name in the "Name" text box for the data block that you want to assign to the function block.
   - If you click on the "Multi-instance" button, you will have to enter the name of the tag in the "Name in the interface" text box; this is the name that you use to enter the called function block as a static tag in the interface of the calling block.
3. Confirm your entries with "OK".

Result

The function or the function block is inserted with its parameters. You can then assign the parameters.

See also: Auto-Hotspot

Note

If when calling a function block you specify an instance data block that does not exist, it will be created. If you have called a function block as a multi-instance, this will be entered as a static tag in the interface.

Single instances (Page 1427)

Multi-instances (Page 1427)

Updating block calls in LAD

If interface parameters of a called block are changed, the block call can no longer be executed correctly. You can avoid such inconsistent block calls by updating the block calls.

You have the following options for updating the block calls:

- Explicit updating of all inconsistent block calls in the program editor.
  The inconsistent block calls within the open block are updated. The following actions are carried out in the process:
  - New parameters are added.
  - Deleted parameters are removed if they are not connected.
  - Renamed parameters get the new parameter names.
- Explicit updating of a block call in the program editor.
  The "Interface update" dialog is displayed. In this dialog, you have the option of changing the connection of the operands of the new interface. The inconsistent call of this block is then updated. The following actions are carried out in the process:
  - New parameters are added.
  - Deleted parameters are removed if they are not connected.
  - Renamed parameters get the new parameter names.
- Implicit updating during compilation.
  All block calls in the program as well as the used PLC data types will be updated. Note that when you call functions (FCs) before the next compilation process, all new formal parameters must be supplied with actual parameters.

Updating all inconsistent block calls in the program editor

To open all block calls in a block, follow these steps:

1. Open the calling block in the program editor.
2. Click "Update inconsistent block calls" in the toolbar.

Updating a specific block call in the program editor

To update a specific block call in the program editor, follow these steps:

1. Open the calling block in the program editor.
2. Right-click on the block call that you want to update.
3. Select the "Update" command in the shortcut menu.
   The "Interface update" dialog opens. This dialog shows the differences between the block interface in use and the changed interface of the called block.
4. If necessary, change the connection of the operands. To do this, you have the following options:
   - You can use either a drag-and-drop operation or a cut/copy-and-paste operation to move the operand from the old interface to the new interface.
   - You can delete an operand.
   - You can rename an operand.
   - You can specify a new operand via autocompletion.
5. Click "OK" to update the block call. If you want to cancel the update, click "Cancel".

Note

Note that the "Update block call" command is only available provided you did not previously update all block calls in the editor with the "Update inconsistent block calls" command.

Update block calls during compilation

Follow these steps to update all block calls and uses of PLC data types during compilation implicitly:

1. Open the project tree.
2. Select the "Program blocks" folder.
3. Select the command "Compile > Software (rebuild all blocks)" in the shortcut menu.

See also

Inserting block calls using a drag-and-drop operation (Page 1595)

Changing the instance type (Page 1598)

Changing the block call

You have the option of changing the called block for a block call. But keep in mind that no new instance data blocks are created, for example, when changing from a function (FC) to a function block (FB).

Procedure

To change the called block of a block call, follow these steps:

1. Click on the name of the called block within the block call and press the <F2> key. Or double-click the name of the called block.
   A text box opens, and the name of the currently called block is selected.
2. Enter the name of the block you want to call or select a block in the autocompletion.
3. If you want to call an FB, create a new instance data block, if necessary, and specify it as operand.

Changing the instance type

Instance type

There are two ways of calling function blocks:

- As a single instance
- As a multiple instance

See also: Auto-Hotspot

You can modify a defined instance type at any time.

Requirement

The user program contains a block call.

Procedure

To change the instance type of a function block, follow these steps:

1. Open the code block and select the block call.
2. Select the "Change instance" command in the shortcut menu.
   The "Call options" dialog opens.
3. Click the "Single instance" or "Multi instance" button.
   - If you select the "Single instance" instance type, enter a name for the data block that is to be assigned to the function block.
   - If you select "Multiple instance" as the instance type, enter in the "Name in the interface" text field the name of the tag with which the called function block is to be entered as a static tag in the interface of the calling block.
4. Confirm your entries with "OK".

Note

The previous single and multiple instances will not be deleted automatically.

Inserting complex LAD instructions

Using the "Calculate" instruction

Requirement

A network is available.

Procedure

Proceed as follows to use the "Calculate" instruction:

1. Open the "Instructions" task card.
2. Navigate to "Math functions > CALCULATE" in the "Basic instructions" pane.
3. Use drag-and-drop to move the element to the desired place in the network.
   The instruction "Calculate" will be inserted for the data type with a placeholder expression and question mark.
4. Enter the data type for the calculation.
5. Enter the operands for the calculation.

   Note

   The calculation is run with the inputs of the "Calculate" instruction. If you want to use constants you must also insert appropriate inputs for them.

6. Click on the "Edit 'Calculate' instruction" button to replace the placeholder expression with the correct expression.
   The "Edit 'Calculate' instruction" dialog will open.
7. Enter the required expression in the "OUT:= " text box.

   Note

   In the "Example" area you can find an example of a valid expression and possible instructions that you can use.

   To determine a value with the help of Pythagoras' theorem, for example, enter "OUT := SQRT (SQR (IN1) + SQR (IN2))".

8. Confirm your entry with "OK".

Using free-form comments

Basic information on using free-form comments in LAD

Introduction

Free-form comments allow you to add comments to the source code for graphic programming languages similar to line comments for textual languages.

Free-form comments can be used for the following elements:

- Boxes
- Coils

See also

Inserting free-form comments (Page 1600)

Editing free-form comments (Page 1601)

Deleting free-form comments (Page 1602)

Inserting free-form comments

Requirement

A network with instructions is available.

Procedure

To insert a free comment on an instruction, proceed as follows:

1. If necessary, activate the "Free-form comments on/off" button in the toolbar.
2. Right-click on the instruction for which you want to insert a free-form comment.
3. Select the "Insert comment" command in the shortcut menu.
   A comment box with a standard comment opens. The comment box is connected by an arrow to the corresponding instruction.
4. Enter the required comment in the comment box.

See also

Basic information on using free-form comments in LAD (Page 1600)

Editing free-form comments (Page 1601)

Deleting free-form comments (Page 1602)

Editing free-form comments

Introduction

Free-form comments can be edited as follows:

- Changing the comment text
- Changing the position and size of the comment box
- Attaching a comment to another element
- Showing and hiding free comments

Changing the comment text

To change the text of free-form comments, follow these steps:

1. Click on the comment box.
2. Enter the desired text.

Changing the position of the comment box

To change the positioning of the comment box, follow the steps below:

1. Left-click the comment box and keep the mouse button pressed.
2. Drag the comment box to the desired location.

Changing the size of the comment box

To change the size of the comment box, follow the steps below:

1. Click on the comment box.
2. Drag the comment box on the move handle in the lower right corner to the desired size.

Attaching a comment to another element

To attach a free-form comment to another element, follow these steps:

1. Left-click the point of the arrow that links the comment box with the instruction and keep the mouse button pressed.
2. Drag the arrow to the element to which you want to attach the comment. Possible insertion points are marked with a green square.
3. Release the mouse button.

Showing and hiding free comments

To show or hide a free-form comments, follow these steps:

1. Click the "Free-form comment on/off" button in the toolbar.

See also

Editing free-form comments (Page 1601)

Editing LAD elements

Selecting LAD elements

You can select several individual elements or all elements in a network.

Requirement

LAD elements are available

Selecting several individual LAD elements

To select several individual LAD elements, follow these steps:

1. Press and hold down the <Ctrl> key.
2. Click on all the LAD elements you wish to select.
3. Now release the <Ctrl> key.

Selecting all LAD elements in a network

To select all LAD elements in a network, follow these steps:

1. Go to the network whose elements you wish to select.
2. Select the "Select all" command in the "Edit" menu or press <Ctrl A>.

Deleting LAD elements (Page 1609)

Copying LAD elements

Requirement

An LAD element is available.

Procedure

To copy a LAD element, follow these steps:

1. Right-click the LAD element that you want to copy.
2. Select "Copy" in the shortcut menu.

Result

The LAD element will be copied and saved to the clipboard.

Removing inputs and outputs (Page 1607)
Enabling and disabling the EN/ENO mechanism (Page 1608)
Deleting LAD elements (Page 1609)

Cutting LAD elements

Requirement

An LAD element is available.

Cutting

To cut a LAD element, follow these steps:

1. Right-click the LAD element that you want to cut.
2. Select "Cut" in the shortcut menu.

Result

The LAD element will be cut and saved to the clipboard.

See also

Selecting LAD elements (Page 1602)

Deleting LAD elements (Page 1609)

Pasting an LAD element from the clipboard

Requirement

An LAD element is available.

Procedure

To paste an LAD element from the clipboard, follow these steps:

1. Copy a LAD element or cut a LAD element.
2. Right-click the point in the network where you want to paste the element.
3. Select "Paste" in the shortcut menu.

Removing inputs and outputs (Page 1607)

Enabling and disabling the EN/ENO mechanism (Page 1608)

Deleting LAD elements (Page 1609)

Replacing LAD elements

You can easily exchange LAD elements with other LAD elements of the same type. This has the advantage that the parameters are retained and need not be entered again. For example, you can exchange normally open contacts and normally closed contacts or RS FlipFlop and SR FlipFlop.

Requirements

A network with at least one LAD element is present.

Procedure

To replace an LAD element with another LAD element, follow these steps:

1. Select the LAD element that you want to replace.
2. Position the cursor over the triangle in the top right-hand corner of the LAD element. A drop-down list is displayed.
3. From the drop-down list, select the LAD element that you want to use to replace the existing LAD element.

Deleting LAD elements (Page 1609)

Inserting additional inputs and outputs in LAD elements

Introduction

You can expand LAD elements which execute commutative arithmetic instructions by adding additional inputs. Such elements are, for example, the instructions "Add" (ADD) and "Multiply" (MUL). You can expand the MOVE and DEMUX instruction boxes by adding additional outputs.

Requirement

An LAD element is available that permits the insertion of additional inputs and outputs.

Inserting an additional input

To add an additional input to the box of a LAD element, follow these steps:

1. Right-click on an existing input of the LAD element.
2. Select "Insert input" in the shortcut menu.
   An additional input is added to the box of the LAD element.

Or:

1. Click on the yellow star symbol beside the last input in the instruction box.
   An additional input is added to the box of the LAD element.

Inserting an additional output

To add an additional output to the box of a LAD element, follow these steps:

1. Right-click on an existing output of the LAD element.
2. Select "Insert output" from the shortcut menu.
   An additional output is added to the box of the LAD element.

Or:

1. Click on the yellow star symbol beside the last input in the instruction box.
   An additional output is added to the box of the LAD element.

Deleting LAD elements (Page 1609)

Removing inputs and outputs

Introduction

Inputs and outputs which you have added to an instruction can be removed.

Requirement

An LAD element is available to which you have added additional inputs and outputs.

Remove input

To remove an input, follow these steps:

1. Select the input that you want to remove.
2. Select the "Delete" command in the shortcut menu.
   The input of the LAD element is removed.

Remove output

To remove an output, follow these steps:

1. Select the output that you want to remove.
2. Select the "Delete" command in the shortcut menu.
   The output of the LAD element will be removed.

Inserting additional inputs and outputs in LAD elements (Page 1606)

Enabling and disabling the EN/ENO mechanism (Page 1608)

Deleting LAD elements (Page 1609)

Enabling and disabling the EN/ENO mechanism

In LAD and FBD, certain instructions have an enable output ENO and thus use the EN/ENO mechanism. This allows you to query runtime errors in instructions and react to them. In order to increase the performance of the CPU, the EN/ENO mechanism is disabled in the default setting. This means that you are not initially able to react to runtime errors of the instruction using the ENO value. However, you can enable the EN/ENO mechanism again at any time, if required.

You can enable the EN/ENO mechanism individually for each instruction in order to generate the ENO. If you enable the EN/ENO mechanism for an instruction, other instructions that you subsequently add to your program are also inserted with the EN/ENO mechanism enabled. You can disable the EN/ENO mechanism again at any time if you do not want to use the evaluation of ENO for an instruction. Further instructions that you subsequently add to your program will then be inserted without the EN/ENO mechanism.

See also: Basics of the EN/ENO mechanism (Page 1473)

Activating the EN/ENO mechanism

Proceed as follows to activate the EN/ENO mechanism of an instruction:

1. In your program, right-click the instruction at which you want to activate the EN/ENO mechanism.
2. Select the "Generate ENO" command from the shortcut menu.
   The ENO value is again generated for the instruction. Other instructions are inserted with the enable output.

Deactivating the EN/ENO mechanism

Proceed as follows to deactivate the EN/ENO mechanism of an instruction:

1. In your program, right-click the instruction at which you want to deactivate the EN/ENO mechanism.
2. Select the "Do not generate ENO" command from the shortcut menu.
   The ENO value is no longer generated for the instruction. Other instructions are inserted without enable output.

Copying LAD elements (Page 1603)

Cutting LAD elements (Page 1604)

Pasting an LAD element from the clipboard (Page 1604)

Replacing LAD elements (Page 1605)

Inserting additional inputs and outputs in LAD elements (Page 1606)

Removing inputs and outputs (Page 1607)

Enabling and disabling the EN/ENO mechanism (Page 1608)

Inserting operands into LAD instructions

Inserting operands

The character strings "<???>", "<??.?>" and "..." are inserted as placeholders for the parameters when an LAD element is inserted. The "<???>" and "<??.?>" strings displayed in red indicate parameters that need to be connected. The "..." string displayed in black indicates parameters that may be connected. "<??.?>" stands for Boolean placeholders.

Note

If you position the cursor over the placeholder, the expected data type will be displayed.

Requirement

An LAD element is available.

Procedure

To connect the parameters of a LAD element, follow these steps:

1. Double-click the placeholder of the parameter.
   An entry field opens, and the placeholder is selected.
2. Enter the appropriate parameter.

   Note

   If you enter the absolute address of a parameter that has already been defined, this absolute address will be changed to the symbolic name of the parameter as soon as the input is confirmed. If you have not yet defined the parameter, a new tag with this absolute address and the default name "Tag_<n>" will be entered in the PLC tag table. When you confirm your input, the absolute address will be replaced with the symbolic name "Tag_<n>".

3. Confirm the parameter with the Enter key.
4. If you have not yet defined the parameter, you can define it directly in the program editor using the shortcut menu.
   See also:
   Declaring PLC tags in the program editor (Page 1487)
   Declaring local tags in the program editor (Page 1558)

Or drag from it the PLC tag table:

1. In the project tree, select the "PLC tags" folder or open the PLC tag table.
2. If you have opened the PLC tag table, drag the symbol from the first column of the desired tag to the appropriate place in your program. If you have not opened the PLC tag table yet, open the detail view now. Drag the desired tag from the detail view to the appropriate place in your program.

Or drag from it the block interface:

1. Open the block interface.
2. Drag the required operand from the block interface to the instruction window.

Result

- If the syntax is error-free, the displayed parameter is black. The editor then jumps to the next placeholder.
- If there is an error in the syntax, the cursor stays in the entry field and a corresponding error message is displayed in the status line. If you press the Enter key again, the entry field is closed and the faulty entry is displayed in red italics.

Wiring hidden parameters

Introduction

Depending on the CPU used, you can use complex instructions in your program that are included with the TIA Portal. These instructions can contain parameters that are declared as hidden.

If an instruction contains hidden parameters, the instruction box has a small arrow on the lower edge. You can recognize hidden parameters by their white font.

You can show and wire the hidden parameters at any time.

Showing or hiding hidden parameters

To show or hide hidden parameters, follow these steps:

1. Click on the down arrow at the bottom edge of the instruction box to show hidden parameters.
2. Click on the up arrow at the bottom edge of the instruction box to hide hidden parameters.

Wiring hidden parameters

To wire parameters, follow these steps:

1. Wire the hidden parameters like normally visible parameters.
   The hidden parameter is transformed into a visible parameter.

Using libraries (Page 470)

Displaying or hiding variable information

Introduction

You can display the following information about the tags to be used in the Program editor:

- Name of the tag
- Address of the tag
- Simple or hierarchical comments for tag documentation

The information is taken from the block interface for local tags and DB tags and from the PLC tag table for tags that are valid CPU-wide.

You can display the tag information either for all the blocks or for individually opened blocks. If you display the tag information for all the blocks, the tag information for all the blocks currently opened and opened in future is shown.

You can hide the tag information at any time again. If you have hidden the tag information for all blocks, you can display it again for individual blocks that are open.

When you select the display of tag information with hierarchical comments, the comments of the higher structure levels are also displayed for structured tags. The comments are shown in brackets after the tag comment; the comments of the individual levels are separated by a dot. If there is no comment for a tag on a structure level, it is not displayed. This is indicated by two successive dots.

Displaying or hiding tag information for all the blocks

Proceed as follows to display or hide the tag information for all the blocks:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. In the area navigation, select the "PLC programming" group.
3. If you want to display the tag information, select the "Show" option or the "Tag information with hierarchical comments" option in the drop-down list, depending on whether you want to display simple or hierarchical comments.
4. If you want to hide the tag information, select the option "Collapse" in the "Tag information" drop-down list.
   The tag information is displayed or hidden for all the blocks. When you open additional blocks, the tag information is displayed or hidden depending on the selected setting.

Displaying or hiding tag information for an opened block

Proceed as follows to display or hide the tag information for an opened block:

1. If you want to display the tag information, select the "Show tag information" option or the "Tag information with hierarchical comments" option in the "Shows the tag information" drop-down list, depending on whether you want to display simple or hierarchical comments.
2. If you want to hide the tag information, select the option "Hide tag information" in the "Shows the tag information" drop-down list.
   The tag information is displayed or hidden.

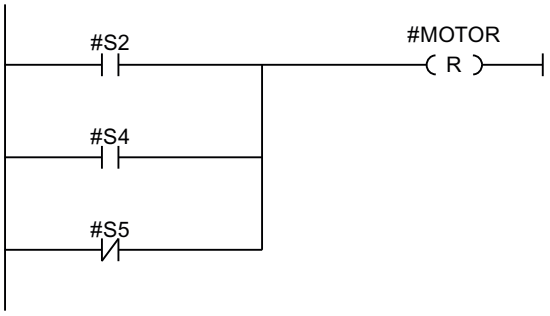
Branches in LAD

Basic information on branches in LAD

Definition

You use branches to program parallel circuits with the Ladder Logic (LAD) programming language. Branches are inserted in the main rung. You can insert several contacts into the branch and thus achieve a parallel circuit of series connections. This allows you to program complex ladder logic.

The figure below shows an example of the use of branches:



MOTOR carries signal 1, if one of the following conditions is fulfilled:

- Signal 1 is pending on S2 or S4
- Signal 0 is pending on S5.

See also

Rules for branches in LAD (Page 1613)

Inserting branches into the LAD network (Page 1614)

Closing branches in the LAD network (Page 1614)

Deleting branches in LAD networks (Page 1615)

Rules for branches in LAD

Rules

The following rules apply to simultaneous branches:

- A simultaneous branch can only be inserted if the main branch already contains an LAD element.
- Simultaneous branches are opened downwards or are connected directly to the power rail. They are terminated upwards.
- Simultaneous branches are opened after the selected LAD element.
- Simultaneous branches are terminated after the selected LAD element.
- To delete a simultaneous branch, you must delete all LAD elements of this branch. When the last LAD element is removed from the branch, the rest of the branch is also removed.

See also

Basic information on branches in LAD (Page 1612)

Inserting branches into the LAD network (Page 1614)

Deleting branches in LAD networks (Page 1615)

Closing branches in the LAD network (Page 1614)

Inserting branches into the LAD network

You can create several branches in a network.

Requirement

- A network is available.
- The network contains elements.

Procedure

To insert a new branch in a network, follow these steps:

1. Open the "Instructions" task card.
2. Navigate to "General > Open branches" in the "Simple instructions" palette.
3. Use drag-and-drop to move the element to the desired place in the network.
   If you want to connect the new branch directly to the power rail, drag the element to the power rail.

See also

Basic information on branches in LAD (Page 1612)

Rules for branches in LAD (Page 1613)

Deleting branches in LAD networks (Page 1615)

Closing branches in the LAD network

Branches must be closed again at suitable places. If necessary, branches will be arranged so that they do not cross each other.

Requirement

A branch is available.

Procedure

To close an open branch, follow these steps:

1. Select the open branch.
2. Press and hold down the left mouse button.
   A dashed line will appear as soon as the cursor is moved.
3. Drag the dashed line to a suitable place on the network. Permissible connections are indicated by green lines.
4. Release the left mouse button.

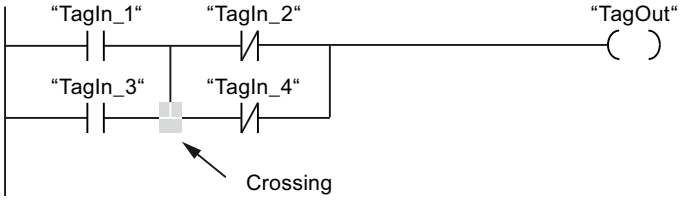
Inserting branches into the LAD network (Page 1614)

Crossings in LAD

Basic information on crossings in LAD

Definition

A crossing is a place in a LAD network where one branch is closed and at the same time another branch is opened.



"TagOut" receives signal 1, if the following two conditions are met:

- "TagIn_1" or "TagIn_3" has signal 1
- "TagIn_2" or "TagIn_4" has signal 0

Inserting crossings

You can insert crossings in a LAD network by creating connections between the main branch and an additional branch or between different branches.

Requirements

A branch is available.

Procedure

To insert a new crossing in an LAD network, follow these steps:

1. Open the "Instructions" task card.
2. Navigate to "General > Open branches" in the "Simple instructions" palette.
3. Drag the element behind the existing branch.
4. Insert any element into the open branch.
5. Click the arrow of the open branch after the inserted element.
6. Hold down the left mouse button and drag the dashed connecting line to the main branch.
7. Release the left mouse button.

See also

Deleting crossings (Page 1617)

Inserting branches into the LAD network (Page 1614)

Rearranging crossings

Requirement

A crossing is available.

Procedure

To rearrange a connection, follow these steps:

1. Select the connection line that defines the crossings in the respective branches.
2. Select the "Delete" command in the shortcut menu.
3. Open the "Instructions" task card.
4. Navigate to "General > Open branches" in the "Simple instructions" palette.
5. Use a drag-and-drop operation to move the element to the place in the network where you want to insert the new crossing.
6. Click on the arrow for the open branch.

7. Hold down the left mouse button and drag the dashed connecting line to the subsidiary branch in which you wish to insert the new crossing.
8. Release the left mouse button.

Inserting crossings (Page 1616)

Rearranging crossings (Page 1616)

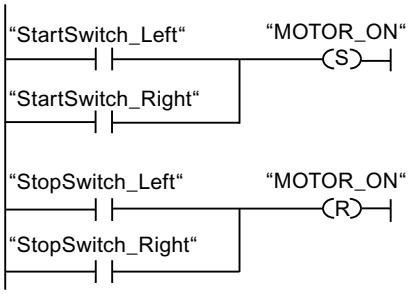
Rungs in LAD

Basic information on rungs in LAD

Using rungs

The program is mapped in one or more networks. A network contains a power rail on the left where one or more rungs originate. The binary signal scans are arranged in the form of contacts on the rungs. The serial arrangement of the elements on a rung creates a series connection; arrangement on simultaneous branches creates a parallel connection. A rung is closed by a coil or a box in which the result of logic operation will be written.

The figure below shows an example of the use of several rungs within a network:



Rules

Remember the following rules when using several rungs:

- Connections are not permitted between rungs.
- Only one jump instruction is permissible per network. The positioning rules for jump instructions remain valid.

Running rungs

Rungs and networks are executed from top to bottom and from left to right. This means that the first instruction in the first rung of the first network is processed first. All instructions of this rung are then processed. After this come all other rungs of the first network. The next network is processed only after all rungs have first been run.

Differences between branches and rungs

The difference between branches and rungs is that the rungs are independent branches that can also stand in a different network. Branches, on the other hand, permit the programming of a parallel connection.

Insert rung (Page 1618)

Deleting a rung (Page 1619)

Insert rung

Requirement

- A block is open.
- A network is available.

Procedure

To insert a new rung in a network, proceed as follows:

1. Insert any coil on the power rail.
   A new rung will be inserted and the coil positioned at the end of the rung.
2. Insert additional instructions in the new rung.

Deleting a rung (Page 1619)

Deleting a rung

Requirement

A rung is available.

Procedure

To delete a rung, proceed as follows:

1. Hold down the left mouse button and draw a frame around the rung. At the same time, make sure that you select all instructions. Alternatively, you can hold down the <Shift> key and select the first the last instruction of the rung.
2. Right-click on one of the instructions in the rung.
3. Select the "Delete" command in the shortcut menu.

Creating FBD programs

Basic information on FBD

FBD programming language

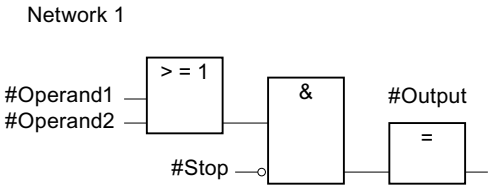
Overview of the Function Block Diagram (FBD) programming language

FBD is a graphical programming language. The representation is based on electronic circuit systems.

The program is mapped in one or more networks. A network contains one or more logic operation paths. The binary signal scans are linked by boxes. The representation of the logic is based on the graphical logic symbols used in Boolean algebra.

Example of networks in FBD

The following figure shows an FBD network with AND and OR boxes and an assignment:



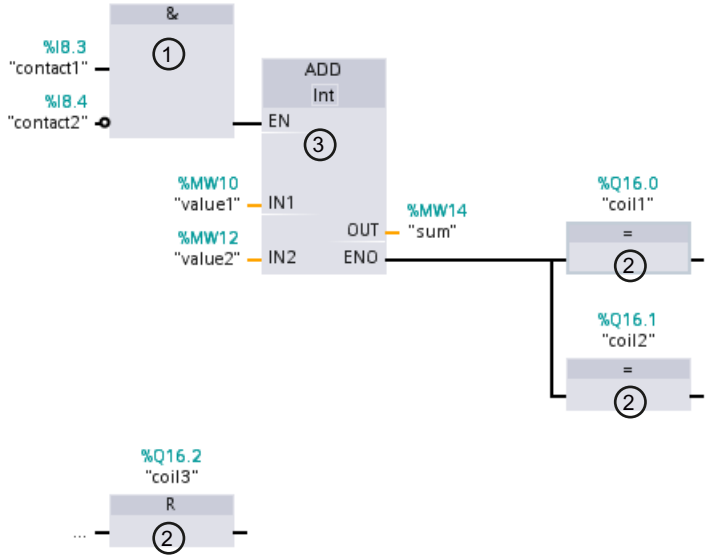
Overview of the FBD elements

FBD elements

An FBD program consists of separate elements that are linked by means of a binary signal flow. Most program elements must be supplied with tags.

A FBD network is programmed from left to right.

For example, the following figure shows elements of an FBD network:



1) Binary function

2) Standard box

3) Complex box

Binary functions

You can use binary functions to query binary operands and to combine their signal states. The following operations are examples of binary functions: "AND operation", "OR operation" and "EXCLUSIVE OR operation".

Standard boxes:

You can use standard boxes to control binary operands, perform RLO edge detection or execute jump functions in the program. Standard boxes generally have only one single input.

Complex boxes

Complex boxes represent program elements with complex functions. The empty box is an exception. You can use the empty box as a placeholder in which you can select the required instruction.

The following types of boxes are available to you in an FBD program:

- Complex boxes without EN/ENO mechanism:
  A box is executed independently of the signal state at the box inputs. The error status of the processing cannot be queried.
- Complex boxes with EN/ENO mechanism:
  A box is only executed if the enable input "EN" has the signal state "1". If the box is processed correctly, the "ENO" enable output has signal state "1". If an error occurs during processing, the "ENO" output is reset.
  If the EN enable input is not interconnected, the box is always executed.

Calls of code block are also shown in the network as complex boxes with EN/ENO mechanism.

Settings for FBD

Overview of the settings for FBD

Overview

The following table shows the settings that you can make:

Group	Setting	Description
Font	Font size	Font size in program editor
View	Layout	Compact or wide Changes the vertical spacing between operands and other objects (such as operand and contact). The change becomes visible once the block is reopened.
	With absolute information	Additional display of the absolute addresses

Group	Setting	Description
Operand field	Maximum width	Maximum number of characters that can be entered horizontally in the operand field. This setting recalculates the layout of the networks.
	Maximum height	Maximum number of characters that can be entered vertically in the operand field. This setting recalculates the layout of the networks.

Changing the settings (Page 1622)

Changing the settings

Procedure

To change the settings, follow these steps:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. In the area navigation, select the "PLC programming" group.
3. Change the settings.

Result

The change will be loaded directly, there is no need to save it explicitly.

Working with networks

Using networks

Function

The user program is created in the block within networks. For a code block to be programmed, it must contain at least one network. To achieve a better overview of the user program, you can also subdivide your program into several networks.

Selecting networks

Requirements

A network is available.

Selecting a network

To select a network, follow these steps:

1. Click the title bar of the network that you want to select.

Selecting several networks

Proceed as follows to select several individual networks:

1. Press and hold down the <Ctrl> key.
2. Click all the networks that you want to select.

To select several successive networks, follow these steps:

1. Press and hold down the <Shift> key.
2. Click the first network that you want to select.
3. Click the last network that you want to select.
   The first and last networks and all those in between are selected.

Copying and pasting networks

Copied networks can be pasted within the block or in another block. Networks that were created in LAD or FBD can also be inserted in blocks of the respective other programming language.

Requirement

A network is available.

Procedure

To copy and paste a network, follow these steps:

1. Select the network or networks to be copied.
2. Select "Copy" in the shortcut menu.
3. Select the network after which you want to paste in the copied network.
4. Select "Paste" in the shortcut menu.

Copying and pasting networks (Page 1624)

Deleting networks (Page 1625)

Inserting network title (Page 1626)

Entering a network comment (Page 1627)

Navigating networks (Page 1628)

Inserting network title

The network title is the header of a network. The length of the network title is limited to one line. You can enter the title manually or set it automatically. When you set it automatically, you can do this for individual networks or use the settings to specify that the network title is always set automatically.

For automatic insertion of the network title, the comment of the operand in one of the following instructions in the network is evaluated:

- Assignment
- Set output
- Reset output

The instruction that is listed first in the network is used.

The network title is only inserted automatically when the following conditions are fulfilled:

- The network does not have a title yet.
- The operand of the instruction used for the comment has a comment.

Note

Note the following restrictions for automatic insertion of the network title:

- The network title is not adapted if you change the comment of the operand at a later time.
- The network title is not adapted if you change the operand of the instruction.
- The network title is only set by the writing instructions listed above.
- If the operand is of the data type array, the comment of the array is used and not the comments of the array elements.
- Comments of invalid operands are not taken into consideration.

Entering the network title manually

To enter a network title, follow these steps:

1. Click on the title bar of the network.
2. Enter the network title.

Setting the network title automatically

To specify that the network titles are always set automatically, follow these steps:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. In the area navigation, select the "PLC programming" group.
3. Select the "Set network title automatically" check box in the "Additional settings" group.
   The network titles are set automatically as of this time if the conditions listed above are fulfilled.

To set an individual network title automatically, follow these steps:

1. Right-click "Network <Number of the network>" in the title bar of a network.
2. Select the "Set network title automatically" command in the shortcut menu.
   The title of the selected network is set based on the comment of the operand if the conditions listed above are fulfilled.

Navigating networks (Page 1628)

Entering a network comment

You can use network comments to provide comments on the program contents of individual networks. For example, you can indicate the function of the network or draw attention to special characteristics.

Requirement

A network is available.

Procedure

To enter a network comment, follow these steps:

1. Click on the right arrow before the network title.
2. If the comment area is not visible, click "Network comments on/off" in the toolbar.
   The comment area is displayed.

3. Click "Comment" in the comment area.
   The "Comment" text passage is selected.
4. Enter the network comment.

Navigating networks (Page 1628)

Navigating networks

You can navigate straight to a specific position within a block.

Procedure

To navigate to a specific position within a block, follow these steps:

1. Right-click in the code area of the programming window.
2. Select the "Go to > Network/line" command in the shortcut menu.
   The "Go to" dialog will open.
3. Enter the network to which you want to navigate.
4. Enter the line number of the network to which you want to navigate.
5. Confirm your entry with "OK".

Result

The relevant line will be displayed if this is possible. If the network or line requested does not exist, the last existing network or the last existing line in the network requested will be displayed.

Inserting FBD elements

Rules for the use of FBD elements

Rules

Note the following rules when inserting FBD elements:

- An FBD network can consist of several elements. All elements of a logic path must be linked to each other according to IEC 61131-3.
- Standard boxes (flip flops, counters, timers, math operations, etc.) can be added as output to boxes with binary logic operations (for example, AND, OR). Comparison boxes are excluded from this rule.
- Only Boolean inputs in an instruction can be combined with preceding logic operations.
- Only the bottom Boolean output in an instruction can be combined with an additional logic operation.
- Enable input EN or enable output ENO can be connected to boxes, but this is not mandatory.
- Constants (for example, TRUE or FALSE) cannot be assigned to binary logic operations. Instead, use tags of the BOOL data type.
- Only one jump instruction can be inserted in each network.
- Only one jump label can be inserted in each network.
- Instructions for positive or negative RLO edge detection may not be arranged right at the left of the network as this requires a prior logic operation.

Placement rules for S7-1200/1500 CPUs

The following table sets out the instructions that can only be positioned at the end of the network:

Instruction		Preceding logic operation required
Mnemonics	Name	
SET_BF	Set bit field	No
RESET_BF	Reset bit field	No
JMP	Jump if RLO = 1	No
JMPN	Jump if RLO = 0	Yes
JMP_LIST	Define jump list	No

Instruction		Preceding logic operation required
Mnemonics	**Name**	
SWITCH	Jump distributor	No
RET	Return	No

Placement rules for S7-300/400 CPUs

The following table sets out the instructions that can only be positioned at the end of the network:

Instruction		Preceding logic operation required
Mnemonics	**Name**	
S	Set output	Yes
R	Reset output	Yes
SP	Start pulse timer	Yes
SE	Start extended pulse timer	Yes
SD	Start on-delay timer	Yes
SS	Start retentive on-delay timer	Yes
SF	Start off-delay timer	Yes
SC	Set counter value	Yes
CU	Count up	Yes
CD	Count down	Yes
JMP	Jump if RLO = 1	No
JMPN	Jump if RLO = 0	Yes
RET	Return	No
OPN	Open global data block	No
OPNI	Open instance data block	No
CALL	Call block	No
SAVE	Save RLO in BR bit	No
MCRA	Enable MCR range	No
MCRD	Disable MCR range	No
MCR<	Open MCR ranges	No
MCR>	Close MCR ranges	No

Inserting FBD elements using the "Instructions" task card

Requirement

A network is available.

Procedure

To insert FBD elements into a network using the "Instructions" task card, follow these steps:

1. Open the "Instructions" task card.
2. Navigate to the FBD element that you want to insert.
3. Use drag-and-drop to move the element to the desired place in the network.
   If the element is an internal system function block (FB), the "Call options" dialog opens. In this dialog you can create an instance data block of the single-instance or multiple-instance type for the function block in which the data of the inserted element will be saved. You will find the new instance data block created in the project tree in the "Program resources" folder under "Program blocks > System blocks". If you have selected "multiple instance", these are located in the block interface in the "Static" section.

Or:

1. Select the point in the network at which you want to insert the element.
2. Open the "Instructions" task card.
3. Double-click on the element you want to insert.
   If the element is an internal system function block (FB), the "Call options" dialog opens. In this dialog you can create an instance data block of the single-instance or multiple-instance type for the function block in which the data of the inserted element will be saved. You will find the new instance data block created in the project tree in the "Program resources" folder under "Program blocks > System blocks". If you have selected "multiple instance", these are located in the block interface in the "Static" section.

Result

The selected FBD element is inserted with dummy entries for the parameters.

See also

Rules for the use of FBD elements (Page 1629)

Inserting FBD elements using an empty box

Requirement

A network is available.

Procedure

To insert FBD elements into a network using an empty box, follow these steps:

1. Open the "Instructions" task card.
2. Navigate to "General > Empty box" in the "Basic instructions" palette.
3. Use a drag-and-drop operation to move the "Empty box" element to the desired place in the network.

4. Position the cursor over the triangle in the top right-hand corner of the empty box.
   A drop-down list is displayed.
5. Select the desired FBD element from the drop-down list.
   If the element is an internal system function block (FB), the "Call options" dialog opens. In this dialog you can create an instance data block of the single-instance or multiple-instance type for the function block in which the data of the inserted element will be saved. You will find the new instance data block created in the project tree in the "Program resources" folder under "Program blocks > System blocks". If you have selected "multi-instance", these are located in the block interface in the "Static" section.

Result

The empty box is changed to the respective FBD element. Placeholders are inserted for the parameters.

Selecting the data type of an FBD element

Selecting a data type

Introduction

Some instructions can be executed with several different data types. If you use one of these instructions in the program, you have to specify a valid data type for the instruction at the specific point in the program. For some instructions, you have to select the data types for the inputs and outputs separately.

Note

The valid data type (BOOL) for the tags on the enable input EN and the enable output ENO is predefined by the system and cannot be changed.

The valid data types for an instruction are listed in the instruction drop-down list. You specify the data type of the instruction by selecting an entry from the drop-down list. If the data type of an operand differs from the data type of the instruction and cannot be converted implicitly, the operand is displayed in red and a rollout with the corresponding error message appears.

Data type selection of mathematical instructions

Some mathematical instructions provide you with the option of having the data type automatically set corresponding to the data types of the operand. In the drop-down list for data type selection, these instructions have the entry "Auto" in addition to the actual data types. If you select this entry and then allocate the first operand, the data type of the operand is selected as data type for the instruction. The entry in the drop-down list changes to "Auto (<Data type>)", e.g. "Auto (Real)". If you allocate additional operands, the automatically set data type of the instruction is adjusted according to the following criteria:

- You supply all other operands with tags of the same data type:
  The data type of the instruction is not changed.
- You supply all other operands with tags whose data type is smaller than the data type of the instruction:
  The data type of the instruction is not changed. For the operand with the smaller data type, an implicit conversion is conducted if necessary.
- You supply an additional operand with a tag whose data type is greater than the data type of the instruction:
  The data type of the instruction is changed to the larger data type. An implicit conversion is performed, if necessary, for operands that deviate from the newly set data type of the instruction.

Each change in the data type of an operand can result in a change of the data type of the instruction. Other operands may possibly be implicitly converted as a result. Operands for which an implicit conversion is performed are marked with a gray square.

Note

Please also observe the information on data type conversion for your device and, in particular, the notes on the IEC check.

See also: Data type conversion (Page 2091)

Defining the data type of an instruction (Page 1633)

Defining the data type of an instruction

Introduction

Some instructions can be executed with several different data types. When you insert such instructions into your program, you must specify the data type for these instructions at the actual point in the program.

Specifying the data type by means of the drop-down list

To define the data type of an instruction using the drop-down list, follow these steps:

1. Insert the instruction at the required point in the program using drag-and-drop.
   The entry "???" (undefined) is displayed in the drop-down list of the inserted instruction.
2. Click the triangle in the upper corner of the drop-down list.
   The drop-down list will open to display the data types valid for the instruction.
3. Select a data type from the drop-down list.
   The selected data type is displayed.
4. If the instruction has two drop-down lists, select the data type for the instruction inputs in the left-hand drop-down list and the data type for the instruction outputs in the right-hand drop-down list.

Specifying data type by assigning tags

To define the data type of an instruction by assigning tags, follow these steps:

1. Insert the instruction at the required point in the program using drag-and-drop.
   The entry "???" (undefined) is displayed in the drop-down list of the inserted instruction.
2. At an input or output, specify a valid tag, the data type of which is to be applied as the instruction data type.
   The data type of the tag is displayed in the drop-down list.
3. Enter a valid tag at an input and a valid tag at an output if data types need to be defined for both the inputs and outputs of the instruction. The tag specified at the input determines the data type of the inputs; the tag specified at the output determines the data type of the outputs of the instruction.

Automatically specifying the data type of mathematical instructions

To automatically specify the data type for mathematical instructions, follow these steps:

1. Insert the mathematical instruction at the required point in the program using drag-and-drop.
   The entry "???" (undefined) is displayed in the drop-down list of the inserted instruction.
2. Select the "Auto" entry from the drop-down list.
3. Enter a valid tag at an input or output.
   The data type of the tag is applied as data type of the instruction. The entry in the drop-down list changes to "Auto (<Data type>)".

Using favorites in FBD

Adding FBD elements to Favorites

Requirement

- A block is open.
- The multipane mode is set for the "Instructions" task card or the Favorites are also displayed in the editor.

Procedure

To add SCL instructions to the Favorites, follow these steps:

1. Open the "Instructions" task card.
2. Maximize the "Basic instructions" pane.
3. Navigate in the "Basic instructions" pane to the instruction that you want to add to the Favorites.
4. Drag-and-drop the instruction into the "Favorites" pane or into the Favorites area in the program editor.

Note

To additionally display the Favorites in the program editor, click the "Display favorites in the editor" button in the program editor toolbar.

Inserting block calls in FBD

Inserting block calls using a drag-and-drop operation

You can insert calls for existing functions (FC) and function blocks (FB) using a drag-and-drop operation from the project tree. If you call function blocks from other function blocks, you can either call them as single-instance or multi-instance blocks. If a function block is called as single instance, it will store its data in a data block of its own. If a function block is called as multi-instance, it will store its data in the instance data block of the calling function block.

Requirement

- A network is available.
- The block that is to be called is available.

Inserting a call of a function (FC)

To insert a call of a function (FC) into a network using a drag-and-drop operation, follow these steps:

1. Drag the function from the project tree to the required network.

Inserting a call for a function block (FB)

To insert a call for a function block (FB), follow these steps:

1. Drag the function block from the project tree to the required network.
   The "Call options" dialog opens.
2. Enter in the dialog whether you wish to call the block as single or multi-instance.
   - If you click on the "Single instance" button, you will have to enter a name in the "Name" text box for the data block that you want to assign to the function block.
   - If you click on the "Multi-instance" button, you will have to enter the name of the tag in the "Name in the interface" text box; this is the name that you use to enter the called function block as a static tag in the interface of the calling block.
3. Confirm your entries with "OK".

Result

The function or the function block is inserted with its parameters. You can then assign the parameters.

See also: Auto-Hotspot

Note

If when calling a function block you specify an instance data block that does not exist, it will be created. If you have called a function block as a multi-instance, this will be entered as a static tag in the interface.

Updating block calls in FBD (Page 1638)

Changing the instance type (Page 1640)

Single instances (Page 1427)

Multi-instances (Page 1427)

Updating block calls in FBD

If interface parameters of a called block are changed, the block call can no longer be executed correctly. You can avoid such inconsistent block calls by updating the block calls.

You have the following options for updating the block calls:

- Explicit updating of all inconsistent block calls in the program editor.
  The inconsistent block calls within the open block are updated. The following actions are carried out in the process:
  - New parameters are added.
  - Deleted parameters are removed if they are not connected.
  - Renamed parameters get the new parameter names.
- Explicit updating of a block call in the program editor.
  The "Interface update" dialog is displayed. In this dialog, you have the option of changing the connection of the operands of the new interface. The inconsistent call of this block is then updated. The following actions are carried out in the process:
  - New parameters are added.
  - Deleted parameters are removed if they are not connected.
  - Renamed parameters get the new parameter names.
- Implicit updating during compilation.
  All block calls in the program as well as the used PLC data types will be updated. Note that when you call functions (FCs) before the next compilation process, all new formal parameters must be supplied with actual parameters.

Updating all inconsistent block calls in the program editor

To open all block calls in a block, follow these steps:

1. Open the calling block in the program editor.
2. Click "Update inconsistent block calls" in the toolbar.

Updating a specific block call in the program editor

To update a specific block call in the program editor, follow these steps:

1. Open the calling block in the program editor.
2. Right-click on the block call that you want to update.
3. Select the "Update" command in the shortcut menu.
   The "Interface update" dialog opens. This dialog shows the differences between the block interface in use and the changed interface of the called block.
4. If necessary, change the connection of the operands. To do this, you have the following options:
   - You can use either a drag-and-drop operation or a cut/copy-and-paste operation to move the operand from the old interface to the new interface.
   - You can delete an operand.
   - You can rename an operand.
   - You can specify a new operand via autocompletion.
5. Click "OK" to update the block call. If you want to cancel the update, click "Cancel".

Note

Note that the "Update block call" command is only available provided you did not previously update all block calls in the editor with the "Update inconsistent block calls" command.

Update block calls during compilation

Follow these steps to update all block calls and uses of PLC data types during compilation implicitly:

1. Open the project tree.
2. Select the "Program blocks" folder.
3. Select the command "Compile > Software (rebuild all blocks)" in the shortcut menu.

See also

Inserting block calls using a drag-and-drop operation (Page 1637)

Changing the instance type (Page 1640)

Changing the block call

You have the option of changing the called block for a block call. But keep in mind that no new instance data blocks are created, for example, when changing from a function (FC) to a function block (FB).

Procedure

To change the called block of a block call, follow these steps:

1. Click on the name of the called block within the block call and press the <F2> key. Or double-click the name of the called block.
   A text box opens, and the name of the currently called block is selected.
2. Enter the name of the block you want to call or select a block in the autocompletion.
3. If you want to call an FB, create a new instance data block, if necessary, and specify it as operand.

Changing the instance type

Instance type

There are two ways of calling function blocks:

- As a single instance
- As a multiple instance

See also: Auto-Hotspot

You can modify a defined instance type at any time.

Requirement

The user program contains a block call.

Procedure

To change the instance type of a function block, follow these steps:

1. Open the code block and select the block call.
2. Select the "Change instance" command in the shortcut menu.
   The "Call options" dialog opens.
3. Click the "Single instance" or "Multi instance" button.
   - If you select the "Single instance" instance type, enter a name for the data block that is to be assigned to the function block.
   - If you select "Multiple instance" as the instance type, enter in the "Name in the interface" text field the name of the tag with which the called function block is to be entered as a static tag in the interface of the calling block.
4. Confirm your entries with "OK".

Note

The previous single and multiple instances will not be deleted automatically.

See also

Inserting block calls using a drag-and-drop operation (Page 1637)

Updating block calls in FBD (Page 1638)

Inserting complex FBD instructions

Using the "Calculate" instruction

Requirement

A network is available.

Procedure

Proceed as follows to use the "Calculate" instruction:

1. Open the "Instructions" task card.
2. Navigate to "Math functions > CALCULATE" in the "Basic instructions" pane.
3. Use drag-and-drop to move the element to the desired place in the network.
   The instruction "Calculate" will be inserted for the data type with a placeholder expression and question mark.
4. Enter the data type for the calculation.
5. Enter the operands for the calculation.

   Note

   The calculation is run with the inputs of the "Calculate" instruction. If you want to use constants you must also insert appropriate inputs for them.

6. Click on the "Edit 'Calculate' instruction" button to replace the placeholder expression with the correct expression.
   The "Edit 'Calculate' instruction" dialog will open.
7. Enter the required expression in the "OUT:= " text box.

   Note

   In the "Example" area you can find an example of a valid expression and possible instructions that you can use.

   To determine a value with the help of Pythagoras' theorem, for example, enter "OUT := SQRT (SQR (IN1) + SQR (IN2))".

8. Confirm your entry with "OK".

Using free-form comments

Basic information on using free comments in FBD

Introduction

Free-form comments allow you to add comments to the source code for graphic programming languages similar to line comments for textual languages.

Free-form comments can be used for all non-binary boxes.

See also

Inserting free-form comments (Page 1642)

Editing free-form comments (Page 1643)

Deleting free-form comments (Page 1644)

Inserting free-form comments

Requirement

A network with instructions is available.

Procedure

To insert a free comment on an instruction, proceed as follows:

1. If necessary, activate the "Free-form comments on/off" button in the toolbar.
2. Right-click on the instruction for which you want to insert a free-form comment.
3. Select the "Insert comment" command in the shortcut menu.
   A comment box with a standard comment opens. The comment box is connected by an arrow to the corresponding instruction.
4. Enter the required comment in the comment box.

See also

Basic information on using free comments in FBD (Page 1642)

Editing free-form comments (Page 1643)

Deleting free-form comments (Page 1644)

Editing free-form comments

Introduction

Free-form comments can be edited as follows:

- Changing the comment text
- Changing the position and size of the comment box
- Attaching a comment to another element
- Showing and hiding free comments

Changing the comment text

To change the text of free-form comments, follow these steps:

1. Click on the comment box.
2. Enter the desired text.

Changing the position of the comment box

To change the positioning of the comment box, follow the steps below:

1. Left-click the comment box and keep the mouse button pressed.
2. Drag the comment box to the desired location.

Changing the size of the comment box

To change the size of the comment box, follow the steps below:

1. Click on the comment box.
2. Drag the comment box on the move handle in the lower right corner to the desired size.

Attaching a comment to another element

To attach a free-form comment to another element, follow these steps:

1. Left-click the point of the arrow that links the comment box with the instruction and keep the mouse button pressed.
2. Drag the arrow to the element to which you want to attach the comment. Possible insertion points are marked with a green square.
3. Release the mouse button.

Showing and hiding free comments

To show or hide a free-form comments, follow these steps:

1. Click the "Free-form comment on/off" button in the toolbar.

See also

Basic information on using free comments in FBD (Page 1642)
Inserting free-form comments (Page 1642)
Deleting free-form comments (Page 1644)

Deleting free-form comments

Procedure

To delete a free-form comment, proceed as follows:

1. Right-click on the free-form comment that you want to delete.
2. Select the "Delete" command in the shortcut menu.

See also

Basic information on using free comments in FBD (Page 1642)
Inserting free-form comments (Page 1642)
Editing free-form comments (Page 1643)

Editing FBD elements

Selecting FBD elements

You can select several individual elements or all elements in a network.

Requirement

FBD elements are available

Selecting several individual FBD elements

To select several individual FBD elements, follow these steps:

1. Press and hold down the <Ctrl> key.
2. Click on all the FBD elements you wish to select.
3. Now release the <Ctrl> key.

Selecting all FBD elements in a network

To select all FBD elements in a network, follow these steps:

1. Go to the network whose elements you wish to select.
2. Select the "Select all" command in the "Edit" menu or press <Ctrl+A>.

See also

Deleting FBD elements (Page 1651)

Copying FBD elements

Requirement

An FBD element is available.

Procedure

To copy an FBD element, follow these steps:

1. Right-click the FBD element that you want to copy.
2. Select "Copy" in the shortcut menu.

Result

The FBD element will be copied and saved to the clipboard.

See also

Removing instruction inputs and outputs (Page 1649)
Enabling and disabling the EN/ENO mechanism (Page 1650)
Deleting FBD elements (Page 1651)

Cutting FBD elements

Requirement

An FBD element is available.

Cutting

To cut an FBD element, follow these steps:

1. Right-click the FBD element that you want to cut.
2. Select "Cut" in the shortcut menu.

Result

The FBD element will be cut and saved to the clipboard.

See also

Selecting FBD elements (Page 1644)

Removing instruction inputs and outputs (Page 1649)
Enabling and disabling the EN/ENO mechanism (Page 1650)
Deleting FBD elements (Page 1651)

Pasting an FBD element from the clipboard

Requirement

An FBD element is available.

Procedure

To paste an FBD element from the clipboard, follow these steps:

1. Copy an FBD element or cut an FBD element.
2. Right-click the point in the network where you want to paste the element.
3. Select "Paste" in the shortcut menu.

See also

Removing instruction inputs and outputs (Page 1649)

Enabling and disabling the EN/ENO mechanism (Page 1650)

Deleting FBD elements (Page 1651)

Replacing FBD elements

You can easily exchange FBD elements with other FBD elements of the same type. This has the advantage that the parameters are retained and need not be entered again. For example, you can exchange OR and AND, RS-FlipFlop and SR-FlipFlop, comparison functions or jump instructions.

Requirements

A network with at least one FBD element is present.

Procedure

To replace an FBD element with another FBD element, follow these steps:

1. Select the FBD element that you want to replace.
   If elements compatible with the selected FBD element are available, a triangle will appear in the upper right-hand corner of the element.
2. Position the cursor above the triangle of the FBD element.
   A drop-down list is displayed.
3. From the drop-down list, select the FBD element that you want to use to replace the existing FBD element.

Removing instruction inputs and outputs (Page 1649)

Enabling and disabling the EN/ENO mechanism (Page 1650)

Deleting FBD elements (Page 1651)

Adding additional inputs and outputs to FBD elements

Introduction

You can expand several FBD elements with additional inputs that execute arithmetic or binary operations. Such elements are, for example, the instructions "Add" (ADD), "Multiply" (MUL), AND or OR. You can expand the "MOVE value" (MOVE) and "Demultiplex" (DEMUX) instruction boxes by adding additional outputs.

The name of the new inputs and outputs is comprised of the type of inserted element and a consecutive number. The name of a new input is may be "IN2"; the name of a new output may be "OUT2".

Requirements

An FBD element is available that permits the insertion of additional inputs and outputs.

Inserting an additional input

To add an additional input to the box of an FBD element, follow these steps:

1. Right-click on an existing input of the FBD element.
2. Select "Insert input" in the shortcut menu.
   An additional input is added to the box of the FBD element.

Or:

1. Click on the yellow star symbol beside the last input in the instruction box.
   An additional input is added to the box of the FBD element.

Inserting an additional output

To add an additional output to the box of an FBD element, follow these steps:

1. Right-click on an existing output of the FBD element.
2. Select "Insert output" from the shortcut menu.
   An additional output is added to the box of the FBD element.

Or:

1. Click on the yellow star symbol beside the last output of the instruction box.
   An additional output is added to the box of the FBD element.

Removing instruction inputs and outputs

Introduction

Inputs and outputs which you have added to an instruction can be removed.

Requirement

An FBD element is available, which you have expanded with additional inputs or outputs.

Remove input

To remove an input, follow these steps:

1. Select the input that you want to remove.
2. Select the "Delete" command in the shortcut menu.
   The input of the FBD element is removed.

Remove output

To remove an output, follow these steps:

1. Select the output that you want to remove.
2. Select the "Delete" command in the shortcut menu.
   The output of the FBD element will be removed.

Cutting FBD elements (Page 1646)
Pasting an FBD element from the clipboard (Page 1646)
Replacing FBD elements (Page 1647)
Adding additional inputs and outputs to FBD elements (Page 1648)

Enabling and disabling the EN/ENO mechanism (Page 1650)

Deleting FBD elements (Page 1651)

Enabling and disabling the EN/ENO mechanism

In LAD and FBD, certain instructions have an enable output ENO and thus use the EN/ENO mechanism. This allows you to query runtime errors in instructions and react to them. In order to increase the performance of the CPU, the EN/ENO mechanism is disabled in the default setting. This means that you are not initially able to react to runtime errors of the instruction using the ENO value. However, you can enable the EN/ENO mechanism again at any time, if required.

You can enable the EN/ENO mechanism individually for each instruction in order to generate the ENO. If you enable the EN/ENO mechanism for an instruction, other instructions that you subsequently add to your program are also inserted with the EN/ENO mechanism enabled. You can disable the EN/ENO mechanism again at any time if you do not want to use the evaluation of ENO for an instruction. Further instructions that you subsequently add to your program will then be inserted without the EN/ENO mechanism.

See also: Basics of the EN/ENO mechanism (Page 1473)

Activating the EN/ENO mechanism

Proceed as follows to activate the EN/ENO mechanism of an instruction:

1. In your program, right-click the instruction at which you want to activate the EN/ENO mechanism.
2. Select the "Generate ENO" command from the shortcut menu.
   The ENO value is again generated for the instruction. Other instructions are inserted with the enable output.

Deactivating the EN/ENO mechanism

Proceed as follows to deactivate the EN/ENO mechanism of an instruction:

1. In your program, right-click the instruction at which you want to deactivate the EN/ENO mechanism.
2. Select the "Do not generate ENO" command from the shortcut menu.
   The ENO value is no longer generated for the instruction. Other instructions are inserted without enable output.

Inserting operands in FBD instructions

Inserting operands

The character strings "<???>", "<??.?>" and "..." are inserted as placeholders for the parameters when a FBD element is inserted. The "<???>" and "<??.?>" strings displayed in red indicate parameters that need to be connected. The "..." string displayed in black indicates parameters that may be connected. "<??.?>" stands for Boolean placeholders.

Note

To display the available data types in a tooltip, move the cursor over the placeholder.

Requirement

An FBD element is available.

Procedure

To connect the parameters of an FBD element, follow these steps:

1. Click the placeholder of the parameter.
   An input field is opened.
2. Enter the corresponding parameters, for example a PLC tag, a local tag or a constant.

   Note

   If you enter the absolute address of a parameter that has already been defined, this absolute address will be changed to the symbolic name of the parameter as soon as the input is confirmed. If you have not yet defined the parameter, a new tag with this absolute address and the default name "Tag_1" will be entered in the PLC tag table. When you confirm your input, the absolute address will be replaced with the symbolic name "Tag_1".

3. Confirm the parameter with the Enter key.
4. If you have not yet defined the parameter, you can define it directly in the program editor using the shortcut menu.
   See also: "Declaring PLC tags in the program editor (Page 1487)".

Or drag from it the PLC tag table:

1. In the project tree, select the "PLC tags" folder and open the PLC tag table.
2. If you have opened the PLC tag table, drag the desired tag to the corresponding location in your program. If you have not opened the PLC tag table yet, open the detail view now. Drag the desired tag from the detail view to the appropriate place in your program.

Or drag from it the block interface:

1. Open the block interface.
2. Drag the desired operand from the block interface to the corresponding location in your program.

Result

- If the syntax is error-free, the displayed parameter is black.
- If there is an error in the syntax, the cursor stays in the input field and a corresponding error message is displayed in the inspector window in the "Info > Syntax" register.

Wiring hidden parameters

Introduction

Depending on the CPU used, you can use complex instructions in your program that are included with the TIA Portal. These instructions can contain parameters that are declared as hidden.

If an instruction contains hidden parameters, the instruction box has a small arrow on the lower edge. You can recognize hidden parameters by their white font.

You can show and wire the hidden parameters at any time.

Showing or hiding hidden parameters

To show or hide hidden parameters, follow these steps:

1. Click on the down arrow at the bottom edge of the instruction box to show hidden parameters.
2. Click on the up arrow at the bottom edge of the instruction box to hide hidden parameters.

Wiring hidden parameters

To wire parameters, follow these steps:

1. Wire the hidden parameters like normally visible parameters.
   The hidden parameter is transformed into a visible parameter.

See also

Using libraries (Page 470)

Displaying or hiding variable information

Introduction

You can display the following information about the tags to be used in the Program editor:

- Name of the tag
- Address of the tag
- Simple or hierarchical comments for tag documentation

The information is taken from the block interface for local tags and DB tags and from the PLC tag table for tags that are valid CPU-wide.

You can display the tag information either for all the blocks or for individually opened blocks. If you display the tag information for all the blocks, the tag information for all the blocks currently opened and opened in future is shown.

You can hide the tag information at any time again. If you have hidden the tag information for all blocks, you can display it again for individual blocks that are open.

When you select the display of tag information with hierarchical comments, the comments of the higher structure levels are also displayed for structured tags. The comments are shown in brackets after the tag comment; the comments of the individual levels are separated by a dot. If there is no comment for a tag on a structure level, it is not displayed. This is indicated by two successive dots.

Displaying or hiding tag information for all the blocks

Proceed as follows to display or hide the tag information for all the blocks:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. In the area navigation, select the "PLC programming" group.
3. If you want to display the tag information, select the "Show" option or the "Tag information with hierarchical comments" option in the drop-down list, depending on whether you want to display simple or hierarchical comments.
4. If you want to hide the tag information, select the option "Collapse" in the "Tag information" drop-down list.
   The tag information is displayed or hidden for all the blocks. When you open additional blocks, the tag information is displayed or hidden depending on the selected setting.

Displaying or hiding tag information for an opened block

Proceed as follows to display or hide the tag information for an opened block:

1. If you want to display the tag information, select the "Show tag information" option or the "Tag information with hierarchical comments" option in the "Shows the tag information" drop-down list, depending on whether you want to display simple or hierarchical comments.
2. If you want to hide the tag information, select the option "Hide tag information" in the "Shows the tag information" drop-down list.
   The tag information is displayed or hidden.

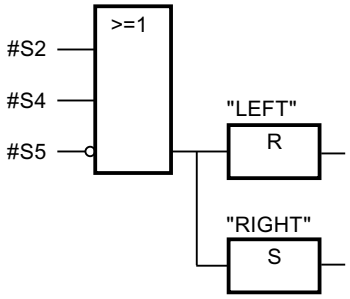
Branches in FBD

Basic information on branches in FBD

Definition

You can use the Function Block Diagram (FBD) programming language to program parallel branches. This is done using branches that are inserted between the boxes. You can insert additional boxes within the branch and in this way build up complex function block diagrams.

The figure below shows an example of the use of branches:



See also

Rules for branches in FBD (Page 1655)

Inserting branches in FBD networks (Page 1655)

Deleting branches in FBD networks (Page 1656)

Rules for branches in FBD

Rules

The following rules apply to the use of branches in FBD:

- Branches are opened downward.
- Branches can be inserted only between FBD elements.
- To delete a branch, you must delete all FBD elements, including the branch itself.
- If you delete the connection between two branches, the FBD elements of the interrupted branch will be positioned freely in the network.

See also

Basic information on branches in FBD (Page 1654)

Inserting branches in FBD networks (Page 1655)

Deleting branches in FBD networks (Page 1656)

Inserting branches in FBD networks

Requirement

A network is available.

Procedure

To insert a new branch in a network, follow these steps:

1. Open the "Instructions" task card.
2. Navigate to "General > Branch" in the "Basic instructions" palette.
3. Drag the element from the "Elements" pane to the a required location on a connection line between two boxes.

See also

Rules for branches in FBD (Page 1655)

Basic information on branches in FBD (Page 1654)

Deleting branches in FBD networks (Page 1656)

Deleting branches in FBD networks

Requirement

A branch is available.

Procedure

To delete a branch, follow these steps:

1. Select the connection line that links the branch to the main branch.
2. Select the "Delete" command in the shortcut menu.

Result

The branch is now deleted. Boxes connected to the deleted branch are placed freely within the network.

Inserting branches in FBD networks (Page 1655)

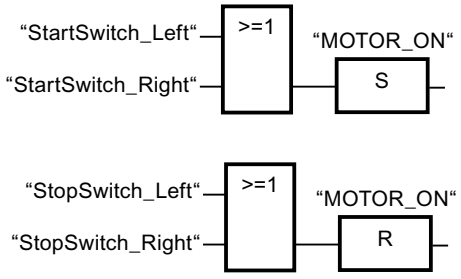
Logic paths in FBD

Basic information on logic paths in FBD

Use of logic paths

The user program will be mapped in one or more networks. The networks can contain one or more logic paths on which the binary signals are arranged in the form of boxes.

The following figure shows an example of the use of several logic paths within a network:



Rules

Remember the following rules when using logic paths:

- Connections are not permitted between logic paths.
- Only one jump instruction is permissible per network. The positioning rules for jump instructions remain valid.

Executing logic paths

Logic paths are executed from top to bottom and from left to right. This means that the first instruction in the first logic path of the first network is executed first. All instructions of this logic path are then executed. After this come all other logic paths of the first network. The next network is executed only after all logic paths have first been executed.

When jumps are used the regular execution of the logic paths is circumvented and the instruction is executed at the jump destination.

Differences between branches and logic paths

The difference between branches and logic paths is that the logic paths are independent branches that can also stand in a different network. Branches, on the other hand, permit the programming of a parallel connection and have a common preceding logic operation.

See also

Inserting a logic path (Page 1658)

Deleting a logic operation path (Page 1658)

Inserting a logic path

Requirement

- A block is open.
- A network is available.

Procedure

To insert a new logic path in a network, follow these steps:

1. Insert any instruction in a network in such a way that it has no connection to existing instructions.
   A new logic path is inserted.
2. Insert an assignment at the end of the new logic path.
3. Insert additional instructions in the new logic path.

See also

Basic information on logic paths in FBD (Page 1657)

Deleting a logic operation path (Page 1658)

Deleting a logic operation path

Requirement

A logic path is available.

Procedure

To delete a logic path, proceed as follows:

1. Hold down the left mouse button and draw a frame around the logic path. At the same time, make sure that you select all instructions of the logic path. Alternatively, you can hold down the <Shift> key and select the first the last instruction of the logic path.
2. Right-click on one of the instructions in the logic path.
3. Select the "Delete" command in the shortcut menu.

Inserting a logic path (Page 1658)

Creating SCL programs

Basics of SCL

Programming language SCL

Programming language SCL

SCL (Structured Control Language) is a high-level programming language based on PASCAL. The language is based on DIN EN 61131-3 (international IEC 1131-3).

The standard standardizes programming languages for programmable logic controllers. The SCL programming language fulfills the PLCopen Basis Level of ST language (Structured Text) defined in this standard.

Language elements

SCL also contains higher programming languages in addition to the typical elements of the PLC, such as inputs, outputs, timers or memory bits.

- Expressions
- Value assignments
- Operators

Program control

SCL provides convenient instructions for controlling the program allowing you, for example, to create program branches, loops or jumps.

Application

SCL is therefore particularly suitable for the following areas of application:

- Data management
- Process optimization
- Recipe management
- Mathematical / statistical tasks

Expressions

Description

Expressions are calculated during the runtime of the program and return a value. An expression consists of operands (such as constants, tags or function calls) and optionally out of operators (such as *, /, + or -). Expressions can be linked together or nested within each other by operators.

Evaluation order

The evaluation of the expression occurs in a specific order that is defined by the following factors:

- Priority of the operators involved
- Left-to-right order
- Brackets

Types of expressions

The following expression types are available depending on the operator:

- Arithmetic expressions
  Arithmetic expressions consist of either a numerical value or combine two values or expressions with arithmetic operators.
- Relational expressions
  Relational expressions compare the values of two operands and yield a Boolean value. The result is TRUE if the comparison is true, and FALSE if it is not met.
- Logical expressions
  Logical expressions combine two operands with logical operators (AND, OR, XOR) or negating operands (NOT).

How expressions are used

You can use the result of an expression in different ways:

- As a value assignment for a tag
- As as a condition for a control instruction
- As a parameter for a calling a block or instruction

See also

Operators and operator precedence (Page 1665)

Arithmetic expressions (Page 1660)

Relational expressions (Page 1663)

Logical expressions (Page 1665)

Arithmetic expressions

Description

Arithmetic expressions consist of either a numerical value or combine two values or expressions with arithmetic operators.

Arithmetic operators can process the data types that are allowed in the CPU in use. If two operands are involved in the operation, the data type of the result is determined based on the following criteria:

- If both operands are integers with sign and have different lengths, the result receives the data type of the longer integer (e. g. INT + DINT = DINT).
- If both operands are integers without sign and have different lengths, the result receives the data type of the longer integer (e. g. USINT + UDINT = UDINT).
- If one operand is an integer with sign and the other integer is an operand without sign, the result receives the next larger data type with sign that covers the integer without sign (e. g. SINT + USINT = INT).
  You can only execute an operation with such operands if the IEC check is not set.
- If one operand is an integer and the other operand is a floating-point number, the result receives the data type of the floating-point number (e. g. INT + REAL = REAL).
- If both operands are floating-point numbers and have different lengths, the result receives the data type of the longer floating-point number (e. g. REAL + LREAL = LREAL).
- The data type of the result of an operation that involves operands of the data type groups "Times" and "Date and time" can be found in the table in section "Data types of arithmetic expressions".
  You cannot use data types of the data type groups "Times" and "Date and time" when the IEC check is set.

Data types of arithmetic expressions

The following table shows the data types you can use in arithmetic expressions:

Operation	Operator	1st Operand	2nd Operand	Result
Power	**	Integer/floating-point number	Integer/floating-point number	Integer/floating-point number
Unary plus	+	Integer/floating-point number TIME, LTIME	-	Integer/floating-point number TIME, LTIME
Unary minus	-	Integer/floating-point number TIME, LTIME	-	Integer/floating-point number TIME, LTIME
Multiplication	*	Integer/floating-point number	Integer/floating-point number	Integer/floating-point number
		TIME, LTIME	Integer	TIME, LTIME
Division	/	Integer/floating-point number	Integer/floating-point number (not equal 0)	Integer/floating-point number
		TIME, LTIME	Integer	TIME, LTIME
Modulo function	MOD	Integer	Integer	Integer

Operation	Operator	1st Operand	2nd Operand	Result
Addition	+	Integer/floating-point number	Integer/floating-point number	Integer/floating-point number
		TIME	TIME	TIME
		TIME	DINT	TIME
		LTIME	TIME, LTIME	LTIME
		LTIME	LINT	LTIME
		TOD	TIME	TOD
		TOD	DINT	TOD
		LTOD	TIME, LTIME	LTOD
		LTOD	LINT	LTOD
		DATE	LTOD	DTL
		DATE	TOD	• S7-300/400: DT • S7-1200/1500: DTL
		DT	TIME	DT
		LDT	TIME, LTIME	LDT
		DTL	TIME, LTIME	DTL
Subtraction	-	Integer/floating-point number	Integer/floating-point number	Integer/floating-point number
		TIME	TIME	TIME
		TIME	DINT	TIME
		LTIME [1)]	TIME, LTIME	LTIME
		LTIME	LINT	LTIME
		TOD	TIME	TOD
			DINT	TOD
		LTOD	TIME, LTIME	LTOD
		LTOD	LINT	LTOD
		DATE	DATE	• S7-300/400/1200: TIME • S7-1500: LTIME
		DT	TIME	DT
		LDT	TIME, LTIME	LDT
		DTL	TIME, LTIME	DTL
		DTL	DTL	• S7-1200: TIME • S7-1500: LTIME
[1)] Combinations between nanoseconds and milliseconds are not possible within expressions.				

For additional information on valid data types, refer to "See also".

Example

The following example shows an arithmetic expression:

```
SCL
"MyTag1":= "MyTag2" * "MyTag3";
```

Expressions (Page 1659)

Operators and operator precedence (Page 1665)

Relational expressions

Description

Relational expressions compare the values of two operands and yield a Boolean value. The result is TRUE if the comparison is true, and FALSE if it is not met.

Relational operators can process the data types that are allowed in the CPU in use. The data type of the result always is BOOL.

Note the following rules when forming relational expressions:

- All tags are comparable within the following data type groups:
  - Integers/floating-point numbers
  - Binary numbers
  - String
- With the following data types/data groups, only tags of the same type can be compared:
  - TIME, LTIME
  - Date and time
- The comparison of strings is based on the ASCII character set. The length of the tags and the numerical value of each ASCII character are used for the comparison.
- S5TIME tags are not permitted as comparison operands. An explicit conversion from S5TIME to TIME or LTIME is necessary.

Data types of relational expressions

The following table shows the data types/data type groups you can use in relational expressions:

Operation	Operator	1st Operand	2nd Operand	Result
Compare for equal, not equal	=, <>	Integer/floating-point number	Integer/floating-point number	BOOL
		Binary number	Binary number	BOOL
		String	String	BOOL
		TIME, LTIME	TIME, LTIME	BOOL
		Date and time	Date and time	BOOL
Compare for less than, less than-equal to, greater than, greater than or equal to	<, <=, >, >=	Integer/floating-point number	Integer/floating-point number	BOOL
		Bit strings (S7-1200/1500 only)	Bit strings (S7-1200/1500 only)	BOOL
		String	String	BOOL
		TIME, LTIME	TIME, LTIME	BOOL
		Date and time	Date and time	BOOL

For additional information on valid data types, refer to "See also".

Example

The following example shows a relational expression:

SCL

```
IF a > b THEN c:= a;
IF A > 20 AND B < 20 THEN C:= TRUE;
IF A<>(B AND C) THEN C:= FALSE;
```

Note

The comparison for STRING and DT are executed internally in the S7-300/400 by extended instructions. The following operands are not permitted for these functions:

- Parameter of a FC
- In-out parameter of an FB of type STRUCT or ARRAY

Expressions (Page 1659)

Operators and operator precedence (Page 1665)

Logical expressions

Description

Logical expressions combine two operands with logical operators AND OR XOR or negating operands NOT.

Logical operators can process the data types that are allowed in the CPU in use. The result of a logical expression is of BOOL data type, if both operands are of BOOL data type. If at least one of both operands is a bit string, then the result is also a bit string and is determined by the type of the highest operand. For example, when you link a BYTE type operand to a WORD type operand, the result is type WORD.

To link a BOOL type operand with a bit string, you must first explicitly convert it to a bit string.

Data types of logical expressions

The following table shows the data types you can use in logical expressions:

Operation	Operator	1st Operand	2nd Operand	Result
Negation	NOT	BOOL	-	BOOL
AND logic operation	AND or &	BOOL	BOOL	BOOL
		Bit string	Bit string	Bit string
OR logic operation	OR	BOOL	BOOL	BOOL
		Bit string	Bit string	Bit string
EXCLUSIVE OR logic operation	XOR	BOOL	BOOL	BOOL
		Bit string	Bit string	Bit string

Example

The following example shows a logical expression:

```
SCL
IF "MyTag1" AND NOT "MyTag2" THEN c:=a;
MyTag:=ALPHA OR BETA;
```

Expressions (Page 1659)

Operators and operator precedence (Page 1665)

Operators and operator precedence

Operators and their order of evaluation

Expressions can be linked together or nested within each other by operators.

The order of evaluation for expressions depends on the precedence of operators and brackets. The following basic rules apply:

- Arithmetic operators are evaluated before relational operators and relational operators are evaluated before logical operators.
- Operators with no precedence are evaluated according to their occurrence from left to right.
- Operations in brackets are evaluated first.

The following table provides an overview of the operators and their precedence:

Operator	Operation	Precedence
Arithmetic expressions		
+ (Page 1660)	Unary plus	2
- (Page 1660)	Unary minus	2
** (Page 1660)	Power	3
* (Page 1660)	Multiplication	4
/ (Page 1660)	Division	4
MOD (Page 1660)	Modulo function	4
+ (Page 1660)	Addition	5
- (Page 1660)	Subtraction	5
Relational expressions		
< (Page 1663)	Less than	6
> (Page 1663)	Greater than	6
<= (Page 1663)	Less than or equal	6
>= (Page 1663)	Greater than or equal	6
= (Page 1663)	Equal	7
<> (Page 1663)	Not equal	7
Logical expressions		
NOT (Page 1665)	Negation	3
AND (Page 1665) or & (Page 1665)	Boolean AND	8
XOR (Page 1665)	Exclusive OR	9
OR (Page 1665)	Boolean OR	10
Miscellaneous operations		
( ) (Page 1659)	Brackets	1
:= (Page 1666)	Assignment	11

Value assignments

Definition

You can use a value assignment to assign the value of an expression to a tag. On the left side of the assignment is the tag that takes the value of the expression on the right.

The name of a function can also be specified as an expression. The function is called by the value assignment and returns its function value to the tag on the left.

The data type of value assignment is defined by the data type of the tag on the left. The data type of the expression on the right must match this type.

For additional information on compatibility and conversion of data types, refer to "See also".

Value assignments for STRUCT data type or PLC data types

An entire structure can be assigned to another if the structures are identically organized and the data types as well as the names of the structural components match.

You can assign a tag, an expression or another structural element to an individual structural element.

Value assignments for the ARRAY data type

An entire ARRAY can be assigned to another ARRAY if both the data types of the ARRAY elements as well as the ARRAY limits match.

You can assign a tag, an expression or another ARRAY element to an individual ARRAY element.

Value assignments for the STRING data type

An entire STRING can be assigned to another STRING.

You can assign another STRING element to an individual STRING element.

Value assignment for data type WSTRING (S7-1200/1500)

An entire WSTRING can be assigned to another WSTRING.

You can assign another WSTRING element to an individual WSTRING element.

Value assignments for the ANY data type

You can assign a tag with the ANY data type only to the following objects:

- Input parameters or temporary local data of FBs that also have the data type ANY.
- Temporary local data of FCs that also have the data type ANY.

Note that you can only point to memory areas with "standard" access mode with the ANY pointer.

Value assignments for the POINTER data type

You cannot use POINTER in value assignments in SCL.

Examples

The following table shows examples for value assignments:

SCL	
`"MyTag1" := "MyTag2";`	`(* Assignment of a tag*)`
`"MyTag1" := "MyTag2" * "MyTag3";`	`(* Assignment of an expression*)`
`"MyTag" := "MyFC"();`	`(* Call for a function that assigns its function value to the "MyTag" tag*)`
`#MyStruct.MyStructElement := "MyTag";`	`(* Assignment of a tag to a structure element*)`
`#MyArray[2] := "MyTag";`	`(* Assignment of a tag to an ARRAY element*)`
`"MyTag" := #MyArray[1,4];`	`(* Assignment of an ARRAY element to a tag*)`
`#MyString[2] := #MyOtherString[5];`	`(* Assignment of a STRING element to another STRING element*)`

Settings for SCL

Overview of the settings for SCL

Overview

The following tables show the settings you can make for SCL:

Editor settings

Group	Setting	Description
View	Keyword highlighting	Notation used to represent the keywords of the programming language. You can choose between uppercase and lowercase letters or a notation corresponding to the conventions of the Pascal programming language.

Default settings for new blocks

If you create new blocks, the following settings are set as default values. You can change these in the block properties at a later point in time.

Group	Setting	Description
Compile	Create extended status information	Allows all tags in a block to be monitored. The memory requirements of the program and execution times increase, however, with this option.
	Check ARRAY limits[1)]	Checks at runtime whether array indices are within the declared range for an ARRAY. If an array index exceeds the permissible range, the enable output ENO of the block is set to "0".
	Set ENO automatically	Checks at runtime whether errors occur in the processing of certain instructions. If a runtime error occurs, the enable output ENO of the block is set to "0".
[1)]For CPUs of the S7-300/400 series: When the ARRAY limits are violated, the enable output ENO is set to FALSE. For CPUs of the S7-1200/1500 series: When the ARRAY limits are violated, the enable output ENO is not set to FALSE. See "Addressing structured variables (Page 1459)" for error query options.

Changing the settings (Page 1669)

Changing the settings

Procedure

To change the settings, follow these steps:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. In the area navigation, select the "PLC programming" group.
3. Change the settings.

Result

The change will be loaded directly, there is no need to save it explicitly.

Overview of the settings for SCL (Page 1668)

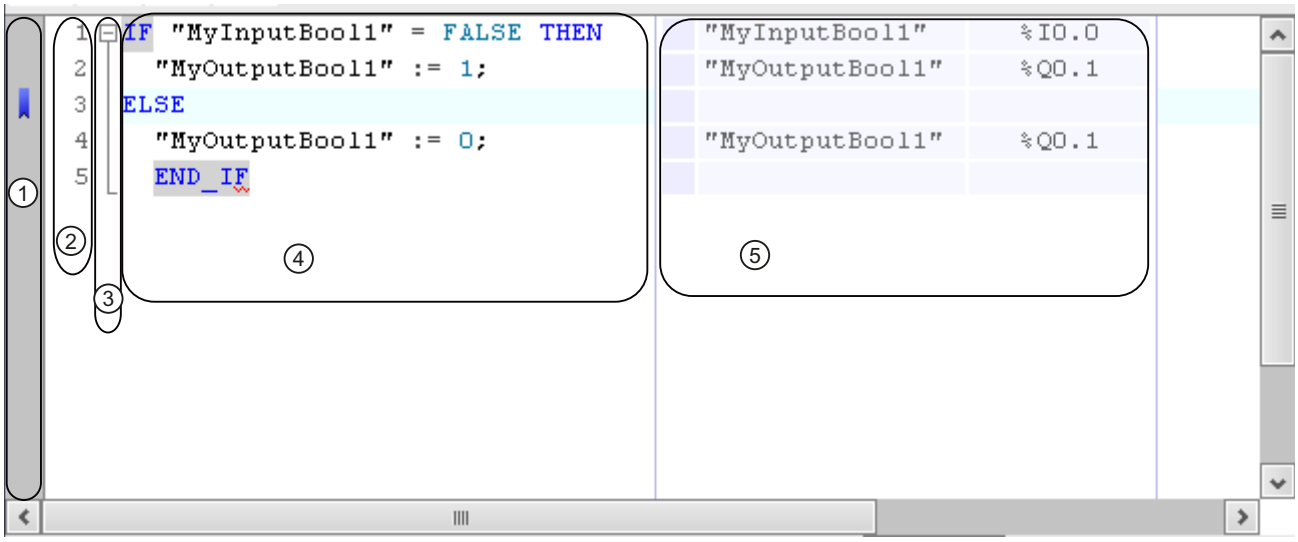
The programming window of SCL

Overview of the programming window

Function

The programming window is the work area, where you enter the SCL program.

The following figure shows the programming window of SCL:



The programming window consists of the following sections:

Section	Meaning
① Sidebar	You can set bookmarks and breakpoints in the sidebar.
② Line numbers	The line numbers are displayed to the left of the program code.
③ Outline view	The outline view highlights related code sections.
④ Code area	You edit the SCL program in the code area.
⑤ Display of the absolute operands	This table shows the assignment of symbolic operands to absolute addresses.

Customizing the programming window (Page 1671)

Formatting SCL code (Page 1672)

Expanding and collapsing sections of code (Page 1673)

Customizing the programming window

Introduction

You can customize the appearance of the programming window and the program code in the following way:

- By setting the font, size and color
- By setting the tab spacing
- By displaying the line numbers
- By showing or hiding the absolute operands

Setting the font, size and color

To set the font, size and color, follow these steps:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. Select the "General > Script/text editors" group.
3. Select the desired font and font size or choose a font color for the individual language elements.

Setting the tab spacing

To provide a better overview of the program, lines are indented according to syntax. Define the depth of indentation with the tab spacing.

To set the tab spacing, follow these steps:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. Select the "General > Script/text editors" group.
3. Set the tab spacing.

Show line numbers

To display the line numbers, follow these steps:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. Select the "General > Script/text editors" group.
3. Select the "Show line numbers" option.

Show or hide the absolute operands

You can show the assignment of symbolic and absolute operands in a table next to the program code, if required.

To hide or show the display of the absolute operands, follow these steps:

1. Click the "Absolute/symbolic operands" icon in the toolbar.
   The display of the absolute operands appears.
2. To move the display, click the table and drag it to the desired position while holding down the mouse button.
3. To change the width of the table, click on the right or left table border and drag it to the right or left while holding down the mouse button.

Formatting SCL code (Page 1672)

Expanding and collapsing sections of code (Page 1673)

Formatting SCL code

Introduction

To make the program clearer, you can indent or outdent individual lines manually or format code sections. Note the following information about formatting code sections:

- The type of formatting is based on the general settings for indents, but at least the line or the section is always indented. If you selected the setting "Smart", unnecessary spaces within the SCL instruction are also removed.
- Only syntactically correct code sections can be formatted.
- If you place the insertion point in the first or last line of an instruction for program control, for example in an IF instruction in the line with the "IF", the entire instruction is formatted.
- If you select text, only the selected text is formatted.

Indenting or outdenting lines

To indent or outdent individual lines, follow these steps:

1. Click on the line you want to indent or outdent.
2. Press the "Indent text", "Outdent text" button into the toolbar of the programming editor.

Note

You can set the width of the indent in "Options > Settings".

Formatting code sections

To format code sections, follow these steps:

1. Select the text that you want to format or place the insertion point in the appropriate line.
2. Select the "Format selected text automatically" button into the toolbar of the programming editor.

Overview of the programming window (Page 1670)

Customizing the programming window (Page 1671)

Expanding and collapsing sections of code (Page 1673)

Overview of the script and text editor settings (Page 304)

Expanding and collapsing sections of code

Introduction

SCL instructions can span several lines. Examples for this are program control instructions or block calls.

Such instructions that belong together are identified as follows:

- An outline view between the display line number and the program code marks the entire code section.
- When you select the opening keyword, the closing keyword is automatically highlighted.

To improve clarity, you can expand or collapse sections of code that belong together in the outline display. The selected outline display is retained when you close the block or the project so that, the next time you open the block, the sections of code are displayed in exactly the same way as they were when you closed it.

Procedure

To expand or collapse the code section, follow these steps:

1. Click the minus sign in the outline view.
   The code section closes.
2. Click the plus sign in the outline view.
   The code section opens.

Formatting SCL code (Page 1672)

Using bookmarks

Basics of bookmarks

Function

You can use bookmarks to mark program locations in extensive programs so that you can find them quickly later if they need revising. Bookmarks are displayed in the sidebar of the programming window. You can navigate between multiple bookmarks within a block using menu commands.

Bookmarks are saved with the project and are therefore available for anyone who wants to edit the block. However, they are not loaded to a device.

Bookmarks are not evaluated when blocks are compared.

Setting bookmarks (Page 1674)

Navigating between bookmarks (Page 1675)

Deleting bookmarks (Page 1675)

Setting bookmarks

Requirement

The SCL block is open.

Procedure

To set a bookmark, follow these steps:

1. Right-click on the desired line in the sidebar.
2. Select the "Bookmarks > Set" command in the shortcut menu.

Or:

1. Click on the line in which you want to place the bookmark.
2. Click the "Set/delete bookmark" button in the toolbar.

Or:

1. Hold down the <Ctrl> key.
2. Click on the line in the sidebar in which you want to place the bookmark.

Result

A bookmark is placed in the program code.

See also

Basics of bookmarks (Page 1674)

Navigating between bookmarks (Page 1675)

Deleting bookmarks (Page 1675)

Navigating between bookmarks

Requirement

Several bookmarks are set in a block.

Procedure

To navigate between bookmarks, follow these steps:

1. Set the insertion cursor in the program code.
2. In the "Edit" menu, select the "Go to > Next bookmark" or "Go to > Previous bookmark" command.

Or:

1. Set the insertion cursor in the program code.
2. In the toolbar of the programming editor, click the "Go to next bookmark", "Go to previous bookmark" button.

Or:

1. Click in the sidebar.
2. Select the "Bookmarks > Next" or "Bookmarks > Previous" command in the shortcut menu.

Result

The line with the bookmark is highlighted.

See also

Basics of bookmarks (Page 1674)

Setting bookmarks (Page 1674)

Deleting bookmarks (Page 1675)

Deleting bookmarks

You can delete individual bookmarks or all bookmarks from the block or the CPU.

Deleting individual bookmarks

To delete an individual bookmark, follow these steps:

1. Right-click in the sidebar on the line in which you want to delete the bookmark.
2. Select the "Bookmarks > Remove" command in the shortcut menu.

Or:

1. Click on the line in which you want to delete the bookmark.
2. In the "Edit" menu, select the "Bookmarks > Remove" command.

Or:

1. Click on the line in which you want to delete the bookmark.
2. Click the "Set/delete bookmark" button in the toolbar.

Deleting all bookmarks from the block

To delete all bookmarks from the block, follow these steps:

1. Right-click in the sidebar.
2. Select the "Bookmarks > Delete all from block" command in the shortcut menu.

Or:

1. In the "Edit" menu, select the "Bookmarks > Delete all from block" command.

Entering SCL instructions

Rules for SCL instructions

Instructions in SCL

SCL recognizes the following types of instructions:

- Value assignments
  Value assignments are used to assign a tag a constant value, the result of an expression or the value of another tag.
- Instructions for program control
  Instructions for program control are used to implement program branches, loops or jumps.

- Additional instructions from the "Instructions" task card
  The "Instructions" task card offers a wide selection of standard instructions that you can use in your SCL program.
- Block calls
  Block calls are used to call up subroutines that have been placed in other blocks and to further process their results.

Rules

You need to observe the following rules when entering SCL instructions:

- Instructions can span several lines.
- Each instruction ends with a semicolon (;).
- No distinction is made between upper and lower case.
- Comments serve only for documentation of the program. They do not affect the program execution.

Examples

The following examples shows the various types of instructions:

```
SCL
// Example of a value assignment
"MyTag":= 0;
// Example of a block call
"MyDB"."MyFB" (ParamInput:= 10);
// Example of a program control instruction
WHILE "Counter" < 10 DO
    "MyTAG" := "MyTag" + 2;
END_WHILE;
```

Entering SCL instructions manually

Requirement

An SCL block is open.

Procedure

To enter SCL instructions, follow these steps:

1. Enter the syntax of the instruction using the keyboard.
   You are supported by the auto-complete function when performing this task. It offers all the instructions and operands that are allowed at the current location.
2. Select the required instruction or the desired operand from the auto-complete function.
   If you select an instruction that requires specification of operands, placeholders for the operands are inserted into the program. The placeholders for the operands are highlighted in yellow. The first placeholder is selected.

3. Replace this placeholder with an operand.
4. Use the <TAB> key to navigate to all other placeholders and replace them with operands.

Note

You can also drag-and-drop a defined operand from the PLC tag table or from the block interface into the program. To replace an operand that has already been inserted, hover the mouse pointer briefly over the operand to be replaced before releasing the mouse button. This selects the operand and when you release the mouse button it is replaced by the new operand.

Result

The instruction is inserted.

The programming editor performs a syntax check. Incorrect entries are displayed in red and italics. In addition, you also receive a detailed error message in the inspector window.

Inserting SCL instructions using the "Instructions" task card

The "Instructions" task card offers a wide selection of instructions that you can use in your SCL program. The SCL-specific instructions for program control are available in the "Instructions" task card.

Requirement

An SCL block is open.

Procedure

To insert SCL instructions into a program using the "Instructions" task card, follow these steps:

1. Open the "Instructions" task card.
2. To insert the instruction, select one of the following steps:
   - Navigate to the SCL instruction you want to insert and drag-and-drop it to the required line in the program code. The insertion location is highlighted by a green rectangle.
   - Select the location in the program code where you want to insert the instruction and then double-click on the instruction you want to insert.

   The instruction is inserted in the program. The placeholders for the operands are highlighted in yellow. The first placeholder is selected.

3. Replace this placeholder with an operand. You can also drag a tag from the interface or the PLC tag table with drag-and-drop to the placeholder.
4. Use the <TAB> key to navigate to all other placeholders and replace them with operands.

Result

The instruction is inserted.

The programming editor performs a syntax check. Incorrect entries are displayed in red and italics. In addition, you also receive a detailed error message in the inspector window.

Defining the data type of an SCL instruction

Basic information on the data types of SCL instructions

Introduction

The SCL instructions that you employ for block programming use specific data types to calculate function values. Certain SCL instructions only support the use of a specific data type. You cannot change the data type for these instructions. However, most of the SCL instructions support the use of different data types. We differentiate between the following two types of such instructions:

- Instructions for which the data type of the function value is determined by the data type of the input parameters. This is the case for most instructions.
- Instructions with default data type. The instructions listed in the following table are of this type.

You will have to change the default data type if this is incompatible with the data type of the input parameter used. You can always change the data type based on the following syntax:
`_<data type>`

SCL instructions with default data type

The following table lists the SCL instructions with default data types:

Instruction	Default data type
CEIL	DINT
DECO	DWORD
FLOOR	DINT
NORM_X	REAL

Instruction	Default data type
PEEK	BYTE
SCALE_X	INT
TRUNC	DINT
CONCAT	STRING

See also

Changing the data type of an SCL instruction (Page 1680)

Example for changing the data type of an SCL instruction (Page 1681)

Changing the data type of an SCL instruction

Procedure

Proceed as follows to insert an SCL instruction and change its data type:

1. Insert the instruction at the required point in the program using drag-and-drop.
2. Specify the operands for the instruction.
   The data type of the function value is specified based on the input parameters, or the default data type of the instruction is used.
3. Append the "_<data type>" string to the instruction name.
   "<data type>" represents the data type you need for the instruction.

See also

Basic information on the data types of SCL instructions (Page 1679)

Example for changing the data type of an SCL instruction (Page 1681)

Modifying the data types of IEC timers and IEC counters

IEC timers and IEC counters are internal system function blocks and require an instance data block. You can create the instance data blocks either as single or multi-instance. The data type of the instance data block is determined according to the associated instruction. For CPUs of the S7-1200 and S7-1500 series, you can, however execute the instructions with different data types, depending on your requirements.

If the newly set data type of the instance data block does not match the data type of the input parameter, an implicit conversion takes place if possible. If the conversion is not possible, you will receive an error message.

Procedure

To change the data type of an IEC timer or IEC-counter instance data block, proceed as follows:

1. Open the block in which you call the IEC timer or IEC counter.
   Depending on the instance type of the instance data block, there is a green-bordered box before (multi-instance) or after (single instance) the name of the instance data block.
2. Click the green-bordered box.
   A drop-down list box with the valid data types for the instance data block is opened.
3. Select the desired data type.

Example for changing the data type of an SCL instruction

Changing the default data type of the "Decode" instruction (DECO)

Data type DWORD is set as default if you insert the "Decode" instruction in the program.

```
"Tag_Result" := DECO(IN := "Tag_Value");
```

Modify the program code as follows to convert the data type from DWORD to BYTE:

```
"Tag_Result_BYTE" := DECO_BYTE(IN := "Tag_Value");
```

Changing the data type of an SCL instruction (Page 1680)

Displaying or hiding tag information

Introduction

Regardless of whether the operands are represented in absolute or symbolic form, you can show and hide simple or hierarchical comments used to document global tags. This information is taken from the PLC tag table.

You can display the tag information either for all the blocks or for individually opened blocks. If you display the tag information for all the blocks, the tag information for all blocks currently opened and opened in future is shown.

You can hide the tag information at any time again. If you have hidden the tag information for all blocks, you can display it again for individual ones that you have opened.

If you select the display of tag information with hierarchical comments, the comments of the higher structure levels of structured tags will also be displayed. The display is in brackets after the comment of the tags; the comments of the individual levels are separated by a period. If there is no comment at a structure level for a tag, it is omitted in the display and this is recognizable because there are two periods.

Displaying or hiding tag information for all blocks

Follow the steps below to display or hide the tag information for all blocks:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. In the area navigation, select the "PLC programming" group.
3. If you want to show the tag information, either select the "Expand" option in the "Tag information" drop-down list or the "Tag information with hierarchy" depending on whether you want to display simple or hierarchical comments.
4. If you want to hide the tag information, select the "Collapse" option in the "Tag information" drop-down list.
   The tag information is displayed or hidden for all blocks. When you open further blocks, the tag information is displayed or hidden depending on the selected setting.

Displaying or hiding tag information for an opened block

Follow the steps below to display or hide the tag information for an opened block:

1. If you want to show the tag information, either select the "Show tag information" option in the "Shows the tag information" drop-down list or the "Tag information with hierarchy" depending on whether you want to display simple or hierarchical comments.
2. If you want to hide the tag information, select the "Hide tag information" option in the "Hides tag information" drop-down list.
   The tag information is displayed or hidden.

Using Favorites in SCL

Adding SCL instructions to the Favorites

Requirement

- A block is open.
- The multipane mode is set for the "Instructions" task card or the Favorites are also displayed in the editor.

Procedure

To add SCL instructions to the Favorites, follow these steps:

1. Open the "Instructions" task card.
2. Maximize the "Basic instructions" pane.
3. Navigate in the "Basic instructions" pane to the instruction that you want to add to the Favorites.
4. Drag-and-drop the instruction into the "Favorites" pane or into the Favorites area in the program editor.

Note

To additionally display the Favorites in the program editor, click the "Display favorites in the editor" button in the program editor toolbar.

Inserting SCL instructions using Favorites

Requirement

- A block is open.
- Favorites are available.

Procedure

To insert an instruction into a program using Favorites, follow these steps:

1. Drag-and-drop the desired instruction from Favorites to the desired position.

Or:

1. Select the position in the program where you want to insert the instruction.
2. In the Favorites, click on the instruction you want to insert.

Note

To additionally display the Favorites in the program editor, click the "Display favorites in the editor" button in the program editor toolbar.

Removing SCL instructions from the Favorites (Page 1684)

Removing SCL instructions from the Favorites

Requirement

A code block is open.

Procedure

To remove instructions from Favorites, follow these steps:

1. Right-click on the instruction you want to remove.
2. Select the "Remove instruction" command in the shortcut menu.

Note

To additionally display the Favorites in the program editor, click the "Display favorites in the editor" button in the program editor toolbar.

Insert block calls in SCL

Basic information on the block call in SCL

Calling function blocks

Syntax of a call

The following syntax is used to call a function block as a single or multi-instance:

- Single instance:
  - If the function block originates from the project:
    `<DBName> (Parameter list)`
  - If the function block originates from the "Instructions" task card:
    `<DB name>.<Instruction name> (Parameter list)`
- Multi-instance
  `<#Instance name> (Parameter list)`

Calling as single instance or multi-instance

Function blocks can be called either as a single instance or a multi-instance.

- Calling as a single instance
  The called function block stores its data in a data block of its own.
- Calling as a multi-instance
  The called function block stores its data in the instance data block of the calling function block.

For additional information on the types of calls, refer to "See also".

Parameter list

If you call another code block from a SCL block, you can supply the formal parameters of the called block with actual parameters.

The specification of the parameters has the form of a value assignment. This value assignment enables you to assign values (actual parameters) to the parameters you have defined in the called block.

The formal parameters of the called code block are listed in brackets directly after the call. Input and in-out parameters have the assignment identifier ":=", output parameters have the assignment identifier "=>". A placeholder placed after the parameter shows the required data type and the type of the parameter.

Rules for supplying parameters

The following rules apply to supplying parameters:

- Constants, tags and expressions can be used as actual parameters.
- The assignment order is not of importance.
- The data types of formal and actual parameters must match.
- The individual assignments are separated by commas.
- If the called block has only one parameter, it is sufficient to specify the actual parameter in the brackets. The formal parameter need not be specified.

See also

Manually inserting block calls (Page 1689)

Inserting block calls with drag-and-drop (Page 1690)

Examples for calling a function block in SCL (Page 1687)

Calling functions

Syntax of a call

The following syntax is used to call a function:

```
<Function name> (Parameter list);     //Standard call
```

```
<Operand>:=<Function name> (Parameter list); // Call in an expression
```

Function value

Functions that provide a return value can be used in any expression in place of an operand. For this reason, the return value is also known as the "function value" in SCL.

The call options of functions depend on whether the function returns a function value to the calling block.

The function value is defined in the RET_VAL parameter. If the RET_VAL parameter is of the VOID data type, then the function will not return a value to the calling block. If the RET_VAL parameter has another data type, then the function returns a function value of this data type.

In SCL, all data types are permitted for the RET_VAL parameter except ANY, ARRAY, STRUCT and VARIANT, as well as the parameter types TIMER and COUNTER.

Call options

There are two possibilities for calling functions in SCL:

- Standard call for functions with and without a function value
  With a standard call, the results of the function is made available as an output and in-out parameter.
- Call in an expression for functions with a function value
  Functions that return a function value can be used in any expression in place of an operand, for example, a value assignment.
  The function calculates the function value, which has the same name as the function and returns it to the calling block. There the value replaces the function call.
  Following the call, the results of the function is made available as a function value or as an output and in-out parameter.

Parameter list

If you call another code block from a SCL block, you need to supply the formal parameters of the called block with actual parameters.

The specification of the parameters has the form of a value assignment. This value assignment enables you to assign values (actual parameters) to the parameters you have defined in the called block.

The formal parameters of the called code block are listed in brackets directly after the call. Input and in-out parameters have the assignment identifier ":=", output parameters have the assignment identifier "=>". A gray placeholder placed after the parameter shows the required data type and the type of the parameter.

Rules for supplying parameters

The following rules apply to supplying parameters to functions:

- All parameters of the function must be supplied.
- The assignment order is not of importance.

- Constants, tags and expressions can be used as actual parameters.
- The data types of formal and actual parameters must match.
- The individual assignments are separated by commas.
- If the called block has only one parameter, it is sufficient to specify the actual parameter in the brackets. The formal parameter need not be specified.
- When you call functions in SCL, you cannot use the release mechanism via EN. Use an IF statement instead to call functions conditionally.

See also

Manually inserting block calls (Page 1689)

Inserting block calls with drag-and-drop (Page 1690)

Examples for calling functions in SCL (Page 1688)

Examples for calling a function block in SCL

Calling as a single instance

The following example shows the call of an FB as a single instance:

```
SCL
// Call as a single instance
"MyDB" (MyInput:=10, MyInout:= "Tag1");
```

Result

After the call is executed, the value determined for the "MyInout" in/out parameter is available in "Tag1" in the "MyDB" data block.

Calling as a multi-instance

The following example shows the call of an FB as a multi-instance:

```
SCL
// Call as a multi-instance
"MyFB" (MyInput:= 10, MyInout:= "Tag1");
```

Result

After the "MyFB" block is executed, the value determined for the "MyInout" in-out parameter is made available in "Tag1" in the data block of the calling code block.

See also

Calling function blocks (Page 1684)

Manually inserting block calls (Page 1689)

Inserting block calls with drag-and-drop (Page 1690)

Examples for calling functions in SCL

Standard call

The following example shows a standard function call:

SCL

```
// Standard function call
"MyFC" (MyInput := 10, MyInOut := "Tag1");
```

Result

After the "MyFC" block is executed, the value determined for the "MyInOut" in/out parameter is available in "Tag1" in the calling block and needs to be further processed there.

Call in a value assignment

The following example shows a function call in a value assignment:

SCL

```
(*Call in a value assignment, a function value was defined for "MyFC" *)
#MyOperand := "MyFC" (MyInput1 := 3, MyInput2 := 2, MyInput3 := 8.9,
MyInOut := "Tag1");
```

Result

The function value of "MyFC" is transferred to "#MyOperand".

Call in an arithmetic expression

The following example shows a function call in an arithmetic expression:

SCL

```
(*Call in a mathematical expression, a function value was defined for
"MyFC"  *)
#MyOperand := "Tag2" + "MyFC" (MyInput1 := 3, MyInput2 := 2, MyInput3 :=
8.9);
```

Result

The function value of "MyFC" will be added to "Tag2" and the result will be transferred to "MyOperand".

Calling functions (Page 1685)

Manually inserting block calls (Page 1689)

Inserting block calls with drag-and-drop (Page 1690)

Manually inserting block calls

You can insert calls for functions (FCs) and function blocks (FBs).

Inserting a call for a function (FC)

Proceed as follows to insert a function call:

1. Enter the function name.
2. Confirm your entry with the Return key.
   The syntax for the function call including the parameter list is added to the SCL program. The placeholders for the actual parameters are highlighted in yellow. The first placeholder is selected.
3. Replace this placeholder with an actual parameter. You can also drag a tag from the interface or the PLC tag table with drag-and-drop to the placeholder.
4. Use the <TAB> key to navigate to all other placeholders and replace them with actual parameters.

Inserting a call for a function block (FB)

To insert a call for a function block (FB), follow these steps:

1. Enter the name of the function block.
2. Confirm your entry with the Return key.
   The "Call options" dialog opens.
3. In the dialog, specify whether you want to call the block as a single or multi-instance.
   - If you click the "Single instance" button, in the "Name" field enter a name for the data block to be assigned to the call.
   - If you click the "Multi-instance" button, in the "Name in the interface" field enter a name of the tag with which the called function block is to be entered as a static tag in the interface of the calling block.
4. Confirm your entries with "OK".
   The syntax for the function block call including the parameter list is added to the SCL program. The placeholders for the actual parameters are highlighted in yellow. The first placeholder is selected.

5. Replace this placeholder with an actual parameter. You can also drag a tag from the interface or the PLC tag table with drag-and-drop to the placeholder.
6. Use the <TAB> key to navigate to all other placeholders and replace them with actual parameters.

Result

The block call is inserted.

If you specify an instance data block that does not exist when calling a function block, it is created.

See also

Updating block calls (Page 1691)

Expanding and reducing the parameter list (Page 1693)

Using autocompletion in textual programming languages (Page 1548)

Inserting block calls with drag-and-drop

You can insert calls for existing functions (FC) and function blocks (FB) using a drag-and-drop operation from the project tree.

Requirement

The function to be called (FC) or the function block (FB) to be called is present.

Inserting a call for a function (FC)

To insert a function call using drag-and-drop, follow these steps:

1. Drag the function from the project tree into the program.
   The syntax for the function call including the parameter list is added to the SCL program. The placeholders for the actual parameters are highlighted in yellow. The first placeholder is selected.
2. Replace this placeholder with an actual parameter. You can also drag a tag from the interface or the PLC tag table with drag-and-drop to the placeholder.
3. Use the <TAB> key to navigate to all other placeholders and replace them with actual parameters.

Inserting a call for a function block (FB)

To insert a call for a function block (FB) using drag-and-drop, follow these steps:

1. Drag the function block from the project tree and drop it into the program.
   The "Call options" dialog opens.
2. In the dialog, specify whether you want to call the block as a single or multi-instance.
   - If you click the "Single instance" button, in the "Name" field enter a name for the data block to be assigned to the call.
   - If you click the "Multi-instance" button, in the "Name in the interface" field enter a name of the tag with which the called function block is to be entered as a static tag in the interface of the calling block.
3. Confirm your entries with "OK".
   The syntax for the function block call including the parameter list is added to the SCL program. The placeholders for the actual parameters are highlighted in yellow. The first placeholder is selected.
4. Replace this placeholder with an actual parameter. You can also drag a tag from the interface or the PLC tag table with drag-and-drop to the placeholder.
5. Use the <TAB> key to navigate to all other placeholders and replace them with actual parameters.

Result

The block call is inserted.

If you specify an instance data block that does not exist when calling a function block, it is created.

See also

Updating block calls (Page 1691)

Expanding and reducing the parameter list (Page 1693)

Using autocompletion in textual programming languages (Page 1548)

Updating block calls

If interface parameters of a called block are changed, the block call can no longer be executed correctly. You can avoid such inconsistent block calls by updating the block calls.

You have the following options for updating the block calls:

- Explicit updating of all inconsistent block calls in the programming editor.
  The inconsistent block calls within the open block are updated. The following actions are carried out in the process:
  - New parameters are added. Please note, however, that the parameters are hidden for function blocks (FBs) and the parameters are supplied via the corresponding instance data block (DB). If required, you can show the parameters using the shortcut menu command "Show all parameters".
  - Deleted parameters are not removed. If necessary, expand the parameter list to remove deleted parameters manually.
  - Renamed parameters get the new parameter names.
- Explicit updating of a block call in the programming editor.
  The inconsistent call of this block is updated at all call locations. The following actions are carried out in the process:
  - New parameters are added.
  - Deleted parameters are not removed. If necessary, expand the parameter list to remove deleted parameters manually.
  - Renamed parameters get the new parameter names.
- Implicit updating during compilation.
  All block calls in the program as well as the used PLC data types will be updated. Make sure that you manually remove deleted parameters before the compilation process and supply all new formal parameters with actual parameters when you call functions.

Updating all inconsistent block calls in the programming editor

To update all block calls in a block, follow these steps:

1. Open the calling block in the programming editor.
2. Click "Update inconsistent block calls" in the toolbar.
   All inconsistent calls are updated. If necessary, supply new formal parameters of functions (FCs) with actual parameters.

Updating a specific block call in the programming editor

To update a specific block call in the programming editor, follow these steps:

1. Open the calling block in the programming editor.
2. Right-click on the block call that you want to update.
3. Select the "Update block call" command in the shortcut menu.
4. If parameters were added, enter the values for the new block parameters.

Note

Note that the "Update block call" command is only available as long as you did not previously update all block calls in the editor with the "Update inconsistent block calls" command.

Updating block calls during compilation

To implicitly update all block calls and uses of PLC data types during compilation, follow these steps:

1. Open the project tree.
2. Select the "Program blocks" folder.
3. Select the "Compile > Software (rebuild all blocks)" command in the shortcut menu.

See also

Manually inserting block calls (Page 1689)

Inserting block calls with drag-and-drop (Page 1690)

Expanding and reducing the parameter list (Page 1693)

Expanding and reducing the parameter list

In SCL, if you call blocks or insert instructions that are system-internal function blocks, the syntax and the parameter list with the placeholders for the actual parameters are inserted in the SCL program. To make the program code easier to read, the unused optional parameters are removed from the parameter list when you edit other instructions. You can restore these at any time. You can also explicitly reduce the parameter list when you have finished assigning the parameters.

Expanding the parameter list

To expand the parameter list, follow these steps:

1. Right-click in the block call or the instruction.
2. Select the "Expand parameter list" command from the shortcut menu or press the key combination <Ctrl+Shift+Space bar>.
   The parameter list is displayed in full again.

Reducing the parameter list

To reduce the parameter list, follow these steps:

1. Right-click in the block call or the instruction.
2. Select the "Reduce parameter list" command from the shortcut menu or press the key combination <Ctrl+Shift+Space bar>.
   All unused optional parameters are hidden.

Inserting comments

Commenting program code

You have various options for commenting SCL programs:

- Line comment
  A line comment starts with "//" and extends to the end of the line.
- Comment section
  A comment section is started with "(* and completed by "*)". It can span several lines.

Inserting a line comment

To insert line comments, follow these steps:

1. Type "//" at the position where you want to place the comment. This does not have to be the beginning of the line.
2. Enter the comment text.

Inserting a comment section

To insert a comment section, follow these steps:

1. Type "(*" at the position where you want to place the comment. This does not have to be the beginning of the line.
2. Enter the comment text.
3. Complete the comment with "*)".

Disabling one or more lines with comments

To disable program code with comments, follow these steps:

1. Select the code lines you want to comment out.
2. Click the "Comment selection" button in the editor.
   "//" is inserted at the beginning of the line in the selected lines. The code that follows is interpreted as a comment. If lines already containing a line comment are disabled, "//" is inserted as well. If these lines are enabled again, the original comments are retained.

Enabling comment lines

To enable lines that have been commented out to be enabled as code again, proceed as follows:

1. Select the code lines you want to enable.
2. Click the "Remove comment" button in the editor.
   The "//" mark for line comments at the beginning of the line is removed.

Example

The following code contains comment sections and line comments

```
(*******************************************************************************
  A description of the instructions that follow can be placed here
*******************************************************************************)
IF "MyVal1" > 0 THEN //No division by 0
    "MyReal" := "MyVal2" (* input value *) / "MyVal1" (* measured value *);
END_IF;
//Data type conversion
"MyInt" := REAL_TO_INT("MyReal");
```

Editing SCL instructions

Selecting instructions

You can select individual instructions or all instructions of a block.

Requirement

An SCL block is open.

Selecting individual instructions

To select individual instructions, follow these steps:

1. Set the insertion mark before the first character that you want to select.
2. Press and hold down the left mouse button.
3. Move the cursor to a position after the last character that you want to select.
4. Release the left mouse button.

Selecting all the instructions of a program

To select all instructions, follow these steps:

1. In the "Edit" menu, select the "Select All" command or use the keyboard shortcut <Ctrl+A>.

Note

When you select the opening keyword of an instructing, the closing keyword is automatically highlighted.

Copying, cutting and pasting instructions

Copying an instruction

To copy an instruction, follow these steps:

1. Select the instruction you want to copy.
2. Select "Copy" in the shortcut menu.

Cutting an instruction

To cut an instruction, follow these steps:

1. Select the instruction you want to cut.
2. Select the "Cut" command in the shortcut menu.

Inserting an instruction from the clipboard

To insert an instruction from the clipboard, follow these steps:

1. Copy or cut an instruction.
2. Click on the position at which you want to insert the instruction.
3. Select "Paste" in the shortcut menu.

Deleting instructions

Requirement

An SCL block is open.

Procedure

To delete an instruction, follow these steps:

1. Select the instruction you want to delete.
2. Select the "Delete" command in the shortcut menu.

Eliminating syntax errors in the program

Basic information on syntax errors

Syntax errors

Below are some examples of syntax errors:

- Missing separators or the use of too many separators
- Incorrect keyword spelling
- Incorrect jump label spelling/notation
- Notation which does not match the set mnemonics (for example, "I2.3" instead of "E2.3")
- The use of key words as operands

Identification of syntax errors

Syntax errors are underlined in red or appear in red type.

This identification allows you to recognise incorrect inputs at a glance and jump from error to error to eliminate them. Syntax errors are also listed in the "Info" tab of the inspector window with an error message.

See also

Finding syntax errors in the program (Page 1697)

Finding syntax errors in the program

Procedure

To find syntax errors in the program, follow these steps:

1. Select the position in the program in which you wish to look for errors.
2. Click "Go to next error" in the toolbar.
   The first error after the position you have selected will be marked.

You can use "Go to next error" and "Go to previous error" in the toolbar to find and correct all errors in the block.

Or:

1. Open the error list in the inspector window with "Info > Syntax".
   All syntax errors are listed in the table with a short description of the error.
2. If there are any errors, click on the blue question mark next to the error text to obtain information on eliminating the problem.
3. Double-click the error you want to correct.
   The corresponding error is highlighted.

See also

Basic information on syntax errors (Page 1697)

Changing the programming language

Rules for changing the programming language

Rules

Observe the following rules if you want to change the programming language for a block:

- All CPU series:
  - You can only change the programming language of entire blocks. The programming language cannot be changed for individual networks.
  - You cannot switch blocks programmed in the programming languages SCL or GRAPH. In GRAPH blocks, however, you can change between LAD and FBD as network languages.
- S7-300/400:
  - You can only change between the programming languages LAD, FBD and STL.
  - You can create networks within a block using another programming language and then copy them into the desired block.
  - If the language of individual networks of the block cannot be changed, these networks is displayed in their original language.
- S7-1200/1500:
  - You can change between the programming languages LAD and FBD.
- S7-1500:
  - You can create STL networks within the LAD and FBD blocks. However, you cannot copy between STL and LAD/FBD.

Change the programming language

Procedure

To change the programming language, follow these steps:

1. Right-click the block in the project tree.
2. Select the "Properties" command in the shortcut menu.
   The dialog with the properties of the block opens.
3. Select the "General" entry in the area navigation.
4. Select the new programming language in the "Language" drop-down list.
5. Confirm your selection with "OK".

See also

Rules for changing the programming language (Page 1698)

Handling program execution errors

Basics of error handling

Introduction

Program execution errors are programming or I/O access errors. You have a number of different options for responding to program execution errors depending on the CPU used.

Handling program execution errors in S7-300/400

You can program the program execution error OB (OB 85) for S7-300/400 CPUs. If a program execution error occurs and you do not use the program execution error OB, the CPU will switch to "STOP" mode.

You will find additional information about the program execution error OB in the description of the mode of operation of S7-300/400 CPUs.

Handling program execution errors in S7-1200/1500

You can select the type of error handling for CPUs of the S7-1200 and S7-1500 series. You have the following two options:

- Use the CPU's global troubleshooting:
  - S7-1200: The CPU generates a diagnostic buffer entry and remains in "RUN" mode.
  - S7-1500: You can program the programming error OB (OB 121) and the I/O access error OB (OB 122) for S7-1500 CPUs. If no programming error OB exists in the CPU, the CPU switches to "STOP" mode when a programming error occurs. In the event of an I/O access error, the CPU always remains in "RUN" mode, regardless of whether the I/O access error OB is present.
    Please note, however, that an existing I/O access or programming error OB is not called synchronously to the error. Therefore, depending on the selected priority, the execution of I/O access or programming error OBs may be delayed instead of taking place immediately when the error occurs. If other errors occur before execution of the I/O access or programming error OB is complete, no further I/O access or programming error OB is called. If you want to prevent I/O access or programming error OBs from being discarded, set the priority correspondingly high.
    You can use the enable output ENO to detect I/O access and programming errors for the instructions "Read field" (FieldRead), "Write field" (FieldWrite) , "Read memory address" (PEEK) and "Write memory address" (POKE).
    You can find more information about these error OBs in the description of the mode of operation of S7-1500 CPUs.
- You use separate local error handling. Local error handling is error handling within a block. Local error handling has the following advantages:
  - The error information is stored in the system memory, which you can query and evaluate.
  - You can use the error information to program a response in the block to the error that has occurred.
  - Programmed error evaluation and error reactions do not interrupt the program cycle.
  - The system performance is not unnecessarily burdened by the local error handling. If no errors occur, programmed error analyses and reactions are not executed.
    Local error handling applies only to blocks for which it has been set explicitly. If local error handling is set for a block, no global error handling is conducted for errors in this block.

Note

Note the following information:

- All memory access errors and I/O access errors must be captured either by global or local error handling.
- If the parameters of an instruction do not cause any memory access errors, you can query the associated ENO.

GET_ERROR: Get error locally (Page 2414)

GET_ERR_ID: Get error ID locally (Page 2417)

Querying and fixing errors in the program code (Page 228)

Local error handling

Principles of local error handling

Introduction

Local error handling makes it possible to query the occurrence of errors within a block and evaluate the associated error information. You can set local error handling for organization blocks (OBs), function blocks (FBs), and functions (FCs). If local error handling is enabled, the system reaction is ignored.

Local error handling applies only to blocks for which it has been set explicitly. The local error handling setting is not assumed by a calling block, nor is it transferred to called blocks. For higher-level blocks and lower-level blocks, the system settings still apply provided dedicated error handling has not been programmed for these blocks.

General procedure for local error handling

When errors occur while a block is being executed with local error handling, a predefined response is initiated based on the following error types:

- Write errors: These errors are ignored, and program execution simply continues.
- Read errors: Program execution continues with the substitute value "0".
- Execution errors: Execution of the instruction is aborted. Program execution resumes with the next instruction.

Information about the first error that occurs is stored in the system memory. This information can be queried and output with an instruction (GET_ERROR or GET_ERR_ID). Error information is output in a format that can undergo additional processing. You can use additional instructions to analyze error information and program a reaction to the error based.

When information about the first error is queried, the error memory space in the system memory is enabled. Then, when additional errors occur, information about the next error is output.

Instructions for local error handling

You can use the following instructions for local error handling:

- GET_ERROR: Get error locally
- GET_ERR_ID: Get error ID locally

The instructions differ in the amount of error information that is output with each one.

For additional information on the instructions, refer to "See also".

See also

GET_ERROR: Get error locally (Page 2694)

GET_ERR_ID: Get error ID locally (Page 2417)

GET_ERR_ID: Get error ID locally (Page 2697)

GET_ERROR: Get error locally (Page 2414)

Error output priorities

Overview of the priorities

In local error handling, information about the first error that occurred is displayed. If multiple errors occur at the same time while an instruction is being executed, these errors are displayed according to their priority. The following table shows the priority of different types of errors.

Priority	Error type
1	Error in the program code
2	Missing reference
3	Invalid range
4	DB does not exist
5	Operands are not compatible
6	Width of specified area is not sufficient
7	Timers or counters do not exist
8	No write access to a DB
9	I/O error
10	Instruction does not exist
11	Block does not exist
12	Invalid nesting depth

The highest priority is 1 and the lowest priority is 12.

GET_ERROR: Get error locally (Page 2414)

Enabling local error handling for a block

Introduction

Local error handling is enabled for a block if you insert one of the following instructions in a network.

- GET_ERROR: Get error locally
- GET_ERR_ID: Get error ID locally

For additional information on the instructions, refer to "See also".

If local error handling is enabled for a block, the system reactions for this block are ignored.

Requirement

- The block is open.
- Die "Instructions" task card is open.

Procedure

To enable local error handling for a block, proceed as follows:

1. Navigate to the "Basic instructions" pane of the "Instructions" task card.
2. Open the "Program Control" folder.
3. Drag the instruction "Get error locally" (GET_ERROR) or "Get error ID locally" (GET_ERR_ID) to the required network.

Result

Local error handling is enabled for the open block. The "Handle errors within block" check box is selected in the Inspector window under "Properties > Attributes". This setting cannot be edited in the Inspector window. Local error handling can be deactivated by deleting the inserted instructions on local error handling.

11.1.4.3 Programming data blocks

Basic principles for programming of data blocks

A data block (DB) is used to save the values that are written during execution of the program.

In contrast to the code block, the data block contains only tag declarations. It contains no networks or instructions. The tag declarations define the structure of the data block.

Types of data blocks

There are two types of data blocks:

- Global data blocks
  The global data block is not assigned to a code block. You can access the values of a global data block from any code block. A global data block contains only static tags.
  The structure of the global data block can be freely defined. In the declaration table for data blocks, you declare the data elements that are to contained in the global data block.
- Instance data blocks
  The instance data block is assigned directly to a function block (FB). The structure of an instance data block cannot be freely defined, but is instead determined by the interface declaration of the function block. The instance data block contains exactly those block parameters and tags that are declared there.
  However, you can define instance-specific values in the instance data block, for example, start values for the declared tags.

ARRAY data blocks (S7-1500)

ARRAY data blocks are global data blocks that consist of an ARRAY. This ARRAY can be based on any data type. For example, an ARRAY of a PLC data type (UDT) is possible. The DB contains no other elements besides the ARRAY. Because of their flat structure, ARRAY data blocks facilitate access to the ARRAY elements and their transfer to called blocks.

The "Move operations" section of the "Instructions" task card offers options for addressing of ARRAY DBs.

PLC data types as a template for global data blocks

PLC data types can be used as templates for the creation of global data blocks with identical data structures. You create the structure as PLC data type only once and then generate the required data blocks by assigning the PLC data type.

System data types as a template for global data blocks

System data types can also be used as templates for creating global data blocks with identical data structure. System data types already have a pre-defined structure. You insert the system data type in the program only once and then generate additional data blocks with an identical structure by assigning the system data type.

Access modes

There are two different modes of accessing data values in data blocks:

- Data blocks with optimized access (only S7-1200)
  Data blocks with optimized access have no fixed defined structure. In the declaration, the data elements are assigned only a symbolic name and no fixed address within the block. You access the data values in these block via symbolic names.
  The "Optimized block access" attribute is always enabled for ARRAY data blocks.
- Data blocks with standard access (all CPU families)
  Data blocks with standard access have a fixed structure. In the declaration, the data elements are assigned both a symbolic name and a fixed address within the block. You can access the data values in these blocks via symbolic names or the address.
  ARRAY data blocks with standard access are not possible.

Retentivity of data values

To prevent data loss in the event of power failure, you can store the data values in a retentive memory area.

Global data blocks (DB) (Page 1416)

Instance data blocks (Page 1417)

Structure of the declaration table for data blocks

Structure of the declaration table for data blocks

The figure below shows the structure of the declaration table for data blocks. The display will vary depending on type of block and type of access.

	Name	Data type	Start value	Retain	Visible in HMI	Comment
	Input					
	MyInput1	Bool	false	☑	☑	
	Output					
	MyOutput1	Byte	0	☐	☑	
	InOut					
	Static					

Display of instance-specific values

In instance data blocks, you can apply the already defined values from the interface of the assigned function block or define instance-specific start values. Values that are applied from the function block cannot be edited. You can replace the grayed-out values with instance-specific values. Values that were already changed instance specific are not grayed out.

Meaning of the columns

The following table shows the meaning of the individual columns. You can show or hide the columns as required. The number of columns displayed varies depending on the CPU series.

Column	Explanation
	Symbol you can click to move or copy the tag. You can, for example, drag-and-drop the tag into a program and use it there as operand.
Name	Name of the tags.
Data type	Data type of the tags.
Offset	Relative address of the tags. The column is only visible in data blocks with standard access.
Default value	Default value of the tag in the interface of a higher-level code block or in a PLC data type. The values contained in the "Default value" column can only be changed in the higher-level code block or PLC data type. The values are only displayed in the data block.
Start value	Value that the tag should assume at startup. The default values defined in a code block are used as start values during the creation of the data block. You can then replace these adopted values with instance-specific start values. Specification of an start value is optional. If you do not specify any value, the tag assumes the default value at startup. If a default is not defined either, the default value valid for the data type is used. For example, the value "FALSE" is specified as standard for BOOL.
Monitor value	Current data value in the CPU. This column only appears if an online connection is available and you click "Monitor".
Snapshot	Shows values that were loaded from the device.
Retentivity	Marks the tag as retentive. The values of retentive tags are retained even after the power supply is switched off.
Visible in HMI	Shows whether the tag is visible by default in the HMI selection list.
Accessible from HMI	Shows whether HMI can access this tag during runtime.
Setting value	Setting values are the values that will probably have to be fine tuned during commissioning. After commissioning, the values of these tags can be transferred to the offline program as start values and stored there.
Comment	Comment to document the tags.

Basic information on start values (Page 1713)

Creating data blocks

Requirement

The "Program blocks" folder in the project tree is open.

Procedure

To create a data block, follow these steps:

1. Double-click the "Add new block" command.
   The "Add new block" dialog box opens.
2. Click the "Data block (DB)" button.
3. Select the type of the data block. You have the following options available to you:
   - To create a global data block, select the list entry "Global DB".
   - To create an ARRAY data block, select the "ARRAY DB" entry in the list.
   - To create an instance data block, select the function block to which you want to assign the instance data block from the list. The list contains only the function blocks that were previously created for the CPU.
   - To create a data block based on a PLC data type, select the PLC data type from the list. The list contains only the PLC data types that were previously created for the CPU.
   - To create a data block based on a system data type, select the system data type from the list. The list contains only those system data types that have already been inserted to program blocks in the CPU.
4. Enter a name for the data block.
5. Enter the properties of the new data block.
6. If you have selected an ARRAY DB as the data block type, enter the ARRAY data type and the high limit for the ARRAY.
   You can change the high limit for the ARRAY at any time in the property window of the created block. The ARRAY data type cannot be changed subsequently.
7. To enter additional properties of the new data block, click "Additional information".
   An area with further input fields is displayed.
8. Enter all the properties you require.
9. Activate the "Add new and open" check box if the block does not open as soon as it is created.
10. Confirm your entry with "OK".

Result

The new data block is created. You can find the data block in the project tree in the "Program blocks" folder.

Overview of block properties (Page 1518)

Updating data blocks

Introduction

Changes in the interface of a function block or a PLC data type can lead to the corresponding data blocks becoming inconsistent. These inconsistencies are marked in red in the declaration table and at the call point of the block. To remedy these inconsistencies, the data blocks must be updated.

You have three options to update block calls:

- Explicit updating in the declaration table for data blocks.
  The data block is updated. Changes from the interface of the assigned function block and changes to the used PLC data types are applied.
- Explicit updating in the program editor.
  The block calls in the open block will be updated. The associated instance data block is also adjusted in the process.
- Implicit updating during compilation.
  All block calls in the program as well as the used PLC data types and the corresponding instance data blocks are updated.

Explicit Updating in the Declaration Table for Data Blocks

To explicitly update an individual data block, follow these steps:

1. Open the data block.
2. Select "Update interface" in the shortcut menu.

Explicit Updating in the Program Editor

To update all block calls or a specific call within a block, follow these steps:

1. Open the block in the program editor.
2. Right-click on the instruction with the block call.
3. Select the "Update" command in the shortcut menu.
4. The "Interface update" dialog opens. This dialog shows the differences between the block interface in use and the changed interface of the called block.
5. If you want to update the block call, click "OK". To cancel the update, click "Cancel".

Implicit Updating during Compilation

To implicitly update all block calls and uses of PLC data types as well as the instance data blocks during the compiling, follow these steps:

1. Open the project tree.
2. Select the "Program blocks" folder.
3. Select the command "Compile > Software (rebuild all blocks)" in the shortcut menu.

Changing the properties of tags in instance data blocks (Page 1720)

Extending data blocks

Description

In order to enable the editing of PLC programs that have already been commissioned and that are running without error on a system, CPUs of the S7-1500 series and most CPUs of the S7-1200 V4 and higher series support the option of extending global data blocks during runtime.

You can download the modified blocks without setting the CPU to STOP and without affecting the values of already loaded tags.

This is a simple means of implementing program changes. This load process (download without reinitialization) will not have a negative impact on the controlled process.

Principle of operation

Each data block is always assigned a default memory reserve. The memory reserve is not used initially. Activate the memory reserve if you decide on loading interface changes after having compiled and downloaded the block. All tags that you subsequently declare will be saved to the memory reserve. A subsequent download has no impact on the values of tags that have already been loaded.

If you decide to review your program at a later time while the plant is not in operation, you are also provided an option of reworking the memory layout of individual or several blocks in a single pass. With this action, you move all tags from the reserve area to the regular area. The memory reserve is now cleared and made available for further interface extensions.

Requirements

This "Download without reinitialization" function is available if the following requirements are met:

- The project is in the "TIA Portal V12" format or a higher version.
- You are working with a CPU that supports "Download without reinitialization".
- The blocks were created in LAD, FBD, STL, or SCL.
- The blocks were created by the user, i.e. they are not included with the blocks delivered in your package.
- These blocks are assigned the optimized access attribute.

Basic steps

Perform the following steps if you want to extend the data block and then load the block without re-initialization.

1. All blocks have a default memory reserve of 100 bytes. You can adapt this memory reserve to suit your requirements.
2. Activate the memory reserve.
3. Extend the block interface.
4. Compile the block.
5. Download the block to the CPU as usual.

Reference

For more information on the various steps, refer to chapter "Loading blocks (S7-1200/1500) ".

Creating a data structure for global data blocks

Declaring tags of elementary data type

Requirement

A global data block is open.

Note

You cannot change the structure of instance data blocks and of data blocks based on a PLC data type directly, since the structures of these blocks are defined by the respective function block or the PLC data type.

The type of the data block is entered in the block properties.

Procedure

To declare a tag of the elementary data type, follow these steps:

1. Enter a tag name in the "Name" column.
2. In the "Data type" column, click the button for the data type selection.
   A list of the permissible data types is opened.
3. Select the desired data type.
4. Optional: Change the properties of the tags that are displayed in the other columns.
5. Repeat steps 1 to 4 for all tags that are to be declared.

Displaying and editing block properties (Page 1523)

Declaring tags of the ARRAY data type (Page 1711)

Declaring tags of STRUCT data type (Page 1712)

Editing tables (Page 347)

Declaring tags of the ARRAY data type

Requirement

A global data block is open.

Procedure

To declare a tag of the ARRAY data type, follow these steps:

1. Enter a tag name in the "Name" column.
2. Enter the "Array" data type in the "Data type" column. You will be supported by autocompletion in this step.
   The "Array" dialog opens.
3. In the "Data type" text box, specify the data type of the array elements.
4. In the "ARRAY limits" text box, specify the high and low limit for each dimension.
   Example of a one-dimensional ARRAY:
   `[0..3]`
   Example of a three-dimensional ARRAY:
   `[0..3, 0..15, 0..33]`
5. Confirm your entry.
6. Optional: Change the properties of the tags that are displayed in the other columns.

The tag is created but remains collapsed. To expand the ARRAY, click the triangle in front of the tag. Not that you cannot expand very large ARRAYs for reasons of clarity.

Entering start values of ARRAY elements

To set default start values for the individual elements of an ARRAY, follow these steps:

1. Click the triangle in front of the ARRAY data type tags.
   The ARRAY opens and the individual ARRAY elements are shown in separate rows.
2. Enter the required value in the "Start value" column.

See also

Array (Page 1941)

Declaring tags of STRUCT data type

Requirement

A global data block is open.

Procedure

To declare a tag of the STRUCT data type, follow these steps:

1. Enter a tag name in the "Name" column.
2. Enter "Struct" in the "Data type" column. You will be supported by autocompletion during input.
   An empty, indented row is inserted after the new tag.
3. Insert the first structural element in the first empty row.
   An additional empty row is inserted after the element.
4. Select a data type for the structure element.
5. Optional: Change the properties of the structural element that is displayed in the other columns of the block interface.
6. Repeat the step 4 to 7 for all additional structure elements.
   It is not necessary to end the structure explicitly. The structure ends with the last element that is entered.
7. To insert a new tag after the structure, leave a blank row after the end of the structure and then start the new tag in the second empty row.

Result

The tag of STRUCT data type is created.

Enter start values of structure elements

To set default start values for the individual elements of a structure, follow these steps:

1. Click the triangle in front of the STRUCT data type tags.
   The structure opens and the individual structure elements are shown in separate rows.
2. Enter the required value in the "Start value" column.

Note

S7-1500: A maximum of 252 structures in one data block

A maximum of 252 structures is permitted in one data block. If you need additional structures, you must restructure your program. You can, for example, create the structures in several global data blocks.

STRUCT (Page 1945)

Declaring tags based on a PLC data type

Requirements

- A global data block is open.
- A PLC data type is declared in the current CPU.

Procedure

To declare a tag based on a PLC data type, follow these steps:

1. Enter a tag name in the "Name" column.
2. Enter the PLC data type in the "Data type" column. You will be supported by autocompletion during input.
3. Optional: Change the properties of the tags that are displayed in the other columns of the table.

Result

The tag is created.

Layout of the block interface (Page 1551)

Define start values

Basic information on start values

Definition of "Start value"

The start value of a tag is a value defined by you which the tag assumes after a CPU startup.

The retentive tags have a special status. Their values take the defined start value only after a "cold restart". After a "warm restart", they retain their values and are not reset to the start value.

Definition of "Default value"

The structure of the data blocks can be derived from higher-level elements.

- An instance data block is based, for example, on the interface of a higher-level code block.
- A global data block can be based on a predefined PLC data type.

In this case you can define a default value for each tag in the higher-level element. These default values are used as start values during the creation of the data block. You can then replace these values with instance-specific start values in the data block.

Specification of an start value is optional. If you do not specify any value, the tag assumes the default value at startup. If a default is not defined either, the default value valid for the data type is used. For example, the value "FALSE" is specified as standard for BOOL.

Structure of the declaration table for data blocks (Page 1705)

Declaring local tags and constants in the block interface (Page 1557)

Applying values from the online program as start values (Page 1733)

Define start values

Define start values

To define the start values for the tags of a data block, follow these steps:

1. Open the data block.
   The "Default value" column shows the default values that were defined for the tags in the interface of a higher-level code block or in a PLC data type.
2. Click the "Expanded mode" button to show all elements of structured data types.
3. Enter the desired start values in the "Start value" column. The value must match the data type of the tag and should not exceed the range of the data type.
   The start values are defined. The tag takes the defined value at startup, provided it was not declared as retentive.

Resetting a tag to the default value

To reset a tag for which you have defined a start value to the default value, follow these steps:

1. Select a modified value in the table.
2. Delete the value.
   The default value is entered. The default value is displayed.

Resetting all tags to the default value

To reset to the default value all tags for which you have defined an start value, follow these steps:

1. Select the "Reset start values" icon in the toolbar.
   The default values are transferred to the "Start value" column. Write-protected start values are not overwritten.

See also

Basic information on start values (Page 1713)

Applying values from the online program as start values (Page 1733)

Loading changed values

Introduction

To apply the changed start values from the offline program to the online program, you must load the changes. The following cases must be distinguished:

- Loading changed start values of non-retentive tags
- Loading changed start values of retentive tags
- Loading changed start values of setting values

Requirement

The start values in the offline program were changed.

Procedure

To load changed start values of non-retentive tags, follow these steps:

1. Select the blocks to be loaded in the project tree.
2. Select the "Download to device > Software (only changes)" command from the shortcut menu.
   The blocks are compiled and loaded.
   The start values of the newly defined tags are placed in the load memory of the CPU. The program runs with the new start values at the next transition from STOP to RUN.

To load changed start values of retentive tags, follow these steps:

1. Select the blocks to be loaded in the project tree.
2. Select the "Compile > Software (rebuild all blocks)" command in the shortcut menu.
3. In the "Online" menu, select the "Download and reset PLC program" command.
   The online blocks are deleted and replaced with the new blocks. This reinitializes all tags, including the retentive tags.

Information about loading changed setting values and general information about loading can be found under "See also".

Initializing setting values in the online program (Page 1732)

Setting retentivity

Retentivity of tags in data blocks

Retentive behavior

To prevent data loss in the event of power failure, you can mark the data as retentive. This data is stored in a retentive memory area. The options for setting the retentivity depend on the type of data block and the type of block access that is set.

See also

Setting retentivity in an instance data block (Page 1716)

Setting retentivity in a global data block (Page 1717)

Setting retentivity in an instance data block

Introduction

In an instance data block, the editability of the retentive behavior depends on the type of access of the higher-level function block:

- Function block with standard access
  You can define the instance data both as retentive or non-retentive. Individual retentivity settings are not possible for individual tags.
- Function block with optimized access
  In the instance data block, you can define the retentivity settings of the tags that are selected in the block interface with "Set in IDB". With these tags also, you cannot individually set the retentive behavior for each tag. The retentivity setting has an impact on all tags that are selected in the block interface with "Set in IDB".

Setting Retentivity for Standard Access

To centrally set the retentivity of all tags in the data block with standard access, follow these steps:

1. Open the instance data block.
2. Select the check box in the "Retain" column of a tag.
   All tags are defined as retentive.
3. To reset the retentivity setting for all tags, clear the check box in the "Retain" column of a tag.
   All tags will be defined as non-retentive.

Setting Retentivity for Optimized Access

To set the retentive behavior of the tags that are selected with "Set in IDB" in data blocks with optimized access, follow these steps:

1. Open the instance data block.
2. Select the check box in the "Retain" column of a tag.
   All tags selected with "Set in IDB" in the data block interface are defined as retentive.
3. To reset the retentivity setting for the tags, clear the check box in the "Retain" column of a tag.
   All tags selected with "Set in IDB" in the data block interface will be defined as non-retentive.

Setting retentivity in a global data block

Introduction

In a global data block, the editability of the retentive behavior depends on the type of access:

- Global data block with standard access
  You can define the data both as retentive or non-retentive. Individual retentivity settings are not possible for individual tags.
- Global data block with optimized access
  You can individually define the retentivity settings of the tags. For tags with structured data types, retentivity settings are transferred for all tag elements.

Setting Retentivity for Standard Access

To centrally set the retentivity of all tags in the data block with standard access, follow these steps:

1. Open the global data block.
2. Select the check box in the "Retain" column of a tag.
   All tags are defined as retentive.
3. To reset the retentivity setting for all tags, clear the check box in the "Retain" column of a tag.
   All tags are defined as non-retentive.

Setting Retentivity for Optimized Access

To individually set the retentivity of all tags in data blocks with optimized access, follow these steps:

1. Open the global data block.
2. In the "Retain" column, select the check box for the tags for which you want to set a retentive behavior.
   The selected tag is defined as retentive.
3. To reset the retentivity setting for the tags, clear the check box in the "Retain" column of a tag.
   All selected tags are defined as non-retentive.

Editing the properties of tags in data blocks

Properties of the tags in data blocks

Properties

The following table provides an overview of the properties of tags in data blocks:

Group	Property	Description
General	Name	Name of the tags.
	Data type	Data type of the tags.
	Default value	Default value of the tag in the interface of a higher-level code block or in a PLC data type. The values contained in the "Default value" column can only be changed in the higher-level code block or PLC data type. The values are only displayed in the data block.
	Start value	Value that the tag should assume at CPU startup. The default values defined in a code block are used as start values during the creation of the data block. You can then replace these adopted values with instance-specific start values. Specification of an start value is optional. If you do not specify any value, the tag assumes the default value at startup. If a default is not defined either, the default value valid for the data type is used. For example, the value "FALSE" is specified as standard for BOOL.
	Comment	Comment on the tag.

Group	Property	Description
Attributes	Retain	Marks the tag as retentive. The values of retentive tags are retained even after the power supply is switched off. This attribute is only available in the interface of the function block with optimized access.
	Accessible from HMI	Indicates whether the tag can be used in HMI. When the attribute is set, you have read or write access to the tag from the HMI. When the attribute is not set, you cannot access the tag from the HMI. Please note, however, that you cannot implement general access protection for the tag with the "Accessible from HMI" attribute. Read or write access from other applications is possible even if the attribute is not enabled.
	Visible in HMI	Shows whether the tag is visible by default in the HMI selection list.
	Hidden parameter	Indicates whether the tag should be hidden for the block call. This is only possible if you have specified a valid predefined actual parameter beforehand.
	Predefined actual parameter	Defines a parameter that is to be used as actual parameter during the block call.
	Visible	Indicates whether a parameter is visible in CFC.
	Configurable	Indicates whether a parameter is configurable in CFC.
	For test	Indicates whether a parameter is registered for the CFC test mode.
	Interconnectable	Indicates whether a parameter is interconnectable in CFC.
	Enable tag readback	Indicates whether a parameter is relevant for the "Read back chart" function in CFC.
	Enumeration texts	Assigns a parameter to an enumeration in CFC.
	Engineering unit	Assigns a parameter to a unit in CFC.
	Low limit	Defines the low limit for the parameter in CFC.
	High limit	Defines the high limit for the parameter in CFC.

Changing the properties of tags in global data blocks (Page 1721)

Changing the properties of tags in instance data blocks

Instance-specific tag properties

Two options are available for defining the tag properties:

- The tag properties are applied from the interface of the assigned function block.
  Properties that are applied from the function block are displayed grayed out out in the columns of the declaration table. The "Name" and "Data type" properties are always applied.
- You define instance-specific properties.
  You can change some properties instance specific. Changeable values are, for example, "Comment" or "Visible in HMI". Properties that were changed instance specific are not grayed out in the columns of the declaration table. The instance-specific changes are retained, even if the interface of the higher-level function block is changed and the instance data blocks are subsequently updated.

Editing properties of an element in the declaration table

To edit the properties of an element, follow these steps:

1. Open the instance data block.
2. Select the required element in the table.
3. Change the entries in the columns.

Editing properties of several elements in the declaration table

You can also simultaneously set or reset the "Retain", "Visible in HMI", "Accessible in HMI" and "Setpoint" columns for one or more selected elements.

To change one of these properties for several elements, follow these steps:

1. Open the data block.
2. Hold down the CTRL key.
3. In the required column, select each of the table cells whose value you want to change.
4. Select the "Set <property>" or "Reset <property>" command in the shortcut menu.

Editing properties in the properties window

To edit the properties of an individual tag, follow these steps:

1. Select a tag in the table.
2. Select the "Properties" command in the shortcut menu.
   The properties window opens. It shows the properties of the tag in the "General" and "Attributes" areas.
3. Select the required area in the area navigation.
4. Change the entries in the text boxes.

Reset individual properties to the default value.

To reset individual tag properties to the value that was defined as default in the function block, follow these steps:

1. Select an instance-specific, modified value in the table.
2. Delete the value.
   The instance-specific value will be deleted and the default value from the interface of the function block entered. The default value is displayed grayed out.

Changing the properties of tags in global data blocks

Introduction

Two options are available for defining the tag properties:

- The tag properties are applied from the PLC data type.
  Properties that are applied from the PLC data type are shown grayed out in the columns of the declaration table. The "Name" and "Data type" properties are always applied.
- You define specific properties.
  You can change some properties in the global data block. Changeable values are, for example, "Comment" or "Visible in HMI". Properties that were changed are not grayed out in the columns of the declaration table. The changes are retained, even if the PLC data type changes and the global data block is subsequently updated.

Editing properties of an element in the declaration table

To edit the properties of an element, follow these steps:

1. Open the global data block.
2. Select the required element in the table.
3. Change the entries in the columns.

Editing properties of several elements in the declaration table

You can also simultaneously set or reset the "Retain", "Visible in HMI", "Accessible in HMI" and "Setpoint" columns for one or more selected elements.

To change one of these properties for several elements, follow these steps:

1. Open the data block.
2. Hold down the CTRL key.

3. In the required column, select each of the table cells whose value you want to change.
4. Select the "Set <property>" or "Reset <property>" command in the shortcut menu.

Editing properties in the properties window

To edit the properties of an individual tag, follow these steps:

1. Select a tag in the table.
2. Select the "Properties" command in the shortcut menu.
   The properties window opens. It shows the properties of the tag in the "General" and "Attributes" areas.
3. Select the required area in the area navigation.
4. Change the entries in the text boxes.

Reset individual properties to the default value.

To reset individual tag properties to the value that was defined as default in the PLC data type, follow these steps:

1. Select a modified value in the table.
2. Delete the value.
   The default value from the PLC data type is entered. The default value is displayed grayed out.

Editing the declaration table for data blocks

Inserting table rows

Procedure

Proceed as follows to insert a row above the selected row:

1. Select the row in front of which you want to insert a new row.
2. Click the "Insert row" button on the toolbar of the table.

Result

A new row is inserted above the selected row.

See also

Editing tables (Page 347)

Inserting table rows

Procedure

Proceed as follows to insert a row below the selected row:

1. Select the row below which you want to insert a new row.
2. Click the "Add row" button on the table toolbar.

Result

A new empty row will be inserted below the selected row.

See also

Editing tables (Page 347)

Deleting tags

Requirements

A global data block is open.

Procedure

To delete a tag, follow these steps:

1. Select the row with the tag to be deleted. You can also select several rows by clicking on them one after the other while holding down the <Ctrl> key or by pressing and holding down <Shift> and clicking on the first and last row.
2. Select the "Delete" command in the shortcut menu.

Note

You cannot directly change the structure of instance data blocks and of global data blocks based on a PLC data type, since the structures of these blocks are defined in the higher-level object.

The type of the data block is entered in the block properties.

See also: Displaying and editing block properties (Page 1523)

Editing tables (Page 347)

Automatically filling in successive cells

You can load the contents of one or several table cells into the cells below, automatically filling in the successive cells.

If you automatically fill in cells in the "Name" column, a consecutive number will be appended to each name. For example, "Motor" will become "Motor_1".

You can define individual or more cells as well as entire rows as source area.

If less rows exist in the open table than you want to fill, then you will first have to insert additional empty rows.

Requirement

- The table is open.
- Sufficient declaration rows are available.

Procedure

To automatically fill in successive cells, follow these steps:

1. Select the cells to be loaded.
2. Click the "Fill" symbol in the bottom right corner of the cell.
   The mouse pointer is transformed into a crosshair.
3. Keep the mouse button pressed and drag the mouse pointer downwards over the cells that you want to fill in automatically.
4. Release the mouse button.
   The cells are filled in automatically.
5. If entries are already present in the cells that are to be automatically filled in, a dialog appears. In this dialog you can indicate whether you want to overwrite the existing entries or insert new rows for the new tags.

Show and hide table columns

You can show or hide the columns in a table as needed.

Procedure

To show or hide table columns, follow these steps:

1. Click a column header.
2. Select the "Show/Hide" command in the shortcut menu.
   The selection of available columns is displayed.
3. To show a column, select the column's check box.
4. To hide a column, clear the column's check box.
5. To hide or show several columns, click "More" and activate or deactivate the check box of the corresponding columns in the "Show/Hide" dialog.

Editing tags with external editors

To edit individual tags in external editors outside the TIA Portal, you can export or import these tags using copy and paste. However, you cannot copy structured tags to an editor.

Requirement

The data block and an external editor are opened.

Procedure

To export and re-import individual tags by drag-and-drop operation, follow these steps:

1. Select one or more tags.
2. Select "Copy" in the shortcut menu.
3. Switch to the external editor and paste the copied tags.
4. Edit the tags as required.
5. Copy the tags in the external editor.
6. Switch back to the declaration table.
7. Select "Paste" in the shortcut menu.

Monitoring and modifying tags in data blocks

Functions for monitoring and modifying tags in data blocks

Overview of functions

The data block editor offers different options for monitoring and modifying tags. These functions directly access the actual values of the tags in the online program. Actual values are the values which the tags have at the current time during program execution in the CPU work memory.

The following table provides an overview of the functions for monitoring and modifying. Detailed descriptions of the individual functions can be found in the following chapters.

Button	Function	Description	S7-300/400	S7-1200/1500
	Monitor tags online (Page 1726)	Displays the actual values which the tags currently have in the CPU.	X	X
-	Modify individual actual values (Page 1726)	Modifies individual tags immediately and once only to specific values in the declaration table. The CPU then uses these values as actual values in the online program.	X	X

Button	Function	Description	S7-300/400	S7-1200/1500
	Create a snapshot of the actual values (Page 1727)	Saves the actual values present at the current time as snapshot. The snapshot always captures the actual values of all tags of the data block.	X	X
	Overwrite actual values with a snapshot (Page 1728)	Overwrites the actual values of all tags of the data block with a snapshot. The CPU then uses these values as actual values in the online program.	-	S7-1200 V4.1 and higher S7-1500 V1.7 and higher

Additional functions

You also have the option of specifically calibrating individual values during commissioning.

See also: Auto-Hotspot

Monitor tags

You can monitor the current values of the tags in the CPU directly in the declaration table.

Requirement

- An online connection is available.
- The data block has been loaded to the CPU.
- The program execution is active (CPU in "RUN").
- The data block is open.

Procedure

To monitor the tags, follow these steps:

1. Start monitoring by clicking the "Monitor all" button.
   The additional "Monitor value" column is displayed in the table. This shows the current data values.
   See also: Structure of the declaration table for data blocks (Page 1705)
2. End the monitoring by clicking the "Monitor all" button again.

Modify tags

You can modify an individual tag in the data block to a specific value. The CPU then uses this values as actual value in the online program.

Danger

Danger when changing tag values

Changing the tag values while the plant is operating can cause serious damage to property or injury to persons if there are functional disturbances or program errors!

Make sure that no dangerous situations can arise before you modify the tags.

Requirement

- An online connection to the CPU is available.
- The data block whose tags you wish to modify is identical offline and online.
- The data block is open.

Procedure

To modify an individual tag in the data block, follow these steps:

1. Start monitoring by clicking the "Monitor all" button.
   The additional "Monitor value" column is displayed in the table. This shows the current data values.
2. Select the tag to be modified.
3. Select "Modify operand" in the shortcut menu.
   The "Modify operand" dialog opens.
4. Enter the required value in the "Control word" text box.
   If there is a snapshot, the value is already entered as default.
5. Confirm your entry with "OK".

Result

The tag will have the specified value once when you execute the modify job. The job is executed immediately and is not tied to the next cycle control point.

See also: Introduction to modifying tags (Page 1873)

Create a snapshot of the actual values

You can store the actual values of one or more data blocks as snapshot. Actual values are the values which the tags have at the current time during program processing in the CPU work memory.

You have the following options for creating a snapshot:

- Creating a snapshot of an open data block
- Creating a snapshot of several selected data blocks

A snapshot is also created automatically when you download a block or a program from the device.

Caution
Creating the snapshot

The values in the snapshot may originate in several cycles.

Requirement

- An online connection to the CPU is available.
- The data blocks for which you want to create a snapshot are identical offline and online.

Procedure

To create a snapshot of an open data block, follow these steps:

1. Open the data block.
2. Click "Snapshot of the monitored values".

To create a snapshot of several selected data blocks, follow these steps:

1. Select the blocks in the project tree.
   You can select the blocks individually or select devices, groups or folders in the project tree which include the data blocks.
2. In the shortcut menu, select "Snapshot of the monitored values" or select the menu command "Options > Snapshot of the monitored values".

Result

- The latest monitored values will be applied in the "Snapshot" column.
- An alarm is shown in the Inspector window after the operation is complete.
- The time stamp of the snapshot is displayed above the declaration table.

Note

If you subsequently change the structure of the data block, the display of the current values gets lost. The "Snapshot" column will then be empty.

Overwrite actual values with a snapshot

You can overwrite the actual values of all tags with a snapshot. The values from the snapshot are written directly to the CPU work memory. The CPU then uses these values as actual values in the online program.

Danger

Danger when changing tag values

Changing the tag values while the plant is operating can cause serious damage to property or injury to persons if there are functional disturbances or program errors!

- Make sure that the plant is in a safe state before you overwrite the actual values.
- Make sure that the program does not read or write the affected data during transmission.
- You may want to use the "Modify tag" function in the watch table or in the DB editor as an alternative.

Dependencies on the CPU mode

You can execute this function in "RUN" mode as well as "STOP" mode. The table below shows the reactions of the CPU in the different modes:

Action	System reaction	Consequences for the online program
Overwrite actual values in "RUN" mode	The values of all DB tags are overwritten in the current program. No distinction is made between retentive and non-retentive values.	Changing the actual values can result in inconsistencies between the program and the actual process. If the transmitted amount of data is too large, the values may be transmitted in several cycles. If the program accesses tags before all values are completely transmitted, there is a risk that inconsistent value combinations may be created and processed. Even copying the values of elementary data types may take several cycles. These values are potentially invalid until they have been completely transmitted. Dangerous states may occur if the program accesses these values before they have been completely transmitted.
Overwrite actual values in "STOP" mode	Only the actual values of the retentive tags are overwritten by the snapshot. Non-retentive tags are initialized with their start values during the transition from STOP to RUN. The values from the snapshot are not taken into consideration.	Because only the data from the snapshot are transmitted, there is a risk that inconsistent value combinations may be created and processed.

Requirement

- You are using an S7-1200 V4.1 or higher or an S7-1500 V1.7 or higher.
- An online connection to the CPU is available.
- The data blocks whose actual values you wish to overwrite are identical offline and online.
- A snapshot of the data block exists.

Procedure

To overwrite the actual values of a block with a snapshot, follow these steps:

1. Open the data block.
2. Click "Copy all values from the snapshot to the actual values of the CPU".

Result

The actual values in the online program are overwritten with the start values from the snapshot.

Setting data values during commissioning

Basic information on adjusting data values during commissioning

Introduction

During commissioning of a plant, data values have to be frequently adjusted in order to optimally adapt the program to the general operating conditions on site. The declaration table for data blocks offers some functions for this purpose.

To use the function, first define specific tags as "Setting values" in the program. Setting values are the values that will probably have to be fine tuned during commissioning.

The following table provides an overview of the functions for tuning values during commissioning. Detailed descriptions of the individual functions can be found in the following chapters.

Button	Function	Description
	Initialize setting values in "RUN" mode (Page 1732)	This function enables you to change the values of individual tags online to quickly determine the optimum tag values.
 	Apply values from the online program as start values to the offline program	When you have determined the optimum tag values, you can apply these as start values in the offline program. This allows you to ensure that the program starts with the optimized values the next time it is loaded. You can either apply all values or only the setting values.

Additional functions

There are still some more general functions for monitoring and modifying the data block.

See also: Functions for monitoring and modifying tags in data blocks (Page 1725)

See also

Marking data as values that can be set (Page 1731)

Applying values from the online program as start values (Page 1733)

Marking data as values that can be set

You can mark specific tags in the program as "Setting values". Setting values are the values that will probably have to be fine tuned during commissioning.

Rules

You can mark tags as "Setting value" in the following block types:

- In function blocks (FB), but only in the "Static" section
- in global data blocks (DB)
- in PLC data types (UDT)
  In the case of PLC data types (UDT), however, the setting is only effective, if the UDT is used in the "Static" section of a function block or data block.

It is not possible to define setting values in the following block types:

- In data blocks based on a PLC data type, and in instance data blocks. These inherit the setting from the higher-level FB or UDT.
- You cannot mark tags as a "Setting value" in ARRAY data blocks.
- You also cannot mark tags as a "Setting value" at the call point of a multi-instance. You have to make the setting in the interface of the function block that is called as multiple instance.
- You cannot change the "Setting value" marking in know-how-protected blocks. To do so, you must first remove the know-how protection.

Requirement

A function block, a global data block or a PLC data type (UDT) is open.

Procedure

To mark a tag as "Setting value", follow these steps:

1. Select a tag from the "Static" section.
2. Select the check box in the "Setting value" column.
   - You cannot define the higher-level element of a structure or a PLC data type as "Setting value". You have to make the setting for the lower-level elements individually.
   - In the case of ARRAYs, you can only mark the higher-level element as "Setting value". The lower-level elements inherit the setting.
   - For ARRAYs of STUCT, you can only mark the elements below the first structure as setting values. The elements of other structures inherit the setting.

Result

The tags are marked as setting values. During commissioning, these tags can be initialized online. You do not need to set the CPU to "STOP" mode; it can remain in "RUN". In addition, the current tag values can be transferred as start values to the offline program and saved there.

Initializing setting values in the online program

Basics on initializing setting values

You can initialize all tags marked as a "Setting value" with new values in the online program. At the same time, the start values will be loaded from the offline program to the online program. The CPU remains in "RUN" mode. All tags that are marked as a setting value are initialized once at the next cycle control point. This applies both to retentive and non-retentive tags. The program execution is then continued with the new tag values.

Danger

Danger when changing tag values

Changing the tag values while the plant is operating can cause serious damage to property or injury to persons if there are functional disturbances or program errors!

Make sure that no dangerous situations can arise before you re-initialize the setting values.

Requirement

- An online connection to the CPU exists.
- The structure of the data block is identical offline and online.
- One or more tags are marked as a "Setting value".

Procedure

To initialize all setting values of the data block, follow these steps:

1. Open a global data block or an instance data block.
2. Enter the desired values in the "Start value" column. The start values must correspond to the indicated data type.
3. Click the "Initialize setting values" button.

Result

The setting values in the online program are initialized with the start values from the offline program at the next cycle control point.

The maximum number of tags that can be initialized is dependent on the CPU. If too many setting values are marked, an alarm informs you about this. In this case, you can insert the tags in a watch table and initialize them using the "Modify" function in the watch table.

Alternatively, you can also load the entire data block. For more information on this, refer to "See also".

See also

Loading changed values (Page 1715)

Applying values from the online program as start values

In order to apply tag values from the online program to the offline program as start values, first create a snapshot of the tag values from the online program. You can then apply them to the offline program. Note that the values from the snapshot are always copied. There is no check to determine whether all values originate from the same cycle.

Write-protected start values are not overwritten.

You have the following basic options for applying the values:

- Applying the values of an open data block
  You can apply all values or only the values of the tags marked as a "setting value" as start values in an open data block.
- Applying the values of multiple blocks in the project tree
  You can either apply all setting values or all retentive values as start values in the project tree.

Requirement

- An online connection to the CPU is available.
- As least one data block has been loaded to the CPU.

Procedure

In order to apply all values or only the values of the tags marked as a "setting value" in a data block, follow these steps:

1. Open the data block.
2. Start monitoring by clicking the "Monitor all" button.
   The "Monitor value" column is displayed in the table. This shows the current data values.
3. On the toolbar, click "Snapshot of monitored values".
   The latest monitored values will be applied in the "Snapshot" column.
4. Click one of the following buttons on the toolbar:
   – "Apply setting values from the snapshot as start values"
   – "Apply all values from the snapshot as start values"

The values from the "Snapshot" column are applied to the "Start value" column.

To apply the monitored values of multiple data blocks in the project tree, follow these steps:

1. Select the blocks in the project tree.
2. Select the "Snapshot of the monitored values" command in the shortcut menu.
   The current monitored values of all selected blocks will be applied in the "Snapshot" column.
   An alarm is shown in the Inspector window after the operation is complete.
3. Then select one of the following commands in the shortcut menu:
   - "Apply snapshot values as start values > All values"
   - "Apply snapshot values as start values > Only setpoints"
   - "Apply snapshot values as start values > Only retain values"

The values from the "Snapshot" column are applied to the "Start value" column.

Result

The new start values are stored in the offline program.

Note

Applying values of individual tags

You can also transfer the values of individual tags that were not marked as a setting value beforehand from the "Snapshot" column to the "Start values" column. Use the "Copy" and "Paste" commands from the shortcut menu to copy the values and insert them in the "Start value" column. Note that only the values that are currently located in the visible area of the table are copied.

Define start values (Page 1714)

11.1.4.4 Programming PLC data types

Basics of PLC data types

Description

PLC data types are data structures that you define and that can be used multiple times within the program. The structure of a PLC is made up of several components, each of which can contain different data types. You define the type of components during the declaration of the PLC data type.

You can create up to 65534 PLC data types for a CPU of the S7-1200 or S7-1500 series. Each of these PLC data types can include up to 252 components.

PLC data types can be used for the following applications:

- PLC data types can be used as data types for variables in the variable declaration of logic blocks or in data blocks.
- PLC data types can be used as templates for the creation of global data blocks with identical data structures.
- PLC data types can be used in S7-1200 and S7-1500 as a template for the creation of structured PLC tags.

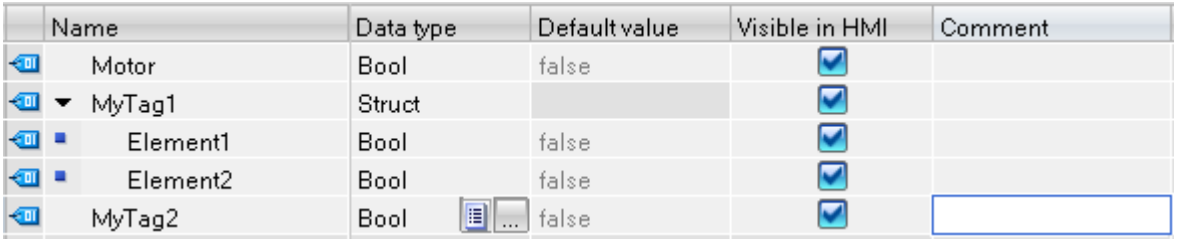
See also

Creating PLC data types (Page 1736)

Structure of the declaration table for PLC data types

Structure of the declaration table for PLC data types

The figure below shows the structure of the declaration table for PLC data types.



Meaning of the columns

The following table shows the meaning of the individual columns. You can show or hide the columns as required. The number of columns displayed varies depending on the CPU series.

Column	Explanation
	Symbol you can click to move or copy the tag.
Name	Name of the tags.
Data type	Data type of the tags.
Default value	Value with which you predefine the tag in the declaration of the PLC data type. Specification of the default value is optional. If you do not specify any value the predefined value for the indicated data type is used. For example, the value "false" is predefined for BOOL.
Visible in HMI	Shows whether the tag is visible by default in the HMI selection list.
Accessible from HMI	Shows whether HMI can access this tag during runtime.

Column	Explanation
Setting value	Setting values are the values that will probably have to be fine tuned during commissioning. After commissioning, the values of these tags can be transferred to the offline program as start values and stored there.
Comment	Comment to document the tags.

Creating PLC data types (Page 1736)

Show and hide table columns (Page 1744)

Creating PLC data types

Requirement

The "PLC data types" folder opens in the project tree.

Procedure

To create a PLC data type, proceed as follows:

1. In the "PLC data types" folder, click the "Add new data type" command.
   A new declaration table for creating a PLC data type will be created and opened.
2. Select the PLC data type and select the "Rename" command in the shortcut menu.
3. Enter the name of the PLC data type.

Result

The new PLC data type is created. You can find the PLC data type in the project tree in the "PLC data types" folder.

See also

Structure of the declaration table for PLC data types (Page 1735)

Basics of PLC data types (Page 1734)

Delete PLC data types

Requirement

The PLC data type you want to delete is not open.

Procedure

To delete a PLC data type, follow these steps:

1. In the project tree, open the "PLC data types" folder.
2. Select the PLC data type to be deleted. You can also select several PLC data types by clicking on them one after the other while holding down the <Ctrl> key or by pressing and holding down <Shift> and clicking on the first and last data type.
3. Select the "Delete" command in the shortcut menu.

Note

If you delete a PLC data type, the blocks that use the data type will become inconsistent. These inconsistencies are marked in red in the block used. To remedy these inconsistencies, the data blocks have to be updated.

See also:

Updating the block interface (Page 1564)

Updating data blocks (Page 1708)

Renumbering PLC data types

For performance reasons, PLC data types are processed internally with numbers. If there are number conflicts, these are resolved automatically. But this is not possible for a PLC data type which is used by a know-how protected block. The block must be recompiled when you change the number of the PLC data type which results in a password prompt for the know-how protected block. You can bypass this step by setting up a separate numbering scheme for your PLC data types. Use numbers greater than 5000.

Procedure

To change the default number of a PLC data type, follow these steps:

1. Open the project library in the "Libraries" task card.
2. Drag the compilable PLC data type to the "Types" folder.
   The "Add type" dialog opens.
3. Enter the properties of the new type.
4. Click "OK" to confirm.
5. Right-click the PLC data type in the project library and select the "Edit type" command from the shortcut menu.
6. Click "OK" to confirm your selection of the instance.
   The library view opens.
7. Close the library view.
   The extension "in testing" is now added to the name of the PLC data type.
8. Right-click the PLC data type and select the "Properties" command from the shortcut menu.

9. Select the "General" group in the area navigation.
   You can now edit the number of the PLC data type.
10. Change the number of the PLC data type.
11. Click "OK" to confirm.
12. Right-click the PLC data type in the project library and select the "Release version" command from the shortcut menu.
    The PLC data type has a new number. The assigned number is retained even if the type of the PLC data type is revoked.

Programming the structure of PLC data types

Declaring tags of elementary data type

Requirement

A PLC data type is open.

Procedure

To declare a tag, follow these steps:

1. Enter a tag name in the "Name" column.
2. Enter the required data type in the "Data type" column. You will be supported by autocompletion during input.
3. Optional: Change the properties of the tags that are displayed in the other columns.
4. Repeat steps 1 to 3 for all tags that are to be declared.

See also

Editing tables (Page 347)

Declaring tags of the ARRAY data type

Requirement

A PLC data type is open.

Procedure

To declare a tag of the ARRAY data type, follow these steps:

1. Enter a tag name in the "Name" column.
2. Enter the "Array" data type in the "Data type" column. You will be supported by autocompletion in this step.
   The "Array" dialog opens.
3. In the "Data type" text box, specify the data type of the array elements.
4. In the "ARRAY limits" text box, specify the high and low limit for each dimension.
   Example of a one-dimensional ARRAY:
   `[0..3]`
   Example of a three-dimensional ARRAY:
   `[0..3, 0..15, 0..33]`
5. Confirm your entry.
6. Optional: Change the properties of the tags that are displayed in the other columns.

Note

You cannot define specific default values for ARRAY elements. You can, however, assign them start values at the usage point in the data block.

See also

Array (Page 1941)

Structure of the declaration table for PLC data types (Page 1735)

Declaring tags of STRUCT data type

Requirements

A PLC data type is open.

Procedure

To declare a tag of the STRUCT data type, follow these steps:

1. Enter a tag name in the "Name" column.
2. Enter "Struct" in the "Data type" column. You will be supported by autocompletion during input.
   An empty, indented row is inserted after the new tag.
3. Insert the first structural element in the first empty row.
   An additional empty row is inserted after the element.
4. Select a data type for the structure element.

5. Optional: Change the properties of the structural element that is displayed in the other columns.
6. Repeat steps 3 to 5 for all additional structure elements.
   It is not necessary to end the structure explicitly. The structure ends with the last element that is entered.
7. To insert a new tag after the structure, leave a blank row after the end of the structure and then start the new tag in the second empty row.

Result

The tag of STRUCT data type is created.

See also

STRUCT (Page 1945)

Structure of the declaration table for PLC data types (Page 1735)

Declaring tags based on a different PLC data type

Requirements

- A global data block is open.
- A PLC data type is declared in the current CPU.

Procedure

To declare a tag based on a different PLC data type, follow these steps:

1. Enter a tag name in the "Name" column.
2. Enter the PLC data type in the "Data type" column. You will be supported by autocompletion during input.

Result

The tag is created.

Note

You define the default values of tags within a PLC data type when the PLC data type is created. You cannot change these values at the point of use of the PLC data type.

See also

Basics of PLC data types (Page 1734)

Editing tag properties in PLC data types

Properties of tags in PLC data types

Properties

The following table gives an overview of tag properties in PLC data types:

Group	Property	Description
General	Name	Name of the tags.
	Data type	Data type of the tags.
	Default value	Default value of the tag in the interface of a higher-level code block or in a PLC data type. The values contained in the "Default value" column can only be changed in the higher-level code block or PLC data type. The values are only displayed in the data block.
	Start value	Not relevant in PLC data types
	Comment	Comment on the tag.
Attributes	Retain	Not relevant in PLC data types
	Visible	Indicates whether a parameter is visible in CFC.
	Configurable	Indicates whether a parameter is configurable in CFC.
	For test	Indicates whether a parameter is registered for the CFC test mode.
	Interconnectable	Indicates whether a parameter is interconnectable in CFC.

Editing the declaration table for PLC data types

Inserting table rows

Procedure

Proceed as follows to insert a row above the selected row:

1. Select the row in front of which you want to insert a new row.
2. Click the "Insert row" button on the toolbar of the table.

Result

A new row is inserted above the selected row.

Inserting table rows

Procedure

Proceed as follows to insert a row below the selected row:

1. Select the row below which you want to insert a new row.
2. Click the "Add row" button on the table toolbar.

Result

A new empty row will be inserted below the selected row.

Deleting tags

Procedure

Follow the steps below to delete elements:

1. Select the row with the element to be deleted. You can also select several rows by clicking on them one after the other while holding down the <Ctrl> key or by pressing and holding down <Shift> and clicking on the first and last row.
2. Select the "Delete" command in the shortcut menu.

Updating the block interface (Page 1564)

Updating data blocks (Page 1708)

Automatically filling in successive cells

You can load the contents of one or several table cells into the cells below, automatically filling in the successive cells.

If you automatically fill in cells in the "Name" column, a consecutive number will be appended to each name. For example, "Motor" will become "Motor_1".

You can define individual or more cells as well as entire rows as source area.

If less rows exist in the open table than you want to fill, then you will first have to insert additional empty rows.

Requirement

- The table is open.
- Sufficient declaration rows are available.

Procedure

To automatically fill in successive cells, follow these steps:

1. Select the cells to be loaded.
2. Click the "Fill" symbol in the bottom right corner of the cell.
   The mouse pointer is transformed into a crosshair.
3. Keep the mouse button pressed and drag the mouse pointer downwards over the cells that you want to fill in automatically.
4. Release the mouse button.
   The cells are filled in automatically.
5. If entries are already present in the cells that are to be automatically filled in, a dialog appears. In this dialog you can indicate whether you want to overwrite the existing entries or insert new rows for the new tags.

Show and hide table columns

You can show or hide the columns in a table as needed.

Procedure

To show or hide table columns, follow these steps:

1. Click a column header.
2. Select the "Show/Hide" command in the shortcut menu.
   The selection of available columns is displayed.
3. To show a column, select the column's check box.
4. To hide a column, clear the column's check box.
5. To hide or show several columns, click "More" and activate or deactivate the check box of the corresponding columns in the "Show/Hide" dialog.

11.1.4.5 Using external source files

Basics of using external source files

Function

The textual programming languages STL and SCL allow you to enter the program code in any ASCII editor and save it as an external source file. This enables you to perform a range of tasks, for example:

- Declaring tags
- Specify block properties
- Programming blocks

You can import these source files to your project and use them to generate blocks. You can generate a number of different blocks from one source file. Observe the following special features when generating blocks from a source file:

- A block that exists under the same name in the project will be overwritten.
- If a block was programmed with its absolute block number instead of a symbolic name in the source file and this number is already assigned by a block in the project, the new generated block is initially assigned the next free symbolic name.

- If you have not explicitly defined the access mode for a block in the external source file, the block access mode is set depending on the CPU series used:
  - Blocks generated for a CPU of the S7-1200/1500 series are assigned "optimized" access mode by default.
  - Blocks generated for a CPU of the S7-300/400 product range are assigned "standard" access mode by default.

  Organization blocks are the exception in this case, as they are always assigned the "standard" access mode by default, regardless of the CPU series. You have the option of changing the block access mode manually.
- It is possible that not all comments from the source file will be applied in the block.
- If you use absolute addressing in the external source file, a symbolic tag is created for each absolute address during the generation of the block. The names of these tags are made up of "Tag_" and a time stamp. This may result in relatively long tag names, which you can change manually if required.
- If you are using instructions in a different version in the external source file than in the target device, this may result in compilation errors. Correct the respective instructions in this case and start the compilation process once again. You can also select a different version for the target device.

You also have the option of saving existing blocks as external source files.

See also

Rules for programming external source files (Page 1745)

Saving blocks as external source files (Page 1746)

Inserting external source files (Page 1748)

Opening and editing external source files (Page 1748)

Generating blocks from external source files (Page 1749)

Rules for programming external source files

An external source file basically consists of continuous text. To compile the source into blocks, certain structures and syntax rules must however be adhered to.

Syntax rules

The syntax of the instructions in external source files is very similar to that in the creation of user programs in the program editor with STL or SCL. Note, however, the following additional syntax rules:

- Block call
  When calling a block, transfer the parameters in the defined order in the ASCII editor. If you do not, the comment assignments for these lines may not match.
  Enter the parameters in brackets. The individual parameters are separated by a comma.
- Upper or lower case
  The program editor generally disregards upper or lower case. Jump labels are an exception to this. Character string entries are also case-sensitive ("STRING" data type). Keywords are displayed in upper case. For compilation purposes, however, case is disregarded; you can therefore specify keywords in upper or lower case or a mixture of the two.
- Semicolon
  Mark the end of every instruction and every tag declaration with a semicolon. You can enter several instructions per line.
- Forward slashes
  Begin every comment with two forward slashes (//) and end the comment with the <Enter> key.
- Use of String constants
  To avoid compilation errors when using String constants, enter the text in the language of the target project. You can explicitly use the data type WSTRING for CPUs of the S7-1200/1500 series by using the prefix "WString#":
  `Operand := WString#'<String constant>';`

Basics of using external source files (Page 1744)

Saving blocks as external source files (Page 1746)

Inserting external source files (Page 1748)

Opening and editing external source files (Page 1748)

Generating blocks from external source files (Page 1749)

Saving blocks as external source files

You have the following options for saving STL and SCL blocks as external source files:

- Copying a block as text
- Generating external source file from blocks

Copying a block as text

To copy a block as text and save it to an external source file, follow these steps:

1. In the project tree, right-click on the block that you want to save in an external source file.
2. Select the "Copy as text" command in the shortcut menu.

3. Open an external text editor.
4. Paste the copied text from the clipboard.
5. Save the file with one of the following file name extensions:
   - ".scl", if you want to generate a source file for an SCL block
   - ".stl", if you want to generate a source file for an STL block
   - ".DB" if you wish to generate a source file for a data block
   - ".UDT", if you want to generate a source file for a PLC data type

Generating external source file from blocks

To generate external source files from STL or SCL blocks, follow these steps:

1. In the project tree or in the overview window, select the STL or SCL blocks from which you want to generate an external source file.
2. Select the "Generate source from blocks" command from the shortcut menu.
   The "Generate source from blocks" dialog opens.
3. Specify a path and a name for the external source file.
4. Click "OK".

You can also generate an opened STL or SCL block as external source file. To do this, follow these steps:

1. Click on the "Generate source from block" button in the program editor.
   The "Generate source from blocks" dialog opens.
2. Specify a path and a name for the external source file.
3. Click "OK".

Result

The block has been saved as an external source file. You can include this source file in a project in the TIA Portal and use it to generate other blocks. However, please note that you can use STL source files only in S7-300/400/1500 CPUs.

See also

Basics of using external source files (Page 1744)

Rules for programming external source files (Page 1745)

Inserting external source files (Page 1748)

Opening and editing external source files (Page 1748)

Generating blocks from external source files (Page 1749)

Inserting external source files

Requirement

- An external source file is available and complies with the syntax and structure rules.
- The "External source files" folder is open in the project tree.

Procedure

Follow these steps to insert an external source file:

1. Double-click on the "Add new external file" command.
   The "Open" dialog box is opened.
2. Navigate to and select existing external source files.
3. Confirm your selection with "Open".

Result

The new source file will be added to the "External source files" folder.

See also

Basics of using external source files (Page 1744)

Rules for programming external source files (Page 1745)

Saving blocks as external source files (Page 1746)

Opening and editing external source files (Page 1748)

Generating blocks from external source files (Page 1749)

Opening and editing external source files

By linking the files with the file name extensions "stl" and "scl" to an editor you will be able to open and edit external source files with these formats directly. Use Notepad as editor because other text editors may not let you open several sources at the same time.

This means you do not need to insert the external source files again after editing.

Linking files with the file name extensions "stl" and "scl" file types to an editor

Proceed as follows to link files with the file name extensions "stl" and "scl" to an editor:

1. Open Windows Explorer.
2. Right-click on an STL file.
3. Select "Properties" in the shortcut menu.
   The "Properties" dialog box opens.
4. Click "Change" in the "File type" area on the "General" tab.
   The "Open with" dialog box opens.

5. Select the text editor you want to link to the "stl" file type.
6. Confirm your selection with "OK".
7. Close the "Properties" dialog with "OK".
8. Repeat steps 2 to 7 with an SCL file.

Opening and editing an external source file

To open an external source file, follow these steps:

1. Open the "External source files" folder in the project tree.
2. Double-click on the external source file you want to open.
   The external source file will open in the linked editor and can be edited.

Basics of using external source files (Page 1744)

Rules for programming external source files (Page 1745)

Saving blocks as external source files (Page 1746)

Inserting external source files (Page 1748)

Generating blocks from external source files (Page 1749)

Generating blocks from external source files

Requirement

- The "External source files" folder is open in the project tree.
- An external source file is available.

Procedure

To generate blocks from an external source file, follow these steps:

1. Open the external source file from which you wish to generate blocks.
2. Select the "Generate blocks from source" command in the "Edit" menu.
3. A prompt will appear telling you any existing blocks will be overwritten.
4. Confirm the safety prompt with "Yes".

Result

The external source file blocks will be generated and inserted in the "Program blocks" folder in the project tree. In the event of errors, information about the errors which have occurred will be displayed in the inspector window. This information, however, relates to the external source file and not to the block generated.

11.1.5 Comparing PLC programs

11.1.5.1 Basic information on comparing PLC programs

Introduction to comparing PLC programs

Function

You can compare the following objects of a PLC program in order to detect any differences:

- Code blocks with other code blocks
- Data blocks with other data blocks
- PLC tags of a PLC tag table with the PLC tags of another PLC tag table
- PLC data types with other PLC data types

Types and levels of comparison

Two different basic types of comparison can be used:

- Online/offline comparison:
  The objects in the project are compared with the objects of the corresponding device. An online connection to the device is necessary for this comparison.
- Offline/offline comparison:
  The objects of two devices either within a project or from different projects or libraries are compared. No online connection is required for this comparison.

Please note that you cannot carry out an unlimited number of comparisons at the same time, but only one comparison per comparison type (online/offline or offline/offline).

You can choose between the following levels of comparison depending on how in-depth an object comparison you require:

- Compare editor
- Detailed comparison

When you start a comparison, you will first receive an overview in the compare editor. For some comparison objects, you can then start a detailed comparison in which the objects

compared will be opened side-by-side, each in its own program editor instance. Any differences will be highlighted.

The table below gives an overview of the types and levels of comparison you can apply for each object:

Object	Online/offline		Offline/offline	
Compare editor	Detailed comparison	Compare editor	Detailed comparison	
LAD block	X	X	X	X
FBD block	X	X	X	X
STL block[1]	X	X	X	X
SCL block	X	X[3] [4]	X	X
GRAPH block[2]	X	X[4]	X	X[5]
Global data block	X	X	X	X
Instance data block	X	X	X	X
PLC tags	-	-	X	X
PLC data type	X[4]	X[4]	X	X

Legend:

X: available
-: not available

[1]: STL is not available for S7-1200

[2]: GRAPH is not available for S7-1200

[3]: not for S7-1200 prior to version 2.0

[4]: not for S7-300/400

[5]: only comparable with a GRAPH block from the same CPU family

Note

Please note the following:

- You cannot perform a detailed comparison for know-how protected blocks.
- If the detail comparison detects differences only with respect to the data types of local tags, with offline being an interrupt data type (C_ALARM C_ALARM_S C_ALARM_8 C_ALARM_8P C_ALARM_T C_AR_SEND C_NOTIFY C_NOTIFY_8P) and online a DWORD, this difference is not marked as such.
- You cannot run a detailed comparison for types and master copies from libraries.

Using the compare editor (Page 405)

Comparison of code blocks

Introduction

The blocks to be compared in a code block comparison are assigned for comparison on the basis of the following criteria:

- Online/offline comparison: Addresses, e.g. FB100
- Offline/offline comparison: Symbolic names of the blocks

The comparison involves an evaluation of the block time stamps. The results are displayed as an overview in the comparison editor. You can then use actions to define what is to be done about the differences. You can also start detailed comparisons for the individual blocks. The versions of a block compared are opened beside each other and the differences are highlighted.

For the comparison of code blocks, both the block interfaces and the individual networks are compared. Any differing tag names are also determined. All comments and other block attributes are excluded from an online/offline comparison.

If the block interface changes, the time stamp of the code block interface will also change. This change means a change in the time stamp of the program code. The first step in comparing block interfaces is therefore a comparison of the program code time stamps. If these time stamps are the same, it is assumed that the interfaces are the same. If the time stamps of the interfaces differ, the next step is to compare the data types of the interfaces, section by section. Multiple instances and PLC data types are included in the comparison. If the data types in the sections are the same, the start values of the tags are compared. All differences are displayed.

When networks are compared, first inserted or deleted networks are detected. Then the other networks are compared. Instructions are the same if the operator and operand are the same. The first difference in each instruction is displayed. However, several differences per network can be displayed.

Using the compare editor (Page 405)

Comparison of data blocks

Introduction

The blocks to be compared in a data block comparison are assigned for comparison on the basis of the following criteria:

- Online/offline comparison: Addresses, e.g. DB100
- Offline/offline comparison: Symbolic names of the blocks

The first step in data block comparison is comparing the time stamps of the data block. If these time stamps are the same, it is assumed that the data structures are the same. If the time stamps differ, the structures are then compared until the first difference is found. If the data structures in the sections are the same, the initial values of the tags are then compared. All differences are displayed. Any differing tag names are also determined. Comments and PLC data type structures used in the data block are not included in the comparison.

Using the compare editor (Page 405)

Comparing PLC tags and PLC data types

Introduction

The device PLC tag tables and the device PLC data types will also be shown in the comparison editor if you carry out an offline/offline comparison. The PLC tag tables and the PLC data types will be matched by name and you will receive the following information:

- Status: A symbol shows whether the PLC tags/PLC data types are identical or differ.
- Missing PLC tag tables / PLC data types: You can see at a glance whether the PLC tag tables / PLC data types are available in both devices.

You obtain the following information with an online/offline comparison of CPUs of the S7-1200/1500 series:

- PLC tags: A symbol shows whether the PLC tags are identical or differ. Because PLC tag tables are not downloaded to the device during loading, they cannot be displayed during an online/offline comparison.
- PLC data types: You receive the status symbol for each PLC data type. You can see at a glance whether the PLC data types are available in both devices.

11.1.5.2 Comparing blocks

Comparing blocks in the compare editor

You have the following options for comparing blocks in the compare editor:

- Online/offline comparison
  The blocks in the project are compared with the blocks of the selected device.
- Automatic offline/offline comparison
  All blocks of the selected devices are compared offline.
- Manual offline/offline comparison
  The selected blocks of the devices are compared offline.

Carrying out an online/offline comparison of blocks

To perform an online/offline comparison, follow these steps:

1. In the project tree, select a device that allows online/offline comparison.
2. Select the "Compare > Offline/online" command in the shortcut menu.
3. If you have not already established an online connection to this device, the "Go online" dialog opens. In this case, set all the necessary parameters for the connection and click "Connect".
   The online connection is established and the compare editor opens.
4. Open the "Program blocks" folder.
   You can identify the status based on the symbols in the status and action area. You can define certain actions depending on the status of the objects. Note, however, that you can only perform actions in one direction in a synchronization action.

Carrying out an automatic offline/offline comparison of blocks

To perform an automatic offline/offline comparison of blocks, follow these steps:

1. Select a device in the project tree that allows offline/offline comparison.
2. Select the "Compare > Offline/offline" command in the shortcut menu.
   The compare editor opens and the selected device is displayed in the left area.

3. Drag-and-drop an additional device to the drop area of the right pane. The device to be compared can originate from the same project, a reference project or the library.
4. Open the "Program blocks" folder.
   You can identify the status of the objects based on the symbols in the status and action area. You can define certain actions depending on the status of the objects. When you select an object, the object's properties and the corresponding object of the assigned device are clearly shown in the properties comparison.

You can drag any other device to the drop area at any time to perform further comparisons.

Carrying out a manual offline/offline comparison of blocks

To perform a manual offline/offline comparison of blocks, follow these steps:

1. Select a device in the project tree that allows offline/offline comparison.
2. Select the "Compare > Offline/offline" command in the shortcut menu.
   The compare editor opens and the selected device is displayed in the left area.
3. Drag-and-drop an additional device to the drop area of the right pane. The device to be compared can originate from the same project, a reference project or the library.
4. In the status and action area, click on the button for switching between automatic and manual comparison.
5. Select the objects that you want to compare.
   The properties comparison is displayed. You can identify the status of the objects based on the symbols. You can define certain actions depending on the status of the objects.

You can drag any other device to the drop area at any time to perform further comparisons.

Performing detailed block comparisons

Start a detailed comparison for LAD/FBD/STL/SCL blocks

You can start a detailed comparison for blocks. The versions of a block compared are opened beside each other and the differences highlighted.

Note

Please note the following:

- For blocks that are created in the programming language SCL, the detail comparison is not available for S7-1200 series CPUs with a version older than 2.0.
- S7-1500: It is possible that another user can carry out a loading process on the CPU through joint parallel working on a CPU. If the currently compared block is changed or deleted by this loading process, the detailed comparison is terminated and a message is displayed. In this case, re-start the detailed comparison, if required.

Starting detailed comparisons using the compare editor

To start a detailed comparison for a block using the compare editor, follow these steps:

1. First, perform an online/offline or an offline/offline comparison.
   The compare editor opens.
2. In the compare editor, select the block for which you want to perform a detailed comparison.
3. Click "Start detailed comparison" in the toolbar.

Starting detailed comparisons in the program editor

For the comparison type online/offline, you can start the detailed comparison directly in the program editor. To do this, follow these steps:

1. Open the block for which you wish to carry out a detailed comparison.
2. Establish an online connection.
   See also: Go online and Go offline

   Note

   Please note that the block must be available online in order for you to be able to start the detailed comparison for the block within the programming editor.

3. Click "Detailed comparison" in the toolbar.
4. Confirm the dialog for closing the block with "Yes".

Result

One instance of the program editor will be opened for each version of the block compared and the two instances are displayed side by side. Any differences will be highlighted.

Navigating in the detailed comparison (Page 1775)

Changing blocks during the detailed comparison (Page 1776)

Updating comparison results (Page 1778)

Start detailed comparison for GRAPH blocks

You can start a detailed comparison for GRAPH blocks. The versions of a block compared are opened beside each other and the differences highlighted.

The following comparison methods are available for GRAPH blocks:

- Compare sequence
  Complete sequencers are compared with each other in this mode. A detailed comparison for a GRAPH block always starts in the "Compare sequence" comparison mode. This means the comparison starts at the beginning of the sequencer and the differences between the sequencers are displayed. If there are structural differences between the sequencers, the comparison results are only displayed up to the first structural difference.
- Compare selection
  You can use the "Compare selection" comparison mode to compare any areas with each other. This means you can compare sections of the sequencer which are downstream from a structural difference in the sequence.

You can toggle at random between both comparison modes.

Note

S7-1500: It is possible that another user can carry out a loading process on the CPU through joint parallel working on a CPU. If the currently compared block is changed or deleted by this loading process, the detailed comparison is terminated and a message is displayed. In this case, re-start the detailed comparison, if required.

Procedure

To start a detailed comparison, follow these steps:

1. First, perform an online/offline or an offline/offline comparison between the two devices. The compare editor opens.
2. In the compare editor, select the block for which you want to perform a detailed comparison.

   Note

   The manual comparison is also available for an offline/offline comparison. It lets you select any block in the comparison editor for the comparison.

3. Click "Start detailed comparison" in the toolbar.
   One instance of the program editor is opened for each version of the blocks compared and the two instances are displayed side by side. Any differences will be highlighted. The comparison takes place in the "Compare sequence" mode.
4. To compare specific areas within the displayed sequencers, select the step from which you want to start the comparison in each sequencer.
5. Click "Comparison mode" in the toolbar.
   The comparison mode changes to "Compare selection" and the comparison result is updated. The sequencers are compared as of the selected steps. The compared substrings are highlighted.
6. To compare other areas, select the steps which are to serve as starting point for the comparison.
7. Click "Update the comparison result" in the toolbar.

   Note

   When you change the comparison mode, you are also updating the comparison results at the same time. If you stay in "Compare selection" mode, you must manually update the comparison results every time you change the starting point.

8. To compare the complete sequencers once again, click "Comparison mode" in the toolbar. Each time you click "Comparison mode" you are changing the comparison mode. You can also open the drop-down list with the arrow and select the required mode from the list.

Visualization of the comparison result

Visualization of the comparison result for LAD/FBD

Introduction

The detailed comparison allows you to identify the exact places where versions of a block differ. The following color coding allows you to find these places as quickly as possible:

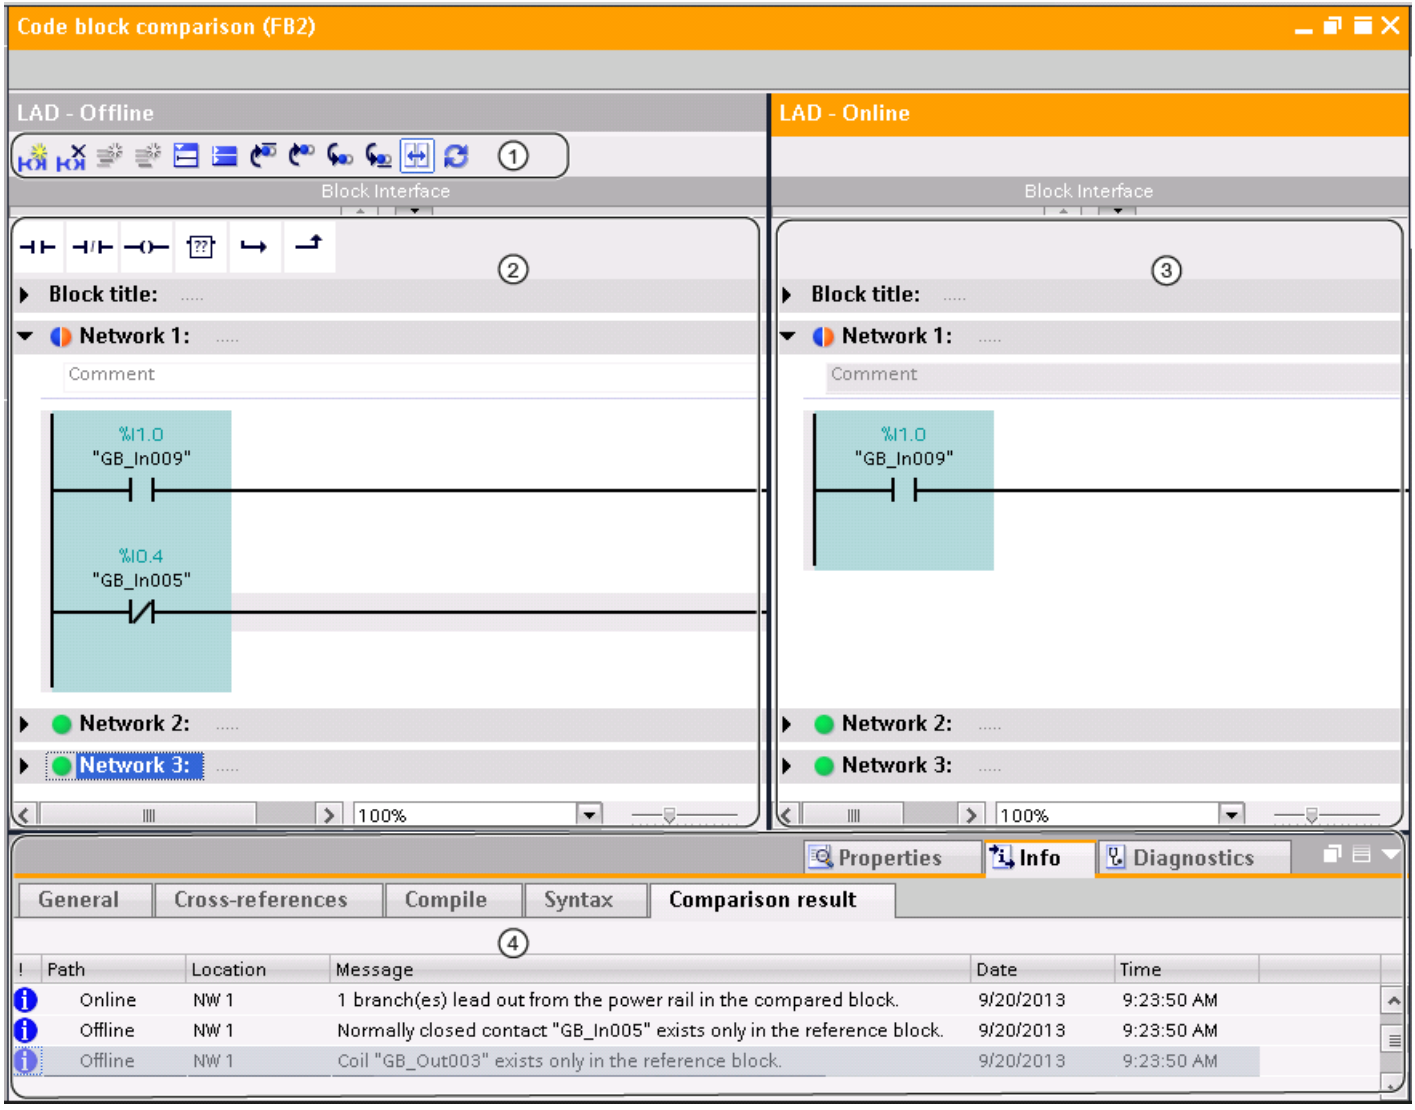
- The lines where there are differences are highlighted in gray.
- Differing operands and instructions are highlighted in green.
- If the number of networks differs, pseudo-networks are added to allow the display of identical networks to be synchronized. These pseudo-networks are highlighted in gray and contain the text "No corresponding network found" in the title bar of the network. Pseudo-networks cannot be edited.

For the sake of clarity, not all the differences are highlighted but rather the first difference of an operation in each case. For example, if all the inputs in an instruction with multiple inputs are different in the offline and online versions of the block, only the first input is highlighted as a difference. You can resolve this difference and update the comparison list. The next input will then be highlighted as a difference.

The number of differences highlighted within a network therefore depends on the number of instructions.

Structure of the detailed comparison

The following figure shows an example of the online/offline detailed comparison for the LAD programming language:



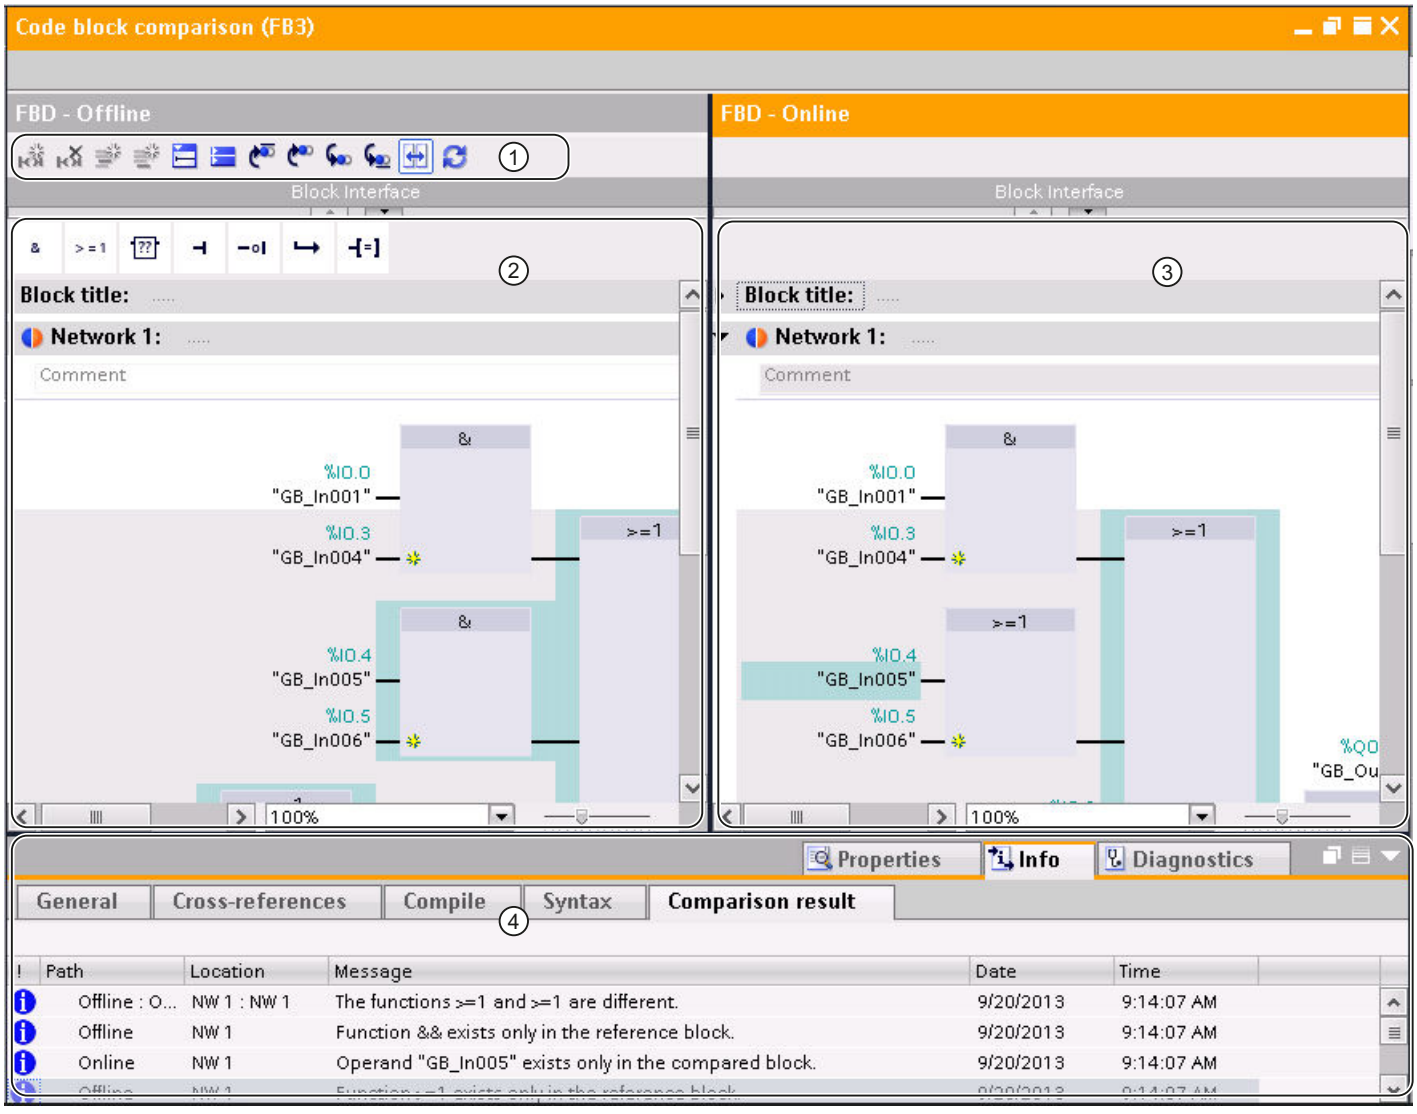
① Toolbar of the detailed comparison for LAD

② Reference block

③ Compared block

④ Comparison result in the Inspector window

The following figure shows an example of the online/offline detailed comparison for the FBD programming language:



① Toolbar of the detailed comparison for FBD

② Reference block

③ Compared block

④ Comparison result in the Inspector window

Note

Display of the symbolic names of the online version of the block is only possible for S7-1200 and S7-1500.

Toolbar of the detailed comparison

With the toolbar, you can access the following functions:

- General functions
  - Insert network
  - Delete network
  - Insert row
  - Add row
  - Open all networks
  - Close all networks
- Comparison-specific functions
  - Position on first difference
  - Position on previous difference
  - Position on next difference
  - Position on last difference
  - Synchronize scrolling between editors
  - Update comparison results

Reference block

The reference block is displayed in the left window. In an online/offline comparison, the reference block is the offline version of the block.

Compared block

The compared block is displayed in the right window. In an online/offline comparison, the compared block is the online version of the block.

Comparison result in the Inspector window

The differences are displayed in the form of a table in the "Info > Comparison result" tab of the Inspector window. Double-click on a row to navigate to the corresponding difference in the block.

Updating comparison results (Page 1778)

Visualization of the comparison result for SCL

Introduction

The detailed comparison allows you to identify the exact places where versions of a block differ. The following color coding allows you to find these places as quickly as possible:

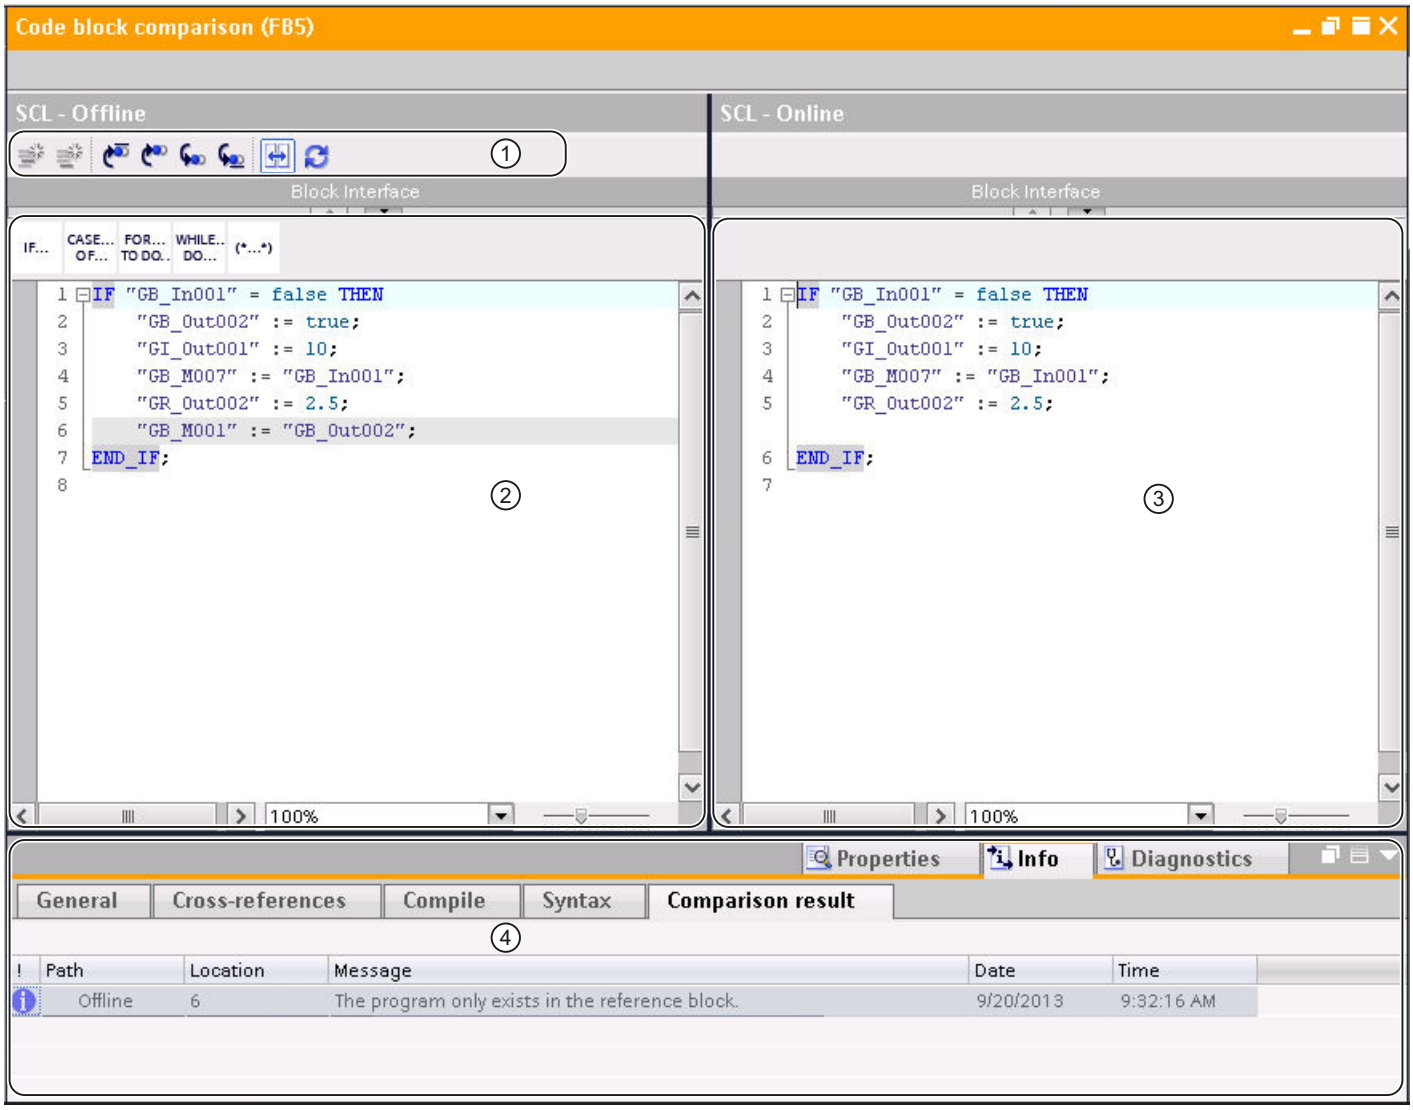
- The lines where there are differences are highlighted in gray.
- Differing operands and instructions are highlighted in green.

Note

The online/offline detailed comparison is not available for the CPU families S7-300/400 and for S7-1200 with a version less than 2.0.

Structure of the detailed comparison

The following figure shows an example of the online/offline detailed comparison for the SCL programming language:



① Toolbar of the detailed comparison for SCL

② Reference block

③ Compared block

④ Comparison result in the Inspector window

Note

The display of the symbolic name of the online version of the block is only possible for S7-1200 and S7-1500.

Toolbar of the detailed comparison

With the toolbar, you can access the following functions:

- General functions
  - Insert row
  - Add row
- Comparison-specific functions
  - Position on first difference
  - Position on previous difference
  - Position on next difference
  - Position on last difference
  - Synchronize scrolling between editors
  - Update comparison results

Reference block

The reference block is displayed in the left window. In an online/offline comparison, the reference block is the offline version of the block.

Compared block

The compared block is displayed in the right window. In an online/offline comparison, the compared block is the online version of the block.

Comparison result in the Inspector window

The differences are displayed in the form of a table in the "Info > Comparison result" tab of the Inspector window. Double-click on a row to navigate to the corresponding difference in the block.

Updating comparison results (Page 1778)

Visualization of the comparison result for GRAPH

Introduction

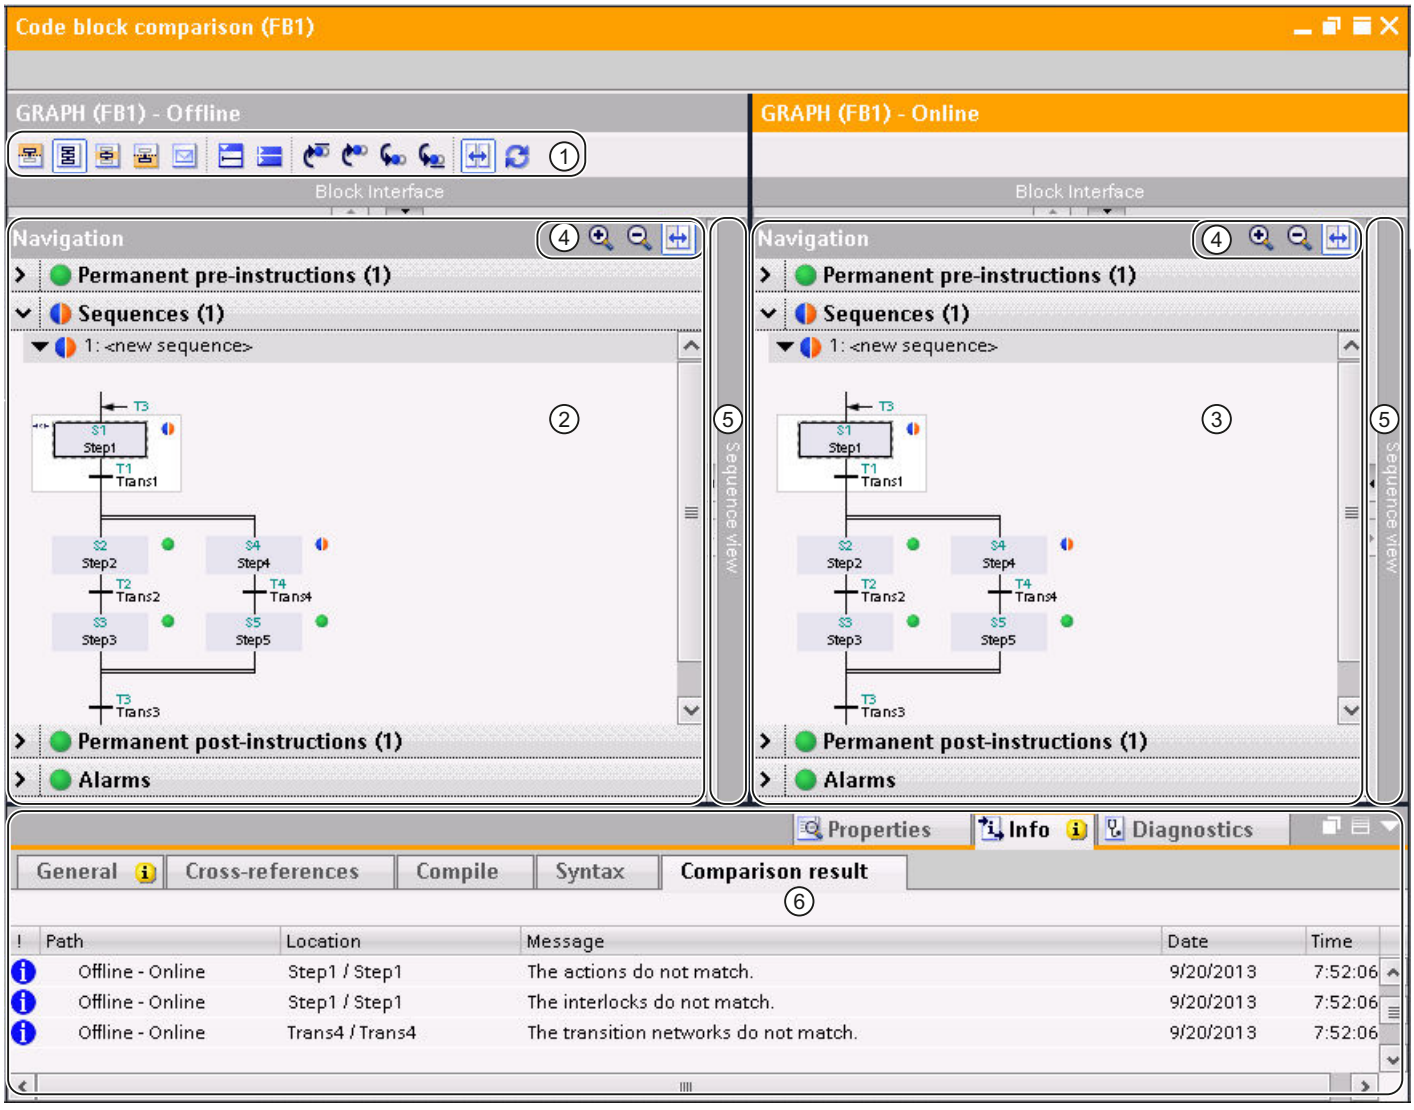
The detailed comparison allows you to identify the exact places where versions of a block differ. When you start a detailed comparison for a GRAPH block, navigation is opened first. Use the dividers to toggle between the navigation and the currently set view. You can select other views with the toolbar of the detailed comparison.

The result of the comparison is indicated by the comparison symbols.

See also: Overview of the comparison editor (Page 405)

Structure of the detailed comparison

The following figure shows an example for the navigation view with an online/offline detailed comparison for the GRAPH programming language:



① Toolbar of the detailed comparison for GRAPH

② Reference block

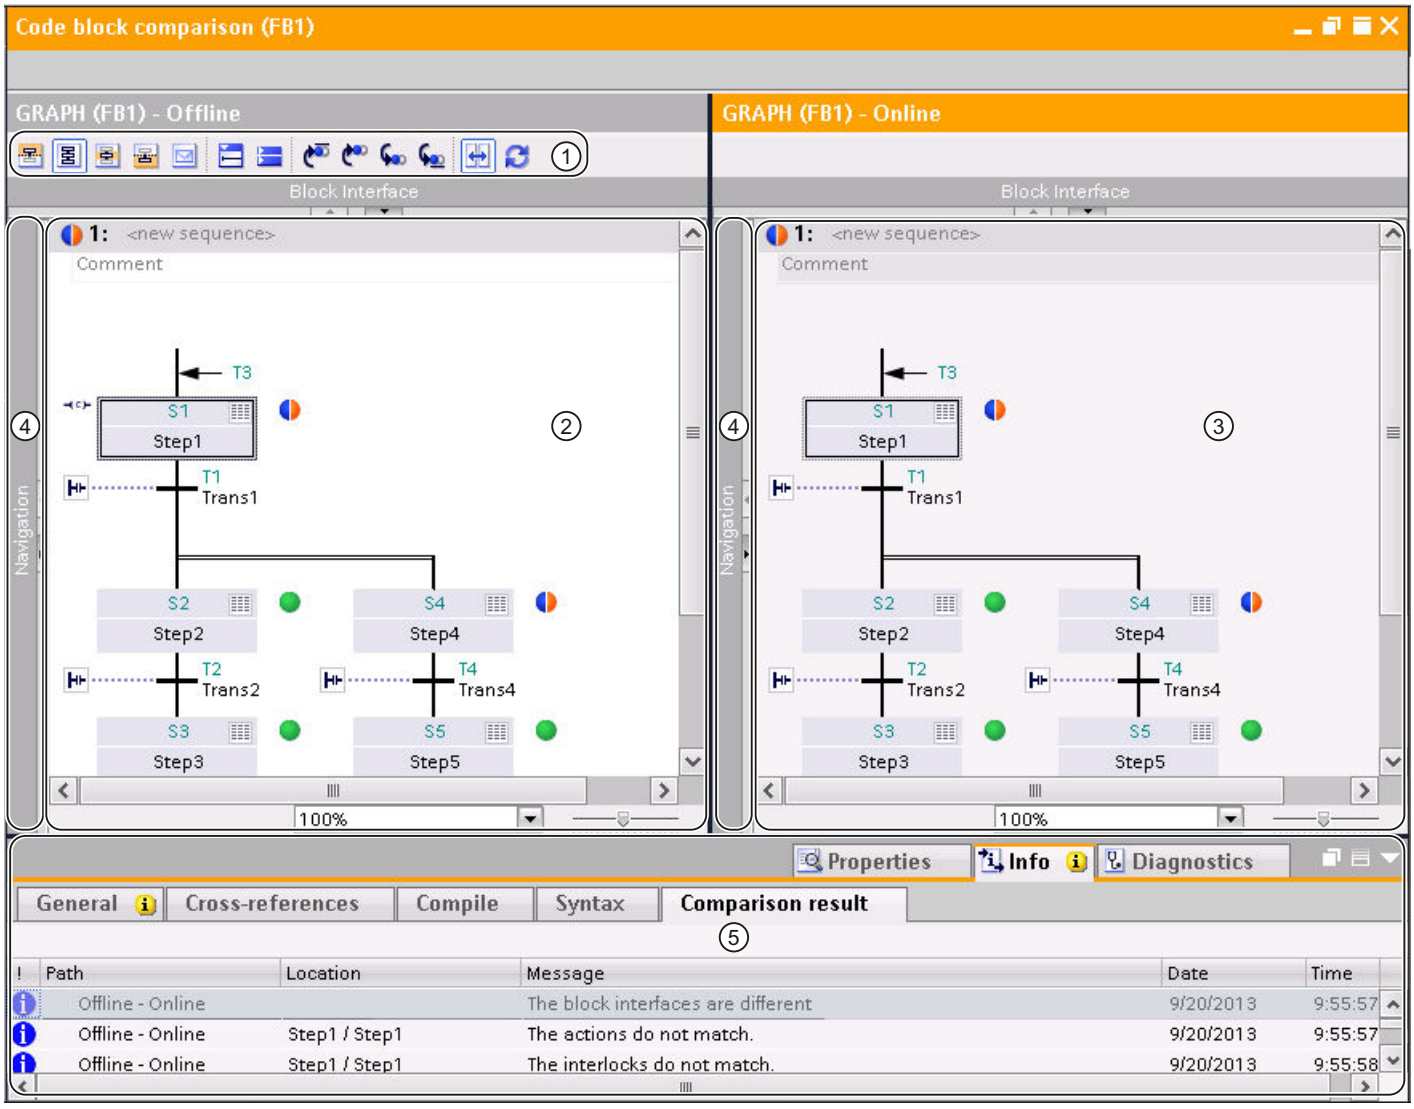
③ Compared block

④ Navigation toolbar

⑤ Dividers

⑥ Comparison result in the Inspector window

The following figure shows an example for the sequence view with an online/offline detailed comparison for the GRAPH programming language:



① Toolbar of the detailed comparison for GRAPH

② Reference block

③ Compared block

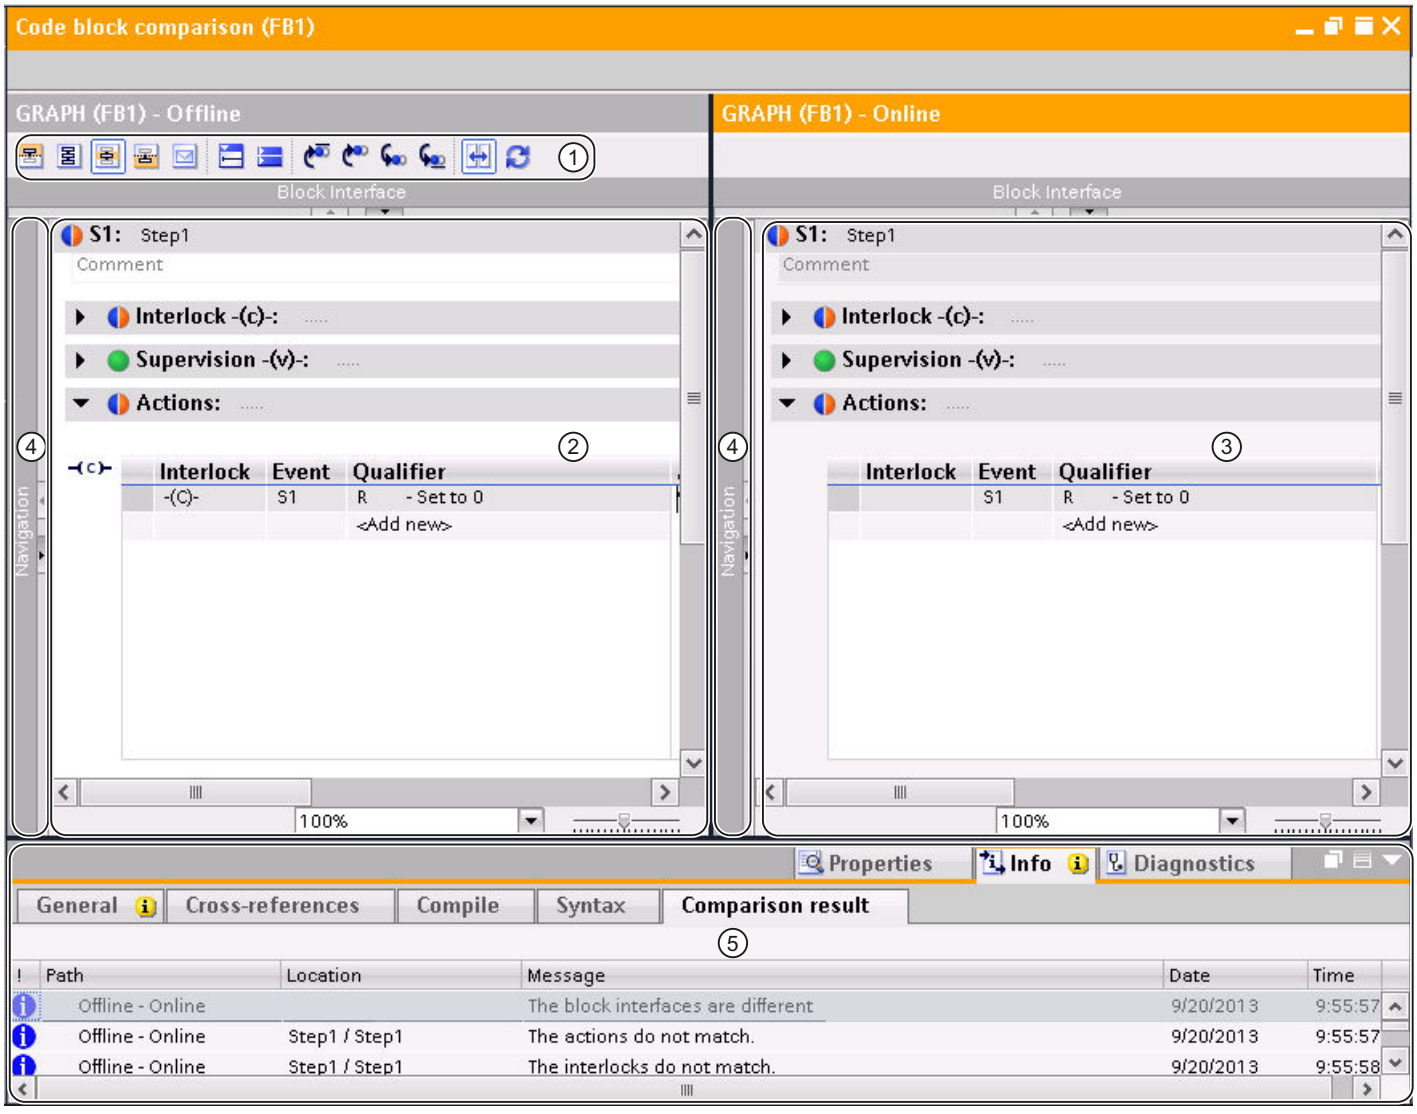
④ Dividers

⑤ Comparison result in the Inspector window

Note

If there are structural differences between the blocks, the comparison results are only displayed up to the first structural difference in the sequence view.

The following figure shows an example for the single step view with an online/offline detailed comparison for the GRAPH programming language:



① Toolbar of the detailed comparison for GRAPH

② Reference block

③ Compared block

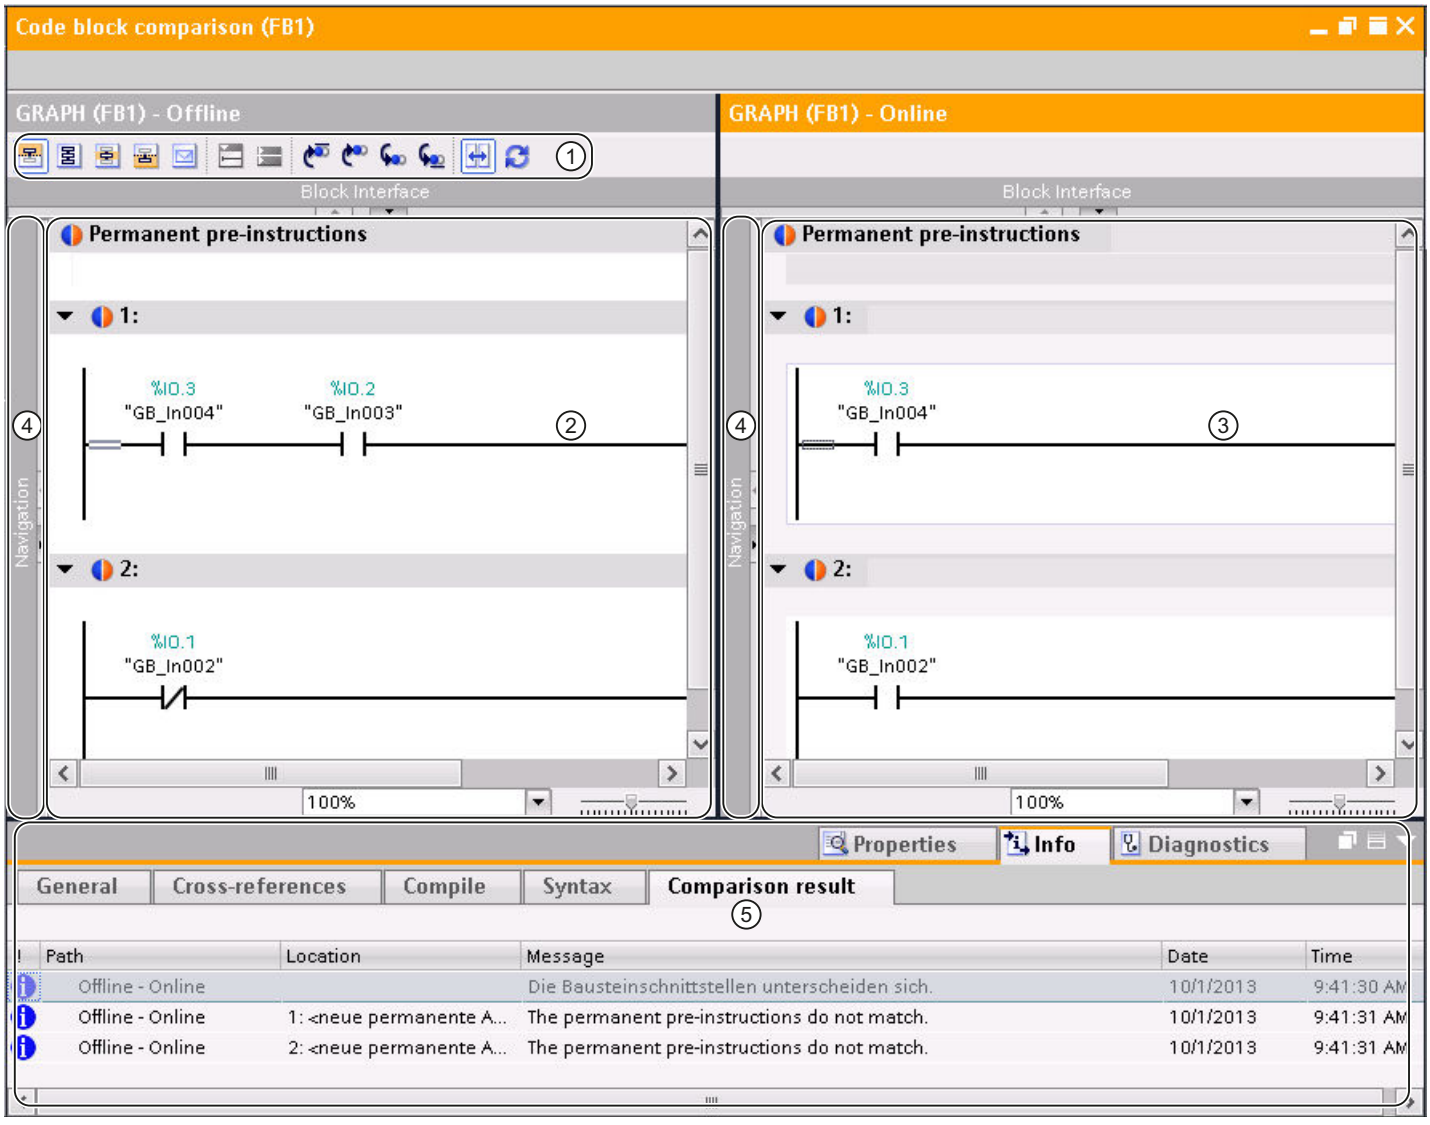
④ Dividers

⑤ Comparison result in the Inspector window

Note

The result of the comparison refers to the complete network Differences within the networks are not identified.

The following figure shows an example for the view of permanent instructions with an online/ offline detailed comparison for the GRAPH programming language:



① Toolbar of the detailed comparison for GRAPH

② Reference block

③ Compared block

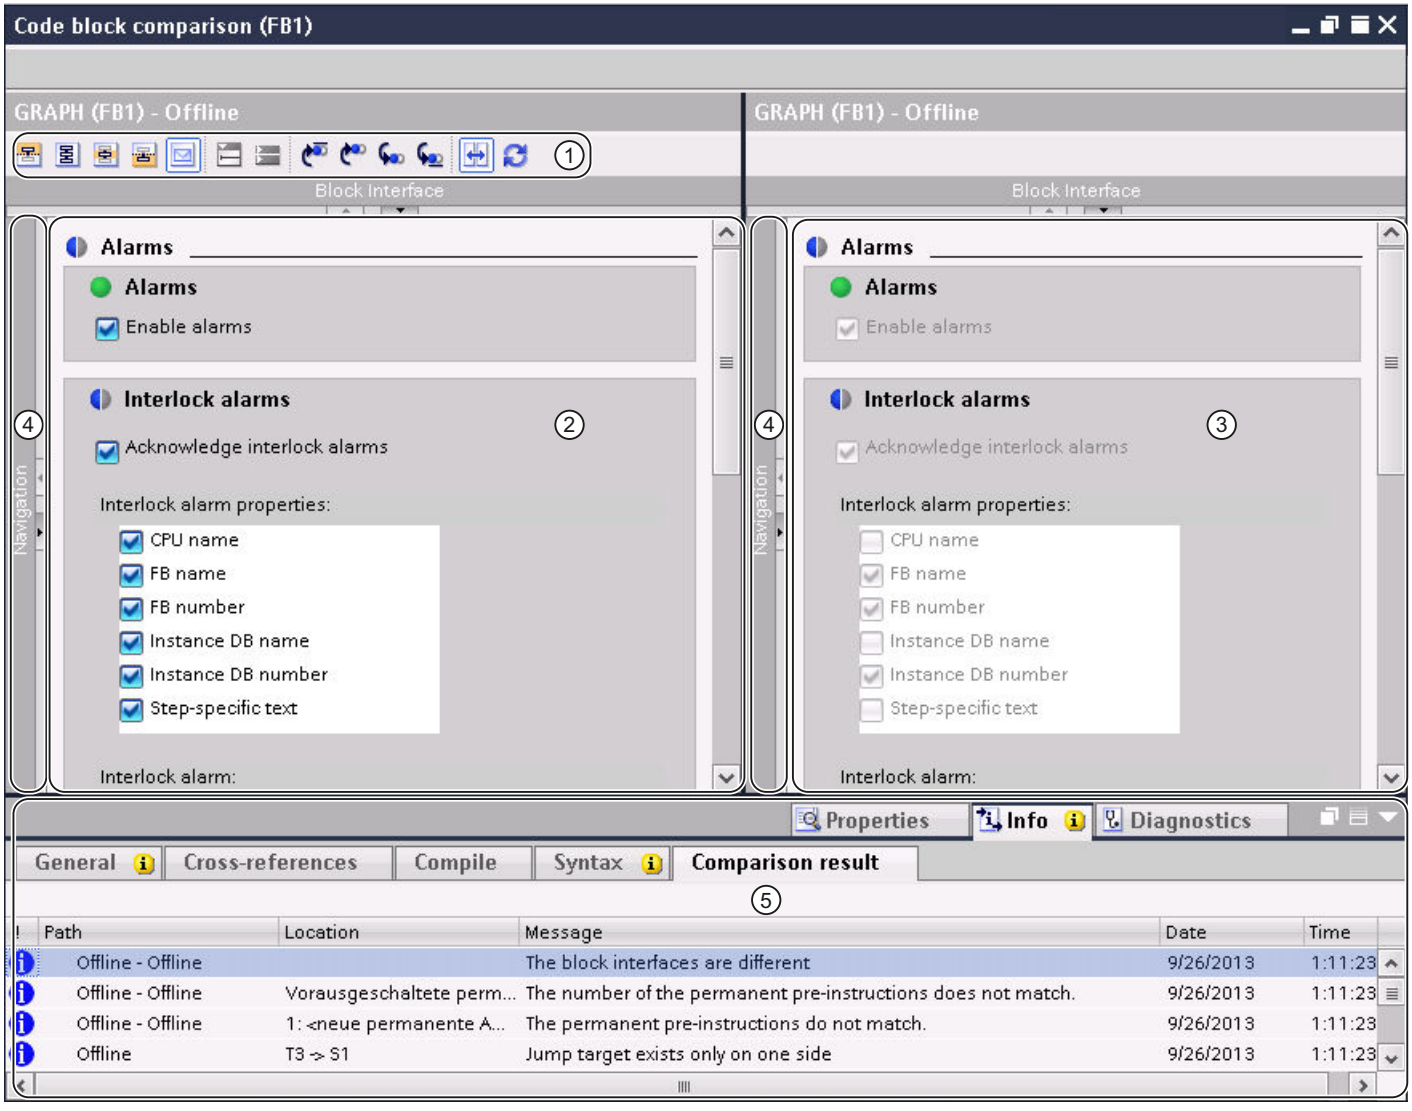
④ Dividers

⑤ Comparison result in the Inspector window

Note

The result of the comparison refers to the complete network Differences within the networks are not identified.

The following figure shows an example for the alarm view with an online/offline detailed comparison for the GRAPH programming language:



① Toolbar of the detailed comparison for GRAPH

② Reference block

③ Compared block

④ Dividers

⑤ Comparison result in the Inspector window

Toolbars

With the toolbar of the detailed comparison, you can access the following functions:

- General functions
  - Change to permanent pre-instructions
  - Change to sequence view
  - Change to single step view
  - Change to permanent post-instructions
  - Change to alarm view
  - Open all networks
  - Close all networks
- Comparison-specific functions
  - Position on first difference
  - Position on previous difference
  - Position on next difference
  - Position on last difference
  - Synchronize scrolling between editors
  - Update comparison results

The navigation has its own toolbar with the following functions:

- Zoom in or zoom out of elements within the navigation
- Synchronize navigation

Reference block

The reference block is displayed in the left window. In an online/offline comparison, the reference block is the offline version of the block.

Compared block

The compared block is displayed in the right window. In an online/offline comparison, the compared block is the online version of the block.

Dividers

You can click the dividers to toggle quickly between the navigation and the current view.

Comparison result in the Inspector window

The differences are displayed in the form of a table in the "Info > Comparison result" tab of the Inspector window. Double-click on a row to navigate to the corresponding difference in the block.

Updating comparison results (Page 1778)

Navigating in the detailed comparison

Requirement

You have run a detailed comparison.

Navigate to the differences

To navigate to a difference between the two blocks, follow these steps:

1. Open the list of results for the detailed comparison under "Info > Comparison result" in the Inspector window.
2. Double-click a difference.
   The difference is selected in both editors.

Or:

1. Click one of the following navigation buttons on the toolbar:
   - Position on first difference
     Navigates to the first difference in the block, and displays the difference in both editors.
   - Position on previous difference
     Navigates to the previous difference starting from the current position, and displays the difference in both editors.
   - Position on next difference
     Navigates to the next difference starting from the current position, and displays the difference in both editors.
   - Position on last difference
     Navigates to the last difference in the block, and displays the difference in both editors.

Switching off/on the synchronization of the vertical scrolling between the editors

The scrolling for both editors is synchronized to ensure that the corresponding networks are visible parallel to each other during vertical scrolling. You can switch this mode off and on. To do this, follow these steps:

1. To switch off synchronized scrolling, click the "Synchronize scrolling between editors" button in the toolbar.
2. To switch on synchronized scrolling again, click the "Synchronize scrolling between editors" button one more time in the toolbar.

Changing blocks during the detailed comparison (Page 1776)

Updating comparison results (Page 1778)

Changing blocks during the detailed comparison

While you are carrying out the detailed comparison, you can make changes to the blocks that are being compared. Remember the following:

- Online/offline comparison: You can change only the offline block.
- Offline/offline comparison: You can change only the offline block in the left-hand area.

After a block change, it may be necessary to manually update the comparison result in the comparison editor to ensure that the comparison status is displayed correctly. You can then specify actions to synchronize the objects.

Note

You cannot change SCL blocks manually. However, you can apply changes from one block to the other block. In this regard, note the following points:

- You cannot apply any changes in an online block.
- You can only apply changes in an offline block if this is not write-protected. This is the case, for example, if the blocks of the detailed comparison come from different CPUs. It is then also possible to apply the changes to the block in the right-hand area.

Changing LAD, FBD or STL blocks

To change LAD, FBD or STL blocks, follow these steps:

1. Change the block in the left-hand area according to your requirements.
2. If necessary, click on "Update comparison results" in the toolbar.

Changing GRAPH blocks

To change a GRAPH block, follow these steps:

1. Switch to sequence view by clicking "Sequence view" between the two blocks.
2. Change the block in the left-hand area according to your requirements.
3. If necessary, click on "Update comparison results" in the toolbar.

Changing SCL blocks

To apply a change from one block to another one, follow these steps:

1. In the sidebar of the block from which you want to apply a change to another block, click on the arrow in the corresponding line.
   The line is inserted in the other block and the arrow buttons are removed.

   Note

   The colors of the arrows have the following meanings:
   - Gray: The changes cannot be applied to the other block, as the other block is either an online block or write-protected.
   - Blue: The changes are applied from an offline block to the other block.
   - Orange: The changes are applied from an online block to the other block.

2. If necessary, click on "Update comparison results" in the toolbar.

11.1.5.3 Comparing PLC tags

You have the following options for comparing PLC tags:

- Automatic offline/offline comparison in the compare editor
  The PLC tag tables of the selected devices are compared offline.
- Manual offline/offline comparison in the compare editor
  The selected PLC tag tables of the devices are compared offline.
- Detailed comparison
  Use the detailed comparison to determine differences within the PLC tag tables.

Performing automatic offline/offline comparison in the compare editor

To perform an automatic offline/offline comparison of PLC tag tables, follow these steps:

1. Select a device in the project tree that allows offline/offline comparison.
2. Select the "Compare > Offline/offline" command in the shortcut menu.
   The compare editor opens and the selected device is displayed in the left area.
3. Drag-and-drop an additional device to the drop area of the right pane. The device to be compared can originate from the same project, a reference project or the library.
4. Open the "PLC tags" folder.
   You can identify the status of the PLC tag tables based on the symbols in the status and action area. You can define certain actions depending on the status.

You can drag any other device to the drop area at any time to perform further comparisons.

Performing manual offline/offline comparison in the compare editor

To perform a manual offline/offline comparison of PLC tag tables, follow these steps:

1. Select a device in the project tree that allows offline/offline comparison.
2. Select the "Compare > Offline/offline" command in the shortcut menu.
   The compare editor opens and the selected device is displayed in the left area.
3. Drag-and-drop an additional device to the drop area of the right pane. The device to be compared can originate from the same project, a reference project or the library.
4. In the status and action area, click on the button for switching between automatic and manual comparison.
5. Select the PLC tag tables that you want to compare.
   The properties comparison is displayed. You can identify the status based on the symbols.

You can drag any other device to the drop area at any time to perform further comparisons.

Running a detailed comparison

To start a detailed comparison for a PLC tag table, follow these steps:

1. Perform an automatic or manual offline/offline comparison.
2. For an automatic offline/offline comparison in the compare editor, select the PLC tag table for which you want to run a detailed comparison. Note that two PLC tag tables must be selected for comparison for a manual offline/offline comparison.
3. Click the "Start detailed comparison" button in the toolbar.
   A separate compare editor opens. All existing PLC tags of the selected PLC tag tables are displayed depending on the settings of the compare editor. User and system constants are not shown, however. You can identify the status of the PLC tags based on the symbols. You can define certain actions depending on the status of the PLC tags.

Comparing PLC data types (Page 1780)

11.1.5.4 Comparing PLC data types

You have the following options for comparing PLC data types:

- Online/offline comparison (S7-1200/1500 only)
  The PLC data types in the project are compared with the PLC data types of the selected device.
- Automatic offline/offline comparison in the compare editor
  The PLC data types of the selected devices are compared offline.
- Manual offline/offline comparison in the compare editor
  The selected PLC data types of the devices are compared offline.
- Detailed comparison
  Use the detailed comparison to determine differences between PLC data types.

Performing online/offline comparison of PLC data types

To perform an online/offline comparison, follow these steps:

1. In the project tree, select a device that allows online/offline comparison.
2. Select the "Compare > Offline/online" command in the shortcut menu.
   If you have not already established an online connection to this device, the "Go online" dialog opens. In this case, set all the necessary parameters for the connection and click "Connect".
   The online connection is established and the compare editor opens.
3. Open the "PLC data types" folder.
   You can identify the status based on the symbols in the status and action area. When you select an object, the properties of the PLC data type and the corresponding PLC data type of the assigned device are displayed in the properties comparison.

Performing automatic offline/offline comparison in the compare editor

To perform an automatic offline/offline comparison of PLC tag tables, follow these steps:

1. Select a device in the project tree that allows offline/offline comparison.
2. Select the "Compare > Offline/offline" command in the shortcut menu.
   The compare editor opens and the selected device is displayed in the left area.
3. Drag-and-drop an additional device to the drop area of the right pane. The device to be compared can originate from the same project, a reference project or the library.
4. Open the "PLC data types" folder.
   You can identify the status of the PLC tag tables based on the symbols in the status and action area. You can define certain actions depending on the status.

You can drag any other device to the drop area at any time to perform further comparisons.

Performing manual offline/offline comparison in the compare editor

To perform a manual offline/offline comparison of PLC data types, follow these steps:

1. Select a device in the project tree that allows offline/offline comparison.
2. Select the "Compare > Offline/offline" command in the shortcut menu.
   The compare editor opens and the selected device is displayed in the left area.
3. Drag-and-drop an additional device to the drop area of the right pane. The device to be compared can originate from the same project, a reference project or the library.
4. In the status and action area, click on the button for switching between automatic and manual comparison.
5. Select the PLC data types that you want to compare.
   The properties comparison is displayed. You can identify the status based on the symbols.

You can drag any other device to the drop area at any time to perform further comparisons.

Running a detailed comparison

To start a detailed comparison for a PLC data type, follow these steps:

1. Perform an offline/offline comparison. You can also perform an online/offline comparison for CPUs of the S7-1200/1500 series.
2. For an automatic offline/offline comparison in the compare editor, select the PLC data type for which you want to run a detailed comparison. Note that two PLC data types must be selected for comparison with a manual offline/offline comparison.
3. Click the "Start detailed comparison" button in the toolbar.
   The two PLC data types are opened next to each other so that you can easily identify the differences.

11.1.6 Compiling and downloading blocks

11.1.6.1 Compiling blocks

Basic information on compiling blocks

Introduction

A user program must first be compiled before the CPU can execute it. You need to recompile your program each time you make a change.

The following procedures take place during compilation:

- The user program is checked for syntax errors.
- Unneeded instructions are removed from the user program.
- All the block calls within the compiled blocks are checked. In case of changes to the interface of called blocks, errors will be shown in the "Compilation" tab of the information window. You have to correct these errors first.
- The blocks must be numbered uniquely in the user program. If more than one block has the same number, the blocks with number conflicts are renumbered automatically during compilation. A block will not be renumbered in the following cases:
  - The block was selected either individually or as part of a multiselection for the compilation.
  - The block is know-how protected.
  - The number assignment is set to "manual" in the properties of the block.

  Number conflicts that cannot be resolved by automatic renumbering must be corrected manually. Note the messages in the Inspector window for this. You can only correct know-how-protected blocks manually if you know the password since the blocks must then be recompiled.
- Finally, the user program is compiled into a code that can be read by the CPU.

Compilation methods

You can start compilation in the following windows or editors:

- Compiling blocks in the project tree
  Serves to compile individual blocks or the simultaneous compilation of one or several blocks in the "Program blocks" folder.
- Compiling blocks in the program editor
  This is intended for compilation of a single open block.
- Compiling blocks in the call or dependency structure
  Used to compile individual blocks.
  See also: Call structure (Page 1818), Dependency structure (Page 1824)

Compilation options

If you are compiling blocks in project tree, you have further options:

- Software (changes only)
  All program changes of the selected blocks are compiled. If you have selected a block folder, all program changes to the bocks contained in the folder are compiled.
- Software (compile all blocks)
  All blocks are compiled. This is recommended for the first compilation and after major revisions.
- Software (reset memory reserve)
  All tags declared in the reserve area of the interface of selected blocks are moved to the standard area of the interface. Memory reserve is now available for further interface extensions.

Note

This option is only available for CPUs of the S7-1500 and S7-1200 V4 and higher series.

Consistency check

Changing the interfaces of blocks called or PLC data types used can result in inconsistencies between calling blocks and called blocks or between the PLC data types and the global data blocks which use these PLC data types.

To avoid such inconsistencies in the user program, the system performs an automatic consistency check before each compilation process. The time stamps are compared and compilation is then either carried out or canceled depending on the results of the comparison.

- The calling block can only be compiled if the time stamps of the interfaces of the called blocks are older than those of the calling block.
- A global data block based on a PLC data type can only be compiled correctly if the time stamp of the global data block is newer than the time stamp of the PLC data type used.
- The instance data block can only be compiled correctly if the interface time stamps for the interface of the instance data block are identical to those of the assigned function block.

If the compilation process is cancelled, an alarm is displayed in the inspector window. Update the block calls in the relevant blocks and the PLC data types in the global data blocks and then restart compilation. The consistency check also finds know-how protected blocks which cannot be compiled. The corresponding messages will also be shown in the inspector window.

If you start loading immediately instead of first compiling, the blocks selected will be automatically compiled and the block call and global data blocks implicitly updated. Please note the following differences between the CPU families:

- S7-1200/1500: All blocks affected are loaded to ensure no inconsistencies can arise.
- S7-300/400: Only the block selected is loaded.

Updating block calls in FBD (Page 1638)

Compiling project data (Page 392)

Compiling blocks in the project tree

You can compile one block, multiple blocks or all of the blocks in the project tree.

For CPUs of the S7-1500 and S7-1200 V4 series, you can also reset the memory layout of blocks with memory reserve by running a compilation. For more information on memory reserve, refer to chapter "Loading blocks (S7-1200/1500) > Loading block changes without reinitialization".

Requirement

The project tree is open.

Compiling one or more blocks in the project tree

To compile multiple blocks in the project tree, follow these steps:

1. Open the "Program blocks" folder in project tree.
2. Select the blocks you want to compile.
3. Select the "Compile > Software (only changes)" command from the shortcut menu.

Compiling all blocks in the project tree

To compile all blocks in the "Program blocks" folder in project tree, follow these steps:

1. Select the "Program blocks" folder in the project tree.
2. You can select one of two different options for the compilation:
   - If you want to compile only the changes since the last compilation, select the "Compile > Software (only changes)" command in the shortcut menu.
   - If you want to compile all blocks completely, select the "Compile > Software (compile all blocks)" command in the shortcut menu.

Resetting memory layout (S7-1500/S7-1200 V4)

Proceed as follows to reset the memory layout of blocks:

1. Select the "Program blocks" folder, or specific blocks in this folder.
2. Select the "Compile > Software (Reset memory reserve)" command from the shortcut menu.

Result

The code for the blocks will be generated if the consistency check has been successful. Instance data blocks generated by the system which are no longer needed will be deleted.

The message under "Info > Compilation" in the inspector window reports whether the compilation was successful.

See also

Basic information on compiling blocks (Page 1782)

Compiling blocks in the program editor (Page 1785)

Correcting compilation errors (Page 1786)

Finding syntax errors in the program (Page 1697)

Compiling blocks in the program editor

Note

Note that the block is recompiled even if you have not made any changes and the time stamp of the block is modified.

Requirement

The block to be compiled is open.

Procedure

To compile a block in the program editor, follow these steps:

1. Right-click in the instruction window of the programming editor.
2. Select the "Compile" command in the shortcut menu.

Result

The code for the block is generated. Instance data blocks generated by the system which are no longer needed will be deleted.

The message under "Info > Compilation" in the inspector window reports whether the compilation was successful.

See also

Basic information on compiling blocks (Page 1782)

Compiling blocks in the project tree (Page 1784)

Correcting compilation errors (Page 1786)

Correcting compilation errors

In the Inspector window in "Info > Compile", you can see whether any compilation was successful or whether errors were detected in the program. If errors occur, you will need to correct them and then start the compilation again.

Procedure

To correct errors following compilation, follow these steps:

1. Open the error list in the Inspector window with "Info > Compile".
2. If there is one, click on the blue question mark next to the error text for information on remedying errors.
3. Double-click the error you want to correct.
   The corresponding error is highlighted.
4. Correct the error.
5. Restart compilation.

11.1.6.2 Downloading blocks for S7-1200/1500

Introduction to downloading blocks

Downloading blocks to device

So that the CPU can execute the user program, the program must first be compiled and then downloaded to the device. Loading into the device can be started through different methods:

- By using the commands in the "Online" menu
- By using the the context menu
- By using the "Load" button in the toolbar

Depending on the selected object (such as individual blocks in the programming editor, the complete block folder or the connected CPU in the project navigation) and the command respectively selected, you can load the following components:

- Hardware and software (only changes)
- Hardware configuration
- Software (only changes)
- Software (all)

During the loading operation, all information that is required for the reconstruction of the program, including symbolic information such as the names and comments for code and data blocks, is also loaded in the current project language. If you change the project language, you must therefore re-load the program.

The symbolic information is not loaded to the work memory, but rather to the load memory.

After the data has been loaded from a device, the symbolic information is available again in your program, which increases the readability of your program code. Please note, however, that loading to and from a device is not a substitute for storing data in an offline project, as watch tables or multi-language capability of projects cannot be reproduced by loading to and from a device.

After loading from a device, you can only display all data from know-how-protected blocks by entering the correct password.

Note

No valid hardware configuration available

If no valid hardware configuration was found on the CPU while loading the software, the existing hardware is loaded as well during a "Download to device".

Please note that in this case hardware components are also loaded during the download, even though you executed the command for loading software!

Note

To avoid inconsistencies between calling and called blocks, all blocks affected are compiled and loaded after each global change, such as a change in the block interface.

Note

S7-1200 Version 1.0

If you download an element of your project to the CPU, for example a program block, a data block or the hardware configuration, the CPU runs a cold restart the next time it changes to RUN mode. Apart from deleting the inputs, initializing the outputs and deleting the non-retentive memory, cold restart also deletes the retentive memory areas. All subsequent changes from STOP to RUN are warm restarts in which the retentive memory is not deleted.

Note

S7-1500

The load memory of S7-1500 series CPUs is on the SIMATIC memory card. Therefore, a SIMATIC memory card absolutely must be inserted in order to operate the CPU.

Uploading blocks from device

You can load the blocks of a device to your project. This is necessary, for example, if you want to edit blocks that only exist in this device. You have the option of loading either all available blocks (organization blocks, function blocks, functions and data blocks) and global PLC tags or individual blocks to the project.

Uploading blocks from or downloading blocks to a memory card

Memory cards are plug-in cards used with an S7-1200 series CPU, for example, to replace the load memory of a device. In the case of S7-1500 series CPUs, they contain the load memory. Only the SIMATIC memory card from Siemens can be used for devices of the S7-1200 and S7-1500 series.

To use a memory card as load memory, you must download the user program or individual blocks to a memory card. You can just as well upload blocks from a memory card back into the project.

Note

S7-1200

Note the following when uploading to or downloading from a memory card:

- If the CPU contains no previous program and you insert an empty memory card in the CPU the program will be loaded from the PG/PC to the memory card and not to the CPU.
- If you insert an empty memory card prior to the startup of the CPU, the program that is on the CPU will be transferred automatically to the memory card. The program on the CPU will then be deleted.
- If you insert a memory card with a program in the CPU prior to the startup of the CPU and the CPU already contains a program, the program on the memory card will be executed and not the program on the CPU. The program on the CPU will be deleted.

Loading GRAPH function blocks

If you load a GRAPH function block together with its instance data block, the processing of the sequencer starts over at the initial step. As a result, problems may occur when synchronizing the sequencer with the process. You can avoid these problems by switching off the sequencer before loading.

Downloading changes without reinitialization

It often proves necessary to edit or expand a PLC program that was already commissioned and that is running on the plant without error. Such operations should be performed without causing any major interruptions of current operations.

S7-1500 therefore offers the option of extending the interfaces of function or data blocks during runtime and loading the modified blocks without setting the CPU to STOP or affecting the value of tags that are already loaded. This is a simple means of implementing program changes. This load process (download without reinitialization) will not have a negative impact on the controlled process.

Effects of a load operation on the tag values of a data blocks

When data blocks are downloaded to a device in STOP mode, the next transition of the device to RUN affects the current tag values as follows:

- Tags not marked as being retentive retain their defined start values.
- Retentive tags of the S7-1200 only retain their values if the following conditions are met:
  - You loaded the data block by means of "Download to device > Software (changes only)".
  - You made no changes to the DB structure.

  Otherwise the retentive tags will also retain their defined start values.
- Retentive tags of the S7-1500 only retain their values if the following conditions are met:
  - You loaded the data block by means of "Download to device > Software (changes only)".
  - You made no changes to the structure of the data block or modified it within the memory reserve.

  Otherwise the retentive tags will also retain their defined start values.

Loading blocks with synchronization

In team engineering, it is possible for several users to work on one project with several engineering systems at the same time and access one S7-1500 CPU. To ensure consistency within the shared project, it is necessary to synchronize the changed data prior to loading so that nothing gets overwritten unintentionally.

If differences are determined between the online and offline data management within the shared project during loading that were caused by a different engineering system, automatic synchronization of the data to be loaded is offered during loading.

In this case, the "Synchronization" dialog displays the data to be synchronized with the current status (online-offline comparison) and the possible actions.

The following options are available for synchronization:

Application case	Recommendation	Synchronization
One or more blocks on the CPU (online) are more recent than in the engineering system (offline).	These blocks should be downloaded from the CPU to the engineering system before loading.	Automatic synchronization is possible: The blocks in the engineering system are updated prior to loading.
One or more new blocks have been created and exist only in the CPU (online).	These blocks should be downloaded from the CPU to the engineering system before loading.	Automatic synchronization is possible: The new blocks are added prior to the download in the engineering system.
One or more blocks on the CPU have been deleted.	The blocks should also be deleted prior to the download in the engineering system.	Automatic synchronization is not possible. The blocks deleted on the CPU should be manually deleted in the offline project in the engineering system.
One or more blocks on the CPU and in the engineering system are different. This is the case when a different user has changed blocks to which you have also made corrections and has already downloaded them to the CPU.	These blocks with competing changes must be adapted manually. You decide in this case which changes you are going to accept. If the blocks on the CPU are to be retained, you should accept these blocks prior to download from the CPU to your engineering system. If the blocks that you have changed are to be applied, you can continue with the download without synchronization.	Automatic synchronization is not possible: The affected blocks on the CPU or in the engineering system must be adapted manually. One of the existing block versions (online or offline) will be overwritten in the process.
There are differences in the hardware configuration on the CPU (online) and in the engineering system (offline).	Differences in the hardware configuration must be adapted manually. You decide in this case which hardware configuration you are going to accept. If the existing hardware configuration on the CPU is to be retained, you should apply these in your engineering system prior to loading. If you want to apply the changed hardware configuration, you can continue with the download without synchronization.	Automatic synchronization is not possible: The hardware configuration must be adapted manually. One of the existing hardware configurations (online or offline) will be overwritten in the process.

You can use the "Force download to device" command to download blocks without synchronization, if desired.

Downloading blocks in the "RUN" operating mode to the device

Basics on downloading blocks in the "RUN" operating mode

When you download modified blocks to the device, it is not always necessary to switch the device to the "STOP" operating mode. Prior to a download operation, the Engineering System checks whether the device must be stopped before downloading. The result of this check is displayed in the "Load preview" dialog.

If it is necessary to change to the "STOP" operating mode, you cannot continue the download process until you have stopped the CPU.

If the requirements are met, you can also download a modified program or program parts to a CPU in "RUN" operating mode.

The quantity structures may be exceeded for very complex programs which prevents a download in "RUN". In this case you must first create the prerequisites for a download in "RUN".

Tips:

- Use a memory card with sufficient capacity.
- Select a CPU with sufficient work memory.
- If necessary, reduce the number of downloaded objects (blocks, constants, PLC tags, data types).
  If you cannot download all objects at once, proceed in several steps and download a smaller number of objects in each step.

Note

Actual parameters are not overwritten by a download process in the "RUN" operating mode. Changes to the actual parameters will not become effective until the next time you change the operating mode from "STOP" to "RUN".

Downloading changes in "RUN"

The table below shows which program and configuration changes can be downloaded in "RUN" operating mode, sorted by CPU family and taking into consideration the firmware versions of the CPUs.

Explanations on the table:

- "RUN": Change can be downloaded in "STOP" operating mode as well as in "RUN" operating mode to the CPU.
- "RUN (< 57)": The CPU can integrate up to 56 new or modified objects/blocks in one program cycle. If you download more objects/blocks, they are integrated in several successive program cycles. If you want to download all objects/blocks consistently, you must set the CPU to "STOP" operating mode. This number depends on the setting for S7-300 CPUs with configuration option "Process mode/test mode".
- "RUN (Init)": Change can be downloaded in "RUN" operating mode; downloaded data blocks are re-initialized.
- "STOP": Change can only be downloaded in "STOP" operating mode.
- "STOP (Reset)": Change can only be downloaded in "STOP" operating mode; all data including retentive data is reset.

	S7-300	S7-400	S7-1200 V4.0 and higher	S7-1500
Action/type of change	**Download possible in mode ...**			
Modified properties of HW components. This includes changes to comments in the HW configuration.	STOP	STOP	STOP	STOP
Added HW components	STOP	STOP	STOP	STOP
New/revised text lists (messages)	**RUN**	**RUN**	STOP	**RUN (V1.1 and higher)**
Revised comments (new, revised, deleted) with the exception of comments in the HW configuration	-	-	**RUN**	**RUN**
Number of blocks downloaded at the same time	**RUN (<17)**	**RUN (<57)**	**RUN (<21)**	**RUN (all)**
Download PLC program to the device and reset	STOP (Reset)	STOP (Reset)	STOP (Reset)	STOP (Reset)

Modified User Data Type (UDT)	STOP	STOP	**RUN (Init)**	**RUN (Init)**
Add new PLC tags (timer, counter, bit memory)	**RUN**	**RUN**	**RUN**	**RUN**
Modified retentivity settings (timer, counter, bit memory, DB area)	STOP	STOP	STOP	STOP
Motion Control technology objects: Changes to MC Servo cycle clock, change from free-running to cyclical (and vice versa). Changes to the HW interface of the TO	-	-	-	STOP

* If the interface change results in structural changes at the instance DB, see "Modified DB...".

** For the effect of download of data block changes to the data block content, see section "Downloading data blocks to the CPU"

Download of changes in "RUN" with older CPU firmware versions

The table below shows which changes you can download in "RUN" operating mode, in particular, for which older CPU firmware versions.

	S7-1200 V1.0 - 2.1	S7-1200 V2.2 - V3.0
Action/type of change	**Download possible in mode ...**	
Modified properties of HW components. This includes changes to comments in the HW configuration.	STOP	STOP
Added HW components	STOP	STOP
New/revised text lists (messages)	STOP	STOP
Revised comments (new, revised, deleted) with the exception of comments in the HW configuration	STOP	**RUN**
Number of blocks downloaded at the same time	STOP	**RUN (<11)**
Download PLC program to the device and reset	STOP (Reset)	STOP (Reset)
New OB	STOP	STOP
Modified OB: Code changes	STOP	**RUN**
OB with modified properties (e.g., cycle time change)	STOP	STOP
Deleted OB	STOP	STOP
New FB/FC/DB/User Data Type (UDT)	STOP	**RUN**
Deleted FB/FC/DB/User Data Type (UDT)	STOP	**RUN**
Revised FB/FC: Code change	STOP	**RUN**
Revised FB/FC: Interface change	STOP	STOP
Modified DB: Modified property ("Only store in load memory" attribute changed)	STOP	STOP
Modified DB (memory reserve not enabled): Name/type of tags modified, tags added or deleted	STOP	STOP
Modified User Data Type (UDT)	STOP	STOP
Add new PLC tags (timer, counter, bit memory)	STOP	STOP
Modified retentivity settings (timer, counter, bit memory, DB area)	STOP	STOP

Downloading data blocks to the CPU

Depending on the conditions, the download of new or modified data blocks has an effect on the actual values in the data block:

Download new data blocks	Actual values in the new data blocks are set to start values.
Download structurally modified data blocks (memory reserve not enabled)	Actual values of added tags in the structurally modified data blocks are set to start values.

Download structurally modified data blocks (memory reserve enabled)	The following actual values are retained: • Actual values of tags outside the memory reserve • Actual values of tags that were not modified within the memory reserve Actual values of added tags within the memory reserve are set to start values.
Download of simply modified data blocks (no structural modification)	Actual values are retained.

Additional information

Additional information on download of block extensions without re-initialization and download of modified values for data blocks is available at "See also".

Downloading blocks from the project tree to the device (Page 1796)

Downloading project data to a device (Page 396)

Downloading blocks from program editor to device

Requirement

The block to be downloaded is open.

Procedure

To download a block from the program editor to the device, follow these steps:

1. Right-click in the instruction window of the programming editor.
2. Select the "Download to device" command in the shortcut menu.
   - If you have not already established an online connection, the "Extended download to device" dialog opens. In this case, set all parameters required for the connection and click "Load".
   - You can save your preferred connection parameters as default under "Options > Settings > Online & Diagnostics". When you first load with new connection parameters, a query is automatically displayed whether you want to store it as a default setting. Click "Yes", if you want to save the current connection parameters as default.
   - You have the option of showing all compatible devices by selecting the corresponding option and clicking the "Start search" command. You can also open the "Extended download to device" dialog explicitly via the "Online" menu.
     See also: Establishing and terminating an online connection
   - If you have already specified an online connection, then the project data is compiled if necessary and the "Load preview" dialog opens. This dialog displays alarms and proposes actions necessary for loading.
3. Check the alarms and, where necessary, enable the actions in the "Action" column.
   As soon as downloading becomes possible, the "Load" button is enabled.

   Note

   Actions

   Performing the proposed actions during ongoing plant operation can cause serious damage to property or injury to persons if there are functional faults or program errors.

   Make sure that no dangerous situations can arise before you start the actions.

   Note

   To avoid inconsistencies between calling and called blocks, download all affected blocks each time you make global changes, such as changes in the block interface. Select the "Consistent download" action.

4. Click "Load".
   If there is a need for synchronization, the system automatically displays the "Synchronization" dialog. This dialog displays messages and suggests actions that are needed for the synchronization. You have the option of performing these actions or forcing the download without synchronization by clicking "Force download to device". If you have performed the suggested actions, you will be asked whether you want to continue with the download. Click "Continue download" in order to download the block. The "Load results" dialog then opens and shows you the status and the actions after the download operation.
5. If you want to start the modules again directly after downloading, select the "Start all" check box.
6. To close the "Load results" dialog box, click "Finish".

Result

The code for the block will be downloaded to the device. If the changes affect additional blocks, these will be compiled and also downloaded to the device. Blocks that only exist online in the device are deleted. Existing CPU data blocks are retained, however. Inconsistencies between the blocks in the user program are avoided by loading all blocks affected and deleting the unneeded blocks in the device.

The messages under "Info > General" in the Inspector window show whether the downloading process was successful.

Downloading blocks from the project tree to the device

In the project tree you can download one block, multiple blocks or all blocks to a device.

Downloading one or more blocks from the project tree to the device

To download one block or multiple blocks to the device from the project tree, follow these steps:

1. Open the "Program blocks" folder in project tree.
2. Select the blocks you want to download.
3. Select the "Download to device > Software (only changes)" command from the shortcut menu.
   - If you have not already established an online connection, the "Extended download to device" dialog opens. In this case, set all parameters required for the connection and click "Load".
   - You can save your preferred connection parameters as default under "Options > Settings > Online & Diagnostics". You will be prompted as such when you download new connection parameters for the first time. Select "Yes", if you want to save the current connection parameters as default.
   - You have the option of showing all compatible devices by selecting the corresponding option and clicking the "Start search" command. You can also open the "Extended download to device" dialog explicitly via the "Online" menu.
     See also: Go online and Go offline
   - If you have already specified an online connection, then the project data is compiled if necessary and the "Load preview" dialog opens. This dialog displays alarms and proposes actions necessary for loading.

4. Check the alarms and, where necessary, enable the actions in the "Action" column.

   Note

   Performing the proposed actions during ongoing plant operation can cause serious damage to property or injury to persons if there are functional faults or program errors.

   Make sure that no dangerous situations can arise before you start the actions.

   As soon as downloading becomes possible, the "Load" button is enabled.

5. Click "Load".
   If there is a need for synchronization, the system automatically displays the "Synchronization" dialog. This dialog displays messages and suggests actions that are needed for the synchronization. You have the option of performing these actions or forcing the download without synchronization by clicking "Force download to device". If you have performed the suggested actions, you will be asked whether you want to continue with the download. Click "Continue download" in order to download the block. The "Load results" dialog then opens and shows you the status and the actions after the download operation.
6. If you want to start the modules again directly after downloading, select the "Start all" check box.
7. To close the "Load results" dialog box, click "Finish".

Downloading blocks from the project tree to the device

To download all blocks in the "Program blocks" folder to the device from the project tree, follow these steps:

1. Select the "Program blocks" folder in the project tree.
2. Select the "Download to device" submenu in the shortcut menu.
3. If you only want to download the changes since the last download, select the "Software (only changes)" option. If all blocks are to be fully loaded and all values are to be reset to their start values, select "Download PLC program to the device and reset".
   - If you have not already established an online connection, the "Extended download to device" dialog opens. In this case, set all parameters required for the connection and click "Load". You have the option of showing all compatible devices by selecting the corresponding option and clicking the "Start search" command. You can also open the "Extended download to device" dialog with the "Online" menu.
     See also: Go online and Go offline
   - If you have already specified an online connection, then the project data is compiled if necessary and the "Load preview" dialog opens. This dialog displays alarms and proposes actions necessary for loading.
4. Check the alarms and, where necessary, enable the actions in the "Action" column.

   Note

   Performing the proposed actions during ongoing plant operation can cause serious damage to property or injury to persons if there are functional faults or program errors.

   Make sure that no dangerous situations can arise before you start the actions.

   As soon as downloading becomes possible, the "Load" button is enabled.

5. Click "Load".
   If there is a need for synchronization, the system automatically displays the "Synchronization" dialog. This dialog displays messages and suggests actions that are needed for the synchronization. You have the option of performing these actions or forcing the download without synchronization by clicking "Force download to device". If you have performed the suggested actions, you will be asked whether you want to continue with the download. Click "Continue download" in order to download the block. The "Load results" dialog then opens and shows you the status and the actions after the download operation.
6. If you want to start the modules again directly after downloading, select the "Start all" check box.
7. To close the "Load results" dialog box, click "Finish".

Result

The code for the blocks is downloaded to the device. If the changes affect additional blocks, these will be compiled and also downloaded to the device. Blocks that only exist online in the device are deleted. Inconsistencies between the blocks in the user program are avoided by loading all blocks affected and deleting the unneeded blocks in the device.

The messages under "Info > General" in the Inspector window show whether the downloading process was successful.

Downloading blocks in the "RUN" operating mode to the device (Page 1790)

Uploading blocks from device

You can load either all blocks or individual blocks from a device into your project.

Note

Please note the following:

- Please note that when you load individual blocks, no tags or other required blocks to which you may refer are loaded together with the individual blocks. During the loading operation, reference to tags and blocks are reassigned where possible based on the names. After the loading operation, check whether these assignments are correct.
- When uploading from a device to an empty project, any existing folder structures for blocks and objects from libraries may not be downloaded.
- S7-1500: When GRAPH function blocks are loaded from a device to your project, the step-specific alarm texts for the interlock and supervision alarms are not loaded.

Requirement

The online and offline versions of a block to be loaded are different or the blocks only exists online.

Uploading all blocks from a device

To upload all blocks from a device, follow these steps:

1. Establish an online connection with the device from which you want to upload the blocks.
   See also: Go online and Go offline
2. In the project tree, select the device folder from which you want to upload blocks.
3. In the "Online" menu, select the "Upload from device" command.
   The "Upload preview" dialog box opens. This dialog displays alarms and proposes actions necessary for loading.
4. Check the alarms and, where necessary, enable the actions in the "Action" column.
   The "Upload from device" button will be enabled as soon as uploading becomes possible.
5. Click on the "Upload from device" button.
   The load is executed.

Uploading individual blocks from a device

To upload individual blocks from a device, follow these steps:

1. Establish an online connection with the device from which you want to upload the blocks.
   See also: Go online and Go offline
2. In the project tree, select the blocks that you want to upload from the device.
3. In the "Online" menu, select the "Upload from device" command.
   The "Upload preview" dialog box opens. This dialog displays alarms and proposes actions necessary for loading.
4. Check the alarms and, where necessary, enable the actions in the "Action" column.
   The "Upload from device" button will be enabled as soon as uploading becomes possible.
5. Click on the "Upload from device" button.
   The load is executed.

Result

The blocks will be uploaded from the device to the project. You can edit them as normal, recompile them and download them to the device again.

Downloading blocks to a memory card

Requirement

- The memory card is marked as a program card.
- The "Program blocks" folder of the memory card is open.

Procedure

To download blocks to a memory card, follow these steps:

1. Open the "Program blocks" folder of the device in the project tree.
2. Select the blocks you want to download to the memory card.
3. Drag the blocks in project tree to the "Program blocks" folder of the memory card. You can also copy the blocks and add them to the memory card.
   If necessary, the blocks are compiled. The "Load preview" dialog then opens. This dialog displays alarms and proposes actions necessary for loading.
4. Check the alarms and, where necessary, enable the actions in the "Action" column.
5. As soon as downloading becomes possible, the "Load" button is enabled.
6. Click the "Load" button.
   If there is a need for synchronization, the system automatically displays the "Synchronization" dialog. This dialog displays messages and suggests actions that are needed for the synchronization. You have the option of performing these actions or forcing the download without synchronization by clicking "Force download to device". If you have performed the suggested actions, you will be asked whether you want to continue with the download. Click "Continue download" to download the block. The "Load results" dialog then opens and shows you the status and the actions after the download operation.
7. Click "Finish".

Or:

1. In the project tree, select the blocks that you want to upload.
2. Select the "Card reader/USB memory > Write to memory card" command in the "Project" menu.
   The "Select memory card" dialog opens.
3. Select a memory card which is compatible with the CPU.
   A button with a green check mark is activated at the bottom of the dialog.
4. Select the button with the green check mark.
   If necessary, the project data are compiled. The "Load preview" dialog then opens. This dialog displays alarms and proposes actions necessary for loading.
5. Check the alarms and, where necessary, enable the actions in the "Action" column.
   As soon as downloading becomes possible, the "Load" button is enabled.
6. Click the "Load" button.
   If there is a need for synchronization, the system automatically displays the "Synchronization" dialog. This dialog displays messages and suggests actions that are needed for the synchronization. You have the option of performing these actions or forcing the download without synchronization by clicking "Force download to device". If you have performed the suggested actions, you will be asked whether you want to continue with the download. Click "Continue download" to download the block. The "Load results" dialog then opens and shows you the status and the actions after the download operation.
7. Click "Finish".

Result

The blocks are downloaded to the memory card. If the changes affect additional blocks, these will also be downloaded to the memory card. Blocks that exist only on the memory card are deleted. Inconsistencies between the blocks in the user program are avoided by downloading all affected blocks and the deleting of the non-required blocks on the memory card.

The messages under "Info > General" in the Inspector window show whether the downloading process was successful.

See also

Uploading blocks from a memory card (Page 1801)

Accessing memory cards (Page 468)

Uploading blocks from a memory card

You can only upload all blocks from one memory card back into your project.

Requirement

The memory card is displayed.

See also: Accessing memory cards (Page 468)

Procedure

To upload blocks from a memory card to your project, follow these steps:

1. In the project tree, drag the folder of the memory card to the folder of the device in the project. You can also copy the memory card and insert it in the device.
   The "Upload preview" dialog box opens. This dialog displays alarms and proposes actions necessary for loading.
2. Check the alarms and, where necessary, enable the actions in the "Action" column.
   The "Upload from device" button will be enabled as soon as uploading becomes possible.
3. Click on the "Upload from device" button.

Downloading blocks to a memory card (Page 1799)

Switching off the sequencer prior to loading a GRAPH DB

You can specify the switching off of the sequencer prior to loading an instance data block either globally or during the load operation.

Globally switching off the sequencer

To switch off the sequencer globally for each loading operation of an instance data block, follow these steps:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. Select the "PLC programming > GRAPH" group in the area navigation.
3. Select the "Turn off sequence before downloading DB" check box.
   For future loading operations, the sequencer is switched off prior to loading of the instance data block.

Switching off the sequencer during the loading operation

To switch off the sequencer during the loading operation, follow these steps:

1. Load the GRAPH function block to the device.
   During the loading operation, the "Load preview" dialog opens. This dialog displays alarms and suggests the required actions for loading. If the instance data block must be loaded together with the GRAPH function block, the "Load preview" dialog suggests the action "Turn off sequence before downloading the DB".
2. Select the "Turn off sequence before downloading DB" check box.

11.1.7 Protecting blocks

11.1.7.1 Protecting blocks

Introduction

You can use a password to protect one or more blocks of the OB, FB, FC type and global data blocks from unauthorized access. Note the following particularities:

- You can not manually protect instance data blocks; they depend on the know-how protection of the assigned FB. This means that when you create an instance data block for a know-how protected FB, the instance data block also receives this know-how protection. This is independent of whether you explicitly create the instance data block or if it is created by a block call.
- The know-how protection acts as write protection in global blocks and in instance data blocks.
- You cannot provide ARRAY data blocks with know-how protection.

If a block is know-how protected, only the following data is readable without the correct password:

- Interface parameters Input, Output, InOut, Return, Static
- Block title
- Block comment

- Block properties
- Tags of global data blocks without specification of the location of use

The following actions can be performed with a know-how protected block:

- Copying and deleting
- Calling in a program
- Online/offline comparison
- Downloading

The code of the block, on the other hand, is protected from unauthorized reading and modification. For S7-1200/1500 CPUs, you can also set up copy protection which binds execution of the block to the CPU or the memory card with the defined serial number.

Note

Please note the following:

- S7-1200 version 1.0 and S7-300/400 (only GRAPH and SCL blocks): If you download a know-how-protected block to a device, no restore information is loaded along with it. This means that you cannot open a know-how-protected block again even with the correct password if you upload it from the device.
- Only the non-protected data is compared in offline-online comparison of know-how protected blocks.
- You will no longer be able to access the block if you do not have the password.
- If you add a know-how-protected block to a library, the master copy created will also be know-how protected.
- For S7-1500, you can select the "Block can be used as know-how protected library item" check box in the block properties to obtain the information on whether or not the block can be used as protected library item. For this purpose, the block cannot use any tags from the operand areas Output (Q), Input (I), Bit memory (M), Timer function (T) or Count function (C), and cannot access data blocks.
- Cross references to used tags, bit memories, inputs and outputs in know-how protected blocks are not displayed even after the correct password is entered..
- If you change the number of a block, the loadable binary component of the block is out of date. This means that the block must be recompiled before loading it to a device. For know-how-protected blocks, this is only possible with the correct password. Keep this in mind particularly if you want to copy a know-how-protected block to another device in which there is already a block with the same number.
- Always pass on a project that includes know-how-protected blocks as a project archive or library archive. In this way, you ensure that the know-how protection cannot be bypassed.
- If you wish to assign know-how protection to several blocks using multiple selection, no instance data block can be included in the selection. Otherwise, it will not be possible to set know-how protection.
- You cannot change the know-how protection settings for an open, know-how protected block.

11.1.7.2 Setting up and removing block copy protection

For S7-1200 /1500 CPUs, you can set up copy protection which binds execution of the block to a specific CPU or a specific memory card. The block can then only be executed if it is in the device with the set serial number.

It is important that you also know-how-protect any block for which you have set up copy protection. If you do not, anyone can reset the copy protection.

Note

S7-1500 and S7-1200 V2.2 and higher: If you download a copy protected block to a device that does not match the specified serial number, the entire download operation will be rejected. This means that blocks without copy protection, too, will not be downloaded.

Setting up copy protection

To set up copy protection for a block, follow these steps:

1. Open the block you wish to copy-protect.
2. Open the "Properties" tab in the inspector window.
3. Select "Protection" in the area navigation in the inspector window.
4. Select either "Bind to serial number of the CPU" or "Bind to serial number of the memory card" from the drop-down list in the "Copy protection" area.
5. Enter the serial number of the CPU or the memory card for a S7-1500 CPU. You can either enter the serial number directly for a S7-1200 CPU or enable the option "Serial number inserted when downloading to a device or memory card" if the serial number is to be inserted automatically during loading.
6. You can now set up the know-how protection for the block in the "Know-how protection" area, if the block does not already have know-how protection.

Removing copy protection

To remove copy protection, follow these steps:

1. Open the block for which you wish to remove copy protection.
2. Open the "Properties" tab in the inspector window.
3. Select "Protection" in the area navigation in the inspector window.
4. Select "No binding" in the drop-down list in the "Copy protection" area.

Changing a password (Page 1808)

11.1.7.3 Setting up block know-how protection

You can set up know-how protection for blocks in the devices in your project.

Procedure

To set up block know-how protection, follow these steps:

1. Select the blocks with no know-how protection which you want to protect.
2. Select the command "Know-how protection" in the "Edit" menu.
   The "Know-how protection" dialog will open.
3. Click "Define".
   The "Define password" dialog box opens.
4. Enter a password in the "New" field.
5. Enter the same password in the "Confirm" field.
6. Confirm your entries with "OK".
7. Close the "Know-how protection" dialog by clicking on "OK".

Result

The blocks selected will be know-how-protected. Know-how protected blocks are marked with a lock in the project tree. The password entered is valid for all blocks selected.

Changing a password (Page 1808)

11.1.7.4 Opening know-how protected blocks

You can only open multiple know-how protected blocks at once if they are protected with the same password.

Procedure

To open a know-how protected block, follow these steps:

1. Double-click on the block you wish to open.
   The "Access protection" dialog will open.
2. Enter the password for the know-how protected block.
3. Confirm your entry with "OK".

Result

The know-how protected block will open provided you have entered the correct password. However, the block will remain know-how protected. If you copy the block or add it to a library, for example, the copies will also be know-how protected.

Once you have opened the block, you can edit the program code and the block interface of the block for as long as the block or TIA Portal is open. The password must be entered again the next time the block is opened. If you close the "Access protection" dialog with "Cancel", the block will open but the block code will not be displayed and you will not be able to edit the block.

Changing a password (Page 1808)

11.1.7.5 Printing know-how protected blocks

You can only print complete know-how protected blocks if they have been opened with the correct password. If you print a closed block or if the block was not opened with the correct password, only the non-protected block data will be printed.

Procedure

To print a know-how protected block in full, follow these steps:

1. Open the know-how protected block you wish to print.
   See also: Opening know-how protected blocks (Page 1806)
2. Select the "Print" command in the "Project" menu.
   The "Print" dialog will open.
3. Select the printer in the "Name" field.
4. Click "Advanced" to modify the Windows printer settings.
5. Select the documentation information set in the "Document information" drop-down list that you want to use for the frame layout.
6. Under "Print objects/area" select whether you want to print all objects or the complete area, or only a selection.
7. Under "Properties" select the print scope.
   - Select "All" to print the complete block.
   - Choose "Visible" to print all the information within the block that is visible on the screen.
   - Select "Compact" to print a shortened form of the block.
8. Click "Preview" to generate a print preview in advance.
   A print preview is created in the work area.
9. Click "Print" to start the printout.

Changing a password (Page 1808)

11.1.7.6 Changing a password

Procedure

To change the password, follow these steps:

1. Select the know-how protected blocks for which you want to change the password.

   Note

   You can only change the password for several blocks at once if all blocks selected have the same password.

2. Select the command "Know-how protection" in the "Edit" menu.
   The "Know-how protection" dialog will open.
3. Click the "Change" button.
4. Enter the old password in the "Old" field.
5. Enter the new password in the "New" field.
6. Enter the new password again in the "Confirm" field.
7. Confirm your entries with "OK".
8. Close the "Know-how protection" dialog by clicking on "OK".

Removing block know-how protection (Page 1808)

11.1.7.7 Removing block know-how protection

Procedure

To remove block know-how protection, follow these steps:

1. Select the blocks for which you want to remove know-how protection.

   Note

   You can only remove know-how protection for several blocks at once if all blocks selected have the same password.

2. Select the command "Know-how protection" in the "Edit" menu.
   The "Know-how protection" dialog will open.

3. Deactivate the check box "Hide code (know-how protection)".
4. Enter the password.
5. Confirm your entries with "OK".

Result

Know-how protection will be disabled for the blocks selected.

11.2 Displaying program information

11.2.1 Overview of available program information

Program information

The program information of a user program contains the view specified in the following table.

View	Application
Assignment list (Page 1810)	Provides an overview of the address bits for the I, Q, and M memory areas already allocated within the user program. Also indicates if an address has been allocated by access from an S7 program or if the address has been assigned to a SIMATIC S7 module.
Call structure (Page 1818)	Shows the call structure of the blocks within the user program and provides an overview of the blocks used and their relationships.

View	Application
Dependency structure (Page 1824)	Shows the list of blocks used in the user program. A block is shown at the first level and blocks that call or use this block are indented below it. In contrast to the call structure, instance blocks are listed separately.
Resources (Page 1830)	Shows the hardware resources of the CPU for objects (OB, FC, FB, DB, user-defined data types and PLC tags), for CPU memory areas and for the existing I/O modules.

Displaying several views simultaneously

You can generate and display several views for one or more user programs to facilitate testing and changing your user program.

Displaying multiple views, for example, enables you to:

- Display all program information for a user program next to one another
- Compare different user programs

11.2.2 Displaying an assignment list

11.2.2.1 Introduction to the assignment list

Program information in the assignment list

The assignment list shows if an address has been allocated by access from an S7 program or if the address has been assigned to a SIMATIC S7 module. It is therefore an important basis for locating errors or changes in the user program.

In the assignment list, you have a CPU-specific overview of which bit is used in which byte of the memory areas listed below:

- Input (I)
- Output (O)
- Bit memory (M)
- Timer (T)
- Counter (C)
- I/O (P)

Display of the assignment list

The assignment list of inputs, outputs, and bit memory is displayed in several separate work windows.

Filters

You can filter the display within the assignment list. You can use predefined filters or create your own.

Displaying cross-reference information

You have the option of displaying cross-reference information for selected addresses in the assignment list.

You can display the cross-references for a selected address in the Inspector window using the "Cross-reference information" shortcut menu command. The command "Tools > Cross-references" allows you to also open the cross-reference list for the selected object.

Displaying the PLC tag table

You can open the PLC tag table from the assignment list and edit the properties of the tags used.

To do this select an address of the assignment list and select the "Open editor" command in the shortcut menu.

Enabling the display of retentivity

You can enable and disable the display of the retentive state of bit memory by selecting the "Hide/show retain area" toolbar button.

See also

Symbols in the assignment list (Page 1812)

Layout of the assignment list (Page 1811)

11.2.2.2 Layout of the assignment list

Layout of the assignment list

Depending on the CPU, the assignment list is displayed in several work windows with the following operands.

For S7-300/400 CPUs:

- Inputs
- Outputs
- Bit memory
- Timers
- Counters

For S7-1200 CPUs:

- Inputs
- Outputs
- Bit memory

Displaying inputs, outputs, bit memory, timers and counters

It shows all operands used and their assignment in the S7 program.

For all displayed operands, each line in the assignment list is dedicated to a byte of the memory area, in which the corresponding eight bits from 7 to 0 are labeled according to their access. In conclusion, a "bar" indicates if access is made by a byte (B), word (W) or double word (D).

You can find an explanation of the symbols in the assignment list here. (Page 1812)

See also

Introduction to the assignment list (Page 1810)

11.2.2.3 Symbols in the assignment list

Meaning of the symbols in the assignment list

The following table shows the meaning of the symbols in the assignment list:

Symbol	Meaning
	Indicates the address assignment in the selected state.
	Indicates the address assignment in the non-selected state.
	Indicates that a pointer start address and a tag address access the same address range and that they are selected.
	Indicates that a pointer start address and a tag address access the same address range and that they are not selected.
	Indicates the pointer assignment in the selected state.
	Indicates the pointer assignment in the non-selected state.
	Indicates that the byte is in use with byte access and the corresponding tag is selected. The shortcut menu allows you to display cross-reference information for the selected variables as well as the PLC tag table.
	Indicates that the byte is in use with byte access and the corresponding tag is not selected.
	Indicates that the byte is in use with word access and the corresponding tag is selected. The shortcut menu allows you to display cross-reference information for the selected variables as well as the PLC tag table.

Symbol	Meaning
	Indicates that the byte is in use with word access and the corresponding tag is not selected.
	Indicates that the byte is in use with double word access and the corresponding tag is selected. The shortcut menu allows you to display cross-reference information for the selected variables as well as the PLC tag table.
	Indicates that the byte is in use with double word access and the corresponding tag is not selected.
Background color: gray	Indicates that a byte is in use with byte, word or double word access and that the address is also in use by the hardware. The gray background color indicates overlapping memory access.
Background color: yellow	Indicates that the address is not in use by the hardware.
	Indicates that the memory area has been defined as system memory.
	Indicates that the memory area has been defined as clock memory.

Introduction to the assignment list (Page 1810)

11.2.2.4 Displaying an assignment list

Requirement

A project has been created with programmed blocks.

Procedure

Proceed as follows to display the assignment list:

1. Select the "Program blocks" folder or one or more of the blocks it contains.
2. Select the "Assignment list" command in the "Tools" menu.

Result

The assignment list for the selected program is displayed.

View options in the assignment list

Refer to view respective view options that are set to display the desired information in the assignment list.

See also

Setting the view options for the assignment list (Page 1814)

Layout of the assignment list (Page 1811)

11.2.2.5 Setting the view options for the assignment list

Introduction

The following view options are available for the assignment list:

- Used addresses:
  When this check box is activated, the addresses, I/Os and pointers used in the program are displayed.
- Free hardware addresses:
  When this check box is activated, only the free hardware addresses are displayed.

Requirement

- A project has been created with programmed blocks.
- The assignment list is open.

Procedure

Proceed as follows to set the view options for the assignment list:

1. Click on the arrow of the  symbol ("View options") in the task bar.
   The view options for the assignment list are opened. Check marks are set in front of the activated view options.
2. If you want to activate or deactivate a view option, click on the respective check box and set or remove the check mark.

Result

The view options are set and the desired information is displayed in the assignment list.

11.2.2.6 Filter options in the assignment list

Filter settings

You can define your own filter settings for the assignment list. The following options are available for defining filters:

- Display all addresses of the address areas specified.
- Display of single, defined addresses from the selected address area, for example, "0" and "200".
- Display of complete areas from the selected address area, for example, "0 - 256".

The following table provides an overview of all available options:

Selection in the	Selection	Symbol	Meaning
Address area	All CPU-dependent displayed addresses (I, O, M, T, C) can be activated as they are by default, or individual address areas can be activated.	Check box is activated	Only the activated address areas (I, O, M, T, C) are shown in the assignment list.
Filter area	Show assignment for all addresses	*	Displays the assignment of all addresses of the enabled address areas (I, Q, M).
	Show assignment for selected addresses, for example, for the inputs "IB 0" and "IB 256"	0;256 Separate individual addresses and areas by a semicolon.	Assignments of selected addresses for the activated address areas (I) are shown.
	Show assignment for selected areas, for example, for the inputs "IB 0 to IB 100" and "IB 200 to IB 256".	0-100;200-256 Contiguous areas should be connected by a hyphen.	Assignments of selected areas for the activated address areas (I) are shown.

11.2.2.7 Defining filters for assignment list

Requirement

- A project has been created with programmed blocks.
- The assignment list is open.

Defining filter

Proceed as follows to define a filter for the assignment list:

1. Click on the symbol ("Filter") in the task bar.
   The "Assignment List Filter" dialog opens.
2. Click on the symbol ("Create new filter") in the task bar.
   A new filter is created with the name "Filter_1". The check boxes for all addresses (inputs, outputs, memory bits, timers and counters) are activated by default for the filter.

3. If you want to change the name of the filter, click on the drop-down list in the task bar and enter a new filter name.
4. Deactivate the check boxes of addresses that are not to be affected by the filter.
5. Enter one of the following options in the filter area of the activated address:
   - Show all addresses used = "*"
   - Show single, defined addresses, for example, IB 0" and IB 25 = "0.25". Individual addresses and address areas are separated by commas or semicolons.
   - Show complete address areas, for example, IB 0 to IB 256 = "0-256". Complete address areas should be connected by a hyphen.
6. Confirm your entries with "OK".
   The newly defined filter is shown in the task bar of the assignment list under the specified name.

Delete filter

Proceed as follows to delete a filter:

1. Click on the symbol ("Filter") in the task bar.
   The filter dialog for the assignment list opens.
2. In the drop-down list of the task bar, select the filter you want to delete.
3. Click on the symbol ("Delete selected filter") in the task bar.
   The selected filter is deleted.

See also

Filter options in the assignment list (Page 1815)

Displaying an assignment list (Page 1813)

Introduction to the assignment list (Page 1810)

11.2.2.8 Filtering an assignment list

Requirement

- A project has been created with programmed blocks.
- The assignment list is open.

Procedure

1. Click on the arrow on the drop-down list.
   The available filter are displayed.
2. Select the desired filter.

Result

The assignment list is filtered according to the settings of the selected filter.

Note

The filter settings are saved when the project is closed.

11.2.2.9 Defining retentive memory areas for bit memories

Introduction

In the assignment list you can define the width of the retentive memory area for bit memories. The content of tags which are addressed in retentive memory is retained after power off and at the STOP to RUN transition after power on.

The display of retentive bit memories can be enabled and disabled in the assignment list. If their display is enabled, retentive bit memories are identified by an icon in the "Address" column.

Requirement

The assignment list is open.

Procedure

Proceed as follows to define the width of the retentive memory area for bit memories:

1. Click "Retain" in the toolbar.
   The "Retain memory" dialog will open.
2. Starting at the count of 0, define the width of the retentive memory area by entering the last byte of this area in the input field. Watch out for any addresses of tags already assigned to the retentive area.
3. Load the block to the target system. Select the "Program blocks" folder in the Project tree and select the "Download to device" submenu in the shortcut menu.

Result

The width of the retentive memory area is defined. If enabled in the assignment list, an icon will indicate the retentive state of all tags in the "Address" column.

11.2.2.10 Enabling the display of retentive bit memories

Introduction

In the assignment list you can enable and disable the display of retentive bit memories. The retentive bit memories are identified by means of an icon in the "Address" column if the display of retentivity is enabled.

Requirement

The assignment list is open.

Procedure

Proceed as follows to enable and disable the display of retentive bit memories:

1. Click "Display/hide retentivity" in the toolbar.

Result

The retentive tags are identified by means of an icon in the "Address" column of the bit memory area if the display of retentivity is enabled. The icons in the "Address" column are hidden if the display of retentivity is disabled.

11.2.3 Displaying the call structure

11.2.3.1 Introduction to the call structure

Call structure

The call structure describes the call hierarchy of the block within an S7 program.

It provides an overview of:

- The blocks used
- Jumps to the places of use of the blocks
- Relationships between blocks
- Local data requirements of the blocks
- Status of the blocks

Information in the call structure

Displaying the call stucture provides you with a list of the blocks used in the user program. The first level of the call structure is highlighted in color and shows the blocks that are not called by any other block in the program. Organization blocks are always shown on the first level of the call structure. Functions, function blocks and data blocks are only shown on the first level if they are not called by an organization block. When a block calls other blocks or functions, they are listed indented under the calling block. Instructions and blocks are shown in the call structure only if they are called by a block.

View options

The following view options are available for the call structure:

- Show conflicts only:
  When this check box is activated, only the conflicts within the call structure are displayed.
- Group multiple calls together:
  When this check box is activated, several block calls are grouped together. The number of block calls is displayed in the "Call frequency" column. The links to the various call locations are offered in a drop-down list in the "Details" column.

Displaying the block calls

You can display the block calls in a block by clicking on the arrow in front of the block title. To display the call information of all blocks, click on the "Expand list" icon in the toolbar.

You can hide the total overview by clicking the "Collapse list" icon.

Displaying cross-reference information

You can display the cross-reference information for a block in the Inspector window by right-clicking on the relevant block and selecting the "Cross-reference information" command from the shortcut menu.

To open the "Cross-references" view, click the "Cross-references" command in the shortcut menu.

Displaying blocks in the program editor

You can open the program editor and edit blocks there from the call structure.

To do this select the required block in the call structure and select the "Open editor" command in the shortcut menu.

Displaying deleted blocks

The rows belonging to deleted blocks are identified by an icon.

Note

Please note that any existing local data can only be displayed or updated after compiling a block.

See also

Symbols in the call structure (Page 1820)

11.2.3.2 Symbols in the call structure

Meaning of the symbols in the call structure

The following table shows the meaning of the symbols in the call structure:

Symbol	Meaning
	Indicates an organization block (OB).
	Indicates a function block (FB).
	Indicates a function (FC).
	Indicates a data block (DB).
	Indicates that the block is declared as a multiinstance.
	The object has an interface dependency to an object connected to the left.
	Indicates that the block needs to be compiled again.
	Indicates that the data block needs to be compiled again.
	Indicates that the object is not available.
	Indicates that the interface causes a time stamp conflict.
	Indicates that the variable causes a time stamp conflict.
	Indicates that the block is not called directly or indirectly from an OB.
	Indicates that an object has know-how protection.

Symbol	Meaning
	Indicates that the block is normally called recursively.
	Indicates that a tag declaration in the interface has a recursive dependency: • Scenario 1: FB1 calls FB2 and this then calls FB1. The instance data blocks of these FBs have a recursion in the interface. • Scenario 2: A multiple instance FB uses the instance DB of its parent FB as a global DB.

11.2.3.3 Layout of the call structure

Layout of the call structure

The view of the call structure consists of the following columns:

Column	Content/meaning
Call structure	Shows an overview of the blocks called If the viewing option "Group multiple calls together" is enabled, several block calls are grouped together and the "Number of calls" column is displayed.
Call type (!)	Shows the type of call, for example recursive block call.
Address	Shows the absolute address of the block. With a function block, the absolute address of the corresponding instance data block is also shown.
Call frequency	Indicates the number of multiple calls of blocks.
Details	Shows the network or interface of the calling block. All information are offered as a link in this column. With this link, you can jump to the location of the block call in the program editor. If the viewing option "Group multiple calls together" option is enabled, the calls are grouped together and are available as links in a drop-down list.
Local data (in path)	Indicates the local data requirement of the full path. Blocks with optimized access have higher local data requirements because the information for the symbolic addressing is stored with them. Please note that any existing local data can only be displayed or updated after compiling a block.
Local data (for blocks)	Show the local data requirements of the block. Blocks with optimized access have higher local data requirements because the information for the symbolic addressing is stored with them. Please note that any existing local data can only be displayed or updated after compiling a block.

See also

Symbols in the call structure (Page 1820)

Introducing the consistency check in the call structure (Page 1823)

11.2.3.4 Displaying the call structure

Requirement

A project has been created with blocks.

Procedure

Proceed as follows to display the call structure:

1. Select the "Program blocks" folder or one or more of the blocks it contains.
2. Select the "Call structure" command in the "Tools" menu.

Result

The call structure for the selected program is displayed.

Note

Please note that any existing local data can only be displayed or updated after compiling a block.

See also

Setting the view options for the call structure (Page 1822)

11.2.3.5 Setting the view options for the call structure

Introduction

The following view options are available for the call structure:

- Show conflicts only:
  Only the blocks causing conflicts within the call structure are displayed if this check box is activated.
  The following blocks cause conflicts:
  - Blocks executing any calls with older or newer code time stamps.
  - Blocks calling a block with modified interface.
  - Blocks using a tag with modified address and/or data type.
  - Block called neither directly, nor indirectly by an OB.
  - Blocks calling a block which no longer exists.
- Group multiple calls together:
  When this viewing option is enabled, several block calls and data block accesses are grouped together. The number of block calls is displayed in the "Call frequency" column. The links to the various call locations are offered in a drop-down list in the "Details" column.

Requirement

- A project has been created with programmed blocks.
- The call structure is open.

Procedure

Proceed as follows to set the view options for the call structure:

1. Click on the arrow of the  symbol ("View options") in the task bar.
   The view options for the call structure opens. Check marks are set in front of the activated view options.
2. If you want to activate or deactivate a view option, click on the respective check box and set or remove the check mark.

Result

The view options are set and the required information is displayed in the call structure.

11.2.3.6 Introducing the consistency check in the call structure

Consistency check

Changing the time stamp of a block during or after the program is generated can lead to time stamp conflicts, which in turn cause inconsistencies among the blocks that are calling and being called.

Using the consistency check

The "Consistency check" function is used to visualize inconsistencies when time stamp conflicts occur. Whe the consistency check is performed, the inconsistent blocks are shown in the call structure and marked with the correspoinding symbols.

- Most time stamp and interface conflicts can be rectified by recompiling the blocks.
- If compilation fails to clear up inconsistencies you can use the link in the "Details" column to go to the source of the problem in the program editor and manually eliminate any inconsistencies.
- The blocks marked in red must be recompiled.

See also

Symbols in the call structure (Page 1820)

11.2.3.7 Checking block consistency in the call structure

Requirement

- A project has been created with programmed blocks.
- The call structure is open.

Procedure

Proceed as follows to check the block consistency:

1. Click on the  symbol ("Consistency check") in the task bar.
   The block consistency is checked. Blocks found to be inconsistent are marked accordingly by a symbol.
2. If a block is inconsistent, click on the arrow in front of the block title in the call structure.
   The inconsistent blocks are displayed. The exact problem locations are listed as links in the "Details" column.
3. Click on the respective link in the "Details" column to jump to the location in the block requiring correction.
4. Check and correct the inconsistencies in the blocks.
5. Recompile the blocks by selecting the required blocks and clicking on the command "Compile" in the shortcut menu.
6. Download the corrected blocks to the target system by clicking the command "Download to device" in the shortcut menu.

Result

The block consistency is checked. The inconsistencies in the blocks are corrected. The corrected blocks are loaded to the target system.

See also

Symbols in the call structure (Page 1820)

11.2.4 Displaying the dependency structure

11.2.4.1 Introduction to the dependency structure

Introduction

The dependency structure shows the dependencies each block has to other blocks in the program.

Information in the dependency structure

Displaying the dependency structure provides you with a list of the blocks used in the user program. A block is shown at the far left and blocks that call or use this block are indented below it.

The dependency structure also shows the status of the individual blocks using symbols.

Objects causing a time stamp conflict and perhaps leading to an inconsistency in the program are marked with various symbols.

The dependency structure is an extension of the cross-reference list for objects.

View options

The following view options are available for the dependency structure:

- Show conflicts only:
  When this check box is activated, only the conflicts within the dependency structure are displayed.
- Group multiple calls together:
  When this check box is activated, several block calls are grouped together. The number of block calls is shown numerically in the "Dependency structure" column. The links to the various call locations are offered in a drop-down list in the "Details" column.

Displaying the dependency structure

Clicking on the arrow in front of the block title displays the blocks that call or use this block. To display the dependencies of all blocks,

click the "Expand list" icon in the toolbar.

You can hide the total overview by clicking the "Collapse list" icon.

Displaying cross-reference information

You can display the cross-reference information for a block in the Inspector window by right-clicking on the respective block and selecting the "Display Usage" command from the shortcut menu.

Displaying blocks in the program editor

You can open the program editor and edit blocks there from the dependency structure. To do this select the required block in the dependency structure and select the "Open editor" command in the shortcut menu.

11.2.4.2 Layout of the dependency structure

Layout of the dependency structure

The view of the dependency structure consists of the following columns:

Column	Content/meaning
Dependency	It indicates the dependencies between each block and the other blocks in the program.
Call type (!)	Shows the type of call, for example recursive block call.
Address	Shows the absolute address of the block.
Call frequency	Indicates the number of multiple calls of blocks.
Details	Shows the network or interface of the called block. All information are offered as a link in this column. With this link, you can jump to the location of the block call in the program editor. If the viewing option "Group multiple calls together" option is enabled, the calls are grouped together and are available as links in a drop-down list.

Symbols in the dependency structure (Page 1826)

11.2.4.3 Symbols in the dependency structure

Meaning of the symbols in the dependency structure

The following table shows the meaning of the symbols in the dependency structure:

Symbol	Meaning
	Indicates an organization block (OB).
	Indicates a function block (FB).
	Indicates a function (FC).
	Indicates a data block (DB).
	The object has an interface dependency to an object connected to the left.
	Indicates that the block needs to be compiled again.
	Indicates that the data block needs to be compiled again.
	Indicates that there is an inconsistency with this object.

Symbol	Meaning
	Indicates that an object has know-how protection.
	Indicates that a tag declaration in the interface has a recursive dependency: • Scenario 1: FB1 calls FB2 and this then calls FB1. The instance data blocks of these FBs have a recursion in the interface. • Scenario 2: A multiple instance FB uses the instance DB of its parent FB as a global DB.

11.2.4.4 Displaying the dependency structure

Requirement

A project has been created with programmed blocks.

Procedure

Proceed as follows to display the dependency structure:

1. Select the block folder or one or more of the blocks contained therein.
2. Select the "Dependency structure" command in the "Tools" menu.

Result

The dependency structure for the selected program is displayed.

See also

Setting the view options for the dependency structure (Page 1828)

11.2.4.5 Setting the view options for the dependency structure

Introduction

The following view options are available for the dependency structure:

- Show conflicts only:
  When this check box is activated, only the conflicts within the dependency structure are displayed.
  The following blocks cause conflicts:
  - Blocks executing any calls with older or newer code time stamps.
  - Blocks called by a block with modified interface.
  - Blocks using a tag with modified address and/or data type.
  - Block called neither directly, nor indirectly by an OB.
- Group multiple calls together:
  When this check box is activated, several block calls are grouped together. The number of block calls is shown in the relevant column. The links to the various call locations are offered in a drop-down list in the "Details" column.

Requirement

- A project has been created with programmed blocks.
- The dependency structure is open.

Procedure

Proceed as follows to set the view options for the dependency structure:

1. Click on the arrow of the  symbol ("View options") in the task bar.
   The view options for the dependency structure are opened. Check marks are set in front of the activated view options.
2. If you want to activate or deactivate a view option, click on the respective check box and set or remove the check mark.

Result

The view options are set and the required information is displayed in the dependency structure.

11.2.4.6 Introducing the consistency check in the dependency structure

Consistency check

Changing the time stamp of a block during or after the program is generated can lead to time stamp conflicts, which in turn cause inconsistencies among the blocks that are calling and being called.

Using the consistency check

The "Consistency check" function is used to visualize inconsistencies. Whe the consistency check is performed, the inconsistent blocks are shown in the dependency structure and marked with the correspoinding symbols.

- Most time stamp and interface conflicts can be rectified by recompiling the blocks.
- If compilation fails to clear up inconsistencies you can use the link in the "Details" column to go to the source of the problem in the program editor and manually eliminate any inconsistencies.
- The blocks marked in red must be recompiled.

Layout of the dependency structure (Page 1826)

Symbols in the dependency structure (Page 1826)

11.2.4.7 Checking block consistency in the dependency structure

Requirement

- A project has been created with programmed blocks.
- The dependency structure is open.

Procedure

Proceed as follows to check the block consistency:

1. Click on the  symbol ("Consistency check") in the task bar.
   The block consistency is checked. Blocks found to be inconsistent are marked accordingly by a symbol.
2. If a block is inconsistent, click on the arrow in front of the block title in the dependency structure.
   The inconsistent blocks are displayed. The exact problem locations are listed as links in the "Details" column.
3. Check and correct the inconsistencies in the blocks.
4. Recompile the blocks by selecting the required blocks and clicking on the command "Compile" in the shortcut menu.
5. Download the corrected blocks to the target system by clicking the command "Download to device" in the shortcut menu.

Result

The block consistency is checked. The inconsistencies in the blocks are corrected. The corrected blocks are loaded to the target system.

Symbols in the dependency structure (Page 1826)

11.2.5 Displaying CPU resources

11.2.5.1 Introducing resources

Introduction

The "Resources" tab indicates the hardware resources of the configured CPU for:

- the used programming objects,
- the assignment of the different memory areas within the CPU and
- the assigned inputs and outputs of the existing input and output modules.

Information provided in the "Resources" tab

The resources tab provides an overview of the hardware resources. The display in this tab depends on the CPU which you are using. The following information is displayed:

- the programming objects used in the CPU (e.g. OB, FC, FB, DB, data types and PLC tags)
- the memory areas available on the CPU (load memory, work memory - divided into code work memory and data work memory depending on the CPU -, retentive memory), their maximum size and utilization by the programming objects stated above
- the I/O of modules which can be configured for the CPU (I/O modules, digital input modules, digital output modules, analog input modules, and analog output modules), including the I/O already in use.

Display of the maximum available load memory

The maximum size of available load memory can be selected from a drop-down list box in the "Total" row of the "Load memory" column.

Display of the maximum available work memory

The maximum size of available work memory is displayed in the "Work memory" column or in the "Code work memory" and "Data work memory" columns in the "Total" row.

Display of the maximum available retentive memory

The maximum size of available retentive memory can be selected from a drop-down list box in the "Total" row of the "Retentive memory" column.

Note

Retentive memory data

All bit memories and data blocks specified as retentive will be integrated in the calculation of the retentive data.

Updating the display in the "Resources" tab

Click the "Update view" toolbar button to update the display of objects.

Benefits of the display in the "Resources" tab

The "Resources" tab of the program information dialog provides a detailed list of all objects and of the corresponding memory area used.

The tab also indicates shortage of resources and helps to avoid such states.

Blocks which are not compiled can be identified as their size is indicated by a question mark.

See also

Layout of the "Resources" tab (Page 1832)

Displaying resources (Page 1833)

Selecting the maximum load memory available (Page 1834)

11.2.5.2 Layout of the "Resources" tab

Layout of the "Resources" tab in the program information

The view of the "Resources" tab consists of the following columns:

Column	Content/meaning
Objects	The "Details" area provides an overview of the programming objects available in the CPU, including their memory assignments.
Load memory	Displays the maximum load memory resources of the CPU as a percentage and as absolute value. The values displayed under "Total" provide information on the maximum memory available in the load memory. The values displayed under "Used" provide information on the memory actually used in the load memory. If a value is displayed in red, the available memory capacity has been exceeded.
Work memory or code and data work memory	Displays the maximum work memory resources of the CPU as a percentage and as absolute value. The work memory depends on the CPU and is divided into "Code work memory" and "Data work memory" for a CPU from the S7-400 or S7-1500 series, for example. The values displayed under "Total" provide information on the maximum memory available in the work memory. The values displayed under "Used" provide information on the memory space actually used in the work memory. If a value is displayed in red, the available memory capacity has been exceeded.
Retentive memory	Displays the maximum resources for retentive memory in the CPU as a percentage and as absolute value. The values displayed under "Total" provide information on the maximum memory available in the retentive memory. The values displayed under "Used" provide information on the memory actually used in the retentive memory. If a value is displayed in red, the available memory capacity has been exceeded.

Column	Content/meaning
I/O	Displays the I/Os which are available on the CPU, including their module-specific availability in the next columns. The values displayed at "Configured" provide information about the maximum number of I/O available. The values displayed under "Used" provide information on the actually used inputs and outputs.
DI / DQ / AI / AQ	Displays the number of configured and used inputs/outputs: DI = Digital inputs DQ = Digital outputs AI = Analog inputs AQ = Analog outputs The values displayed at "Configured" provide information about the maximum number of I/O available. The values displayed under "Used" provide information on the actually used inputs and outputs.

See also

Displaying resources (Page 1833)

Selecting the maximum load memory available (Page 1834)

Introducing resources (Page 1830)

11.2.5.3 Displaying resources

Requirement

A project with programmed blocks has been created.

Procedure

Proceed as follows to display the resources of the respective CPU memory areas:

1. Select the block folder below the relevant CPU, or one or several of the blocks contained therein.
2. Select the "Resources" command in the "Tools" menu.

Result

The memory resources of the assigned CPU are displayed.

11.2.5.4 Selecting the maximum load memory available

Requirement

A project with programmed blocks has been created.

Procedure

Proceed as follows to display the available maximum of load memory resources:

1. Select the block folder below the relevant CPU, or one or several of the blocks contained therein.
2. Select the "Resources" command in the "Tools" menu.
3. In the dialog that is displayed, open the drop-down list in the "Total" field of the "Load memory" column by clicking the icon.
4. Select a corresponding value for the CPU used by clicking it in the drop-down list box.

Result

The "Total" field displays the selected maximum memory resources.

Note

Display of maximum memory resources

If a value is displayed in red for the maximum memory resources, the available memory capacity has been exceeded.

In this case, adapt the memory capacity as described above.

11.3 Displaying cross-references

11.3.1 General information about cross references

Introduction

The cross-reference list provides an overview of the use of operands and tags within the user program.

Uses of cross-references

The cross-reference list offers you the following advantages:

- When creating and changing a program, you retain an overview of the operands, tags and block calls you have used.
- From the cross-references, you can jump directly to the point of use of operands and tags.
- During a program test or when troubleshooting, you are informed of the following:
  - Which operand is processed by which command in which block.
  - Which tag is used in which picture.
  - Which block is called by which other block.
  - Cross-reference information for subordinate and higher-level structures.
- As part of the project documentation, the cross-references provide a comprehensive overview of all operands, memory areas, blocks, tags and pictures used.

See also

Structure of the cross-reference list (Page 1835)

Displaying the cross-reference list (Page 1836)

Displaying cross-references in the Inspector window (Page 1838)

11.3.2 Structure of the cross-reference list

Views of the cross-reference list

There are two views of the cross-reference list. The difference between the two views is in the objects displayed in the first column:

- Used by:
  Display of the referenced objects. Here, you can see where the object is used.
- Used:
  Display of the referencing objects. Here, you can see the users of the object.

The assigned tool tips provide additional information about each object.

Structure of the cross-reference list

The cross-reference list has the following structure:

Column	Content/meaning
Object	Name of the object that uses the lower-level objects or that is being used by the lower-level objects.
Number	Number of uses
Point of use	Each point of use, for example, network

Column	Content/meaning
Property	Special properties of referenced objects, for example, the tag names in multi-instance declarations.
as	Shows additional information about the object, e.g., that an instance DB is used as template or as multiple instance.
Access	Type of access, whether access to the operand is read access (R) and/or write access (W).
Address	Address of the operand
Type	Information on the type and language used to create the object
Path	Path of object in project tree

Depending on the installed products, additional columns or different columns are displayed for the cross-references.

Settings in the cross-reference list

You can make the following settings using the buttons in the toolbar of the cross-reference list:

- Update cross-reference list
  Updates the current cross-reference list.
- Making settings for the cross-reference list
  Here, you select check boxes to specify whether all used, all unused, all defined or all undefined objects will be displayed. If the "Undefined objects" option is enabled, references to previously deleted objects are also displayed.
- Collapse entries
  Reduces the entries in the current cross-reference list by closing the lower-level objects.
- Expand entries
  Expands the entries in the current cross-reference list by opening the low-level objects.

Sorting in the cross-reference list

You can sort the entries in the "Object" column, including other product-specific columns, in ascending or descending order. To do this, click on the relevant column title.

See also

General information about cross references (Page 1834)

Displaying the cross-reference list (Page 1836)

11.3.3 Displaying the cross-reference list

Requirements

You have created a project.

Introduction

There are several ways of displaying cross-references depending on whether you are in the Portal view or in the Project view and which object you have selected in the project tree.

In the Portal view, you can only display cross-references for the entire CPU; in the Project view, you can, for example, display cross-references for the following objects:

- "PLC tags" folder
- "PLC data types" folder
- "Program blocks" folder
- "Tags and connections" folder
- Individual tags
- Individual PLC data types
- Individual blocks
- Technological objects
- Watch tables

Displaying cross-references

Proceed as follows to display cross-references:

1. Select the required action in the Portal view, for example "PLC programming" and the "Show cross-references" command or select one of the objects listed above in the Project view and select the "Cross-references" command in the "Tools" menu.
   The cross-reference list is displayed.
2. Click the "Used by" button to display where the objects shown in the cross-reference list are used.
3. Click the "Uses" button to view the users of the objects displayed in the cross-reference list.
4. You can perform the following actions using the buttons in the toolbar:
   - Update cross-reference list
   - Making settings for the cross-reference list
   - Collapse entries
   - Expand entries
5. You can sort the entries in the "Object" and "Address" columns in ascending or descending order by clicking on the relevant column title.
6. To go to the point of use of the object, click on the displayed link.

See also

General information about cross references (Page 1834)

Structure of the cross-reference list (Page 1835)

11.3.4 Displaying cross-references in the Inspector window

Introduction

The Inspector window displays cross-reference information about an object you have selected in the "Info > Cross-references" tab. This tab displays the instances where a selected object is being used and the other objects using it.

The Inspector window also includes blocks which are only available online in the cross-references.

You can use the "Show overlapping access..." shortcut menu command to also have overlapping access displayed for specific objects.

Note

Displaying "Overlapping accesses"

Please note that you can only have overlapping accesses displayed online and solely for structures such as for structured variables or structured elements in data blocks.

Structure

The Inspector window displays the cross-reference information in tabular format. Each column contains specific and detailed information on the selected object and its application. The table below shows the additional information listed in the "Info > Cross-reference" tab:

Column	Meaning
Object	Name of the object that uses the lower-level objects or that is being used by the lower-level objects.
Number	Number of uses
Point of use	Each location of use, for example, network
Property	Special properties of referenced objects, for example, the tag name in multi-instance declarations
as	Shows additional information about the object, e.g., that an instance DB is used as template or as multiple instance.
Access	Access mode Shows whether the operand is accessed by a read (R) and/or write (W) operation.
Address	Address of the operand
Monitor value	This column will only be displayed when the program editor is open.
Type	Information about the type and language used to create the object
Path	Path of object in project tree

Depending on the installed products, additional columns or different columns are displayed for the cross-references.

11.4 Testing the user program

11.4.1 Basics of testing the user program

Functions

You have the option of testing the running of your user program on the device. You can then monitor signal states and values of tags and can assign values to tags to simulate certain situations in the running of the program.

Requirement

There must be an executable program loaded on the device.

Test options

The following test options are available:

- Testing with program status
  The program status allows you to monitor the running of the program. You can display the values of operands and the results of logic operations (RLO) allowing you to recognize and fix logical errors in your program.
- Testing in single step mode (S7-300/400 only)
  You can test blocks you created in STL or SCL in the single step mode. You do this by setting breakpoints in the program code at which program execution stops. You can then continue to run the program one step at a time. Within a CPU, you can test either with program status or in single step mode. You cannot, however, use both test options at the same time within a CPU.
- Testing with the watch table
  With the watch table, you can monitor and modify the current values of individual tags in the user program or on a CPU. You can assign values to individual tags for testing and run the program in a variety of different situations. You can also assign fixed values to the I/O outputs of a CPU in STOP mode, for example to check the wiring.
- Testing with the force table
  With the force table, you can monitor and force the current values of individual tags in the user program or on a CPU. When you force, you overwrite individual tags with specified values. This allows you to test your user program and run through various situations. When forcing, make sure that you keep to the necessary safety measures for forcing (Page 1899)!

See also

Introduction to testing with program status (Page 1840)

Introduction to testing with the watch table (Page 1854)

Introduction for testing with the force table (Page 1881)

11.4.2 Testing with program status

11.4.2.1 Introduction to testing with program status

Program Status function

If you display the program status, you can monitor the execution of the program. This provides you with an overview of the values of the individual operands and the results of the logic operations and you can check whether the components of the automation system are correctly controlled.

The display of the program execution in the program status can differ slightly, depending on the CPU family used.

Testing with program status for S7-300/400

During testing with program status, the CPU cycle time can become extended in test mode because the recording of all test data can deviate from the duration of the programmed instructions due to the CPU capacity and therefore not run in realtime.

During the execution of the following test functions an alarm indicating the danger of a time-out is displayed once for each online session.

- During testing with call conditions
- During testing with breakpoints

You can only perform these test functions after you have acknowledged the alarm.

Note

With older CPUs from the S7-300/400 CPU family, you will need to change the operating response using the hardware configuration and then download the hardware configuration to the device. You have the option to set the "Process operation" or "Test operation" operating response.

Testing with program status for S7-1500

When you run the "Test with program status" function with a CPU from the S7-1500 family, the cycle time may increase notably while monitoring loops, which may result in the CPU changing to STOP mode.

Note

To avoid a possible STOP in the CPU , ensure that no programmed loops are displayed in the active monitoring window during "Testing with program status". Alternatively you can also increase the maximum permissible cycle time of the CPU.

Restrictions with the "Program status" function

The monitoring of loops can increase the cycle time significantly, depending in each case on the number of tags to be monitored and on the actual number of loops processed.

To ensure that the cycle time is influenced as little as possible, the "Program status" function is restricted as follows:

- The status display of a programmed loop is stopped at the return point.

Warning

Testing with program status

A test with the "Program status" function can cause serious damage to property or injury to persons if there are functional disturbances or program errors.

Make sure that no dangerous situations can arise before you conduct a test with the "Program status" function.

11.4.2.2 Setting the call environment

Basics of the call environment

Function

You can define the call environment for blocks and for breakpoints. With this, you specify the conditions for recording the program status of a block or for stopping program execution at a breakpoint.

Specification of the call environment for blocks

You can alternatively activate one of the following options to specify the call environment:

- No condition defined
  If no other option was selected this option is the default.
- Instance data block
  The program status of a function block will then only be recorded when you call the function block with the selected instance data block.
- Call path
  The program status of a block will then only be recorded when you call the block with a specific block or from a specific path.
- Manually adapted call path
  You can enter the desired call environment manually in this field. The "Transfer to "Adjusted manually"" button is used to transfer the content selected under "Call environment", which you can edit further if required.
  The program status of a block will then only be recorded when you call the block with a specific block or from a specific path.

Specification of the call environment for breakpoints

You can also specify a separate condition for each breakpoint.

If you do not specify the call environment, the program status of a block call is selected at random and recorded within the call structure and program execution is always interrupted at the relevant breakpoint. You should therefore always specify the call environment if you want to display the program status for a specific call.

See also

Setting the call environment of the block (Page 1842)

Setting the call environment of the block

By setting the call environment, you can specify when the program status of a block is recorded.

The section "Setting the call environment for breakpoints" describes how to set the call environment for breakpoints.

Requirement

- The block is open.

Specifying the call environment

To set the call environment, follow these steps:

1. Open the "Testing" task card.
2. Click the "Change" button in the "Call environment" pane.
   The "Call environment of the block" dialog opens.
3. Select the condition you want to apply.
   See also: Basics of the call environment (Page 1841)
4. Confirm your selection with "OK".

Result

The selected call environment is displayed in the "Testing" task card within the "Call environment" pane. The program status is now carried out in accordance with the set call environment.

Changing the call environment

Proceed as follows to change the call environment:

1. Open the "Testing" task card.
   If a call environment is already set, this is displayed in the "Call environment" pane.
2. Click the "Change" button in the "Call environment" pane.
   The "Call environment of the block" dialog opens.
3. Select the condition you want to apply.
   See also: Basics of the call environment (Page 1841)
4. Confirm your selection with "OK".

Result

The selected call environment is displayed in the "Testing" task card within the "Call environment" pane. The program status is now carried out in accordance with the set call environment.

See also

Basics of the call environment (Page 1841)

Introduction to testing with program status (Page 1840)

11.4.2.3 Switching test with program status on/off

You can monitor all blocks by switching on the program status of the block. This function is available to you for all code blocks, regardless of the programming language used. For blocks that were programmed with LAD, FBD or SCL you can also enable the program status from a specific position or for a specific selection. You can switch on the program status for an open block directly, or open a block from the calling block and view the program status.

Note

Note the following:

- The resources for testing with program status are limited. If there are not enough resources for the current test, earlier tests will be terminated.
- It is possible that another user can carry out a loading process on the selected CPU through joint parallel working on a CPU. It is therefore possible in the following cases that you can either not start the test with program status or that a running test is terminated:
  - Through the loading process the block for which you want to start or already have carried out the test with program status is loaded.
  - You use an instance data block as the call environment for the test with program status and the block changes structurally through the loading process, e.g. by renumbering.
  - You use a call path as the test condition for the test with program status and a block within the call path changes through the loading process.

  If a running test is terminated, a corresponding message is displayed in the Inspector window.

Requirement

- Code block: The code of the offline block is identical with the code of the online block. In this case the "Code" time stamps of the blocks are identical.
- Data block: The structure of the offline block is identical with the structure of the online block. In this case the "Interface" time stamps of the blocks are identical.

Switching the program status on or off directly in the block

To switch the program status for a block on or off directly in the block, follow these steps:

1. Open the block for which you wish to switch on the program status.
2. Click the "Monitoring on/off" button in the toolbar.
   If you have not already established an online connection, the "Go online" dialog opens. In this dialog, you can establish an online connection.
   See also: Establishing and terminating an online connection
3. Click the "Monitoring on/off" button in the toolbar again to switch the program status off.

Switching on or off program status starting at a specific point in a network

To start the program status for LAD and FBD at a specific point, follow these steps:

1. Open the block for which you wish to switch on the program status.
2. Click the "Monitoring on/off" button in the toolbar.
3. Right-click on the tag you want program status to start from.
4. Select "Modify > "Monitor from here" in the shortcut menu.
5. Click the "Monitoring on/off" button in the toolbar again to switch the program status off.

Switching on or off program status for selected tags

To start the program status for LAD and FBD for selected tags, follow these steps:

1. Open the block for which you wish to switch on the program status.
2. Click the "Monitoring on/off" button in the toolbar.
3. Select the tags for which you want to start the program status.
4. Select "Modify > Monitor selection" in the shortcut menu.
5. Click the "Monitoring on/off" button in the toolbar again to switch the program status off.

Switching on program status from the calling block

To switch on the program status for a block from the calling block (e.g. OB1), follow these steps:

1. Open the calling block.
2. Right-click on the block call.
3. Select the command "Open and monitor" in the shortcut menu.
   The block will open in the program editor. An online connection is established and the program status is displayed.

Result

If you enable the display of the program status, an online connection is established and the program status is displayed. When you turn off the display of the program status, you can terminate the online connection at the same time.

The call path of the block is shown under the block interface. If necessary, you can change the call environment in the "Call environment" section at the right-hand edge at "Test" and "Options". In the case of CPUs of the S7-1200/1500 series the "Call hierarchy" is displayed additionally on the right-hand edge. You can open the calling block by clicking the link.

11.4.2.4 Editing blocks during the program test

If you edit blocks while the test with program status is still running, online monitoring will be interrupted and you will be able to edit the block offline. If the block is not available offline in the project, you will first have to load it from the device to the project. After editing the block, you will also have to compile and download it again.

Procedure

To edit blocks while the test with program status is still running, follow these steps:

1. Edit the block as necessary.
   The test with program status is interrupted and the block is switched offline assuming it exists offline.
2. If the block does not exist offline, load it to the project from the device.
3. Compile the block.
   See also: Auto-Hotspot
4. Download the block to the device.
   See also: Auto-Hotspot

Result

The block now contains your modifications both online and offline. The online connection is re-established and testing with program status continues.

11.4.2.5 Modifying tags in the program status

While testing with the program status, you have the option of modifying tags to the following values once and immediately:

- Modify to 1
  Modifies tags of the "Bool" data type to the value "True".
- Modify to 0
  Modifies tags of the "Bool" data type to the value "False"
- Modify operand
  You can enter a modify value for tags that do not belong to the "Bool" data type.

Note that you cannot modify peripheral inputs, for example, via TagName:P.

Procedure

To modify tags during testing with the program status, proceed as follows:

1. Right-click on the tag you want to modify.
2. Select one of the following commands in the shortcut menu:
   - "Modify > Modify to 1"
   - "Modify > Modify to 0"
   - "Modify > Modify operand"
3. If you select "Modify operand", the "Modify operand" dialog opens. Enter the value you require in the "Modify value" box and confirm with "OK".

11.4.2.6 Switching display formats in the program status

Introduction

The display formats for tags are generally displayed in "integer" form. In the program status, you have the option of switching the current display format by means of the shortcut menu. The possible display formats for a tag are offered in a list. This is useful, for example, when you need a hexadecimal display in order to search for a hexadecimal error code.

Procedure

To switch the display format, follow these steps:

1. Open the desired block in the programming editor.
2. Switch on the program status by clicking "Monitoring on/off" in the toolbar.
   If you have not already established an online connection, the "Go online" dialog opens. In this dialog, you can establish an online connection.
3. Select the tags for which you want to start the program status.
4. Select "Modify > Monitor selection" in the shortcut menu to start monitoring this tag.
5. Select the desired tag at the corresponding block output and then select the desired display format in the shortcut menu, for example, "Modify > Display format > Hexadecimal".

Result

The display format for the selected tag is shown in hexadecimal form.

Note

Switching the display format in the program status

Please note that it is not possible to switch the display format for unconnected outputs, as no monitoring value is output in this case.

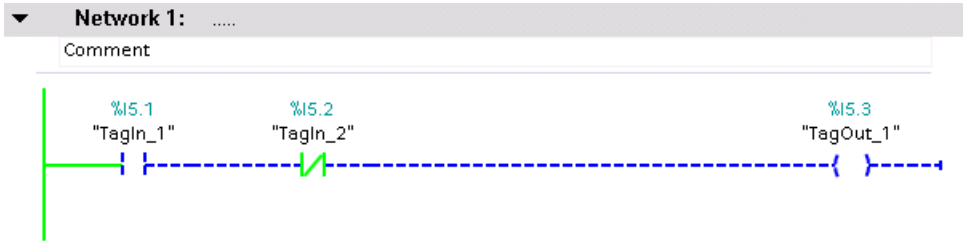
11.4.2.7 Examples of program status display

Program status display for LAD programs

Displays in program status

The display of the program status is updated cyclically.

The following figure shows an example of the program status display for LAD:



Representation of the program status

You can recognize the status of individual instructions and lines of a network quickly based on the color and type of lines and symbols. The following table shows the relationship between representation and status:

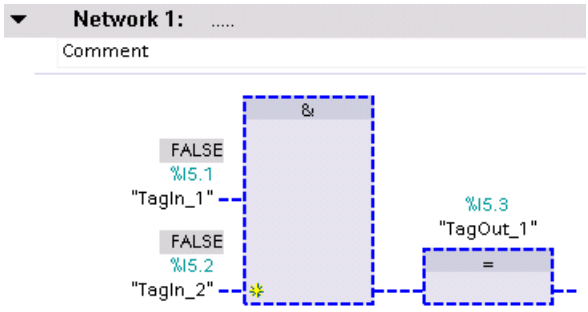
Representation	Status
Green solid	Satisfied
Blue dashed	Not satisfied
Gray solid	Unknown or not executed
Black	Not interconnected
Parameter in a frame with a saturation of 100 %	Value is current
Parameter in a frame with a saturation of 50 %	Value originates from an earlier cycle. The point in the program was not executed in the current cycle.

Program status display for FBD programs

Displays in program status

The display of the program status is updated cyclically.

The following figure shows an example of the program status display for FBD:



Representation of the program status

You can recognize the status of individual instructions and lines of a network quickly based on the color and type of lines and symbols. The following table shows the relationship between representation and status:

Representation	Status
Green solid	Satisfied
Blue dashed	Not satisfied
Gray solid	Unknown or not executed
Black	Not interconnected
Parameter in a frame with a saturation of 100 %	Value is current
Parameter in a frame with a saturation of 50 %	Value originates from an earlier cycle. The point in the program was not executed in the current cycle.

The values of the operands are displayed above the relevant operand name in a gray box.

Note

Program status display for outputs which are not interconnected

Please note that a monitor value cannot be displayed for outputs which are not interconnected.

Program status display for STL programs

Displays in program status

The display of the program status is updated cyclically and shown in tables. The tables are shown directly next to the STL program. You can read the program status for each line of the program. The display depends on the CPU in use (S7-300, S7-400, S7-1200 or S7-1500).

The tables to be displayed in the program status always contain the following information:

- RLO
  The "RLO" column shows the result of logic operation for each line of program. You can recognize the value of the RLO based on the background color of the table cell. Here, green means an RLO of 1 and lilac an RLO of 0.
- Value
  The current value of the operand is shown in the "Value" column.
- Extra
  The "Extra" column shows additional information depending on the particular operation, for example, relevant status bits for mathematical instructions, time or count values for timers and counters or memory addresses for indirect addressing.

The following figure shows an example of the program status display of a CPU S7-300 under STL:

Network 1: .....

Comment

			RLO	Value	Extra
1	OPN "DB1"	%DB1	0	DB1	
2	L %DBW2	%DBW2	0	16#4D2	DB1
3	L %DBW4	%DBW4	0	16#3333	DB1

39	= Q ["Tag_51"]	%MD64	1	1	P#5.1
40					

Program status display for SCL programs

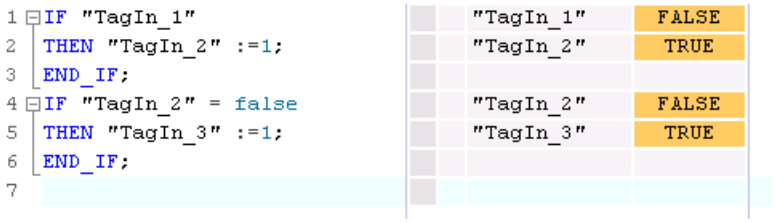
Displays in program status

The display of the program status is updated cyclically and shown in a table. The table is displayed immediately beside the SCL program and you can see the program status for each line of the program. The table contains the following information:

- Tag names
- Value

You can move the table to the left or right at any time.

The following figure shows an example of the program status display for SCL:



In the first column, you can see the name of the tag for which the current value is being displayed. If the line includes the "IF", "WHILE" or "REPEAT" instruction, the result of the instruction is displayed in the line as "True" or "False". If the line contains more than one tag, the value of the first tag is displayed. In both cases, all tags of these lines are displayed with their values in a separate list as soon as you select a line. If you place the cursor in a tag in the program code, this is shown in bold face in the list. You can also display the other tags of a line explicitly by clicking the arrow right located in front of lines containing more than one tag.

If the code of the line is not executed, the tag name is displayed in the values table in gray text.

The current values of the tags are displayed in the last column. If no values can be displayed for a tag, the line has a yellow background and three question marks are shown. In this case, select the "Create extended status information" check box in the properties of the block and download the block to the device again. All values are then displayed.

Program status display for GRAPH programs

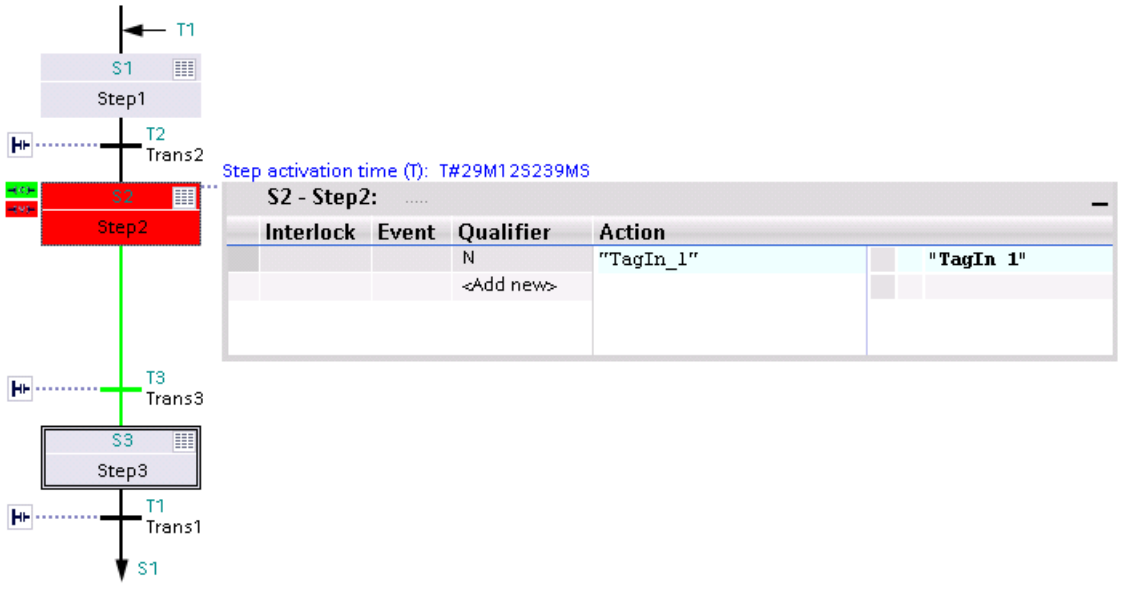
Displays in program status

For GRAPH programs you can have the program status displayed in sequence view and in single step view and for the permanent instructions. The program status display of permanent instructions corresponds to the program status display for LAB/FBD programs. The display of the program status is updated cyclically.

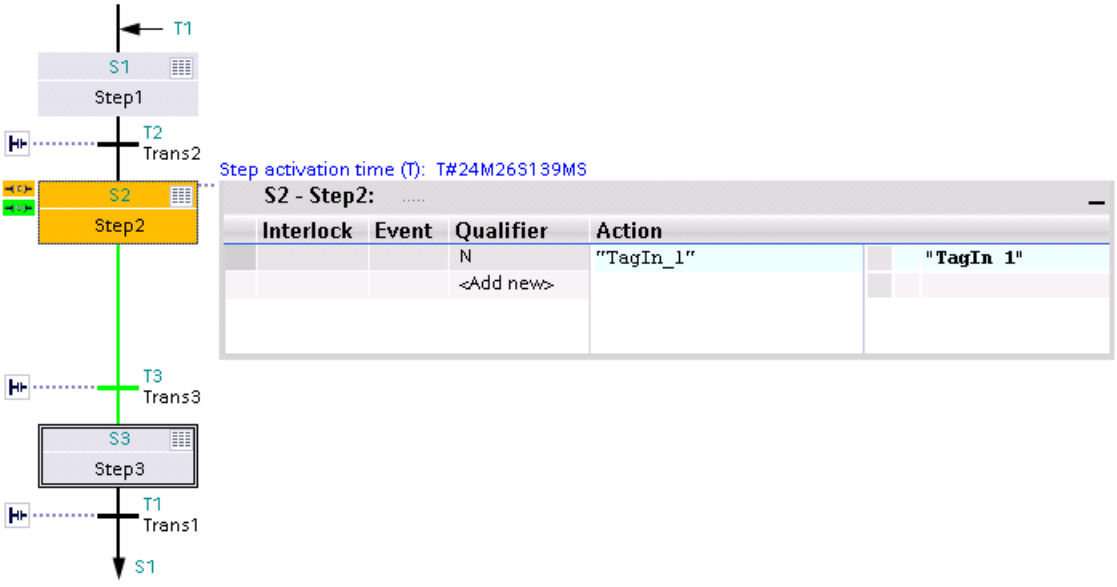
The following table shows the relationship between representation and status:

Representation	Area	Status
Green	Step, sequencer	There are no faults.
	Condition	The transition is fulfilled.
Red	Step, sequencer	There is a supervision error.
Yellow	Step, sequencer	There is an interlock error.
Black	Condition	The transition is not fulfilled.

The following figures show examples of the display for the program status in the sequence view:

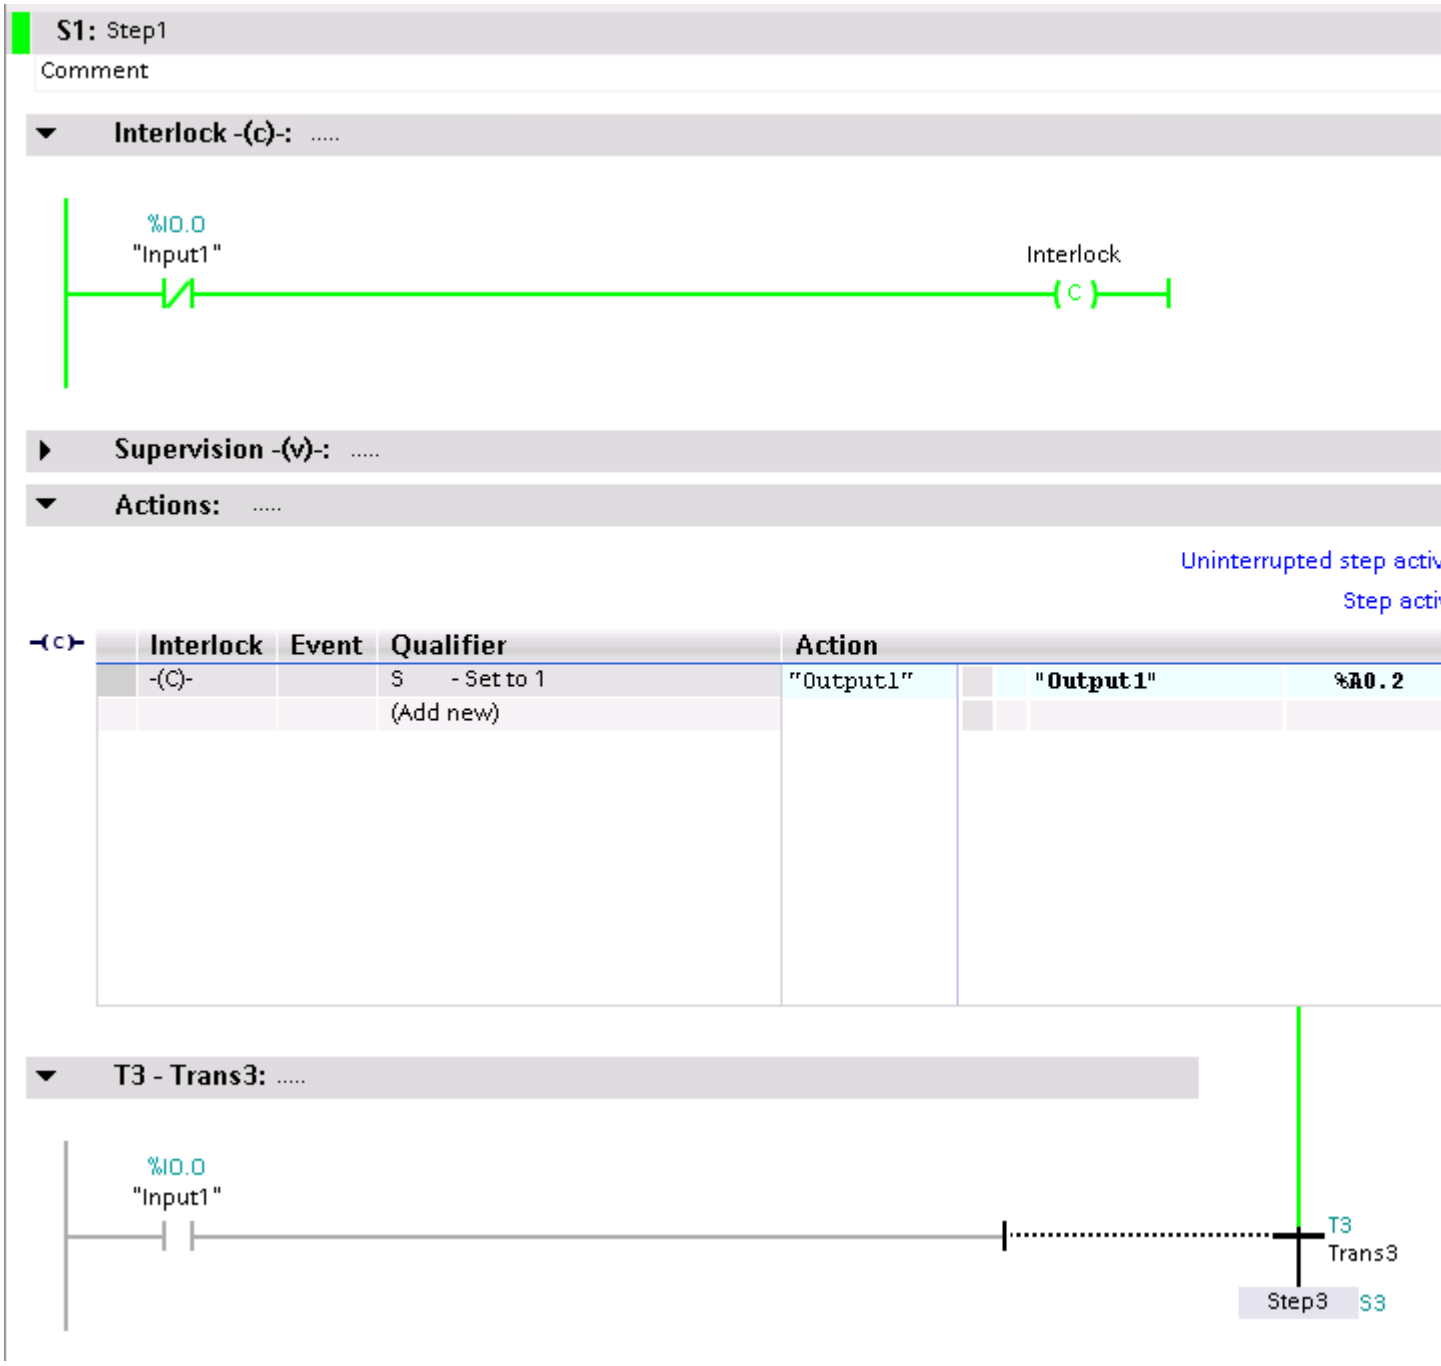


Step 2 contains a supervision error. The transition for switching to step 3 is fulfilled.



Step 2 contains an interlock error. The transition for switching to step 3 is fulfilled.

The figure below shows an example of the display for the program status in the single step view of a S7-300:



The step does not contain an interlock error. The subsequent transition is not satisfied.

11.4.3 Testing with the watch table

11.4.3.1 Introduction to testing with the watch table

Overview

The following functions are available in the watch table:

- **Monitoring tags**
  This allows the current values of the individual tags of a user program or a CPU to be displayed on the programming device or PC.
- **Monitoring tags**
  You can use this function to assign fixed values to the individual tags of a user program or CPU. Modifying is also possible with Test with program status .
- **"Enable peripheral outputs" and "Modify now"**
  These two functions enable you to assign fixed values to individual peripheral outputs of a CPU in the STOP mode. You can also use them to check your wiring.

Monitoring and modifying tags

The following tags can be monitored and modified:

- Inputs, outputs, and bit memories
- Contents of data blocks
- Content of UDTs
- I/O

Team engineering in the watch table

As of TIA Portal V13 SP1, within the framework of team engineering with an S7-1500 CPU with firmware version >= 1.7, several Engineering Systems can access the CPU online simultaneously, for example to monitor and modify tags and download blocks. If you use this function, make sure that you keep to the requirements and rules that apply to team engineering as explained in the information system in "Using Team Engineering" in the section "Shared commissioning of projects".

Possible applications

The advantage of the watch table is that a variety of test environments can be stored. This enables you to reproduce tests during commissioning or for service and maintenance purposes.

Creating and editing watch tables (Page 1858)

Layout of the watch table (Page 1855)

Basic mode and expanded mode in the watch table (Page 1856)

Icons in the watch table (Page 1857)

11.4.3.2 Layout of the watch table

Introduction

A watch table contains the tags you defined for the entire CPU. A "Watch and force tables" folder is automatically generated for each CPU created in the project. You create a new watch table in this folder by selecting the "Add new Watch table" command.

Layout of the watch table

The columns displayed in the watch table depend on the mode you are working in: basic mode or expanded mode.

The following additional columns are shown in expanded mode:

- Monitor with trigger
- Modify with trigger

The names of the columns can also be changed dynamically based on the action.

Meaning of the columns

The following table shows the meaning of the individual columns in basic mode and expanded mode:

Mode	Column	Meaning
Basic mode		Identifier column
	Name	Name of the inserted tag
	Address	Address of the inserted tag
	Display format	Selected display format
	Monitor value	Values of the tags, depending on the selected display format.
	Modify value	Value with which the tag is modified.
		Select the tag to be modified by clicking the corresponding check box.
	Comment	Comment for documentation of the tags
The following additional columns are shown in expanded mode:	Monitor with trigger	Display of selected monitoring mode
	Modify with trigger	Display of selected modify mode

See also

Icons in the watch table (Page 1857)

11.4.3.3 Basic mode and expanded mode in the watch table

Difference between basic mode and expanded mode in the watch table

Depending on the mode specified, the watch table displays different columns and column headings that can be used to perform different actions.

You will find a detailed list of the columns in Layout of the watch table (Page 1855).

Switching between basic mode and expanded mode

You have the following options of toggling between the basic and expanded mode:

- Click the icon "Show/hide advanced setting columns". Click this icon again to return to the basic mode.
  Or:
- In the "Online" menu, select the "Expanded mode" check box. Deactivate this check box to return to the basic mode.

Functionality in expanded mode

The following functionality is only possible in expanded mode:

- Monitor with trigger
- Modify with trigger
- Enable peripheral outputs
- Monitor peripheral inputs
- Modify peripheral outputs

Notice

Danger of a time-out while monitoring peripheral inputs and controlling peripheral outputs

Note that the monitoring of peripheral inputs and the controlling of peripheral outputs in the watch table can result in a time-out.

The CPU assumes the "STOP" mode.

See also

Setting the monitoring and modify mode (Page 1869)

11.4.3.4 Icons in the watch table

Meaning of the icons

The following table shows the meaning of the icons in the watch table:

Icon	Meaning
	Identifies a table inside the project tree as a watch table.
	Shows information in the identifier column.
	Inserts a row before the selected row.
	Inserts a row after the selected row.
	Modifies the addresses of all selected tags immediately and once. This command is executed once and as quickly as possible without reference to a defined trigger point in the user program.
	Modifies the addresses of all selected tags with reference to a defined trigger point in the user program.
	Disables the command output disable of the peripheral outputs. You can then modify the peripheral outputs when the CPU is in STOP mode.
	Displays all columns of expanded mode. If you click this icon again, the columns of expanded mode will be hidden.
	Displays all modify columns. If you click this icon again, the modify columns will be hidden.
	Starts monitoring of the visible tags in the active watch table. The default setting for the monitoring mode in basic mode is "permanent". In expanded mode, you can set defined trigger points for the monitoring of tags.
	Starts monitoring of the visible tags in the active watch table. This command is executed immediately and the tags are monitored once.
	Displays the check box for the selection of tags to be modified.
	Indicates that the value of the selected tag has been modified to "1".
	Indicates that the value of the selected tag has been modified to "0".
	Indicates that the address is being used multiple times.
	Indicates that the substitute value is being used. Substitute values are values that are output to the process in case of signal output module faults or are used instead of a process value in the user program in case of signal input module faults. The substitute values can be assigned by the user (e.g., retain old value).
	Indicates that the address is blocked because it is already being modified.
	Indicates that the address cannot be modified.
	Indicates that the address cannot be monitored.
	Indicates that an address is being forced.
	Indicates that an address is being partly forced.

Icon	Meaning
	Indicates that an associated I/O address is being fully or partly forced.
	Indicates that an address cannot be fully forced. Example: It is indeed possible to force the address QW0:P, but it is not possible to force the address QD0:P since this address area is eventually not available on the CPU.
	Indicates that a syntax error occurred.
	Indicates that the address is selected but at the moment e.g. has not yet been modified.

11.4.3.5 Creating and editing watch tables

Creating a watch table

Introduction

The watch table allows you to monitor and modify tags in the user program. Once you have created a watch table, you can save it, duplicate it, and print it and use it again and again to monitor and modify tags.

Requirement

A project is open.

Procedure

To create a watch table, follow these steps:

1. Click "Project view" in the status bar.
   The project view is displayed.
2. In the project tree, double-click the CPU for which you want to create a watch table.
3. Double-click the "Watch and force tables" folder and then the "Add new watch table" command.
   A new watch table is added.
4. In the "Name" column or in the "Address" column, enter the name or the absolute address for the tags that you want to monitor or modify.
5. You can select a display format from the drop-down list in the "Display format" column if you want to change this default setting.
6. Now decide whether you want to monitor or modify the entered tags and, if applicable, enter the desired values for modifying.

Opening a watch table

Requirement

A watch table has been created.

Procedure

To open a watch table, follow these steps:

1. Open the "Watch and force tables" folder below the desired CPU.
2. Double-click on the required watch table in the folder.

Result

The selected watch table opens.

Copying and pasting a watch table

Requirement

A watch table has been created.

Procedure

To copy a watch table, follow these steps:

1. Right-click the watch table that you want to copy.
2. In the context menu, select "Copy".
3. In the project tree, open the folder structure for the CPU in which you want to paste the copied watch table.
4. Right-click on the "Watch and force tables" folder.
5. In the context menu, select "Paste".
6. Alternatively, you can select the entire contents of the watch table and Drag & Drop it onto another watch table.

Result

A copy of the selected watch table is placed in the "Watch and force tables" folder of the relevant CPU.

Saving a watch table

Prerequisite

A watch table has been created.

Procedure

To save a watch table, follow these steps:

1. In the project tree select the watch table you want to save.
2. If you wish to change the preset name of the table, select the "Rename" command in the context menu and enter a new name for the table.
3. In the "Project" menu, select "Save". Note that this save operation will save the entire project.

Result

The contents of the watch table and the project are saved.

Note

You can reuse saved watch tables to monitor and modify tags when retesting your program.

11.4.3.6 Entering tags in the watch table

Basic information on entering tags in the watch table

Recommended procedure

- Select the tags whose values you want to monitor or modify, and enter them in the watch table.
- When entering tags into the watch table, please note that these tags must be previously defined in the PLC tag table.
- When entering tags, work from the outside to the inside. This means that you start by entering the tags for the inputs in the watch table. Then, you enter the tags that are affected by the inputs or that affect the outputs. Finally, you enter the tags for the outputs.

Example of filling out a watch table

- Enter the absolute address to be monitored or modified in the "Address" column.
- Enter the symbolic name for the tag in the "Name" column.

- Select the display format you require from the drop-down list in the "Display format" column, if you do not want to use the default setting.
- Now decide whether you want to monitor or modify the entered tags. Enter the desired values for modifying as well as a comment in the corresponding columns of the watch table.

Create comment row

If required, you can create a comment row by entering the string "//" in the "Name" column.

Syntax check

When you enter the tags in the watch table, the syntax of each cell is checked when you exit the cell. Incorrect entries are marked in red.

Note

When you place the mouse pointer in a cell marked in red, brief information is displayed with additional notes on the error.

See also

Permitted operands for the watch table (Page 1861)

Permissible modify values for the watch table (Page 1862)

Permitted operands for the watch table

Permissible operands for the watch table

The following table shows the operands that are permitted for the watch table:

Permitted operand	Example of data type	Example (International mnemonics)
Input/output/bit memory	BOOL	I1.0, Q1.7, M10.1 I0.0:P; Q0.0:P
Input/output/bit memory	BYTE	IB1/QB10/MB100 IB1:P; QB1:P
Input/output/bit memory	WORD	IW1; QW10; MW100 IW2:P; QW3:P
Input/output/bit memory	DWORD	ID4; QD10; MD100 ID2:P; QD1:P
Timers	TIMER	T1
Counters	COUNTER	C1
Data block	BOOL	DB1.DBX1.0
Data block	BYTE	DB1.DBB1

Permitted operand	Example of data type	Example (International mnemonics)
Data block	WORD	DB1.DBW1
Data block	DWORD	DB1.DBD1

Note

Please observe the following notes to work with the watch table.

- You cannot enter "DB0..." because it is used by the system!
- Peripheral outputs can be modified but not monitored.
- Peripheral inputs can be monitored but not modified.

Notice

Danger of a time-out while monitoring peripheral inputs and controlling peripheral outputs

Note that the monitoring of peripheral inputs and the controlling of peripheral outputs in the watch table can result in a time-out.

The CPU assumes the "STOP" mode.

See also

Basic information on entering tags in the watch table (Page 1860)

Overview of the valid data types (Page 1908)

Permissible modify values for the watch table

Entry of modify values in the watch table

The following table shows the operands that are permitted for the entry of modify values in the watch table:

Table 11-1 Bit operands

Possible bit operands	Example for permitted modify values
I1.0	True
M1.7	False
Q1.0	0
Q1.1:P	1
DB1.DBX1.1	2#0
M1.6	2#1

Table 11-2 Byte operands

Possible byte operands	Example for permitted modify values
IB1	2#00110011
MB12	B#16#1F
QB10	1F
QB11:P	'a'
DB1.DBB1	10

Table 11-3 Word operands

Possible word operands	Example for permitted modify values
IW1	2#0011001100110011
MW12	W#16#ABCD
MW14	ABCD
QW10	B#(12, 34)
QW12:P	12345
DB1.DBW1	'ab'
MW16	S5T#9s_340ms
MW18	C#123
MW9	D#2006-12-31

Table 11-4 Double word operands

Possible double word operands	Example for permitted modify values
ID1	2#00110011001100110011001100110011
QD10	Dw#16#abcdef10
QD12:P	ABCDEF10
DB1.DBD2	b#(12,34,56,78)
MD8	L#-12
MD12	L#12
MD16	123456789
MD20	123456789
MD24	T#12s345ms
MD28	Tod#1:2:34.567
MD32	P#e0.0

Table 11-5 Timers

Possible operands of the "Timer" type	Permitted control values	Explanation
T1	0 ms	Time value in milliseconds (ms)
T12	20 ms	Time value in milliseconds (ms)

Possible operands of the "Timer" type	Permitted control values	Explanation
T14	12345 ms	Time value in milliseconds (ms)
T16	S5t#12s340ms	Time value 12s 340 ms

Table 11-6 Counters

Possible operands of the "Counter" type	Permitted control values
C1	0
C14	20
C16	C#123

Notes on timers and counters

- Timers

  Note

  Modifying a timer influences only the value, not the status. Timer T1 can be modified to the value "0", but the result of logic operation for A T1 is not changed.

  The time sequences "s5t" and "s5time" can be written in both lower-case and upper-case characters.

- Counter

  Note

  Modifying a counter influences only the value, not the status. Counter C1 can be changed to the value "0", but the result of the logic operation for A C1 is not changed.

Overview of the display formats

Display formats in the watch table

The display format you select specifies the representation of a tag value.

When entering the address a display format is automatically preset. If you want to change this, you can select a display format from the drop-down list in the "Display formats" column. The drop-down list only offers the display formats which are valid for this data type. The display format that appears first in the list is the pre-selected format.

Example

The following table shows the 32-bit data types permitted for all CPU families in the watch table and their possible display formats:

Data type	Possible display formats
BOOL	Bool, Hex, BCD, Octal, Bin, Dec, Dec+/-
BYTE	Hex, BCD, Octal, Bin, Dec, Dec+/-, Character
WORD	Hex, BCD, Octal, Bin, Dec, Dec+/-, Dec_Sequence, Character, Unicode_Character, SIMATIC_Timer, Date, Counter
DWORD	Hex, BCD, Octal, Bin, Dec, Dec+/-, Dec_Sequence, Character, Unicode_Character, Floating-point number, Time of day, Timer, Pointer
SINT	Dec, Dec+/-, Hex, BCD, Octal, Bin, Character
INT	Dec, Dec+/-, Hex, BCD, Octal, Bin, Character, Unicode_Character, Dec_Sequence, SIMATIC_Timer, Counter, Date
DINT	Dec, Dec+/-, Hex, BCD, Octal, Bin, Character, Unicode_Character, Dec_Sequence, Floating-point number, Time of day, Timer, Pointer
USINT	Dec, Dec+/-, Hex, BCD, Octal, Bin, Character
UINT	Dec, Dec+/-, Hex, BCD, Octal, Bin, Character, Unicode_Character, Dec_Sequence, SIMATIC_Timer, Counter, Date
UDINT	Dec, Dec+/-, Hex, BCD, Octal, Bin, Character, Unicode_Character, Dec_Sequence, Floating-point number, Time of day, Timer, Pointer
REAL	Floating-point number, Hex, BCD, Octal, Bin, Character, Unicode_Character,Dec, Dec+/-, Dec_Sequence, Time of day, Timer, Pointer
DATE	Date, Dec, Hex, BCD, Bin
TIME_OF_DAY	Time of day, Dec, Hex, BCD, Bin
TIME	Timer, Hex, BCD, Bin
DATE_AND_TIME	Date and time,
TIMER	SIMATIC_Timer, Hex, BCD, Bin
CHAR	Character, Hex, BCD, Octal, Bin, Dec, Dec+/-
WCHAR	Unicode_Character, Character, Hex, BCD, Octal, Bin, Dec, Dec+/-
STRING	Character string
WSTRING	Unicode_character string
POINTER	Pointer, Hex, BCD, Octal, Bin, Character, Unicode_Character, Dec, Dec+/-, Dec_Sequence, Floating-point number, Time of day, Timer, Block number
COUNTER	Counter, Hex, BCD, Bin
S5TIME	SIMATIC_Timer, Hex, BCD, Bin

For the S7-1200 CPU family, all 32-bit data types are permitted (see table above), as well as the 64-bit data type LREAL with the following possible display formats:

Data type	Possible display formats
LREAL	In a project created with TIA Portal < V12: Floating-point number Note: The display of LREAL is limited to 13 digits plus exponent.
LREAL	In a project created with TIA Portal >= V12: Floating-point number, Hex, BCD, Octal, Bin, Character, Unicode_Character, Dec, Dec+/-, Dec_Sequence, Time of day, Timer, Date and time Note: The display of LREAL is limited to 13 digits plus exponent.

For the S7-1500 CPU family, in addition to 32-bit data types, the 64-bit data types listed in the table are also permitted with the following possible display formats:

Data type	Possible display formats
LWORD	Hex, Octal, BCD, Bin, Character, Unicode_Character, Dec, Dec+/-, Dec_Sequence, Floating-point number, Time of day, Timer, Date and time
LINT	Dec+/-, Dec, Hex, BCD, Octal, Bin, Character, Unicode_Character, Dec_Sequence, Time of day, Timer, Date and time
ULINT	Dec, Dec+/-, Hex, BCD, Octal, Bin, Character, Unicode_Character, Dec_Sequence, Time of day, Timer, Date and time
LREAL	Floating-point number, Hex, BCD, Octal, Bin, Character, Unicode_Character, Dec, Dec+/-, Dec_Sequence, Time of day, Timer, Date and time
LTIME	Timer, Dec+/-, Dec, Hex
LTOD	Time of day, Dec, Hex, BCD, Bin
LDT	Date and time, Dec, Hex

For more information, refer to the description of the valid data types (Page 1908).

Note

Rounding of floating-point numbers

In the watch table, floating-point numbers are stored as binary numbers in IEEE format. Because not every floating point number (real, longreal) that can be displayed on the user interface can be mapped to the IEEE format, there is a possibility that floating-point numbers will be rounded. If a rounded floating-point number in the watch table is copied and, in turn, inserted in another input field, the rounding may cause a slight difference.

Note

Only symbolic addressing is possible

In the watch table, LongDataTypes such as LWORD or LREAL can only be addressed symbolically.

Selecting the display format for tags

Procedure

To select the display format of the tags, follow these steps:

1. Enter the desired address in the watch table.
2. Click the desired cell in the "Display format" column, and open the drop-down list. The permissible display formats are shown in the drop-down list.
3. Select the desired display format from the drop-down list.

Note

If the selected display format cannot be applied, then the last selected display format will be displayed automatically.

See also

Overview of the valid data types (Page 1908)

Creating and editing comment lines

Basic principles of comment lines

In addition to the row related comments in the comment column, you can now also create complete comment lines to enhance the structure of the watch table.

The contents of the comment line are stored in the "Languages & Resources" folder in the "Project texts" tab and can be compiled in other project languages.

Creating comment lines

To create comment lines, follow these steps:

1. Open the watch table and enter the required addresses.
2. To create a comment line, enter the character string "//" in the "Name" column. No comment lines can be created in the other columns.

3. Enter the required comment in the comment line. The entered comment is shown in green.
4. To show all comments you entered, double-click "Project texts" in the project tree under "Languages & Resources".
5. If you are working in multi-lingual projects and want your comment to be translated into other languages, you can set the project languages required in addition to the editing language in the project tree under "Languages & Resources > Project languages".

Deleting comment lines

To delete comment lines, follow these steps:

1. Open a watch table containing comment lines.
2. Delete the entire comment including the introductory string "//", if you no longer required this.
3. Alternatively, delete only the introductory string "//". In this case the existing comment is retained and is displayed in the "Comment" column in the watch table.

Note

Deleting comment lines

When you delete comment lines the project languages and any existing translations for these comments are also deleted.

11.4.3.7 Monitoring tags in the watch table

Introduction to monitoring tags in the watch table

Introduction

The watch table allows you to monitor the tags of the configured input and output modules in the CPU, depending on the monitoring and modify mode (Page 1869) selected. To monitor tags, an online connection to the CPU must exist.

Notice

Danger of a time-out while monitoring peripheral inputs

Note that the monitoring of peripheral inputs can result in a time-out.

The CPU assumes the "STOP" mode.

Options for monitoring tags

The following options are available for monitoring tags:

- Monitor now
  This command starts the monitoring of the visible tags in the active watch table immediately and once only.
- Monitor all
  This command starts the monitoring of all visible tags in the active watch table, depending on the selected watch mode:
  - In basic mode, the monitoring mode is set to "permanent" by default.
  - In expanded mode, you can specify defined trigger points for the monitoring of tags.

  Note

  If the monitoring mode is changed while in expanded mode and then a switch is made to basic mode, the monitoring mode set before will also be applied in basic mode.

CPU-specific limitations when monitoring tags

The following CPU-specific differences exist:

- CPU S7-300/400:
  CPUs from this family can only monitor the first 30 characters of a string.
- CPU S7-1200/1500:
  CPUs from this family can monitor a string up to the total size of 254 characters.

Setting the monitoring and modify mode

Introduction

By selecting the monitoring and modify mode, you specify the trigger point and the duration of the tag monitoring in the watch table and the force table.

Possible monitoring and modify modes (duration of monitoring or modifying)

The following monitoring and modifying modes are available:

Trigger	Execution	CPU status	Duration
Permanent	Permanent During monitoring: The inputs are monitored at the end of the cycle and the outputs at the start of the cycle. During modify: The inputs are modified at the start of the cycle and the outputs at the end of the cycle.	RUN	Will be executed until the user stops the action or the online connection to the CPU is interrupted.
Permanently, at start of scan cycle	Permanently, at start of scan cycle	RUN	Will be executed until the user stops the action or the online connection to the CPU is interrupted.
Permanently, at end of scan cycle	Permanently, at end of scan cycle	RUN	Will be executed until the user stops the action or the online connection to the CPU is interrupted.
Permanently, at transition to STOP	Permanently, at transition from RUN to STOP	RUN > STOP	Will be executed until the user stops the action or the online connection to the CPU is interrupted.
Once only, at start of scan cycle	Once only, at start of scan cycle	RUN	Ends automatically after being executed once.
Once only, at end of scan cycle	Once only, at end of scan cycle	RUN	Ends automatically after being executed once.
Once only, at transition to STOP	Once only, at transition from RUN to STOP	STOP > RUN	Ends automatically after being executed once.

Special features when using "Permanent" mode

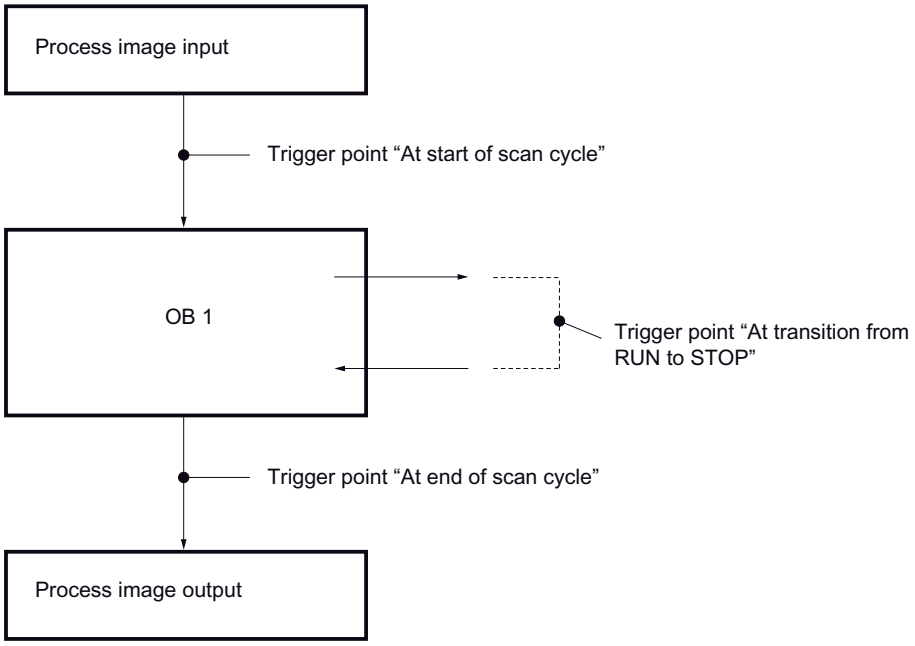
The "Permanent" mode is executed differently for the monitoring and modifying of tags.

- Monitoring: The inputs are monitored at the end of the cycle and the outputs at the start of the cycle.
- Modifying: The inputs are modified at the start of the cycle and the outputs at the end of the cycle.

Selecting the trigger point

The trigger points "Beginning of scan cycle", "End of scan cycle", and "Switch to stop" specify the time at which the tags are to be read from the CPU or updated in the CPU.

The following diagram shows the position of these trigger points:



Position of the trigger points

From the position of the trigger points, it follows that:

- Modifying of inputs is only appropriate at the beginning of the scan cycle (corresponding to the beginning of the user program OB 1), because otherwise the process image input is updated again after modifying and is thus overwritten.
- Modifying of outputs is only appropriate at the end of the scan cycle (corresponding to the end of the user program OB 1), because otherwise the process image output can be overwritten by the user program.
- The modified value is displayed in the "Monitor value" column, provided that monitoring is active and the modified value is not overwritten by the user program.

Monitoring tags

When tags are being modified, the following applies to the trigger points:

- If you have specified the modify mode as "once only", you will receive an alarm if the selected tags cannot be modified.
- In "permanent" modify mode, you do not receive an alarm.

Note regarding the "Modify now" command

You can modify the values of selected tags immediately using the "Online > Modify >Modify now" command. This command is executed once only and as quickly as possible without reference to a defined position (trigger point) in the user program. This function is used mainly for modifying when the CPU is in STOP mode.

"Monitor all" command for tags

Introduction

The "Monitor all" command allows you to start monitoring the visible tags in the active watch table. The default setting for the monitoring mode in basic mode of the watch table is "permanent". In expanded mode, you can specify defined trigger points for the monitoring of tags. In this case, the tags are monitored with reference to the specified trigger points.

Notice

Danger of a time-out while monitoring peripheral inputs

Note that the monitoring of peripheral inputs can result in a time-out.

The CPU assumes the "STOP" mode.

Requirements

- A watch table has been created.
- An online connection to the CPU exists.

Procedure

To execute the "Monitor all" command, follow these steps:

1. Enter the tags to be monitored and the corresponding addresses in the watch table.
2. Switch to expanded mode by clicking the icon "Show/hide advanced setting columns" in the toolbar.
3. If you want to change the default monitoring mode for a tag, click the appropriate cell in the "Monitor with trigger" column and select the desired monitoring mode from the drop-down list.
4. Click the "Monitor all" icon in the toolbar.

Result

The tags of the active watch table are monitored using the monitoring mode selected.

"Monitor now" command for tags

Introduction

The "Monitor now" command starts the monitoring of tags immediately without reference to defined trigger points. The tag values are read out once only and displayed in the watch table.

Notice

Danger of a time-out while monitoring peripheral inputs

Note that the monitoring of peripheral inputs can result in a time-out.

The CPU assumes the "STOP" mode.

Requirements

- A watch table has been created.
- An online connection to the CPU exists.

Procedure

To execute the "Monitor now" command, follow these steps:

1. Enter the tags to be monitored and the corresponding addresses in the watch table.
2. Click the "Monitor now" icon in the toolbar.

Result

The tags of the active watch table are monitored immediately and once only.

11.4.3.8 Modifying tags in the watch table

Introduction to modifying tags

Introduction

The watch table allows you to modify the tags of the configured input and output modules in the CPU, depending on the monitoring and modify mode (Page 1869) selected.

To monitor the tags, an online connection to the CPU must exist.

Danger

Danger when modifying:

Serious personal injury and material damage can result from changes in the tags or addresses during plant operation in the event of malfunctions or program errors!
Make sure that dangerous conditions cannot occur before you execute the "Modify" function.

Notice

Danger of a time-out while controlling peripheral outputs

Note that the controlling of peripheral outputs in the watch table can result in a time-out.

The CPU assumes the "STOP" mode.

Notice

Danger due to modifying an identical operand in parallel with different modify values in more than one watch table

When working with more than one watch table, avoid modifying identical operands permanently multiple times with different modify values.

If an identical operand is modified permanently with different modify values at the same time in different watch tables, all watch tables will display the last modified value, because the modify value assigned last will be used in this case.

Options for modifying tags

The following options are available for modifying tags:

- Modify to "0"
  This command modifies the selected address to the modify value "0".
- Modify to "1"
  This command modifies the selected address to the modify value "1".
- Modify once only and immediately
  This command modifies all selected addresses in the active watch table "once only and immediately".

- Modify with trigger
  This command modifies all selected addresses in the active watch table using the monitoring and modify mode (Page 1869) selected.
  The "Modify with trigger" function is only available in expanded mode. You will not receive an alarm indicating whether or not the selected addresses were actually modified with the specified value. You should use the "Modify once only and immediately" function if you require such a confirmation.
- Enable peripheral outputs
  This command disables the command output disable.
  This function can only be executed in expanded mode, when the CPU is in STOP and the option Force (Page 1898) of tags is not enabled. If desired, deactivate this function in the force table.

Note

When modifying, note the following:

Modifying of tags **cannot** be undone.

Modify tags to "0"

Introduction

You can assign one-time values to tags independent of the monitoring and modify mode and modify them. The modify command is executed as fast as possible, similar to a "Trigger now" command, without reference to a defined position in the user program.

Danger

Danger when modifying:

Serious personal injury and material damage can result from changes in the tags or addresses during plant operation in the event of malfunctions or program errors!
Make sure that dangerous conditions cannot occur before you execute the "Modify" function.

Notice

Danger of a time-out while controlling peripheral outputs

Note that the controlling of peripheral outputs in the watch table can result in a time-out.

The CPU assumes the "STOP" mode.

Requirements

- A watch table has been created.
- An online connection to the CPU exists.

Procedure

To modify tags to "0", follow these steps:

1. Enter the desired address in the watch table.
2. Select the "Online > Modify > Modify to 0" command in order to modify the selected address with the specified value.

Result

The selected address is modified to "0".

Note

When modifying, note the following:

Modifying can **not** be undone!

Modify tags to "1"

Introduction

You can assign one-time values to tags independent of the monitoring and modify mode and modify them. The modify command is executed as fast as possible, similar to a "Trigger now" command, without reference to a defined position in the user program.

Danger

Danger when modifying:

Serious personal injury and material damage can result from changes in the tags or addresses during plant operation in the event of malfunctions or program errors!
Make sure that dangerous conditions cannot occur before you execute the "Modify" function.

Notice

Danger of a time-out while controlling peripheral outputs

Note that the controlling of peripheral outputs in the watch table can result in a time-out.

The CPU assumes the "STOP" mode.

Requirements

- A watch table has been created.
- An online connection to the CPU exists.

Procedure

To modify tags to "1", follow these steps:

1. Enter the desired address in the watch table.
2. Select the "Online > Modify > Modify to 1" command in order to modify the selected address with the specified value.

Result

The selected address is modified to "1".

Note

When modifying, note the following:

Modifying can **not** be undone!

"Modify now" command for tags

Introduction

You can assign one-time values to tags independent of the monitoring and modify mode and modify them immediately. The modify command is executed as fast as possible, similar to a "Trigger now" command, without reference to a defined position in the user program.

Danger

Danger when modifying:

Serious personal injury and material damage can result from changes in the tags or addresses during plant operation in the event of malfunctions or program errors!
Make sure that dangerous conditions cannot occur before you execute the "Modify" function.

Notice

Danger of a time-out while controlling peripheral outputs

Note that the controlling of peripheral outputs in the watch table can result in a time-out.

The CPU assumes the "STOP" mode.

Requirements

- A watch table has been created.
- An online connection to the CPU exists.

Procedure

To modify tags immediately, follow these steps:

1. Enter the desired addresses and modify values in the watch table.
2. Select the addresses to be modified by selecting the check boxes for modifying in the column after the "Modify value".
   A yellow triangle appears behind the selected check box, indicating that the address is now selected for modifying but has not yet been modified.
3. Select the "Online > Modify > Modify once and now" command in order to immediately modify the selected address once only with the specified value.

Result

The selected addresses are modified immediately and once only.

Note

When modifying, note the following:

Modifying can **not** be undone!

"Modify with trigger" command for tags

Introduction

You can assign values to addresses dependent on the defined monitoring and modify mode and modify them. The modify command is executed as specified in the monitoring and modify mode, with reference to the defined trigger position in the user program.

Danger

Danger when modifying:

Serious personal injury and material damage can result from changes in the tags or addresses during plant operation in the event of malfunctions or program errors!
Make sure that dangerous conditions cannot occur before you execute the "Modify" function.

Notice

Danger of a time-out while controlling peripheral outputs

Note that the controlling of peripheral outputs in the watch table can result in a time-out.

The CPU assumes the "STOP" mode.

Requirements

- A watch table has been created.
- An online connection to the CPU exists.
- The watch table has to be in expanded mode.

Procedure

To modify tags "with trigger", follow these steps:

1. Enter the desired addresses and modify values in the watch table.
2. Select the addresses to be modified by selecting the check boxes for modifying in the column after the "Modify value".
   A yellow triangle appears behind the selected check box, indicating that the address is now selected for modifying but has not yet been modified.
3. Switch to expanded mode using the icon "Show/hide advanced settings columns" in the toolbar or the "Online > Expanded mode" command.
   The "Monitor with trigger" and "Modify with trigger" columns are displayed.
4. In the "Modify with trigger" column, select the desired modify mode from the drop-down list box. The following options are available:
   - Permanent
   - Permanently, at start of scan cycle
   - Once only, at start of scan cycle
   - Permanently, at end of scan cycle
   - Once only, at end of scan cycle
   - Permanently, at transition to STOP
   - Once only, at transition to STOP
5. Start modifying using the "Online > Modify > Modify with trigger" command.
6. Confirm the prompt with "Yes" if you want to start modifying with trigger.

Result

The selected tags are modified using the selected monitoring and modify mode. The yellow triangle is no longer displayed.

Note

When modifying, note the following:

Modifying can **not** be undone!

Enable peripheral outputs

Introduction

The "Enable peripheral outputs" function deactivates the command output disable of the peripheral outputs. You can then modify the peripheral outputs when the CPU is in STOP mode. This function is available in the watch table in "Expanded mode" only.

Danger

Danger when enabling the peripheral outputs:

Attention, the enabling of the peripheral outputs can cause serious personal injury and material damage!
Make certain that dangerous conditions cannot occur before you execute the "Enable peripheral outputs" function.

Prerequisites

- A watch table has been created.
- An online connection to the CPU exists.
- The CPU is in STOP mode before you can enable the peripheral outputs.
- The watch table has to be in expanded mode.
- The option Force (Page 1898) of tags must not be enabled.

Note

"Enable peripheral outputs" function

- This function is possible only in STOP mode. The function is exited by an operating state change of the CPU and by the termination of the online connection.
- While the function is enabled, forcing is not possible.

Procedure

To enable the peripheral outputs in STOP mode, follow these steps:

1. Enter the desired addresses and modify values in the watch table.
2. Select the addresses to be modified by selecting the check boxes for modifying in the column after the "Modify value".
   A yellow triangle appears behind the selected check box, indicating that the address is now selected for modifying but has not yet been modified.
3. Switch to expanded mode using the icon "Show/hide advanced settings columns" in the toolbar or the "Online > Expanded mode" command.
   The "Monitor with trigger" and "Modify with trigger" columns are displayed.
4. Change the relevant CPU to STOP using the operator panel.

5. Right-click to open the shortcut menu and select "Enable peripheral outputs".
6. Confirm the prompt with "Yes" if you want to unlock the command output disable for the peripheral outputs.
7. Modify the peripheral outputs using the "Online > Modify > Modify now" command.

Result

The peripheral outputs are modified with the selected modify values. The yellow triangle is no longer displayed.

Enabling the peripheral outputs

The "Enable peripheral outputs" function remains active until:

- The "Enable peripheral outputs" command is deactivated again via the shortcut menu or via the "Online > Modify > Enable peripheral outputs" command.
- The CPU is no longer in STOP mode.
- The online connection is terminated.

Note

When modifying, note the following:

Modifying can **not** be undone!

11.4.4 Testing with the force table

11.4.4.1 Introduction for testing with the force table

Overview

You can use the force table to assign permanent values to individual tags

of the user program. This action is referred to as "forcing".

The following functions are available in the force table:

- **Monitoring tags**
  This allows the current values of the individual tags of a user program or a CPU to be displayed on the programming device or PC. Tags can be monitored with or without a trigger condition.
- **Forcing tags**
  This function lets you assign a fixed value to individual I/O tags of the user program.

Monitoring and forcing tags

The monitoring and forcing of tags is always dependent on the operand scope of the CPU used.

The following tags can be monitored:

- Inputs, outputs, and bit memories
- Contents of data blocks
- Peripheral inputs

The following tags can be forced:

- Peripheral inputs
- Peripheral outputs

Example

Independent of the CPU used, only I/O can be forced, such as: "Tag_1":P or "QW0:P" or "IW0:P". Note that "Tag_1":P must not be the symbolic name of a bit memory.

Possible applications

One advantage of the force table is that you can simulate different test environments and overwrite tags in the CPU with a permanent value. This enables you to intervene in the ongoing process for regulating purposes.

See also

Layout of the force table (Page 1883)

Basic mode and expanded mode in the force table (Page 1884)

Icons in the force table (Page 1885)

Open and edit force table (Page 1886)

11.4.4.2 Safety precautions when forcing tags

Safety precautions when forcing tags

Because the forcing function allows you to intervene permanently in the process, observance of the following notices is essential:

Danger

Prevent personal injury and material damage!

Note that an incorrect action when executing the "Force" function can:

- Harm persons or pose a health hazard.
- Cause damage to machinery or the entire plant.

Caution

Prevent personal injury and material damage!

- Before you start the "Force" function, you should ensure that no one else is currently executing this function on the same CPU.
- Forcing can only be stopped by clicking the "Stop forcing" icon or using the "Online > Force > Stop forcing" command. Closing the active force table does **not** stop the forcing!
- Forcing can **not** be undone!
- Review the differences between " modifying tags" (Page 1873) and "forcing tags" (Page 1898).
- If a CPU does not support the "Force" function, the relevant icons cannot be selected.
- If the function "Enable peripheral outputs" is active on your CPU, then forcing is **not** possible on this CPU. If desired, deactivate this function in the watch table.

11.4.4.3 Layout of the force table

Introduction

In the force table, enter the CPU-wide tags that you have defined and selected and which are to be forced in the allocated CPU. Only peripheral inputs and peripheral outputs can be forced.

For each CPU created in the project, a force table will automatically be created in the "Watch and force tables" folder. Only one force table can be allocated to a CPU. This force table displays all the addresses forced in the allocated CPU.

Layout of the force table

The columns displayed in the force table depend on the mode you are working in: basic mode or expanded mode.

In expanded mode the "Monitor with trigger" column is also displayed.

Meaning of the columns

The following table shows the meaning of the individual columns in basic mode and expanded mode:

Mode	Column	Meaning
Basic mode	i	Identification column
	Name	Name of the inserted tag
	Address	Address of the inserted tag
	Display format	Selected display format
	Monitor value	Values of the tags, dependent on the selected display format.
	Force value	Value with which the tag is forced.
	F ("Force")	Select the tag to be forced by activating the corresponding check box.
	Comment	Comment for documentation of the tags
The following additional column is shown in expanded mode:	Monitor with trigger	Display of selected monitoring mode

See also

Icons in the force table (Page 1885)

Basic mode and expanded mode in the force table (Page 1884)

11.4.4.4 Basic mode and expanded mode in the force table

Difference between basic mode and expanded mode in the force table

In expanded mode the "Monitor with trigger" column is also displayed in the force table.

You will find a detailed list of the columns under Layout of the force table (Page 1883).

Switching between basic mode and expanded mode

You have the following options of toggling between the basic and expanded mode:

- Click the icon "Show/hide advanced setting columns". Click this icon again to return to the basic mode.
  Or:
- In the "Online" menu, select the "Expanded mode" check box. Deactivate this check box to return to the basic mode.

Functionality in expanded mode

The following functionality is only possible in expanded mode:

- Monitor with trigger
- Monitor peripheral inputs

11.4.4.5 Icons in the force table

Meaning of the icons

The following table shows the meaning of the icons in the force table:

Icon	Meaning
	Identifies a table inside the project tree as a force table.
	Identification column
	Inserts a row before the selected row.
	Inserts a row after the selected row.
	Displays all columns of expanded mode. If you click this icon again, the columns of the expanded mode will be hidden.
	Updates all operands and values currently being forced on the CPU in the open force table.
	Starts forcing for all addresses of the selected tags. If forcing is already running, the previous action is replaced without interruption.
	Stops forcing of addresses in the force table.
	Starts monitoring of the visible tags in the force table. The default setting for monitoring in basic mode is "permanent". In expanded mode an additional column is shown and you can set certain trigger points for monitoring tags.
	Starts monitoring of the visible tags in the force table. This command is executed immediately and the tags are monitored once.
	Displays the check box for the selection of tags to be forced.
	Indicates that an address cannot be fully forced. Example: It is possible to force the address QW0:P, but it is not possible to force the address QD0:P because this address area is potentially not available on the CPU.
	Indicates that an address cannot be monitored.
	Indicates that an address is being forced.
	Indicates that an address is being partly forced.
	Indicates that the associated peripheral address is being forced.
	Indicates that a syntax error occurred.
	Indicates that the address is selected but has not been forced yet.

Icon	Meaning
	Indicates that the selected tag was monitored for the value "1".
	Indicates that the selected tag was monitored for the value "0".
	Indicates that the address is being used more than once.
	Indicates that a substitute value is being used. Substitute values are values that are output to the process in case of signal output module faults or are used instead of a process value in the user program in case of signal input module faults. The substitute values can be assigned by the user (e.g., retain old value).

Layout of the force table (Page 1883)

11.4.4.6 Open and edit force table

Display force table

Introduction

You cannot create a new force table; one force table already exists for each CPU. It is permanently allocated to this CPU and cannot be copied or duplicated.

Requirements

A project with an allocated CPU has to be open.

Displaying a force table

The force table is always displayed below a CPU in the "Watch and force tables" folder.

Open force table

Requirements

A project with an allocated CPU must be created.

Procedure

Proceed as follows to open a force table:

1. Open the "Watch and force tables" folder below the desired CPU.
2. Double-click the "Force table" in this folder.

Result

The selected force table opens.

Save force table

Requirements

A project with an allocated CPU has been created.

Procedure

Proceed as follows to save a force table:

1. Enter the desired changes in the force table.
2. Select the "Save" command in the "Project" menu or click the "Save project" icon in the toolbar. Note that this save operation will save the entire project.

Result

The contents of the force table and the associated project are saved.

Note

You cannot rename a force table.

11.4.4.7 Entering tags in the force table

Basic principles for entering tags in the force table

Recommended procedure

Select the tags whose values you want to monitor or force, and enter them in the force table.

When entering tags in the force table, please note that these tags must be previously defined in the PLC tag table.

Example of filling out a force table

- You can enter the absolute address that is to be forced or monitored in the "Address" column or you can enter the symbolic name of the tag in the "Name" column.
- Select the display format you require from the drop-down list in the "Display format" column, if you do not want to use the default setting.

- Now you have to decide whether you want to monitor or force the entered tags. Enter the required force value and a comment in the appropriate columns of the force table.
- Note that only peripheral inputs and peripheral outputs can be forced and review the Safety precautions when forcing tags (Page 1899).

Create comment line

If required, you can create a comment row by entering the string "//" in the "Name" column.

Syntax check

When you enter tags in the force table, the syntax of each cell will be checked when you exit the cell. Incorrect entries are marked in red.

Note

When you place the mouse pointer in a cell marked in red, brief information is displayed with additional notes on the error.

Permitted operands for the force table

Permitted operands for the force table

The following table shows the operands that are permitted for forcing in the force table:

Permitted operand	Example of data type	Example (International mnemonics)
Peripheral input/peripheral output	BOOL	I0.0:P; Q0.0:P
Peripheral input/peripheral output	BYTE	IB1:P; QB1:P
Peripheral input/peripheral output	WORD	IW2:P; QW3:P
Peripheral input/peripheral output	DWORD	ID2:P; QD1:P

The following table shows the operands that are permitted for monitoring in the force table:

Permitted operand	Example of data type	Example (International mnemonics)
Input/output/bit memory	BOOL	I1.0, Q1.7, M10.1 I0.0:P
Input/output/bit memory	BYTE	IB1/QB10/MB100 IB1:P
Input/output/bit memory	WORD	IW1; QW10; MW100 IW2:P

Permitted operand	Example of data type	Example (International mnemonics)
Input/output/bit memory	DWORD	ID4; QD10; MD100 ID2:P
Timers	TIMER	T1
Counters	COUNTER	C1
Data block	BOOL	DB1.DBX1.0
Data block	BYTE	DB1.DBB1
Data block	WORD	DB1.DBW1
Data block	DWORD	DB1.DBD1

Note

You cannot enter "DB0..." because it is used by the system!

Permitted force values for the force table

Entering force values in the force table

The following table shows the operands that are permitted for entering force values in the force table:

Table 11-7 Bit operands

Possible bit operands	Example for permitted force values
I1.0:P	True
I1.1:P	False
Q1.0P	0
Q1.1:P	1
I2.0:P	2#0
I2.1:P	2#1

Table 11-8 Byte operands

Possible byte operands	Example for permitted force values
IB1:P	2#00110011
IB2:P	B#16#1F
QB14:P	1F
QB10:P	'a'
IB3:P	10

Table 11-9 Word operands

Possible word operands	Example for permitted force values
IW0:P	2#0011001100110011
IW2:P	W#16#ABCD
QW10:P	ABCD
QW12:P	B#(12, 34)
IW4:P	'ab'
IW6:P	12345
IW8:P	S5T#9S_340ms
IW10:P	C#123
IW12:P	D#2006-12-31

Table 11-10 Double word operands

Possible double word operands	Example for permitted force values
ID0:P	2#00110011001100110011001100110011
ID4:P	1.2
QD10:P	1.234.e4
QD14:P	Dw#16#abcdef10
ID8:P	16#ABCDEF10
ID12:P	b#(12,34,56,78)
ID16:P	L#-12
ID20:P	L#12
ID24:P	123456789
ID28:P	123456789
ID32:P	T#12s345ms
ID36:P	Tod#14:20:40.645
ID40:P	P#e0.0

Overview of the display formats

Display formats in the force table

The display format you select specifies the representation of a tag value.

When entering the address a display format is automatically preset. If you want to change this, you can select a display format from the drop-down list in the "Display formats" column. The drop-down list only offers the display formats which are valid for this data type. The display format that appears first in the list is the pre-selected format.

Example

The following table shows the 32-bit data types permitted for all CPU families in the force table and their possible display formats:

Data type	Possible display formats
BOOL	Bool, Hex, BCD, Octal, Bin, Dec, Dec+/-
BYTE	Hex, BCD, Octal, Bin, Dec, Dec+/-, Character
WORD	Hex, BCD, Octal, Bin, Dec, Dec+/-, Dec_Sequence, Character, SIMATIC_Timer, Date, Unicode_Character, Counter
DWORD	Hex, BCD, Octal, Bin, Dec, Dec+/-, Dec_Sequence, Character, Floating-point number, Time of day, Timer, Pointer, Unicode_Character
SINT	Dec, Dec+/-, Hex, BCD, Octal, Bin, Character
INT	Dec, Dec+/-, Hex, BCD, Octal, Bin, Character, Unicode_Character, Dec_Sequence, SIMATIC_Timer, Counter, Date
DINT	Dec, Dec+/-, Hex, BCD, Octal, Bin, Character, Unicode_Character, Dec_Sequence, Floating-point number, Time of day, Timer, Pointer
USINT	Dec, Dec+/-, Hex, BCD, Octal, Bin, Character
UINT	Dec, Dec+/-, Hex, BCD, Octal, Bin, Character, Unicode_Character, Dec_Sequence, SIMATIC_Timer, Counter, Date
UDINT	Dec, Dec+/-, Hex, BCD, Octal, Bin, Character, Unicode_Character, Dec_Sequence, Floating-point number, Time of day, Timer, Pointer
REAL	Floating-point number, Hex, BCD, Octal, Bin, Character, Unicode_Character,Dec, Dec+/-, Dec_Sequence, Time of day, Timer, Pointer
DATE	Date, Dec, Hex, BCD, Bin
TIME_OF_DAY	Time of day, Dec, Hex, BCD, Bin
TIME	Timer, Hex, BCD, Bin
DATE_AND_TIME	Date and time,
TIMER	SIMATIC_Timer, Hex, BCD, Bin
CHAR	Character, Hex, BCD, Octal, Bin, Dec, Dec+/-
WCHAR	Unicode_Character, Character, Hex, BCD, Octal, Bin, Dec, Dec+/-
STRING	Character string
WSTRING	Unicode_character string
POINTER	Pointer, Hex, BCD, Octal, Bin, Character, Unicode_Character, Dec, Dec +/-,Dec_Sequence, Floating-point number, Time of day, Timer, Block number
COUNTER	Counter, Hex, BCD, Bin
S5TIME	SIMATIC_Timer, Hex, BCD, Bin

For the S7-1200 CPU family, all 32-bit data types are permitted (see table above), as well as the 64-bit data type LREAL with the following possible display formats:

Data type	Possible display formats
LREAL	In a project created with TIA Portal < V12: Floating-point number Note: The display of LREAL is limited to 13 digits plus exponent.
LREAL	In a project created with TIA Portal >= V12: Floating-point number, Hex, BCD, Octal, Bin, Character, Unicode_Character, Dec, Dec+/-, Dec_Sequence, Time of day, Timer, Date and time Note: The display of LREAL is limited to 13 digits plus exponent.

For the S7-1500 CPU family, in addition to 32-bit data types, the 64-bit data types listed in the table are also permitted with the following possible display formats:

Data type	Possible display formats
LWORD	Hex, Octal, BCD, Bin, Character, Unicode_Character, Dec, Dec+/-, Dec_Sequence, Floating-point number, Time of day, Timer, Date and time
LINT	Dec+/-, Dec, Hex, BCD, Octal, Bin, Character, Unicode_Character, Dec_Sequence, Time of day, Timer, Date and time
ULINT	Dec, Dec+/-, Hex, BCD, Octal, Bin, Character, Unicode_Character, Dec_Sequence, Time of day, Timer, Date and time
LREAL	Floating-point number, Hex, BCD, Octal, Bin, Character, Unicode_Character, Dec, Dec+/-, Dec_Sequence, Time of day, Timer, Date and time
LTIME	Timer, Dec+/-, Dec, Hex
LTOD	Dec, Hex, BCD, Bin, Time of day
LDT	Dec, Hex, Date and time

For more information, refer to the description of the valid data types (Page 1908).

Note

Rounding of floating-point numbers

In the force table, floating-point numbers are stored as binary numbers in IEEE format. Because not every floating point number (real, longreal) that can be displayed on the user interface can be mapped to the IEEE format, there is a possibility that floating-point numbers will be rounded. If a rounded floating-point number in the force table is copied and, in turn, inserted in another input field, the rounding may cause a slight difference.

Note

Only symbolic addressing is possible

In the force table, LongDataTypes such as LWORD or LREAL can only be addressed symbolically.

Selecting the display format for tags

Procedure

To select the display format of the tags, follow these steps:

1. Enter the desired address in the force table.
2. Click the desired cell in the "Display format" column, and open the drop-down list. The permitted display formats are shown in the drop-down list.
3. Select the desired display format from the drop-down list.

Note

If the selected display format cannot be applied, then the last selected display format will be displayed automatically.

Creating and editing comment lines

Basic principles of comment lines

In addition to the row-related comments in the comment column, you can now also create complete comment lines to enhance the structure of the force table.

The contents of the comment line are stored in the "Languages & Resources" folder in the "Project texts" tab and can be compiled in other project languages.

Creating comment lines

To create comment lines, follow these steps:

1. Open the force table and enter the required addresses.
2. To create a comment line, enter the character string "//" in the "Name" column. No comment lines can be created in the other columns.

3. Enter the required comment in the comment line. The entered comment is shown in green.
4. To show all comments you entered, double-click "Project texts" in the project tree under "Languages & Resources".
5. If you are working in multi-lingual projects and want your comment to be translated into other languages, you can set the project languages required in addition to the editing language in the project tree under "Languages & Resources > Project languages".

Deleting comment lines

To delete comment lines, follow these steps:

1. Open a force table containing comment lines.
2. Delete the entire comment including the introductory string "//", if you no longer require this.
3. Alternatively, delete only the introductory string "//". In this case the existing comment is retained and is displayed in the "Comment" column in the force table.

Note

Deleting comment lines

When you delete comment lines the project languages and any existing translations for these comments are also deleted.

11.4.4.8 Monitoring tags in the force table

Introduction to monitoring tags in the force table

Introduction

Use the force table to monitor the tags of the configured input and output modules in the CPU, dependent on the monitoring mode (Page 1895) you have selected. An online connection to the CPU must exist to monitor tags.

Options for monitoring tags

The following options are available for monitoring tags:

- Monitor all
  This command starts the monitoring of all visible tags in the active force table, dependent on the selected monitoring mode:
  - In basic mode, the monitoring mode is set to "permanent" by default.
  - In expanded mode, you can specify defined trigger points for the monitoring of tags.

  Note

  If the monitoring mode is changed while in expanded mode and then a switch is made to basic mode, the monitoring mode set before will also be applied in basic mode.

- Monitor now
  This command starts the monitoring of the visible tags in the active force table immediately and once only.

CPU-specific limitations when monitoring tags

The following CPU-specific differences exist:

- CPU S7-300/400:
  CPUs from this family can only monitor the first 30 characters of a string.
- CPU S7-1200:
  CPUs from this family can monitor a string up to the total size of 254 characters.

Setting the monitoring mode in the force table

Introduction

By selecting the monitoring mode, you specify the trigger point and the duration of tag monitoring in the force table.

Possible monitoring mode (duration of monitoring)

The following selection options are available:

- Permanent
- Once only, at start of scan cycle
- Once only, at end of scan cycle
- Permanently, at start of scan cycle
- Permanently, at end of scan cycle
- Once only, at transition to STOP
- Permanently, at transition to STOP

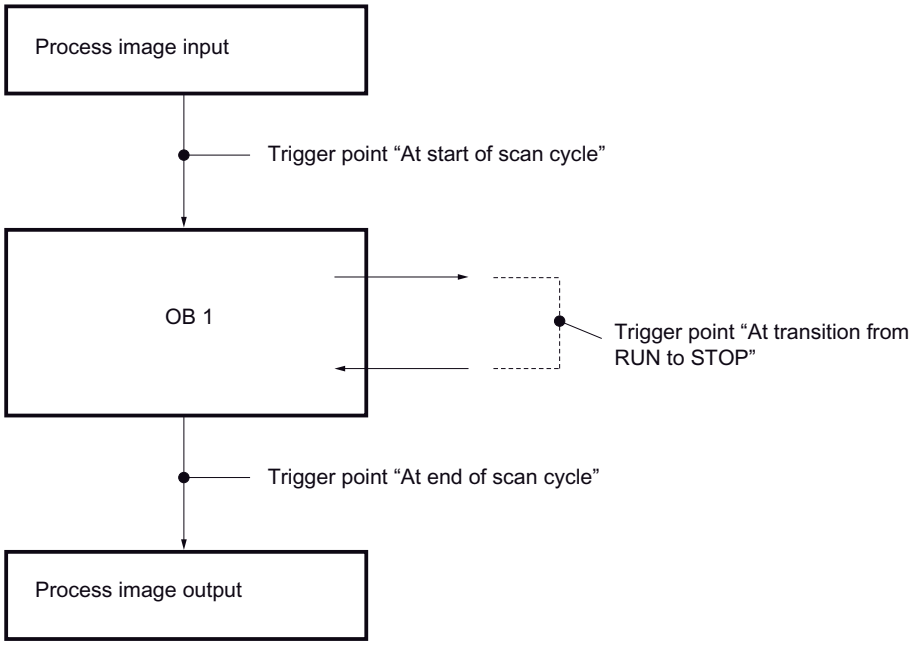
Special features when using "Permanent" mode

The "Permanent" mode is executed as follows for the monitoring of tags: The inputs are monitored at the end of the cycle and the outputs at the start of the cycle.

Selecting the trigger point

The trigger points "Beginning of scan cycle", "End of scan cycle", and "Switch to stop" specify the time at which the tags are to be read from the CPU or updated in the CPU.

The following diagram shows the position of these trigger points:



"Monitor all" command for tags

Introduction

Use the "Monitor all" command to start monitoring the visible tags in the active force table. In basic mode of the force table, the default setting for the monitoring mode is "permanent". In expanded mode, you can specify defined trigger points for the monitoring of tags. In this case, the tags are monitored with reference to the specified trigger points.

Requirements

An online connection to the CPU exists.

Procedure

To execute the "Monitor all" command, follow these steps:

1. Enter the tags to be monitored and the corresponding addresses in the force table.
2. Switch to expanded mode by clicking the icon "Show/hide advanced setting columns" in the toolbar.
3. If you want to change the default monitoring mode for a tag, click the appropriate cell in the "Monitor with trigger" column and select the desired monitoring mode from the drop-down list.
4. Click the "Monitor all" icon in the toolbar.

Result

The tags of the active force table will be monitored using the set monitoring mode.

"Monitor now" command for tags

Introduction

The "Monitor now" command starts the monitoring of tags immediately without reference to defined trigger points. The tag values are read out only once and displayed in the force table.

Requirements

An online connection to the CPU exists.

Procedure

To execute the "Monitor now" command, follow these steps:

1. Enter the tags to be monitored and the corresponding addresses in the force table.
2. Click the "Monitor now" icon in the toolbar.

Result

The tags of the active force table are monitored immediately and once only.

11.4.4.9 Forcing tags in the force table

Introduction to forcing tags

Introduction

You can use the force table to assign permanent values to individual tags of the user program. This action is referred to as forcing. Only peripheral inputs and peripheral outputs can be forced.

To use the forcing function, you must have an online connection to the CPU and the utilized CPU must support this functionality.

If you open a force table in the "Watch and force tables" folder below a CPU on which a force job is already running, you will first be prompted to update the display of the forced operand. Forcing or stopping forcing in the open force table is only possible following this command.

Possible applications

By permanently assigning defined values to tags, you can specify defined default settings for your user program and, thus, test the programmed functions. Forcing is possible in basic mode and in expanded mode (Page 1884).

Caution when forcing tags

Before forcing, make sure that you review the safety precautions for this procedure (Page 1899).

Danger

Prevent personal injury and material damage!

Remember that an incorrect action when executing the "Force" function can:

- Harm persons or pose a health hazard.
- Cause damage to machinery or the entire plant.

Options for forcing tags

The following options are available for forcing tags:

- Force to "0"
  This command forces the selected address in the CPU to the force value "0".
- Force to "1"
  This command forces the selected address in the CPU to the force value "1".

- Force all
  This command starts the forcing of enabled addresses in the active force table or replaces an existing force job without interruption.
- Stop forcing
  This command stops the forcing of all addresses in the active force table.

Constraints when forcing tags

Note the following constraints when forcing:

- Forcing is always dependent on the operand scope of the CPU used.
- In principle, only peripheral inputs and peripheral outputs can be forced.
- If the function "Enable peripheral outputs" is active on your CPU, then forcing is not possible. If desired, deactivate this function in the watch table.

Unique aspects when forcing tags

Note that forcing of tags will overwrite values in the CPU and will continue even after the online connection to the CPU is terminated.

- **Stop forcing**
  Terminating the online connection is not sufficient to stop the forcing operation! To stop forcing, you must select the "Online > Force > Stop forcing" command. Only then will the tags that are visible in the active force table no longer be forced.
- **Stop forcing of individual tags**
  The "Online > Force > Stop forcing" command always applies to all tags displayed in the force table. To stop forcing individual tags, you must clear the check mark for forcing of these tags in the force table and restart forcing using the "Online > Force > Force all" command.

Safety precautions when forcing tags

Safety precautions when forcing tags

Because the forcing function allows you to intervene permanently in the process, observance of the following notices is essential:

Danger

Prevent personal injury and material damage!

Note that an incorrect action when executing the "Force" function can:

- Harm persons or pose a health hazard.
- Cause damage to machinery or the entire plant.

Caution

Prevent personal injury and material damage!

- Before you start the "Force" function, you should ensure that no one else is currently executing this function on the same CPU.
- Forcing can only be stopped by clicking the "Stop forcing" icon or using the "Online > Force > Stop forcing" command. Closing the active force table does **not** stop the forcing!
- Forcing can **not** be undone!
- Review the differences between " modifying tags" (Page 1873) and "forcing tags" (Page 1898).
- If a CPU does not support the "Force" function, the relevant icons cannot be selected.
- If the function "Enable peripheral outputs" is active on your CPU, then forcing is **not** possible on this CPU. If desired, deactivate this function in the watch table.

Updating forced operands

Introduction

If a force job is already running on a CPU, after opening the force table, you first need to make sure that the operands and values currently being forced on the CPU are displayed in the force table.

The command "Online" > "Force" > "Update forced operands" updates all operands and values currently being forced on the CPU in the open force table.

"Force" or "Stop forcing" in the open force table is only possible following this command.

Caution when forcing tags

Before forcing, make sure you are familiar with the safety precautions when forcing tags (Page 1899).

Danger

Prevent personal injury and material damage!

Remember that an incorrect action when executing the "Force" function can:

- Harm persons or pose a health hazard.
- Cause damage to machinery or the entire plant.

Requirement

- An online connection to the CPU is possible.
- A force job is currently running on the CPU being used.

Procedure

To update the forced operands and values, follow these steps:

1. Open a force table.
2. Establish an online connection to the CPU.
3. Confirm the "Update forced operands" dialog that follows with "Yes".

Result

All forced operands in the open force table are updated with the relevant values. A red "F" is displayed in the first column indicating which operands are being forced.

This enables the "Force all" and "Stop forcing" buttons and you can select these functions.

Note

When forcing, note the following:

- Forcing **cannot** be undone!
- Terminating the online connection does **not** stop the forcing function!
- To stop forcing, the forced address must be visible in the active force table.

Force tags to "0"

Introduction

You can use the force function to assign permanent values to individual tags of a user program.

Caution when forcing tags

Before forcing, you must review the safety precautions when forcing tags (Page 1899).

Danger

Prevent personal injury and material damage!

Note that an incorrect action when executing the "Force" function can:

- Pose a risk to the life or health of persons.
- Cause damage to machinery or the entire plant.

Requirements

- An online connection to the CPU exists.
- The utilized CPU supports the force function.
- The "Enable peripheral outputs" function is **not** enabled on the CPU on which the tags are to be forced. If desired, deactivate this function in the watch table.

Procedure

To force tags to "0", follow these steps:

1. Open the force table.
2. Enter the desired address in the force table.
3. Select the "Online > Force> Force to 0" command in order to force the selected address with the specified value.
4. Confirm the next dialog with "Yes".

Result

The selected address is forced to "0". The yellow triangle is no longer displayed. A red "F" is displayed in the first column, for example, indicating that the tag is being forced.

Stop forcing

To stop forcing, follow these steps:

1. Open the force table.
2. Select the "Online > Force > Stop forcing" command.
3. Confirm the next dialog with "Yes".

Result

Forcing of the selected values is stopped. The red "F" in the first column is no longer displayed. The yellow triangle reappears behind the check box again to indicate that the address is selected for forcing but is not being forced at the moment.

Note

When forcing, note the following:

- Forcing **cannot** be undone!
- Terminating the online connection does **not** stop the forcing!
- To stop forcing, the forced address must be visible in the active force table.

Force tags to "1"

Introduction

You can use the force function to assign permanent values to individual tags of a user program.

Caution when forcing tags

Before forcing, you must review the safety precautions when forcing tags (Page 1899).

Danger

Prevent personal injury and material damage!

Note that an incorrect action when executing the "Force" function can:

- Endanger the life or health of personnel
- Cause damage to machinery or the entire plant.

Requirements

- An online connection to the CPU exists.
- The utilized CPU supports the force function.
- The "Enable peripheral outputs" function is **not** enabled on the CPU on which the tags are to be forced. If desired, deactivate this function in the watch table.

Procedure

To force tags to "1", follow these steps:

1. Open the force table.
2. Enter the desired address in the force table.
3. Select the "Online > Force> Force to 1" command in order to force the selected address with the specified value.
4. Confirm the next dialog with "Yes".

Result

The selected address is forced to "1". The yellow triangle is no longer displayed. A red "F" is displayed in the first column, for example, indicating that the tag is being forced.

Stop forcing

To stop forcing, follow these steps:

1. Open the force table.
2. Select the "Online > Force > Stop forcing" command.
3. Confirm the next dialog with "Yes".

Result

Forcing of the selected values is stopped. The red "F" in the first column is no longer displayed. The yellow triangle reappears behind the check box again to indicate that the address is selected for forcing but is not being forced at the moment.

Note

When forcing, note the following:

- Forcing **cannot** be undone!
- Terminating the online connection does **not** stop the forcing!
- To stop forcing, the forced address must be visible in the active force table.

"Force all" command for tags

Introduction

You can use the force function to assign permanent values to individual tags of a user program.

If forcing is already active, this forcing operation is replaced without interruption by the "Online > Force > Force all" command. Any forced addresses that are not selected will no longer be forced.

Caution when forcing tags

Before forcing, you must review the safety precautions when forcing tags (Page 1899).

Danger

Prevent personal injury and material damage!

Note that an incorrect action when executing the "Force" function can:

- Pose a risk to the life or health of persons.
- Cause damage to machinery or the entire plant.

Requirements

- An online connection to the CPU exists.
- The utilized CPU supports the force function.
- The "Enable peripheral outputs" function is **not** enabled on the CPU on which the tags are to be forced. If desired, deactivate this function in the watch table.

Procedure

To force tags with the "Online > Force > Force all" command, follow these steps:

1. Open the force table.
2. Enter the desired addresses and force values in the force table.
3. Select the addresses to be forced by selecting the check boxes for forcing in the column after the "Force value".
   A yellow triangle appears behind the selected check box, indicating that the address is selected for forcing but is not being forced at the moment.
4. Select the "Online > Force> Force all" command in order to force the selected addresses with the specified values.
5. Confirm the next dialog with "Yes".

Result

The selected addresses are forced to the specified values. The yellow triangle is no longer displayed. A red "F" is displayed in the first column, for example, indicating that the tag is being forced.

Stop forcing

To stop forcing, follow these steps:

1. Open the force table.
2. Select the "Online > Force > Stop forcing" command.
3. Confirm the next dialog with "Yes".

Result

Forcing of the selected addresses is stopped. The red "F" in the first column is no longer displayed. The yellow triangle reappears behind the check box again to indicate that the address is selected for forcing but is not being forced at the moment.

Note

When forcing, note the following:

- Forcing **cannot** be undone!
- Terminating the online connection does **not** stop the forcing!
- To stop forcing, the forced address must be visible in the active force table.

11.4.4.10 Stop forcing tags

Stop forcing all tags

Introduction

Note the following before you stop forcing tags:

- Stopping forcing **cannot** be undone!
- Terminating the online connection does **not** stop the forcing!
- To stop forcing, the forced address must be visible in the active force table.

Caution when forcing tags

Before forcing, you must review the safety precautions when forcing tags (Page 1899).

Danger

Prevent personal injury and material damage!

Note that an incorrect action when stopping the "Force" function can:

- Pose a risk to the life or health of persons.
- Cause damage to machinery or the entire plant.

Requirements

- Tags are forced in a force table.
- An online connection to the CPU exists.

- The utilized CPU supports the force function.
- The "Enable peripheral outputs" function is not enabled on the CPU on which the tags are to be forced. If desired, deactivate this function in the watch table.

Procedure

Proceed as follows to stop **forcing all tags** :

1. Open the force table.
2. Select the "Online > Force > Stop forcing" command in order to stop forcing the displayed addresses.
3. Confirm the "Stop forcing" dialog with "Yes".

Result

The forcing of all tags is stopped. The red "F" in the first column is no longer displayed. The yellow triangle reappears behind the check box again to indicate that the address is flagged for forcing but is not being forced at the moment.

Stop forcing individual tags

Introduction

Note the following before you stop forcing tags:

- Stopping forcing **cannot** be undone!
- Terminating the online connection does **not** stop the forcing!
- To stop forcing, the forced address must be visible in the active force table.

Caution when forcing tags

Before forcing, you must review the safety precautions when forcing tags (Page 1883).

Danger

Prevent personal injury and material damage!

Note that an incorrect action when stopping the "Force" function can:

- Pose a risk to the life or health of persons.
- Cause damage to machinery or the entire plant.

Requirements

- Tags are forced in a force table.
- An online connection to the CPU exists.

- The utilized CPU supports the force function.
- The "Enable peripheral outputs" function is not enabled on the CPU on which the tags are to be forced. If desired, deactivate this function in the watch table.

Procedure

Proceed as follows to stop **forcing individual tags** :

1. Open the force table.
2. Deactivate the check boxes for the addresses that are no longer to be forced.
3. Reselect the "Online > Force" command.

Result

Forcing of the disabled addresses will be stopped. The red "F" in the first column is no longer displayed. The yellow triangle reappears behind the check box again to indicate that the address is flagged for forcing but is not being forced at the moment.

11.5 Data types

11.5.1 Overview of the valid data types

Validity of data type groups

The data type groups define the properties of the data, for example, the representation of the contents and the valid memory areas. In the user program, you can use predefined data type or also data types that you have defined.

The following tables show the availability of predefined data types in the various S7-CPUs:

Table 11-11 Binary numbers

Binary numbers	S7-300/400	S7-1200	S7-1500
BOOL (Page 1912)	X	X	X
Bit strings			
BYTE (Page 1913)	X	X	X
WORD (Page 1914)	X	X	X
DWORD (Page 1915)	X	X	X
LWORD (Page 1915)	-	-	X

Note

Depending on the CPU version, the actually valid data types can deviate slightly from the table.

11.5.2 Binary numbers

11.5.2.1 BOOL (bit)

Description

An operand of data type BOOL represents a bit value and contains one of the following values:

- TRUE
- FALSE

The following table shows the properties of data type BOOL:

Length (bits)	Format	Range of values	Examples of value input
1	Boolean	FALSE or TRUE BOOL#0 or BOOL#1 BOOL#FALSE or BOOL#TRUE	TRUE BOOL#1 BOOL#TRUE
	Unsigned integers	0 or 1	1
	Binary numbers	2#0 or 2#1	2#0
	Octal numbers	8#0 or 8#1	8#1
	Hexadecimal numbers	16#0 or 16#1	16#1

Note

Applies to CPUs of the S7-1500 series

For a block with the block property "Optimized block access", the bit has a length of 1 byte.

Data type conversion for S7-1200: (Page 2091)

11.5.2.2 Bit strings

BYTE (byte)

Description

An operand of data type BYTE is a bit string of 8 bits.

The following table shows the properties of data type BYTE:

Length (bits)	Format	Value range	Examples of value input
8	Unsigned integers[1)]	-128 to +127 or 0 to +255	15, BYTE#15, B#15
	Binary numbers	2#0 to 2#11111111	2#00001111, BYTE#2#00001111, B#2#00001111
	Octal numbers	8#0 to 8#377	8#17, BYTE#8#17, B#8#17
	Hexadecimal numbers	B#16#0 to B#16#FF, 16#0 to 16#FF	16#0F, BYTE#16#0F, B#16#0F
[1)] The value range depends on the relevant interpretation or conversion.			

Note

The BYTE data type cannot be compared for more than or less than. It can only be supplied with the same decimal data that can be processed by the SINT and USINT data types.

WORD

Description

An operand of data type WORD is a bit string of 16 bits.

The following table shows the properties of data type WORD:

Length (bits)	Format	Value range	Examples of value input
16	Unsigned integers	-32768 to 65535	61680, WORD#61680, W#61680
	Binary numbers	2#0 to 2#1111111111111111	2#1111000011110000, WORD#2#1111000011110000, W#2#1111000011110000
	Octal numbers	8#0 to 8#177777	8#170360, WORD#8#170360, W#8#170360
	Hexadecimal numbers	W#16#0 to W#16#FFFF, 16#0 to 16#FFFF	16#F0F0, WORD#16#F0F0, W#16#F0F0
	BCD	C#0 to C#999	C#55
	Decimal sequence	B#(0, 0) to B#(255, 255)	B#(127, 200)

Note

The WORD data type cannot be compared for more than or less than. It can only be supplied with the same decimal data that can be processed by the INT and UINT data types.

DWORD

Description

An operand of data type DWORD is a bit string of 32 bits.

The following table shows the properties of data type DWORD:

Length (bits)	Format	Value range	Examples of value input
32	Unsigned integers	-2147483648 to 4294967295	15793935, DWORD#15793935, DW#15793935
	Binary numbers	2#0 to 2#11111111111111111111111111111111	2#00000000111100001111111100001111, DWORD#2#00000000111100001111111100001111, DW#2#00000000111100001111111100001111
	Octal numbers	8#0 to 8#37777777777	8#74177417, DWORD#8#74177417, DW#8#74177417
	Hexadecimal numbers	DW#16#00000000 to DW#16#FFFFFFFF, 16#00000000 to 16#FFFFFFFF	16#00F0FF0F, DWORD#16#00F0FF0F, DW#16#00F0FF0F
	Decimal sequence	B#(0, 0, 0, 0) to B#(255, 255, 255, 255)	B#(127, 200, 127, 200)

Note

The DWORD data type cannot be compared for more than or less than. It can only be supplied with the same decimal data that can be processed by the DINT and UDINT data types.

LWORD

Description

An operand of data type LWORD is a bit string of 64 bits.

The following table shows the properties of data type LWORD:

Length (bits)	Format	Value range	Examples of value input
64	Unsigned integers	-9223372036854775808 to 18446744073709551615	26123590360715, LWORD#26123590360715, LW#26123590360715
	Binary numbers	2#0 to 2#1111111111111111111111111111111111111111111111111111111111111111	2#0000000000000000000010111110000100101111010100101101111010001011, LWORD#2#0000000000000000000101111100001001011110101001011101000101, LW#2#0000000000000000001011111000010010111101010010111010001011
	Octal numbers	8#0 to 8#1777777777777777777777	8#13724557213, LWORD#8#13724557213, LW#8#13724557213
	Hexadecimal numbers	LW#16#00000000 to LW#16#FFFFFFFFFFFFFFFF, 16#00000000 to 16#FFFFFFFFFFFFFFFF	16#000000005F52DE8B, LWORD#16#000000005F52DE8B, LW#16#000000005F52DE8B
	Decimal sequence	B#(0, 0, 0, 0, 0, 0, 0, 0) to B#(255, 255, 255, 255, 255, 255, 255, 255)	B#(127, 200, 127, 200, 127, 200, 127, 200)

Note

The LWORD data type cannot be compared for more than or less than. It can only be supplied with the same decimal data that can be processed by the LINT and ULINT data types.

11.5.3 Integers

11.5.3.1 SINT (8-bit integers)

Description

An operand of data type SINT (Short INT) has a length of 8 bits and consists of two components: a sign and a numerical value in the two's complement. The signal states of bits 0 to 6 represent the number value. The signal state of bit 7 represents the sign. The sign may assume "0" for the positive, or "1" for the negative signal state.

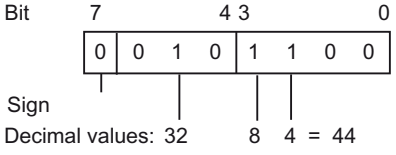
An operand of data type SINT occupies one BYTE in the memory.

The following table shows the properties of data type SINT:

Length (bits)	Format	Range of values	Examples of value input
8	Signed integers	-128 to 127	+44, SINT#+44 The value range is a maximum of SINT#255 when using the type SINT#. This value is interpreted as a whole number with -1.
	Binary numbers (only positive)	2#0 to 2#01111111	2#00101100, SINT#2#00101100
	Octal numbers (only positive)	8#0 to 8#177	8#54, SINT#8#54
	Hexadecimal numbers (only positive)	16#0 to 16#7F	16#2C, SINT#16#2C The value range is a maximum of SINT#16#FF when using the type SINT#. This value is interpreted as a whole number with -1.

Example

The following figure shows the integer +44 as a binary number:



See also

Overview of the valid data types (Page 1908)

11.5.3.2 USINT (8-bit integers)

Description

An operand of data type USINT (Unsigned Short INT) has a length of 8 bits and contains unsigned numerical values:

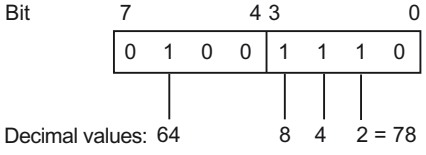
An operand of data type USINT occupies one BYTE in the memory.

The following table shows the properties of data type USINT:

Length (bits)	Format	Range of values	Examples of value input
8	Unsigned integers	0 to 255	78, USINT#78
	Binary numbers	2#0 to 2#11111111	2#01001110, USINT#2#01001110
	Octal numbers	8#0 to 8#377	8#116, USINT#8#116
	Hexadecimal numbers	16#0 to 16#FF	16#4E, USINT#16#4E

Example

The following figure shows the integer 78 as a binary number:



See also

Overview of the valid data types (Page 1908)

Data type conversion for S7-1200: (Page 2091)

11.5.3.3 INT (16-bit integers)

Description

An operand of data type INT has a length of 16 bits and consists of two components: a sign and a numerical value in the two's complement. The signal states of bits 0 to 14 represent the number value. The signal state of bit 15 represents the sign. The sign may assume "0" for the positive, or "1" for the negative signal state.

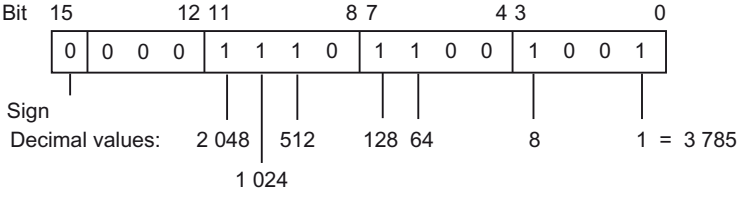
An operand of data type INT occupies two BYTE in the memory.

The following table shows the properties of data type INT:

Length (bits)	Format	Range of values	Examples of value input
16	Signed integers	-32768 to 32767	+3785, INT#+3785
	Binary numbers (only positive)	2#0 to 2#0111111111111111	2#0000111011001001, INT#2#0000111011001001
	Octal numbers	8#0 to 8#77777	8#7311, INT#8#7311
	Hexadecimal numbers (only positive)	16#0 to 16#7FFF	16#0EC9, INT#16#0EC9

Example

The following figure shows the integer +3785 as a binary number:



See also

Overview of the valid data types (Page 1908)

Data type conversion for S7-1200: (Page 2091)

11.5.3.4 UINT (16-bit integers)

Description

An operand of data type UINT (Unsigned INT) has a length of 16 bits and contains unsigned numerical values.

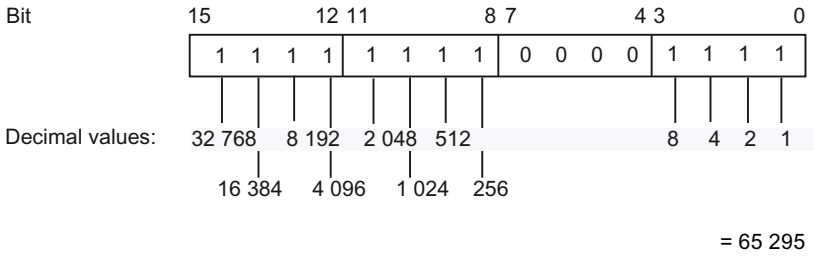
An operand of data type UINT occupies two BYTE in the memory.

The following table shows the properties of data type UINT:

Length (bits)	Format	Range of values	Examples of value input
16	Unsigned integers	0 to 65535	65295, UINT#65295
	Binary numbers	2#0 to 2#1111111111111111	2#1111111100001111, UINT#2#1111111100001111
	Octal numbers	8#0 to 8#177777	8#177417, UINT#8#177417
	Hexadecimal numbers	16#0 to 16#FFFF	16#FF0F, UINT#16#FF0F

Example

The following figure shows the integer 65295 as a binary number:



See also

Overview of the valid data types (Page 1908)

Data type conversion for S7-1200: (Page 2091)

11.5.3.5 DINT (32-bit integers)

Description

An operand of data type DINT (Double INT) has a length of 32 bits and consists of two components: a sign and a numerical value in the two's complement. The signal states of bits 0 to 30 represent the number value. The signal state of bit 31 represents the sign. The sign may assume "0" for the positive, or "1" for the negative signal state.

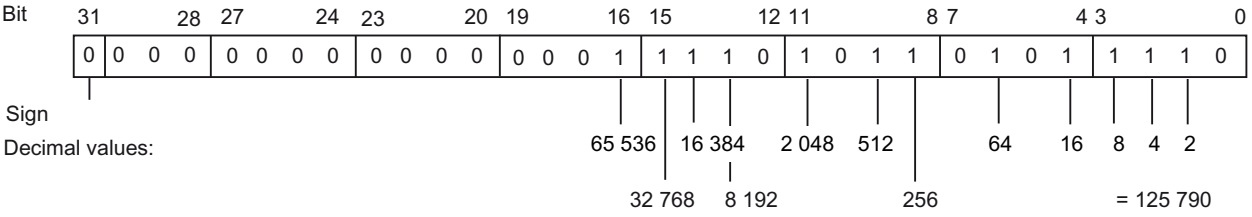
An operand of data type DINT occupies four BYTE in the memory.

The following table shows the properties of data type DINT:

Length (bits)	Format	Range of values	Examples of value input
32	Signed integers	-2147483648 to +2147483647	125790, DINT#125790, L#275
	Binary numbers (only positive)	2#0 to 2#01111111111111111111111111111111	2#00000000000000011110101101011110, DINT#2#00000000000000011110101101011110
	Octal numbers (only positive)	8#0 to 8#17777777777	8#365536, DINT#8#365536
	Hexadecimal numbers	16#00000000 to 16#7FFFFFFF	16#0001EB5E, DINT#16#0001EB5E

Example

The following figure shows the integer +125790 as a binary number:



See also

Overview of the valid data types (Page 1908)

Data type conversion for S7-1200: (Page 2091)

11.5.3.6 UDINT (32-bit integers)

Description

An operand of data type UDINT (Unsigned Double INT) has a length of 32 bits and contains unsigned numerical values.

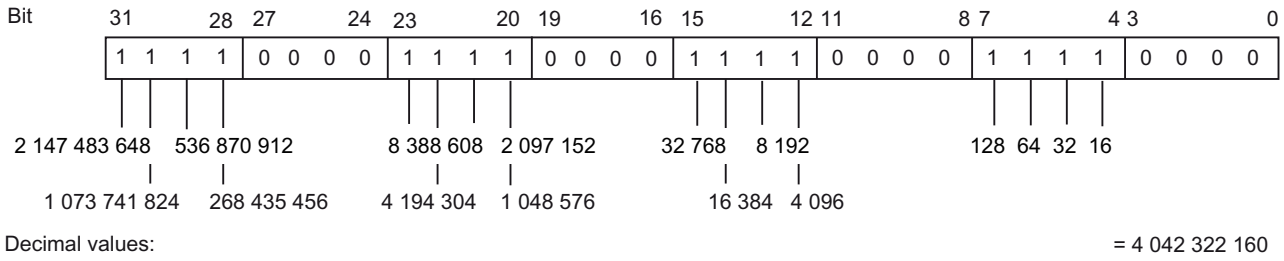
An operand of data type UDINT occupies four BYTE in the memory.

The following table shows the properties of data type UDINT:

Length (bits)	Format	Range of values	Examples of value input
32	Unsigned integers	0 to 4294967295	4042322160, UDINT#4042322160
	Binary numbers	2#0 to 2#11111111111111111111111111111111	2#11110000111100001111000011110000, UDINT#2#11110000111100001111000011110000
	Octal numbers	8#0 to 8#37777777777	8#36074170360, UDINT#8#36074170360
	Hexadecimal numbers	16#00000000 to 16#FFFFFFFF	16#F0F0F0F0, UDINT#16#F0F0F0F0

Example

The following figure shows the integer 4042322160 as a binary number:



See also

Overview of the valid data types (Page 1908)

Data type conversion for S7-1200: (Page 2091)

11.5.3.7 LINT (64-bit integers)

Description

An operand of data type LINT (Long INT) has a length of 64 bits and consists of two components: a sign and a numerical value in the two's complement. The signal states of bits 0 to 62 represent the number value. The signal state of bit 63 represents the sign. The sign may assume "0" for the positive, or "1" for the negative signal state.

An operand of data type LINT occupies eight BYTE in the memory.

The following table shows the properties of data type LINT:

Length (bits)	Format	Value range	Examples of value input
64	Signed integers	-9223372036854775808 to +9223372036854775807	+154325790816159, LINT# +154325790816159
	Binary numbers (only positive)	2#0 to 2#0111111111111111111111111111111111111111111111111111111111111111	2#0000000000000000100011000101101111000101111100001111011110011111, LINT#2#0000000000000000100011000100101101111000101111100001111011110011111
	Octal numbers	8#0 to 8#7777777777777777777	8#4305570574173637, LINT#8#4305570574173637
	Hexadecimal numbers (only positive)	16#0 to 16#7FFFFFFFFFFFFFFF	16#00008C5BC5F0F79F, LINT#16#00008C5BC5F0F79F

Example

The following figure shows the integer +154325790816159 as a binary number:

11.5.3.8 ULINT (64-bit integers)

Description

An operand of data type ULINT (Unsigned Long INT) has a length of 64 bits and contains unsigned numerical values.

An operand of data type ULINT occupies eight BYTE in the memory.

The following table shows the properties of data type ULINT:

Length (bits)	Format	Value range	Examples of value input
64	Unsigned integers	0 to 18446744073709551615	154325790816159, ULINT#154325790816159
	Binary numbers	2#0 to 2#1111111111111111111111111111111111111111111111111111111111111111	2#0000000000000000100011000101101110001011111000011110111100111111, ULINT#2#0000000000000000100011000101101111000101111100001111011110011111
	Octal numbers	8#0 to 8#1777777777777777777777	8#4305570574173637, ULINT#8#4305570574173637
	Hexadecimal numbers	16#0 to 16#FFFFFFFFFFFFFFFF	16#00008C5BC5F0F79F, ULINT#16#00008C5BC5F0F79F

Example

The following figure shows the integer 154325790816159 as a binary number:

11.5.4 Floating-point numbers

11.5.4.1 REAL

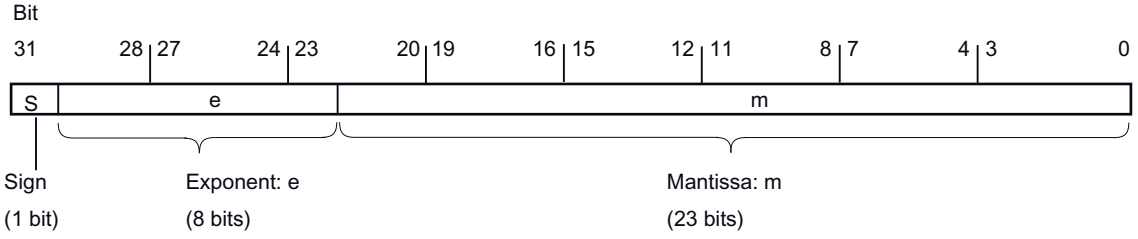
Description

Operands of the data type REAL have a length of 32 bits and are used to represent floating-point numbers. An operand of the REAL data type consists of the following three components:

- Sign: The sign is determined by the signal state of bit 31. The bit 31 assume the value "0" (positive) or "1" (negative).
- 8-bit exponents to basis 2: The exponent is increased by a constant (base, +127), so that it has a value range of 0 to 255.
- 23-bit mantissa: Only the fraction part of the mantissa is shown. The integer part of the mantissa is always 1 with normalized floating-point numbers and is not stored.

The REAL data type is processed with a precision of 6 digits.

The following figure shows the structure of the REAL data type:



Note

With floating-point numbers, only the precision defined by the IEEE754 standard is stored. Additionally specified decimals are rounded off according to IEEE754.

The number of decimal places may decrease for frequently nested arithmetic calculations.

If more decimal places are specified than can be stored by the data type, the number is rounded to the value corresponding to the precision allowed by this value range.

The following table shows the properties of data type REAL:

Length (bits)	Format	Value range	Examples of value input
32	Floating-point numbers according to IEEE754	-3.402823e+38 to -1.175495e-38 ±0,0 +1.175495e-38 to +3.402823e+38	1.0e-5; REAL#1.0e-5
	Floating-point numbers		1.0; REAL#1.0

Overview of the valid data types (Page 1908)

Data type conversion for S7-1200: (Page 2091)

Calculating with floating-point numbers (REAL and LREAL) in SCL (Page 290)

11.5.4.2 LREAL

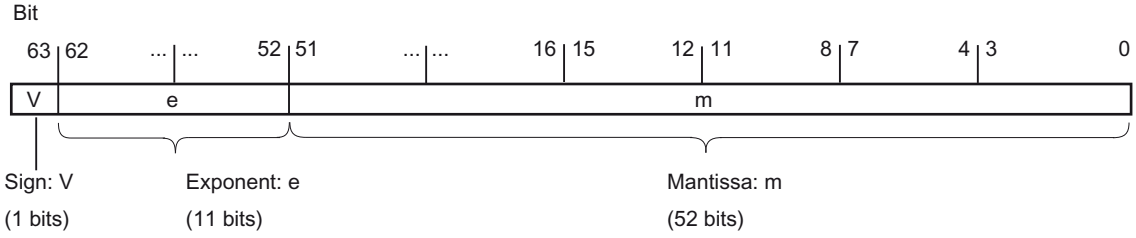
Description

Operands of the data type LREAL have a length of 64 bits and are used to represent floating-point numbers. An operand of the LREAL data type consists of the following three components:

- Sign: The sign is determined by the signal state of bit 63. The bit 63 assumes the value "0" (positive) or "1" (negative).
- 11-bit exponents to base 2: The exponent is increased by a constant (base, +1023), so that it has a value range of 0 to 2047.
- 52-bit mantissa: Only the fraction part of the mantissa is shown. The integer part of the mantissa is always 1 with normalized floating-point numbers and is not stored.

The LREAL data type is processed with a precision of 15 digits.

The following figure shows the structure of the LREAL data type:



The following table shows the properties of data type LREAL:

Length (bits)	Format	Value range	Examples of value input
64	Floating-point numbers according to IEEE754	-1.7976931348623158e+308 to -2.2250738585072014e-308 ±0,0 +2.2250738585072014e-308 to +1.7976931348623158e+308	1.0e-5; LREAL#1.0e-5
	Floating-point numbers		1.0; LREAL#1.0

Note

With floating-point numbers, only the precision defined by the IEEE754 standard is stored. Additionally specified decimals are rounded off according to IEEE754.

The number of decimal places may decrease for frequently nested arithmetic calculations.

If more decimal places are specified than can be stored by the data type, the number is rounded to the corresponding value of the precision allowed by this value range .

Data type conversion for S7-1200: (Page 2091)

Calculating with floating-point numbers (REAL and LREAL) in SCL (Page 290)

11.5.4.3 Invalid floating-point numbers

Description

We distinguish between four number ranges for data types REAL and LREAL:

- normalized numbers stored with full accuracy
- denormalized numbers not stored with full accuracy
- Infinite numbers: +Inf/-Inf (infinity)
- Invalid numbers: NaN (Not a Number)

Note

Floating-point numbers are stored as specified by the IEEE754 standard. Results of conversion or arithmetic functions with a denormalized, infinite or NaN (Not a Number) floating point depend on the CPU.

If you are not working with normalized floating-point numbers in mathematical functions, the result will show significant differences depending on the series of the CPU which you are using.

A CPU cannot calculate with denormalized floating-point numbers, with the exception of older CPU versions of the S7-300 and S7-400 series. The bit pattern of a denormalized number is interpreted as a zero. If the result of calculation falls into this range, it is continued with zero; the status bits OV and OS are set (number range undershoot).

Even though the values of invalid floating-point numbers can only be displayed with limited accuracy for mathematical functions, numbers with an exponent of -39 (e.g. 2.4408e-039) can

be monitored in the TIA Portal and therefore do not necessarily represent a faulty result. This means that floating-point values may be located outside the range of valid numerical values.

Note

The following applies to CPUs of the series S7-1200 V1, V2 and V3:

The comparison operation "Equal" uses the bit pattern of the invalid floating-point number. If two "NaN numbers" with the same bit pattern are compared, the output of the "Equal" comparison operation returns the result TRUE.

Note

The following applies to CPUs of the S7-1200 V4 and S7-1500 series:

If two invalid numbers (NaN) are compared with each other, the result is always FALSE, regardless of the bit pattern of the invalid number or the relation (>, >, ...).

Note

Comparison of denormalized floating-point numbers

For the comparison operation "Equal" with two denormalized floating-point numbers, the output for CPUs of the S7-300/400 series is set to the signal state "0" and for CPUs of the S7-1200/1500 series to the signal state "1".

If the input variables of a mathematical function represent an invalid floating-point number, an invalid floating-point number will also be output as result.

You have the following options to evaluate possible errors caused by invalid floating-point numbers:

- In LAD/FBD and SCL, you can query the enable output ENO for FALSE
- In STL, you can evaluate the status bit OV

Calculating with floating-point numbers (REAL and LREAL) in SCL (Page 290)

11.5.5 Timers

11.5.5.1 S5TIME (duration)

Format

Data type S5TIME stores the duration in BCD format. The duration is the product from a time in the range 0 to 999 and a time basis. The time basis indicates the interval at which a timer decrements the time value by one unit until it reaches "0". The resolution of the times can be controlled via the time basis.

The following table shows the range of values for data type S5TIME:

Length (bits)	Format	Range of values	Examples of value input
16	S7 time in increments of 10 ms (default value)	S5T#0MS to S5T#2H_46M_30S_0MS	S5T#10s, S5TIME#10s
	Hexadecimal numbers	16#0 to 16#3999	16#2

The following table shows the time base coding for S5TIME:

Time basis	Binary code for time basis
10 ms	00
100 ms	01
1 s	10
10 s	11

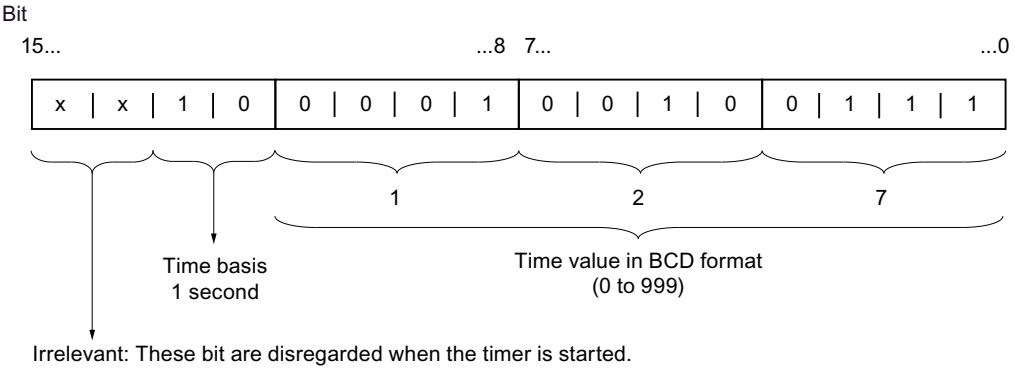
Always observe range limits and the resolution of time values when using data type S5TIME with timers. The table below specifies the range associated with each resolution:

Resolution	Range
0.01 s	10 ms to 9 s 990 ms
0.1 s	100 ms to 1 min 39 s 900 ms
1 s	1 s to 16 min 39 s
10 s	10 s to 2 h 46 min 30 s

Values that exceed 2h46m30s are not accepted.

Example

The following figure shows the content of the time operand for a time value of 127 and a time base of 1 s:



See also

Overview of the valid data types (Page 1908)

Data type conversion for S7-1200: (Page 2091)

11.5.5.2 TIME (IEC time)

Description

The contents of an operand of the data type TIME is interpreted as milliseconds. The representation contains information for days (d), hours (h), minutes (m), seconds (s) and milliseconds (ms).

The following table shows the properties of data type TIME:

Length (bits)	Format	Value range	Examples of value input
32	Signed duration	T#-24d20h31m23s648ms to T#+24d20h31m23s647ms	T#10d20h30m20s630ms, TIME#10d20h30m20s630ms
	Hexadecimal numbers	16#00000000 to 16#7FFFFFFF	16#0001EB5E

It is not necessary to specify all time units. T#5h10s is a valid entry, for example. If only one unit is specified, the absolute value of days, hours, and minutes must not exceed the high or low limits. When more than one time unit is specified, the value must not exceed 24 days, 23 hours, 59 minutes, 59 seconds or 999 milliseconds.

See also

Overview of the valid data types (Page 1908)

Data type conversion for S7-1200: (Page 2091)

11.5.5.3 LTIME (IEC time)

Description

The contents of an operand of data type LTIME is interpreted as nanoseconds. The representation contains information for days (d), hours (h), minutes (m), seconds (s) and milliseconds (ms), microseconds (us) and nanoseconds (ns).

The following table shows the properties of data type LTIME:

Length (bits)	Format	Range of values	Examples of value input
64	Signed duration	LT#-106751d23h47m16s854ms775us808ns to LT#+106751d23h47m16s854ms775us807ns	LT#11350d20h25m14s830ms652us315ns, LTIME#11350d20h25m14s830ms652us315ns
	Hexadecimal numbers	16#0 to 16#8000000000000000	16#2

It is not necessary to specify all time units. LT#5h10s is therefore a valid entry, for example. If only one unit is specified, the absolute value of days, hours, and minutes must not exceed the high or low limits. When more than one time unit is specified, the value must not exceed 106751 days, 23 hours, 59 minutes, 59 seconds, 999 milliseconds, 999 microseconds or 999 nanoseconds.

11.5.6 Date and time

11.5.6.1 DATE

Format

The DATE data type saves the date as an unsigned integer. The representation contains the year, the month, and the day.

The contents of an operand of DATE data type correspond in hexadecimal format to the number of days since 01-01-1990 (16#0000).

The following table shows the properties of data type DATE:

Length (bytes)	Format	Range of values	Examples of value input
2	IEC date (Year-Month-Day)	D#1990-01-01 to D#2168-12-31	D#2009-12-31, DATE#2009-12-31
	Hexadecimal numbers	16#0000 to 16#FF62	16#00F2

See also

Overview of the valid data types (Page 1908)

Data type conversion for S7-1200: (Page 2091)

11.5.6.2 TIME_OF_DAY (TOD)

Format

Data type TOD (TIME_OF_DAY) occupies a double word and stores the number of milliseconds since the beginning of the day (0:00 h) as unsigned integer.

The following table shows the properties of data type TOD:

Length (bytes)	Format	Value range	Examples of value input
4	Time-of-day (hours:minutes:seconds.milliseconds)	TOD#00:00:00.000 to TOD#23:59:59.999	TOD#10:20:30.400, TIME_OF_DAY#10:20:30.400

You always need to specify the hours, minutes and seconds. The specification of milliseconds is optional.

See also

Overview of the valid data types (Page 1908)

Data type conversion for S7-1200: (Page 2091)

11.5.6.3 LTOD (LTIME_OF_DAY)

Format

Data type LTOD (LTIME_OF_DAY) occupies two double words and stores the number of nanoseconds since the beginning of the day (0:00 h) as unsigned integer.

The following table shows the properties of data type LTOD:

Length (bytes)	Format	Value range	Examples of value input
8	Time-of-day (hours:minutes:seconds.nanoseconds)	LTOD#00:00:00.000000000 to LTOD#23:59:59.999999999	LTOD#10:20:30.400_365_215, LTIME_OF_DAY#10:20:30.400_365_215

You always need to specify the hours, minutes and seconds. The specification of nanoseconds is optional.

Implicit conversion (Page 1961)

Explicit conversion (Page 2010)

Data type conversion for S7-1200: (Page 2091)

11.5.6.4 DATE_AND_TIME (date and time of day)

Format

The DT (DATE_AND_TIME) data type saves the information on date and time of day in BCD format.

The following table shows the properties of data type DT:

Length (bytes)	Format	Range of values	Example of value input
8	Date and time (year-month-day-hour:minute:second:millisecond [3])	Min.: DT#1990-01-01-00:00:00.000 Max.: DT#2089-12-31-23:59:59.999	DT#2008-10-25-8:12:34.567, DATE_AND_TIME#2008-10-25-08:12:34.567

The following table shows the structure of the DT data type:

Byte	Contents	Range of values
0	Year	0 to 99 (Years 1990 to 2089) BCD#90 = 1990 ... BCD#0 = 2000 ... BCD#89 = 2089
1	Month	BCD#0 to BCD#12
2	Day	BCD#1 to BCD# 31
3	Hour	BCD#0 to BCD#23
4	Minute	BCD#0 to BCD#59
5	Second	BCD#0 to BCD#59
6	The two most significant digits of MSEC	BCD#0 to BCD#999
7 (4MSB) [1]	The least significant digit of MSEC	BCD#0 to BCD#9
7 (4LSB) [2]	Weekday	BCD#1 to BCD#7 BCD#1 = Sunday ... BCD#7 = Saturday
[1] MSB: Most significant bit [2] LSB: Least significant bit [3] Fixed point number

Overview of the valid data types (Page 1908)

Data type conversion for S7-1200: (Page 2091)

11.5.6.5 LDT (DATE_AND_LTIME)

Format

Data type LDT (DATE_AND_LTIME) stores the date and time-of-day information in nanoseconds since 01/01/1970 0:0.

The following table shows the properties of data type LDT:

Length (bytes)	Format	Value range	Example of value input
8	Date and time (Year-Month-Day-Hour:Minute:Second.Nanoseconds)	Min.: LDT#1970-01-01-0:0:0.000000000 Max.: LDT#2263-04-11-23:47:16.854775808	LDT#2008-10-25-8:12:34.567
	Hexadecimal numbers	16#0 to 16#7FFF_FFFF_FFFF_FFFF	16#7FFF

See also

Explicit conversion (Page 2010)

Data type conversion for S7-1200: (Page 2091)

11.5.6.6 DTL

Description

An operand of data type DTL has a length of 12 bytes and stores date and time information in a predefined structure.

The following table shows the properties of data type DTL:

Length (bytes)	Format	Value range	Example of value input
12	Date and time (Year-Month-Day-Hour:Minute:Second.Nanoseconds)	Min.: DTL#1970-01-01-00:00:00.0 Max.: DTL#2262-04-11-23:47:16.854775807	DTL#2008-12-16-20:30:20.250

The structure of data type DTL consists of several components each of which can contain a different data type and range of values. The data type of a specified value must match the data type of the corresponding components.

The following table shows the structure components of data type DTL and their properties:

Byte	Component	Data type	Value range
0	Year	UINT	1970 to 2262
1			

Byte	Component	Data type	Value range
2	Month	USINT	1 to 12
3	Day	USINT	1 to 31
4	Weekday	USINT	1(Sunday) to 7(Saturday) The weekday is not considered in the value entry.
5	Hour	USINT	0 to 23
6	Minute	USINT	0 to 59
7	Second	USINT	0 to 59
8	Nanosecond	UDINT	0 to 999999999
9			
10			
11

Overview of the valid data types (Page 1908)

Data type conversion for S7-1200: (Page 2091)

11.5.7 Character strings

11.5.7.1 CHAR (character)

Description

An operand of data type CHAR has a length of 8 bits and occupies one BYTE in the memory.

The CHAR data type stores a single character in ASCII format. You can find information on the encoding of special characters under "See also > STRING".

The following table shows the value range of the CHAR data type:

Length (bits)	Format	Value range	Example of value inputs
8	ASCII characters	ASCII character set	'A', CHAR#'A'

See also

Overview of the valid data types (Page 1908)

Data type conversion for S7-1200: (Page 2091)

STRING (Page 1937)

11.5.7.2 WCHAR (character)

Description

An operand of data type WCHAR (Wide Characters) has a length of 16 bits and occupies two BYTE in the memory.

The WCHAR data type saves a single character of an expanded character set which is stored in Unicode format. However, only a subset of the entire Unicode range is covered. When a control character is entered, it is represented with a dollar sign.

The following table shows the value range of the WCHAR data type:

Length (bits)	Format	Range of values	Example of value input
16	Unicode	$0000 - $D7FF	WCHAR#'a'

See also

Overview of the valid data types (Page 1908)

11.5.7.3 STRING

Description

An operand of the STRING data type saves several characters in a character string that can consist of up to 254 characters. In a character string, all characters of the ASCII code are permitted. The characters are specified in single quotation marks.

The following table shows the properties of a STRING tag:

Length (bytes)	Format	Value range	Example of value input
n + 2 *	ASCII character string incl. special characters	0 to 254 characters	'Name', STRING#'NAME'
* An operand of the STRING data type occupies two bytes more than the specified maximum length in the memory.			

A character string can also contain special characters. The escape character $ is used to identify control characters, dollar signs and single quotation marks.

The table below shows examples for the notation of special characters:

Character	Hex	Meaning	Example
$L or $l	0A	Line feed	'$LText', '$0AText'
$N	0A and 0D	Line break The line break occupies 2 characters in the character string.	'$NText', '$0A$0DText'
$P or $p	0C	Page feed	'$PText', '$0CText'
$R or $r	0D	Carriage return (CR)	'$RText','$0DText'
$T or $t	09	Tab	'$TText', '$09Text'

Character	Hex	Meaning	Example
$$	24	Dollar sign	'100$$t', '100$26'
$'	27	Single quotation mark	'$'Text$'','$27Text$27'

The maximum length of the character string can be specified during the declaration of an operand using square brackets after the keyword STRING (for example, STRING[4]). If the specification of the maximum length is omitted, the standard length of 254 characters is set for the respective operand.

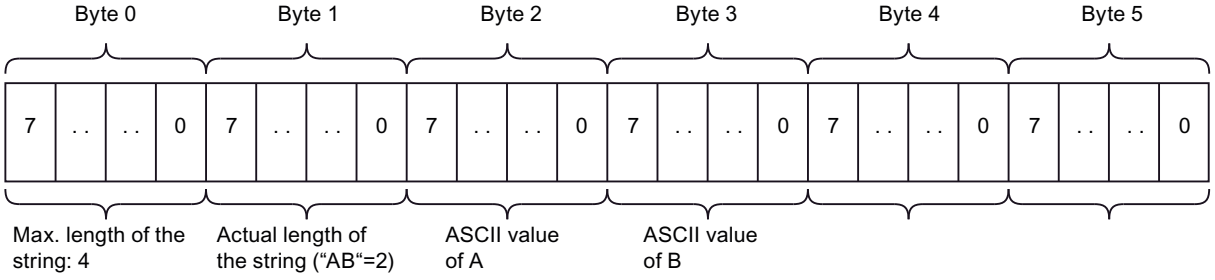
If the actual length of a specified character string is shorter than the declared maximum length, the characters are written to the character string left-justified and the remaining character spaces remain undefined. Only occupied character spaces are considered in the value processing.

Note

For S7-300/400 CPUs, please note: If a temporary tag of the STRING data type was defined, you must describe the BYTE "Max. length of string" with the defined length before you use the tags in the user program.

Example

The example below shows the byte sequence if the STRING[4] data type is specified with output value 'AB':



See also

Overview of the valid data types (Page 1908)

Data type conversion for S7-1200: (Page 2091)

11.5.7.4 WSTRING

Description

An operand of data type WSTRING (Wide String) stores several Unicode characters of data type WCHAR in one character string. If you do not specify a length, the character string has a preset length of 254 characters. In a character string, all characters of the Unicode format are permitted. This means you can also use Chinese characters in a character string.

When declaring an operand of data type WSTRING you can define its length using square brackets (for example WSTRING[10]). If you do not specify a length, the length of the WSTRING is set to 254 characters by default. You can declare a length of up to 16382 characters (WSTRING[16382]).

Note

Use in the watch table

If you wish to monitor or control a tag with data type WSTRING in the watch table, it cannot contain more than 254 characters.

The specification of the characters occurs in single quotes and always with the qualifier WSTRING#.

The table below shows the properties of a WSTRING tag:

Length (WORD)	Format	Range of values	Example of value input
n + 2 *	Unicode character string; n specifies the length of the character string.	Preset value: 0 to 254 characters Max. possible value: 0 to 16382	WSTRING#'Hello World'
* An operand of the WSTRING data type occupies two WORDs more in the memory than the specified maximum length.			

A character string can also contain special characters. The escape character $ is used to identify control characters, dollar signs and single quotation marks.

The table below shows examples for the notation of special characters:

Character	Hex	Meaning	Example
$L or $l	000A	Line feed	'$LText', '$000AText'
$N	000A and 000D	Line break The line break occupies 2 characters in the character string.	'$NText', '$000A $000DText'
$P or $p	000C	Page feed	'$PText', '$000CText'
$R or $r	000D	Carriage return (CR)	'$RText','$000DText'
$T or $t	0009	Tab	'$TText', '$0009Text'
$$	0024	Dollar sign	'100$$t', '100$0024t'
$'	0027	Single quotation mark	'$'Text$'','$0027Text $0027'

The maximum length of the character string can be specified during the declaration of an operand using square brackets after the keyword WSTRING (for example, WSTRING[4]). If the specification of the maximum length is omitted, the standard length of 254 characters is set for the respective operand.

If the actual length of a specified character string is shorter than the declared maximum length, the characters are written to the character string left-justified and the remaining character spaces remain undefined. Only occupied character spaces are considered in the value processing.

Note

Conversion of WSTRING tags

Implicit conversion of the WSTRING data type is not possible. Explicit conversion from the WSTRING data type to STRING is generally possible. However, normally only the conversion of characters in the code range from 0 - 127 will work in all Windows code pages. For all characters outside this range, the code page character and the Unicode character must be in exactly the same position for the conversion to work without errors.

Access to block parameters of data type WSTRING

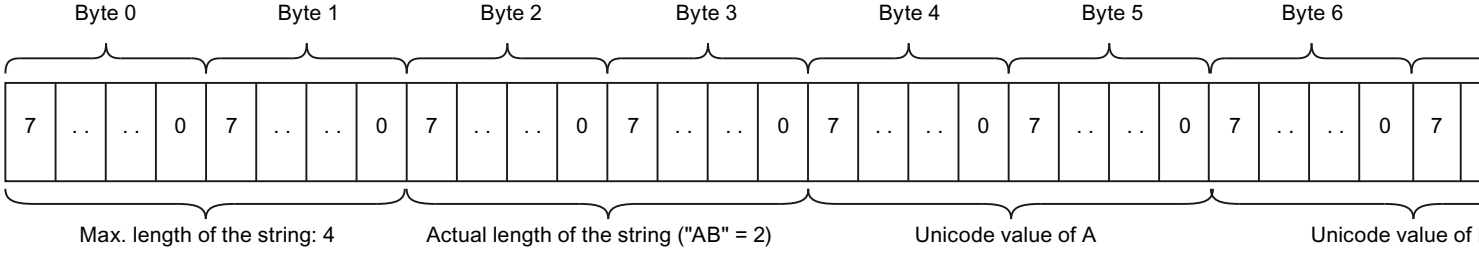
Operands of the data type WSTRING can be transferred as parameters up to the maximum length for blocks with "optimized" access.

For function blocks (FB) with "standard" access, operands of the data type WSTRING can be declared as parameters in all sections of the block interface except in the section "InOut". For a function (FC) with "standard" access, only operands of the data type STRING can be transferred as parameters.

The function value of an FC in the "Return" section and expressions in the SCL programming language are another exception to this rule. In these cases, the WSTRING tag must not be longer than 1022 characters. If you need a WSTRING tag with more than 1022 characters, declare a tag of the data type "WSTRING" with the required character length in the section "Temp" and assign the function value to the tag.

Example

The example below shows the byte sequence if the WSTRING[4] data type is specified with output value 'AB':



See also

Overview of the valid data types (Page 1908)

11.5.8 Array

11.5.8.1 Format of array (16-bit limits)

Description

The Array data type represents a data structure that consists of a fixed number of components of the same data type. All data types except Array are permitted.

A tag with the Array data type always starts at a WORD limit.

The array components are addressed by means of an index. In the array declaration, the index limits are defined in square brackets after the keyword Array. The low limit must be smaller than or equal to the high limit. An array may contain up to six dimensions, the limits of which can be specified separated by a comma.

The following table shows the property of the Array data type:

Length	Format	Index limits	Data type
Number of components * length of the data type	Array [low limit...high limit] of <data type>	[-32768..32767] of <data type>	Bit strings, integers, floating-point numbers, timers, character strings, structures

Example

The following example shows how operands of data type Array can be declared:

Name	Declaration	Comment
Measured value	Array[1..20] of REAL	One-dimensional array with 20 components
Time-of-day	Array[-5..5] of INT	One-dimensional array with 11 components
Character	Array[1..2, 3..4] of CHAR	Two-dimensional array with 4 components

Maximum array limits

The maximum Array limits depend on the following factors:

- Data type of the Array elements
- Maximum storage capacity of the CPU (you can find more information in the relevant device manual)

See also

Overview of the valid data types (Page 1908)

11.5.8.2 Format of array (32-bit limits)

Description

The Array data type represents a data structure that consists of a fixed number of components of the same data type. All data types except Array are permitted.

The array components are addressed by means of an index. In the array declaration, the index limits are defined in square brackets after the keyword Array. The low limit must be smaller than or equal to the high limit. An array may contain up to six dimensions, the limits of which can be specified separated by a comma.

Note

Depending on the CPU, the storage capacity of a data block is limited and the number of components of the Array is therefore also limited. However, you may initialize the addressing of the array components at any position within index limits.

The following table shows the property of the Array data type:

Length	Format	Index limits	Data type
Number of components * length of the data type	Array [low limit...high limit] of <data type>	[-2147483648..2147483647] of <data type>	Bit strings, integers, floating-point numbers, timers, character strings, structures

Note

The length of the array depends on whether the block was created with the "Standard" or "with optimized access" block property.

Note

Applies to CPUs of the S7-1500 series

For a block with the block property "Optimized block access", a bit requires 1 byte of memory. This is also true when you use an ARRAY of <data type>. An ARRAY [0..1] of BOOL, for example, thus requires 2 bytes in an optimized block.

Example

The following example shows how operands of data type Array can be declared:

Name	Declaration	Comment
Measured value	Array[1..20] of REAL	One-dimensional array with 20 components
Time-of-day	Array[-5..5] of INT	One-dimensional array with 11 components
Character	Array[1..2, 3..4] of CHAR	Two-dimensional array with 4 components

Maximum array limits

The maximum array limits depend on the following factors:

- Data type of the array elements
- Memory reserve (only in blocks with optimized access)
  You can find additional information on this topic in the section "Loading block changes without reinitialization".
- Maximum size of a data block for a CPU (you can find more information in the respective device manual)
- The entire length of the array is available within a data block. Within a program block (OB, FB or FC), the possible length is reduced by the memory capacity required by the program code.

Example based on a CPU of the S7-1200 series

The following table shows the maximum number of elements within a block with the "with optimized access" block property:

Data type width (bits)	Maximum number of elements	Note
1	524272	= 65534*8
8	65534	Refer to the respective device manual of the CPU for the value.
16	32767	= 65534/2 (integer division, remainder 0)
32	16383	= 65534/4 (integer division, remainder 2)
64	8191	= 65534/8 (integer division, remainder 6)

Due to various technical/internal constraints, the actual usable memory area may be approximately 70 - 100 bytes less. The memory area may be further restricted due to a default setting, for example, by the "Load without reinitialization" block property.

See also

Overview of the valid data types (Page 1908)

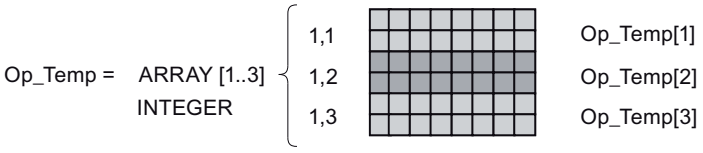
11.5.8.3 Example of a one-dimensional array

Declaration

The following table shows the declaration of a one-dimensional Array tag:

Name	Data type	Comment
Op_Temp	Array[1..3] of INT	One-dimensional array tag with 3 components.

The following figure shows the structure of the declared array tag:



Access to ARRAY components

The individual array components are accessed via an index.. The index of the first ARRAY component is [1], of the second [2], and of the third [3]. To access the value of the second ARRAY component, you need to declare "Op_Temp[2]" in the program.

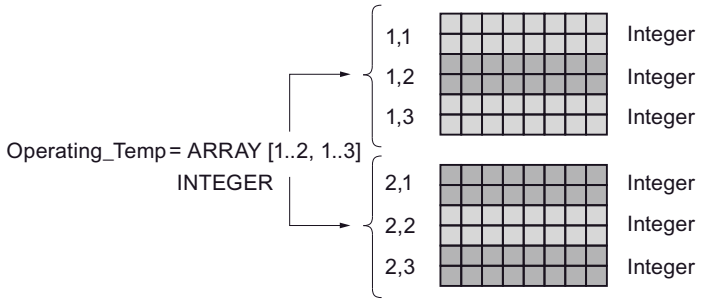
11.5.8.4 Example of a multi-dimensional array

Declaration

The following table shows the declaration of a two-dimensional Array tag:

Name	Data type	Value	Comment
Betr_Temp	Array[1..2, 1..3] of INT	1,1,4(0)	Two-dimensional array tag with 6 components. The first two components are assigned the value "1". The remaining four components are assigned the value "0".

The following figure shows the structure of the declared array tag:



Access to the array components

The values of the individual array components are accessed via an index. The index of the first array component is, for example, [1,1] and the index of the fourth array component is [2,1]. For example, you need to declare "Betr_Temp[2,1]" in the program to enable access to the value of the fourth array component.

Additional access option

You can also declare the "Betr_Temp" TAG as a six-dimensional array. The following table shows an example of the declaration of a six-dimensional Array tag:

Name	Data type	Value	Comment
Betr_Temp	Array[1..3, 1..2, 1..3, 1..4, 1..3, 1..4] of INT	-	Six-dimensional array tag

The index of the first array component is in this case [1,1,1,1,1,1] and the index of the last component is [3,2,3,4,3,4]. Intermediate values are accessed by entering the corresponding value for each dimension.

11.5.9 Structures

11.5.9.1 STRUCT

Description

Data type STRUCT represents a data structure that consists of a fixed number of components of various data types. Components of STRUCT or ARRAY data type can also be nested in a structure. The nesting depth is hereby limited to eight levels. Structures can be used to group data according to the process control system and to transfer parameters as one data unit.

You can create up to 65534 structures for a CPU of the S7-1200 or S7-1500 series. Each of these structures can include up to 252 components. In addition, you can create up to 65534 function blocks, 65535 functions and 65535 organization blocks with up to 252 components each.

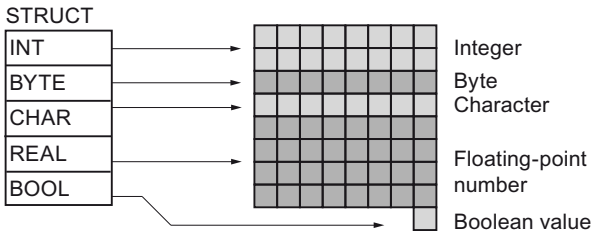
A component of the ARRAY data type always starts at a WORD limit.

The following table shows the properties of data type STRUCT:

Length	Format	Range of values	Example of value input
A STRUCT variable starts with one byte with even address and occupies the memory up to the next word limit.	STRUCT	The value ranges of the used data types apply.	The value input rules of the used data types apply.

Example

The following figure shows an example of the structure of a STRUCT variable:



See also

Overview of the valid data types (Page 1908)

11.5.10 Pointer

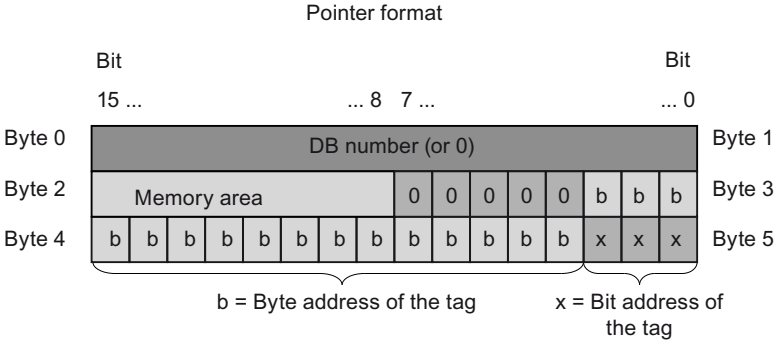
11.5.10.1 POINTER

Description

A parameter of the type POINTER is a pointer that can point to a specific tag. It occupies 6 bytes (48 bits) in memory and may contain the following tag information:

- DB number, or 0 if the data is not stored in a DB
- Memory area in the CPU
- Tag address

The following figure shows the structure of parameter type POINTER:



Types of pointer

Depending on the information, you can use parameter type POINTER to declare the following four types of pointer:

- Area-internal pointer:
  An area-internal pointer contains information on the address of a tag.
- Cross-area pointer:
  A cross-area pointer contains information on the memory area and the address of a tag.
- DB pointer:
  You can use a DB pointer to point to a data block tag. A DB pointer also contains a data block number in addition to the memory area and the address of a tag.
- Zero pointer:
  Use the zero pointer to indicate a missing value. A missing value may indicate that no value exists, or that the value is not yet known. A zero value represents the absence of a value, but is also a value.

The following table shows the formats for the declaration of various pointer types:

P#ByteRepresentation	Format	Example of value input	Description
Symbolic	P#Byte.Bit	"MyTag"	Area-internal pointer
	P#OperandAreaByte.Bit	"MyTag"	Cross-area pointer
	P#Data_block.Data_operand	"MyDB"."MyTag"	DB pointer
	P#Zero value	-	Zero pointer
Absolute	P#Byte.Bit	P#20.0	Area-internal pointer
	P#OperandAreaByte.Bit	P#M20.0	Cross-area pointer
	P#Data_block.Data_operand	P#DB10.DBX20.0	DB pointer
	P#Zero value	P#0.0, ZERO	Zero pointer

You can enter a parameter of the type POINTER without prefix (P#). The entry is then automatically converted to the POINTER format.

Note

If you use the prefix P#, you can only point to memory areas with "standard" access mode.

Memory areas

The following table shows the hexadecimal codes of the memory areas for parameter type POINTER:

Hexadecimal code	Memory area	Description
B#16#80[1)]	P	Peripherals on a CPU S7-300/400
16#1	P	Peripheral inputs on a CPU S7-1500

Hexadecimal code	Memory area	Description
16#2	P	Peripheral outputs on a CPU S7-1500
B#16#81	I	Memory area of inputs
B#16#82	Q	Memory area of outputs
B#16#83	M	Memory area of bit memory
B#16#84	DBX	Data block
B#16#85	DIX	Instance data block
B#16#86	L	Local data
B#16#87	V	Previous local data
[1] These data types can only be used for the POINTER pointer on a CPU S7-300/400.

Data type conversion for S7-1200: (Page 2091)

11.5.10.2 ANY

Description

An ANY type parameter points to the start of a data area and specifies its length. An ANY pointer occupies 10 bytes of memory and may contain the following information:

- Data type:
  Data type of the elements of the data area
- Repetition factor:
  Number of elements of the data area
- DB number:
  Data block that contains the declaration of data area elements.
- Memory area:
  Memory area of the CPU that stores the data area elements.
- Start address of the data in the format "byte.bit":
  Data area start identified by the ANY pointer.
- Zero pointer:
  Use the zero pointer to indicate a missing value. A missing value may indicate that no value exists, or that the value is not yet known. A zero value represents the absence of a value, but is also a value.

In the programming languages SCL and STL, memory of any kind can be transferred upon a block call if an ANY pointer has been programmed at a block parameter.

The ANY pointer cannot, however, store any information on the structure of the memory. For example, the ANY pointer does not save the information that it points to a tag of the PLC data type. The ANY pointer sees this as an ARRAY of BYTE.

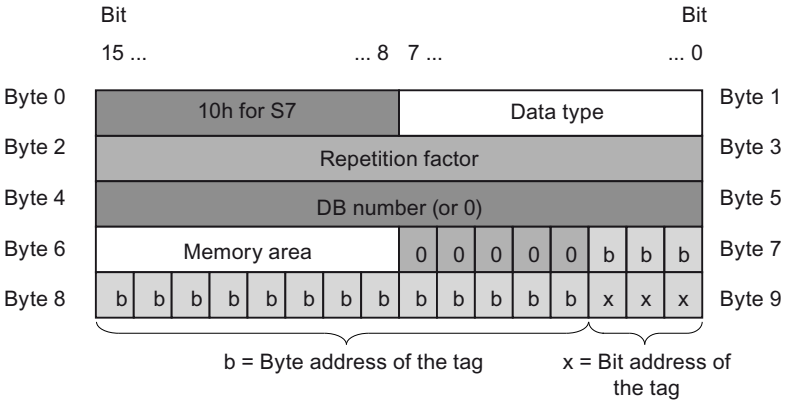
Parameters of the ANY data type can be passed to system function blocks (SFBs) or system functions (SFCs).

Note

Memory area

For an S7-1500 CPU, the ANY pointer can also only point to memory areas with "Standard" access mode.

The following figure shows the structure of the ANY pointer:



An ANY pointer cannot identify structures. It can only be assigned to local tags.

The following table shows the formats for the declaration of an ANY pointer:

Representation	Format	Example of value input	Description
Symbolic	P#DataBlock.MemoryArea DataAddress Type Number	"MyDB".StructTag.InitialComponents	Area with 10 words in global DB11 starting with DBB20.0
	P#MemoryArea DataAddress Type Number	"MyMarkerTag"	Area with 4 bytes starting with MB 20.0
		"MyTag"	Input I1.0
	P#Zero value	-	Zero value
Absolute	P#DataBlock.MemoryArea DataAddress Type Number	P#DB11.DBX20.0 INT 10	Area with 10 words in global DB11 starting with DBB20.0
	P#MemoryArea DataAddress Type Number	P#M20.0 BYTE 10	Area with 10 bytes starting with MB 20.0
		P#I1.0 BOOL 8	Range with 8 bits from input I1.0 (the range length specified must be divisible by 8.)
	P#Zero value	P#P0.0 VOID 0, NULL [1]	Zero value
[1] In the programming languages LAD and FBD, only NULL is a value entry for the zero value.			

Coding of data types

The following table lists the coding of data types for the ANY pointer:

Hexadecimal code	Data type	Description
B#16#00	NIL	Null pointer
B#16#01[1)]	BOOL	Bits
B#16#02	BYTE	bytes, 8 bits
B#16#03	CHAR	8-bit characters
B#16#04	WORD	16-bit words
B#16#05	INT	16-bit integers
B#16#06	DWORD	32-bit words
B#16#07	DINT	32-bit integers
B#16#08	REAL	32-bit floating-point numbers
B#16#0B	TIME	Time duration
B#16#0C	S5TIME	Time duration
B#16#09	DATE	Date
B#16#0A	TOD	Date and time
B#16#0E	DT	Date and time
B#16#13	STRING	Character string
B#16#17[1)]	BLOCK_FB	Function block
B#16#18[1)]	BLOCK_FC	Function
B#16#19[1)]	BLOCK_DB	Data block
B#16#1A[1)]	BLOCK_SDB	System data block
B#16#1C[1)]	COUNTER	Counter
B#16#1D[1)]	TIMER	Timer
[1)] These data types can only be used for the ANY pointer on a CPU S7-300/400.		

Coding of the memory area

The following table lists the coding of the memory areas for the ANY pointer:

Hexadecimal code	Area	Description
B#16#80[1)]	P	I/O
B#16#81	I	Memory area of inputs
B#16#82	Q	Memory area of outputs
B#16#83	M	Memory area of bit memory
B#16#84	DBX	Data block
B#16#85	DIX	Instance data block
B#16#86	L	Local data
B#16#87	V	Previous local data
[1)] These memory areas can only be used for the ANY pointer on an S7-300/400 CPU.

Data type conversion for S7-1200: (Page 2091)

11.5.10.3 VARIANT

Description

A parameter of the VARIANT type is a pointer that can point to tags of different data types other than an instance. The VARIANT pointer can be an object of an elementary data type, such as INT or REAL. It can also be a STRING, DTL, ARRAY of STRUCT, UDT, or ARRAY of UDT. The VARIANT pointer can recognize structures and point to individual structure components. An operand of data type VARIANT occupies no space in the instance data block or work memory. However, it will occupy memory space on the CPU.

A tag of the VARIANT type is not an object but rather a reference to another object. Individual elements of the VARIANT type can only be declared on formal parameters within the block interface of a function in the VAR_IN, VAR_IN_OUT and VAR_TEMP sections. For this reason, it cannot be declared in a data block or in the static section of the block interface of a function block, for example, because its size is unknown. The size of the referenced objects can change.

You can use VARIANT to generate generic function blocks or functions. When a block is called, you can connect the parameters of the block to tags of any data type. When a block is called, the type information of the tag is transferred in addition to a pointer to the tag. The code of the block can then be executed according to its type in line with the tag transferred during runtime.

If, for example, a block parameter of a function has the VARIANT data type, then a tag of the integer data type can be transferred at one point in the program, and a tag of the PLC data type can be transferred at another point in the program. With the help of the VARIANT instructions, the function is then in a position to react to the situation without errors.

Note

You can only point to a complete data block if it was originally derived from a user-defined data type (UDT).

The following table shows the properties of the VARIANT pointer:

Length (bytes)	Repre-sentation	Format	Example of value input
0	Symbolic	Operand	"TagResult"
		NameDataBlock.NameOper-and.Component	"Data_TIA_Portal".StructVariable.First-Component
	Absolute	Operand	%MW10
		DataBlockNumber.Operand Type Length (valid only for blocks with standard access)	P#DB10.DBX10.0 INT 12
		P#Zero value	P#0.0 VOID 0, ZERO

Note

If you use the prefix P#, you can only point to memory areas with "standard" access mode.

Coding of data types

If you use absolute addressing with P#, the following data types are permitted:

Hexadecimal code	Data type	Description
B#16#00	NIL	Null pointer
B#16#01	BOOL	Bits
B#16#02	BYTE	bytes, 8 bits
B#16#03	CHAR	8-bit characters
B#16#04	WORD	16-bit words
B#16#05	INT	16-bit integers
B#16#06	DWORD	32-bit words
B#16#07	DINT	32-bit integers
B#16#08	REAL	32-bit floating-point numbers
B#16#0B	TIME	Time duration
B#16#0C	S5TIME	Time duration
B#16#09	DATE	Date
B#16#0A	TOD	Date and time
B#16#0E	DT	Date and time
B#16#13	STRING	Character string
B#16#17	BLOCK_FB	Function block
B#16#18	BLOCK_FC	Function
B#16#19	BLOCK_DB	Data block
B#16#1A	BLOCK_SDB	System data block
B#16#1C	COUNTER	Counter
B#16#1D	TIMER	Timer

Example

The following example shows how VARIANT works using the "MOVE: Move value" instruction of STL:

STL	Explanation
CALL MOVE	// The "Move value" instruction is called.
VARIANT	// Data type of the instruction
IN := "Data_TIA_Portal".StructVariable.FirstCompo-nent	// The contents of the "FirstComponent" operand are moved from the "Data_TIA_Portal" DB.
OUT := "MotorDB".StructResult.TagResult	// And transferred to the "TagResult" operand from the "MotorDB" DB.

11.5.11 Parameter types

11.5.11.1 Parameter types

Description

The parameter types are data types for formal parameters that are transferred to called blocks. A parameter type can also be a PLC data type.

The following table shows the available parameter data types and their purpose:

Parameter type	Length (bits)	Description
TIMER	16	Is used to specify a timer that is used in the called code block. If you supply a formal parameter of the TIMER parameter type, the associated actual parameter must be a timer. Example: T1
COUNTER	16	Is used to specify a counter that is used in the called code block. If you supply a formal parameter of the COUNTER parameter type, the associated actual parameter must be a counter. Example: C10
BLOCK_FC	16	Is used to specify a block that is used as input in the called code block. The declaration of the parameter determines the block type (for example FB, FC, DB) that is to be used. If you supply a formal parameter of the BLOCK parameter type, specify a block address as the actual parameter. Example: DB3
BLOCK_FB	16	
BLOCK_DB	16	
BLOCK_SDB	16	
BLOCK_SFB	16	
BLOCK_SFC	16	
BLOCK_OB	16	
VOID	-	The VOID parameter type does not save any values. This parameter type is used if the return values of an output are not required. The VOID parameter type can be specified at the STATUS output, for example, if no error information is required.

11.5.12 PLC data types

11.5.12.1 PLC data types

Description

PLC data types are data structures that you define and that can be used multiple times within the program. The structure of a PLC is made up of several components, each of which can contain different data types. You define the type of components during the declaration of the PLC data type.

You can create up to 65534 PLC data types for a CPU of the S7-1200 or S7-1500 series. Each of these PLC data types can include up to 252 components.

PLC data types can be used for the following applications:

- PLC data types can be used as data types for variables in the variable declaration of logic blocks or in data blocks.
- PLC data types can be used as templates for the creation of global data blocks with identical data structures.
- PLC data types can be used in S7-1200 and S7-1500 as a template for the creation of structured PLC tags.

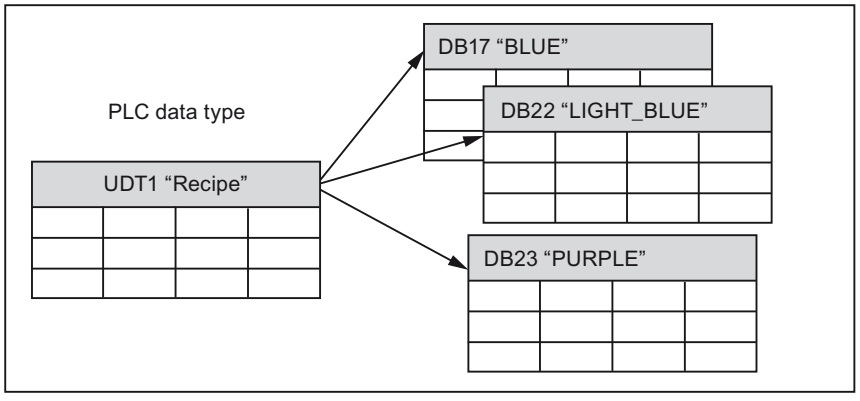
11.5.12.2 Example of a PLC data type

Example

You can declare PLC data types as the type when creating data blocks. Based on this type you can create a number of data blocks, all of which have the same data structure. These data blocks can be adapted by entering different actual values for the corresponding task.

For instance, create a PLC data type for a recipe for blending paints. You can then assign this data type to several data blocks, each of which contains other quantity information.

The following figure shows this application:



11.5.13 System data types

11.5.13.1 System data types

Description

The system data types (SDT) are made available by the system and have a predefined structure. The structure of a system data type consists of a fixed number of components that can have various data types. It is not possible to change the structure of a system data type.

The system data types can only be used for specific instructions. The following table shows the available system data types and their purpose:

System data type	Length (bytes)	Description
IEC_TIMER	16	Structure of a timer whose timer values are of TIME data type. This data type is used for the "TP", "TOF", "TON", "TONR", "RT" and "PT" instructions, for example.
IEC_LTIMER	32	Structure of a timer whose timer values are of LTIME data type. This data type is used for the "TP", "TOF", "TON", "TONR", "RT" and "PT" instructions, for example.
IEC_SCOUNTER	3	Structure of a counter whose count values are of SINT data type. This data type is used for the "CTU", "CTD" and "CTUD" instructions, for example.
IEC_USCOUNTER	3	Structure of a counter whose count values are of USINT data type. This data type is used for the "CTU", "CTD" and "CTUD" instructions, for example.
IEC_COUNTER	6	Structure of a counter whose count values are of INT data type. This data type is used for the "CTU", "CTD" and "CTUD" instructions, for example.
IEC_UCOUNTER	6	Structure of a counter whose count values are of UINT data type. This data type is used for the "CTU", "CTD" and "CTUD" instructions, for example.
IEC_DCOUNTER	12	Structure of a counter whose count values are of DINT data type. This data type is used for the "CTU", "CTD" and "CTUD" instructions, for example.
IEC_UDCOUNTER	12	Structure of a counter whose count values are of UDINT data type. This data type is used for the "CTU", "CTD" and "CTUD" instructions, for example.
IEC_LCOUNTER	24	Structure of a counter with count values of data type UDINT. This data type is used for the "CTU", "CTD" and "CTUD" instructions, for example.

System data type	Length (bytes)	Description
IEC_ULCOUNTER	24	Structure of a counter with count values of data type UINT. This data type is used for the "CTU", "CTD" and "CTUD" instructions, for example.
ERROR_STRUCT	28	Structure of an error information to a programming or I/O access error. This data type is used, for example, for the "GET_ERROR" instruction.
CREF	8	Components of the ERROR_STRUCT data type, in which information about the address of a block is saved.
NREF	8	Components of the ERROR_STRUCT data type, in which information about the address of an operand is saved.
VREF	12	Is used for storage of a VARIANT pointer. This data type is, for example, used for instructions from S7-1200 Motion Control.
STARTINFO	12	Specifies the data structure in which the start information is saved. This data type is used, for example, for the "RD_SINFO" instruction.
SSL_HEADER	4	Specifies the data structure in which information about the data records are saved during the reading of the system status lists. This data type is used, for example, for the "RDSYSST" instruction.
CONDITIONS	52	User-defined data structure defining the conditions for start and end of a data reception. This data type is used, for example, for the "RCV_CFG" instruction.
TADDR_Param	8	Specifies the structure of a data block which stores descriptions of connections for Open User Communication via UDP. This data type is used for the "TUSEND" and "TURSV" instructions, for example.
TCON_Param	64	Specifies the structure of a data block which stores descriptions of connections for Open User Communication via Industrial Ethernet (PROFINET). This data type is used for the "TSEND" and "TRSV" instructions, for example.
HSC_Period	12	Specifies the structure of the data block for the time period measurement with the extended high-speed counter. This data type is used, for example, for the "CTRL_HSC_EXT" instruction.

See also

Overview of the valid data types (Page 1908)

11.5.14 Hardware data types

11.5.14.1 Hardware data types

Description

The hardware data types are made available by the CPU. The number of available hardware data types depends on the CPU.

Constants of a specific hardware data type are stored based on the modules set in the hardware configuration. When an instruction for controlling or activating a configured module is inserted in the user program, the available constants can be used for the parameters.

The following table shows the available hardware data types and their purpose:

Data type	Basic data type	Description
REMOTE	ANY	Serves to specify the address of a remote CPU. This data type is used, for example, for the "PUT" and "GET" instructions.
GEOADDR	HW_IOSYSTEM	Geographical address information
HW_ANY	WORD	Identification of any hardware component, e.g. a module.
HW_DEVICE	HW_ANY	Identification of a DP slave/PROFINET IO device
HW_DPMASTER	HW_INTERFACE	Identification of a DP master
HW_DPSLAVE	HW_DEVICE	Identification of a DP slave
HW_IO	HW_ANY	Identification number of the CPU or the interface The number is automatically allocated and is stored in the properties of the CPU or of the interface in the hardware configuration.
HW_IOSYSTEM	HW_ANY	Identification of a PN/IO system or DP master system
HW_SUBMODULE	HW_IO	Identification of a central hardware component
HW_MODULE	HW_IO	Identification of a module
HW_INTERFACE	HW_SUBMODULE	Identification of an interface component
HW_IEPORT	HW_SUBMODULE	Identification of a port (PN/IO)
HW_HSC	HW_SUBMODULE	Identification of a high-speed counter This data type is used, for example, for the "CTRL_HSC" and "CTRL_HSC_EXT" instructions.
HW_PWM	HW_SUBMODULE	Identification of a pulse width modulation This data type is used, for example, for the "CTRL_PWM" instruction.
HW_PTO	HW_SUBMODULE	Identification of a pulse encoder This data type is used for Motion Control.
AOM_AID	DWORD	Is used only in connection with a system function block.
AOM_IDENT	DWORD	Identification of an object in the runtime system of the AS
EVENT_ANY	AOM_IDENT	Used to identify any event

Data type	Basic data type	Description
EVENT_ATT	EVENT_ANY	Is used to specify an event that can be assigned dynamically to an OB This data type is used, for example, for the "ATTACH" and "DETACH" instructions.
EVENT_HWINT	EVENT_ATT	Is used to specify a hardware interrupt event
OB_ANY	INT	Serves to specify any organization block.
OB_DELAY	OB_ANY	Used to specify an organization block that is called when a time-delay interrupt occurs. This data type is used, for example, for the "SRT_DINT" and "CAN_DINT" instructions.
OB_TOD	OB_ANY	Specifies the number of a time-of-day interrupt OB. This data type is used, for example, for the "SET_TINT", "CAN_TINT", "ACT_TINT" and "QRY_TINT" instructions.
OB_CYCLIC	OB_ANY	Is used to specify an organization block that is called when a watchdog interrupt occurs.
OB_ATT	OB_ANY	Is used to specify an organization block that can be assigned dynamically to an event. This data type is used, for example, for the "ATTACH" and "DETACH" instructions.
OB_PCYCLE	OB_ANY	Is used to specify an organization block that can be assigned to an event of the "Cyclic program" event class.
OB_HWINT	OB_ATT	Is used to specify an organization block that is called when a hardware interrupt occurs.
OB_DIAG	OB_ANY	Is used to specify an organization block that is called when a diagnostic interrupt occurs.
OB_TIMEERROR	OB_ANY	Is used to specify an organization block that is called when a time error occurs.
OB_STARTUP	OB_ANY	Is used to specify an organization block that is called when a startup event occurs.
PORT	HW_SUBMODULE	Serves to specify a communication port. This data type is used for point-to-point communication.
RTM	UINT	Serves to specify the number of an operating hours counter. This data type is used, for example, for the "RTM" instruction.
PIP	UINT	Is used to create and connect a "Synchronous Cycle" OB. This data type is used for the SFCs 26, 27, 126 and 127.
CONN_ANY	WORD	Serves to specify any connection.
CONN_PRG	CONN_ANY	Serves to specify a connection for open communication over UDP.
CONN_OUC	CONN_ANY	Used to specify a connection for open communication over Industrial Ethernet (PROFINET).
CONN_R_ID	DWORD	Data type for the R_ID parameter on the S7 communication blocks.

Data type	Basic data type	Description
DB_ANY	UINT	Identification (number) of any DB The data type "DB_ANY" has the length 0 in the section "Temp".
DB_WWW	DB_ANY	Number of a DB generated via the Web application (for example, "WWW" instruction) The data type "DB_WWW" has the length 0 in the section "Temp".
DB_DYN	DB_ANY	Number of a DB generated by the user program

11.5.15 Data type conversion for S7-1500:

11.5.15.1 Overview of data type conversion

Introduction

If you combine several operands in an instruction, you must make sure that the data types are compatible. This also applies when you assign or supply block parameters. If the operands are not of the same data type, a conversion has to be carried out.

There are two options for conversion:

- Implicit conversion
  Implicit conversion is supported by the programming languages LAD, FBD, SCL and GRAPH. Implicit conversion is not possible in the STL programming language.
- Explicit conversion
  You use an explicit conversion instruction before the actual instruction is executed.

Note

Converting bit strings to SCL

All bit strings (BYTE, WORD, DWORD and LWORD) are handled like the corresponding unsigned integers (USINT, UINT, UDINT and ULINT) in expressions. Therefore, implicit conversion from DWORD to REAL is carried out like a conversion from UDINT to REAL, for example.

Implicit conversion

Implicit conversion is executed automatically if the data types of the operands are compatible. This compatibility test can be carried out according to strict or less strict criteria:

- With IEC check (default setting)
  If IEC check is set, the following rules are applied:
  - Implicit conversion of BOOL into other data types is not possible.
  - Only the data types REAL, BYTE, WORD, DWORD, DINT, INT, SINT, UDINT, UINT, USINT, TIME, LDT, DTL, DT, TOD, WCHAR and CHAR can be converted implicitly.
  - The bit length of the source data type may not exceed the bit length of the destination data type. A WORD data type operand, for example, cannot be specified at a parameter at which the BYTE data type is expected.
- Without IEC check
  If IEC check is not set, the following rules are applied:
  - Implicit conversion of BOOL into other data types is not possible.
  - Only the data types REAL, LREAL, BYTE, WORD, DWORD, LWORD, SINT, INT, DINT, LINT, USINT, UINT, UDINT, ULINT, TIME, LTIME, S5TIME, LDT, DTL, TOD, LTOD, DATE, STRING, WSTRING, WCHAR and CHAR can be converted implicitly.
  - The bit length of the source data type may not exceed the bit length of the destination data type. A DWORD data type operand, for example, cannot be specified at a parameter at which the WORD data type is expected.
  - The bit length of an operand entered at in-out parameters (InOut) must be the same as the programmed bit length for the parameter in question.

  Note

  Implicit conversion without IEC check

  The programming editor uses a gray rectangle to mark operands that are implicitly converted. The dark gray rectangle signals that an implicit conversion is possible without any accuracy loss, for example, if you convert the data type INT to DINT. A light gray rectangle signals that implicit conversion is possible, but errors could occur during runtime. If, for example, you are converting the data type LINT to DINT and an overflow occurs, the enable output ENO is set to "0".

For more information about the setting of the IEC check and the implicit conversion, refer to "See also".

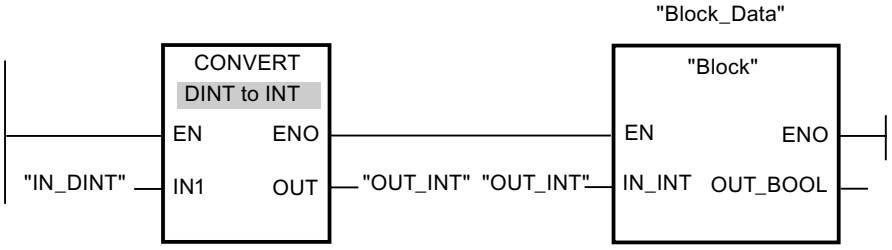
Explicit conversion

If the operands are not compatible and implicit conversion is therefore not possible, you can perform an explicit conversion. You can do this by using the conversion instructions in the "Instructions" Task Card or you can insert the conversion into the program manually. You can find the format for explicit conversion functions under "See also".

Any overflow will be displayed on the ENO enable output. An overflow occurs, for example, if the value of the source data type is greater than the value of the destination data type.

You can find additional information on explicit conversion under "See also".

The following figure shows an example in which explicit data type conversion must be carried out:



The "Block" function block expects a tag of the INT data type at the "IN_INT" input parameter. The value of the "IN_DINT" tag has therefore to the converted first from DINT to INT. Conversion is performed if the value of the "IN_DINT" tag is within the admissible value range for the INT data type. Otherwise an overflow is reported. However, a conversion takes place even in the event of an overflow, but the values are truncated and the ENO enable output is set to "0".

Implicit conversion (Page 1961)

Explicit conversion (Page 2010)

11.5.15.2 Implicit conversion

Setting and disabling the IEC check

The data types of the operands used are checked for compatibility. This compatibility test can be carried out according to criteria that are more or less strict. If "IEC check" is activated, stricter criteria are applied.

You can set the IEC check centrally for all new blocks of the project or for individual blocks.

Setting IEC check for new blocks

To set the IEC check for all new blocks in the project, proceed as follows:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. Select the "PLC programming > General" group in the area navigation.
3. Select or clear the "IEC check" check box in the "Default settings for new blocks" group.
   The IEC check is enabled or disabled for all new blocks in the program.

Setting IEC check for a block

To set the IEC check for a block, proceed as follows:

1. Open the block.
2. Open the "Properties" tab in the inspector window.
3. Select the "Attributes" group in the area navigation.
4. Select or clear the "IEC check" check box.
   The IEC check is enabled or disabled for this block. The setting is stored together with the project.

Binary numbers

Implicit conversion of BOOL

Implicit conversion options

The BOOL data type cannot be implicitly converted.

BOOL (bit) (Page 1912)

Overview of data type conversion (Page 1959)

Setting and disabling the IEC check (Page 1961)

Explicit conversion of BOOL (Page 2010)

Bit strings

Implicit conversion of BYTE

Implicit conversion options

The following table shows the options for the implicit conversion of BYTE data type:

Source	Destination	With IEC check	Without IEC check	Explanation
BYTE	BOOL	-	-	No implicit conversion
	WORD	X	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.
	DWORD	X	X	
	LWORD	X	X	
	SINT	-	X	
	USINT	-	X	
	INT	-	X	
	UINT	-	X	
	DINT	-	X	
	UDINT	-	X	
	LINT	-	X	
	ULINT	-	X	
	REAL	-	-	No implicit conversion
	LREAL	-	-	
	TIME	-	-	
	LTIME	-	-	
	S5TIME	-	-

Implicit conversion options

The following table shows the options for the implicit conversion of WORD data type:

Source	Destination	With IEC check	Without IEC check	Explanation
WORD	BOOL	-	-	No implicit conversion
	BYTE	-	X	The low byte is transferred to the destination data type; the high byte is ignored.
	DWORD	X	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.
	LWORD	X	X	
	SINT	-	X	The low byte is transferred to the destination data type; the high byte is ignored.
	USINT	-	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.
	INT	-	X	
	UINT	-	X	
	DINT	-	X	
	UDINT	-	X	
	LINT	-	X	
	ULINT	-	X	
	REAL	-	-	No implicit conversion
	LREAL	-	-	
	TIME	-	-	
	LTIME	-	-	
	S5TIME	-	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.
	LDT	-	-	No implicit conversion
	DTL	-	-	
	DT	-	-	
	DATE	-	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.
	TOD	-	-	No implicit conversion
	LTOD	-	-	
	STRING	-	-	
	WSTRING	-	-	
	CHAR	-	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.
	WCHAR	-	X	
x: Conversion possible -: Conversion not possible

Implicit conversion of TIME

Implicit conversion options

The following table shows the options for the implicit conversion of TIME data type:

Source	Destination	With IEC check	Without IEC check	Explanation
TIME	BOOL	-	-	No implicit conversion
	BYTE	-	-	
	WORD	-	-	
	DWORD	-	X	The bit pattern of the source value is transferred unchanged to the destination data type. The result of conversion shows the duration in milliseconds.
	LWORD	-	-	No implicit conversion
	SINT	-	-	
	USINT	-	-	
	INT	-	-	
	UINT	-	-	
	DINT	-	X	The bit pattern of the source value is transferred unchanged to the destination data type. The result of conversion shows the duration in milliseconds.
	UDINT	-	X	
	LINT	-	-	No implicit conversion
	ULINT	-	-	
	REAL	-	-	
	LREAL	-	-	
	S5TIME	-	-	
	LTIME	X	X	The bit pattern of the source value is transferred unchanged to the destination data type. The result of the conversion shows the duration in nanoseconds. (1 ms = 1 000 000 ns)
	LDT	-	-	No implicit conversion
	DTL	-	-	
	DT	-	-	
	DATE	-	-	
	TOD	-	X	If the source value is between 0 s and 84599.999 s, the bit pattern of the source value is transferred unchanged to the destination data type. (Display in nanoseconds) The target value remains unchanged otherwise. The result of the conversion shows the time that has passed since midnight.
	LTOD	-	-	No implicit conversion
	STRING	-	-	
	WSTRING	-	-	
	CHAR	-	-	
	WCHAR	-	-	
x: Conversion possible -: Conversion not possible

Implicit conversion of LTIME

Implicit conversion options

The following table shows the options for the implicit conversion of LTIME data type:

Source	Destination	With IEC check	Without IEC check	Explanation
LTIME	BOOL	-	-	No implicit conversion
	BYTE	-	-	
	WORD	-	-	
	DWORD	-	-	
	LWORD	-	X	The bit pattern of the source value is transferred unchanged to the destination data type. The result of the conversion shows the duration in nanoseconds.
	SINT	-	-	No implicit conversion
	USINT	-	-	
	INT	-	-	
	UINT	-	-	
	DINT	-	-	
	UDINT	-	-	
	LINT	-	X	The bit pattern of the source value is transferred unchanged to the destination data type. The result of the conversion shows the duration in nanoseconds.
	ULINT	-	X	
	REAL	-	-	No implicit conversion
	LREAL	-	-	
	S5TIME	-	-	
	TIME	-	X	If the source value is outside the value range of the destination data type, the target value remains unchanged. (0.123456789 s becomes 0.123 s)
	LDT	-	X	The bit pattern of the source value is transferred unchanged to the destination data type. The result of the conversion shows the duration in nanoseconds since 1/1/1970.
	DTL	-	-	No implicit conversion
	DT	-	-	
	DATE	-	-	
	TOD	-	-	
	LTOD	-	X	The bit pattern of the source value is transferred unchanged to the destination data type. The result of the conversion shows the duration in nanoseconds since 1/1/1970.
	STRING	-	-	No implicit conversion
	WSTRING	-	-	
	CHAR	-	-	
	WCHAR	-	-	
x: Conversion possible -: Conversion not possible

Implicit conversion of LDT

Implicit conversion options

The following table shows the options for the implicit conversion of LDT data type:

Source	Destination	With IEC check	Without IEC check	Explanation
LDT	BOOL	-	-	No implicit conversion
	BYTE	-	-	
	WORD	-	-	
	DWORD	-	-	
	LWORD	-	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type. (nanoseconds since 1/1/1970)
	SINT	-	-	No implicit conversion
	USINT	-	-	
	INT	-	-	
	UINT	-	-	
	DINT	-	-	
	UDINT	-	-	
	LINT	-	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type. (nanoseconds since 1/1/1970)
	ULINT	-	X	
	REAL	-	-	No implicit conversion
	LREAL	-	-	
	TIME	-	-	
	LTIME	-	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type. (nanoseconds since 1/1/1970)
	S5TIME	-	-	No implicit conversion
	DT	-	X	The bit pattern of the source value is converted with a loss in accuracy to the destination data type. (12/24/2012 12:34:56.123456789 becomes 12/24/2012 12:34:56.123)
	DTL	X	X	The source value is transferred unchanged with the same value to the destination data type. (12/24/2012 14:30 remains 12/24/2012 14:30)
	DATE	-	-	No implicit conversion

Bit strings

Explicit conversion of BYTE

Options for explicit conversion

The following table shows the options and instructions for the explicit conversion of the BYTE data type:

Source	Destination	Conversion	Explanation	Mnemonics of the instruction
BYTE[1)]	BOOL	X	The following possibilities can occur: • If the source is "0", the destination data type is also "0" and the enable output ENO "1". • If only the LSB (Least Significant Bit) "1" is set in the source value, the destination data type is also "1" and the enable output ENO "1". • If bits are not equal to LSB in the source value, the destination data type is set according to LSB and the enable output ENO is "0".	BYTE_TO_BOOL
	WORD[1)]	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.	BYTE_TO_WORD
	DWORD[1)]	X		BYTE_TO_DWORD
	LWORD[1)]	X		BYTE_TO_LWORD
	SINT	X		BYTE_TO_SINT
	USINT	X		BYTE_TO_USINT
	INT	X		BYTE_TO_INT
	UINT	X		BYTE_TO_UINT
	DINT	X		BYTE_TO_DINT
	UDINT	X		BYTE_TO_UDINT
	LINT	X		BYTE_TO_LINT
	ULINT	X		BYTE_TO_ULINT
	REAL	-	No explicit conversion	-
	LREAL	-		-
	TIME	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.	BYTE_TO_TIME
	LTIME	X		BYTE_TO_LTIME
	S5TIME	-	No explicit conversion	-
	LDT	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.	BYTE_TO_LDT
	DT	-	No explicit conversion	-
	DTL	-		-
	TOD	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.	BYTE_TO_TOD
	LTOD	X		BYTE_TO_LTOD
	DATE	X		BYTE_TO_DATE
	STRING	-	No explicit conversion	-
	WSTRING	-		-
	CHAR	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.	BYTE_TO_CHAR
	WCHAR	X		BYTE_TO_WCHAR

Source	Destination	Conversion	Explanation	Mnemonics of the instruction
x: Conversion possible - : Conversion not possible [1] Bit strings (BYTE, WORD, DWORD, LWORD) are interpreted as an unsigned integer with the same bit length. The data type BYTE is interpreted as USINT, WORD as UINT, DWORD as UDINT and LWORD as ULINT.

Explicit conversion of SINT

Options for explicit conversion

The following table shows the options and instructions for the explicit conversion of the SINT data type:

Source	Destination	Conversion	Explanation	Mnemonics of the instruction
SINT	BOOL	X	The following possibilities can occur: • If the source is "0", the destination data type is also "0" and the enable output ENO "1". • If only the LSB (Least Significant Bit) "1" is set in the source value, the destination data type is also "1" and the enable output ENO "1". • If bit is not equal to LSB in the source value, the destination data type is set according to LSB and the enable output ENO is "0".	SINT_TO_BOOL
	BYTE[1)]	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type. If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0".	SINT_TO_BYTE
	WORD[1)]	X		SINT_TO_WORD
	DWORD[1)]	X		SINT_TO_DWORD
	LWORD[1)]	X		SINT_TO_LWORD
	USINT	X	The bit pattern of the source value is converted and transferred to the destination data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF). If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0".	SINT_TO_USINT
	INT	X		SINT_TO_INT
	UINT	X		SINT_TO_UINT
	DINT	X		SINT_TO_DINT
	UDINT	X		SINT_TO_UDINT
	LINT	X		SINT_TO_LINT
	ULINT	X		SINT_TO_ULINT
	REAL	X	The value is converted to the destination data type format. (The value "-1" is changed to the value "-1.0", for example, with the instruction "Convert value" (CONVERT).	SINT_TO_REAL, NORM_X
	LREAL	X		SINT_TO_LREAL, NORM_X
	TIME	X	The value is transferred to the destination data type and interpreted as milliseconds.	SINT_TO_TIME
	LTIME	X	The value is transferred to the destination data type and interpreted as nanoseconds.	SINT_TO_LTIME
	S5TIME	-	No explicit conversion	-
	LDT	X	The result is returned in nanoseconds since 1970-1-1-0:0:0.0.	SINT_TO_LDT
	DT	-	No explicit conversion	-
	DTL	-		-
	TOD	X	The bit pattern of the source value is converted and transferred to the destination data type. (The value "-1" (16#FF) becomes the value	SINT_TO_TOD

Source	Destination	Conversion	Explanation	Mnemonics of the instruction
			"-1" (16#FFFFFFFF). If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0". (interpretation in milliseconds since 0:0)	
	LTOD	X	The bit pattern of the source value is converted and transferred to the destination data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF). If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0". (interpretation in nanoseconds since 0:0)	SINT_TO_LTOD
	DATE	X	The bit pattern of the source value is converted and transferred to the destination data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF). If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0". (interpretation in days since 1990-1-1)	SINT_TO_DATE
	STRING	X	The value is converted into a character string. The character string is shown preceded by a sign. If the permitted length of the character string is violated, the enable output ENO is set to "0".	SINT_TO_STRING, S_CONV, VAL_STRG
	WSTRING	X		SINT_TO_WSTRING
	CHAR[1)]	X	The bit pattern of the source value is converted and transferred to the destination data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF). If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0".	SINT_TO_CHAR
	WCHAR[1)]	X		SINT_TO_WCHAR

x: Conversion possible

- : Conversion not possible

[1)] Bit strings (BYTE, WORD, DWORD, LWORD) and the data types CHAR and WCHAR are initially extended to the necessary width including sign, and then the bits are copied. The source type determines the interpretation.

Explicit conversion of DINT

Options for explicit conversion

The following table shows the options and instructions for the explicit conversion of the DINT data type:

Source	Destination	Conversion	Explanation	Mnemonics of the instruction
DINT	BOOL	X	The following possibilities can occur: • If the source is "0", the destination data type is also "0" and the enable output ENO "1". • If only the LSB (Least Significant Bit) "1" is set in the source value, the destination data type is also "1" and the enable output ENO "1". • If bits are not equal to LSB in the source value, the destination data type is set according to LSB and the enable output ENO is "0".	DINT_TO_BOOL
	BYTE[1)]	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type. If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0".	DINT_TO_BYTE
	WORD[1)]	X		DINT_TO_WORD
	DWORD[1)]	X		DINT_TO_DWORD
	LWORD[1)]	X		DINT_TO_LWORD
	SINT	X	The bit pattern of the source value is converted and transferred to the destination data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF)). If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0".	DINT_TO_SINT
	USINT	X		DINT_TO_USINT
	INT	X		DINT_TO_INT
	UINT	X		DINT_TO_UINT
	UDINT	X		DINT_TO_UDINT
	LINT	X		DINT_TO_LINT
	ULINT	X		DINT_TO_ULINT
	REAL	X	The value is converted to the destination data type format. (The value "-1" is changed to the value "-1.0", for example, with the instruction "Convert value" (CONVERT).	DINT_TO_REAL, NORM_X
	LREAL	X		DINT_TO_LREAL, NORM_X
	TIME	X	The value is transferred to the destination data type and interpreted as milliseconds.	DINT_TO_TIME, T_CONV
	LTIME	X	The value is transferred to the destination data type and interpreted as nanoseconds.	DINT_TO_LTIME, T_CONV
	S5TIME	-	No explicit conversion	-
	LDT	X	The result is returned in nanoseconds since 1970-1-1-0:0:0.0.	DINT_TO_LDT
	DT	-	No explicit conversion	-
	DTL	-		-
	TOD	X	The bit pattern of the source value is converted and transferred to the destination data type. (The value "-1" (16#FF) becomes the value "-1"	DINT_TO_TOD

Source	Destination	Conversion	Explanation	Mnemonics of the instruction
			(16#FFFFFFFF)). If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0". (interpretation in milliseconds since 0:0)	
	LTOD	X	The bit pattern of the source value is converted and transferred to the destination data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF)). If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0". (interpretation in nanoseconds since 0:0)	DINT_TO_LTOD
	DATE	X	The bit pattern of the source value is converted and transferred to the destination data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF)). If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0". (interpretation in days since 1990-1-1)	DINT_TO_DATE
	STRING	X	The value is converted into a character string. The character string is shown preceded by a sign. If the permitted length of the character string is violated, the enable output ENO is set to "0".	DINT_TO_STRING, S_CONV, VAL_STRG
	WSTRING	X		DINT_TO_WSTRING
	CHAR[1)]	X	The bit pattern of the source value is converted and transferred to the destination data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF)). If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0".	DINT_TO_CHAR
	WCHAR[1)]	X		DINT_TO_WCHAR
	BCD32	X	The value to be converted has type DINT and is accepted as an integer with a value between –999999 and +9999999. The result is available after conversion as a BCD-coded number of the type DWORD. The enable output is set to "0" in the event of overflow. A real conversion takes place. If the value is outside the target area, a synchronous error is not triggered, but rather only the status bit OV is set.	DINT_TO_BCD32
	BCD32_DWORD	X		DINT_TO_BCD32_DWORD

x: Conversion possible

- : Conversion not possible

[1)] Bit strings (BYTE, WORD, DWORD, LWORD) and the data types CHAR and WCHAR are initially extended to the necessary width including sign, and then the bits are copied. The source type determines the interpretation.

Explicit conversion of REAL

Options for explicit conversion

The following table shows the options and instructions for the explicit conversion of the REAL data type:

Source	Destination	Conversion	Explanation	Mnemonics of the instruction
REAL	BOOL	-	No explicit conversion	-
	BYTE	-		-
	WORD	-		-
	DWORD	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.	REAL_TO_DWORD
	LWORD	-	No explicit conversion	-
	SINT	X	The value is converted into the destination data type. The result of conversion depends on the instruction employed. The enable output ENO is set to "0" if the admissible range of values of the destination data type is exceeded during conversion or the value to be converted has an invalid floating-point number.	REAL_TO_SINT, ROUND, CEIL, FLOOR, TRUNC, NORM_X, SCALE_X
	USINT	X		REAL_TO_USINT, ROUND, CEIL, FLOOR, TRUNC, NORM_X, SCALE_X
	INT	X		REAL_TO_INT, ROUND, CEIL, FLOOR, TRUNC, NORM_X, SCALE_X
	UINT	X		REAL_TO_UINT, ROUND, CEIL, FLOOR, TRUNC, NORM_X, SCALE_X
	DINT	X		REAL_TO_DINT, ROUND, CEIL, FLOOR, TRUNC, NORM_X, SCALE_X
	UDINT	X		REAL_TO_UDINT, ROUND, CEIL, FLOOR, TRUNC, NORM_X, SCALE_X
	LINT	X		REAL_TO_LINT, ROUND, CEIL, FLOOR, TRUNC, NORM_X, SCALE_X
	ULINT	X		REAL_TO_ULINT, ROUND, CEIL, FLOOR, TRUNC, NORM_X, SCALE_X
	LREAL	X	The value is converted into the destination data type. The result of the conversion depends on the instruction used, e.g. TRUNC(2.5) = 2.0; CEIL(2.5) = 3.0	REAL_TO_LREAL, ROUND, CEIL, FLOOR, TRUNC, NORM_X, SCALE_X
	TIME	-	No explicit conversion	-
	LTIME	-		-
	S5TIME	-		-
	LDT	-		-
	DT	-		-
	DTL	-		-
	TOD	-		-
	LTOD	-		-
	DATE	-		-
	STRING	X	The value is converted into a character string. The enable output ENO is set to "0" if the character string length is exceeded or the value to be converted has an invalid floating-point number. The min. length of the character string is 14 characters.	REAL_TO_STRING, S_CONV, VAL_STRG
	WSTRING	X		REAL_TO_WSTRING

Explicit conversion of STRING

Options for explicit conversion

The following table shows the options and instructions for the explicit conversion of the STRING data type:

Source	Destination	Conversion	Explanation	Mnemonics of the instruction
STRING	BOOL	-	No explicit conversion	-
	BYTE	-		-
	WORD	-		-
	DWORD	-		-
	LWORD	-		-
	SINT	X	Conversion begins with the first character in the character string (STRING) and stops at the end of the string or at the first inadmissible character. The following characters are admissible for conversion: • Digit • Sign • Dot The first character in the character string may be a sign (+, -) or a digit. Leading spaces are ignored. The dot is used as separation for the conversion of floating-point numbers. The exponential notation "e" or "E" is not permitted. The comma as thousand separator to the left of the decimal point is permitted but is ignored. If the layout of the character string is invalid for the conversion or an overflow occurs, then the enable output ENO will be set to "0".	STRING_TO_SINT, S_CONV, STRG_VAL
	USINT	X		STRING_TO_USINT, S_CONV, STRG_VAL
	INT	X		STRING_TO_INT, S_CONV, STRG_VAL

11.5.16 Data type conversion for S7-1200:

11.5.16.1 Overview of data type conversion

Introduction

If you link several operands in an instruction, you must make sure that the data types are compatible. This applies also for assignments or for supplying block parameters. If the operands are not the same data type, a conversion has to be carried out.

There are two options for the conversion:

- Implicit conversion
  The conversion take place automatically when the instruction is executed.
- Explicit conversion
  You use an explicit conversion instruction before the actual instruction is executed.

Note

The data type conversion options described always refer to the latest version of the CPU (V. 4) Conversions marked as possible may not be available in CPU versions 1 - 3.

Note

Converting bit strings in SCL

All bit strings (BYTE, WORD, and DWORD) are handled like the corresponding unsigned integers (USINT, UINT, and UDINT) in expressions. Therefore, implicit conversion from DWORD to REAL is carried out like a conversion from UDINT to REAL, for example.

Implicit conversion

An implicit conversion is executed automatically if the data types of the operands are compatible. This compatibility test can be carried out according to criteria that are more or less strict:

- With IEC check (default)
  If IEC check is set, the following rules are applied:
  - Implicit conversion of BOOL to other data types is not possible.
  - Only the REAL, BYTE, WORD, DINT, INT, SINT, UDINT, UINT, USINT, TIME, DT, STRING, CHAR and WCHAR data types can be converted implicitly.
  - The bit length of the source data type must not exceed the bit length of the target data type. An operand of data type WORD, for example, cannot be declared at a parameter at which data type BYTE is expected.
- Without IEC check
  If IEC check is not set, the following rules are applied:
  - Implicit conversion of BOOL to other data types is not possible.
  - Only the REAL, LREAL, BYTE, WORD, DWORD, SINT, INT, DINT, USINT, UINT, UDINT, TIME, DTL, TOD, DATE, STRING, CHAR and WCHAR data types can be converted implicitly.
  - The bit length of the source data type must not exceed the bit length of the target data type. An operand of data type DWORD, for example, cannot be declared at a parameter at which data type WORD is expected.
  - The bit length of an operand entered in-out parameters InOut) must be the same as the programmed bit length for the parameter in question.

Note

Implicit conversion without IEC check

The programming editor uses a gray rectangle to mark operands that are implicitly converted. The dark gray rectangle signals that an implicit conversion is possible without any accuracy loss, for example, if you convert the data type SINT to INT. A light gray rectangle signals that implicit conversion is possible, but errors could occur during runtime. If, for example, you are converting the data type DINT to INT and an overflow occurs, the enable output ENO is set to "0".

For more information about the setting of the IEC check and the implicit conversion, refer to "See also".

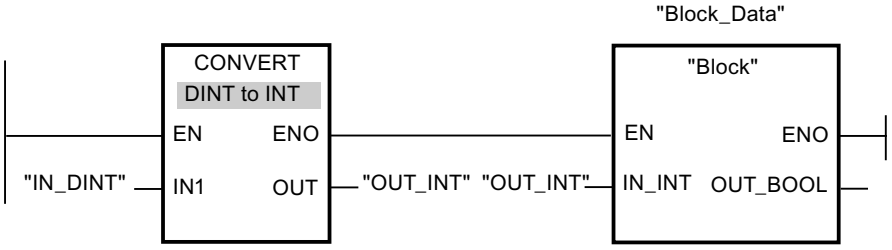
Explicit conversion

If the operands are not compatible and an implicit conversion is therefore not possible, you can use an explicit conversion instruction. You can find the conversion instructions in the "Instructions" task card.

A possible overflow is displayed at the ENO enable output. An overflow is created, for example, if the value of the source data type is greater than the value of the target data type.

For more information about explicit conversion, refer to "See also".

The following figure shows an example in which an explicit data type conversion must be carried out:



The "Block" function block expects a tag of the INT data type at the "IN_INT" input parameter. Therefore, the value of the "IN_DINT" tag must first be converted from DINT to INT. If the value of the "IN_DINT" tag is within the permitted value range of the INT data type, the conversion takes place. Otherwise, an overflow is signaled. A conversion still takes place even in case of an overflow, but the values are cut off and the enable output ENO is set to "0".

Setting and canceling the IEC check (Page 2093)

11.5.16.2 Implicit conversion

Setting and canceling the IEC check

The data types of the operands used are check for compatibility. This compatibility test can be carried out according to criteria that are more or less strict. If "IEC check" is activated, stricter criteria are applied.

You can set the IEC check centrally for all new blocks of the project or for individual blocks.

Setting IEC check for new blocks

To set the IEC check for all new blocks in the project, proceed as follows:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. Select the "PLC programming > General" group in the area navigation.
3. Select or clear the "IEC check" check box in the "Default settings for new blocks" group.
   The IEC check is enabled or disabled for all new blocks in the program.

Setting IEC check for a block

To set the IEC check for a block, proceed as follows:

1. Open the block.
2. Open the "Properties" tab in the Inspector window.
3. Select the "Attributes" group in the area navigation.
4. Select or clear the "IEC check" check box.
   The IEC check is enabled or disabled for this block. The setting is stored together with the project.

Binary numbers

Implicit conversion of BOOL

Options for implicit conversion

The implicit conversion of the BOOL data type is not possible.

Implicit conversion of BYTE

Options for implicit conversion

The following table shows the options for implicit conversion of the BYTE data type:

Source	Target	With IEC check	Without IEC check	Explanation
BYTE	BOOL	-	-	No implicit conversion
	WORD	x	x	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type.
	DWORD	x	x	
	SINT	-	x	
	USINT	-	x	
	INT	-	x	
	UINT	-	x	
	DINT	-	x	
	UDINT	-	x	
	REAL	-	-	No implicit conversion
	LREAL	-	-	
	TIME	-	-	
	DTL	-	-	
	TOD	-	-	
	DATE	-	-	
	STRING	-	-	
	WSTRING	-	-	
	CHAR	-	x	The bit pattern of the source value is transferred unchanged to the target data type.
	WCHAR	-	x	
x: Conversion possible -: Conversion not possible

Implicit conversion of WORD

Options for implicit conversion

The following table shows the options for implicit conversion of the WORD data type:

Source	Target	With IEC check	Without IEC check	Description
WORD	BOOL	-	-	No implicit conversion
	BYTE	-	X	The least significant byte is transferred to the target data type, while the most significant byte is ignored.
	DWORD	X	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type.
	SINT	-	X	The least significant byte is transferred to the target data type, while the most significant byte is ignored.
	USINT	-	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type.
	INT	-	X	
	UINT	-	X	
	DINT	-	X	
	UDINT	-	X	
	REAL	-	-	No implicit conversion
	LREAL	-	-	
	TIME	-	-	
	DTL	-	-	
	TOD	-	-	
	DATE	-	X	The bit pattern of the source value is transferred unchanged to the target data type.
	STRING	-	-	No implicit conversion
	WSTRING	-	-	
	CHAR	-	X	The bit pattern of the source value is transferred unchanged to the target data type.
	WCHAR	-	X	
x: Conversion possible -: Conversion not possible

Implicit conversion of DWORD

Options for implicit conversion

The following table shows the options for implicit conversion of the DWORD data type:

Source	Target	With IEC check	Without IEC check	Explanation
DWORD	BOOL	-	-	No implicit conversion
	BYTE	-	X	The right bytes are transferred to the target data type; the left bytes are ignored.
	WORD	-	X	
	SINT	-	X	
	USINT	-	X	
	INT	-	X	
	UINT	-	X	
	DINT	-	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type.
	UDINT	-	X	
	REAL	-	X	The value is converted to the format of the target data type. (The value "-1", for example, is converted to the value "-1.0".)
	LREAL	-	-	No implicit conversion
	TIME	-	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type.
	DTL	-	-	No implicit conversion
	TOD	-	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type.
	DATE	-	-	No implicit conversion
	STRING	-	-	
	WSTRING	-	-	
	CHAR	-	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type.
	WCHAR	-	X	
x: Conversion possible -: Conversion not possible

Implicit conversion of SINT

Options for implicit conversion

The following table shows the options for implicit conversion of the SINT data type:

Source	Target	With IEC check	Without IEC check	Explanation
SINT	BOOL	-	-	No implicit conversion
	BYTE	-	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type. The remaining bits are filled with "0".
	WORD	-	X	
	DWORD	-	X	
	USINT	-	X	The bit pattern of the source value is converted and transferred to the target data type. (for example, value transfer from SINT #-1 -> INT #-1, not filled with "0".)
	INT	X	X	
	UINT	-	X	
	DINT	X	X	
	UDINT	-	X	
	REAL	X	X	The value is converted to the format of the target data type. (The value "-1", for example, is converted to the value "-1.0".)
	LREAL	X	X	
	TIME	-	-	No implicit conversion
	DTL	-	-	
	TOD	-	-	
	DATE	-	-	
	STRING	-	-	
	WSTRING	-	-	
	CHAR	-	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type.

Implicit conversion of UINT

Options for implicit conversion

The following table shows the options for implicit conversion of the UINT data type:

Source	Target	With IEC check	Without IEC check	Explanation
UINT	BOOL	-	-	No implicit conversion
	BYTE	-	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type.
	WORD	-	X	
	DWORD	-	X	
	SINT	-	X	The bit pattern of the source value is converted and transferred to the target data type. (for example, value conversion from UINT #100 -> DINT #100 or UINT #60 000 -> INT #-5536)
	USINT	-	X	
	INT	-	X	
	DINT	X	X	
	UDINT	X	X	
	REAL	X	X	The value is converted to the format of the target data type. (The value "1", for example, is converted to the value "1.0".)
	LREAL	X	X	
	TIME	-	-	No implicit conversion
	DTL	-	-	
	TOD	-	-	
	DATE	-	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type.
	STRING	-	-	No implicit conversion

Explicit conversion of SINT

Options for explicit conversion

The following table shows the options and instructions for explicit conversion of the SINT data type:

Source	Target	Conversion	Explanation	Mnemonics of the instruction
SINT	BOOL	X	The following scenarios are possible: • If the source is "0", the target data type is also "0" and enable output ENO is "1". • If only the LSB (Least Significant Bit) "1" is set in the source value, the target data type is also "1" and enable output ENO is "1". • If bit is not equal to LSB in the source value, the target data type is set according to LSB and enable output ENO is "0".	SINT_TO_BOOL
	BYTE[1)]	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type. If a negative value is converted to an unsigned target data type, the enable output ENO is set to "0".	SINT_TO_BYTE
	WORD[1)]	X		SINT_TO_WORD
	DWORD[1)]	X		SINT_TO_DWORD
	USINT	X	The bit pattern of the source value is converted and transferred to the target data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF). Enable output ENO is set to "0" if a negative value is converted to an unsigned target data type.	SINT_TO_USINT
	INT	X		SINT_TO_INT
	UINT	X		SINT_TO_UINT
	DINT	X		SINT_TO_DINT
	UDINT	X		SINT_TO_UDINT
	REAL	X	The value is converted into the format of the target data type (the value "-1" will be converted into the value "-1.0" with the "Convert value" (CONVERT) instruction.	SINT_TO_REAL, NORM_X
	LREAL	X		SINT_TO_LREAL, NORM_X
	TIME	X	The value is transferred to the target data type and interpreted as milliseconds.	SINT_TO_TIME
	DTL	-	No explicit conversion	-
	TOD	X	The bit pattern of the source value is converted and transferred to the target data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF). Enable output ENO is set to "0" if a negative value is converted to an unsigned target data type. (interpretation in milliseconds since 0:0)	SINT_TO_TOD
	DATE	X	The bit pattern of the source value is converted and transferred to the target data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF). Enable output ENO is set to "0" if a negative value is converted to an unsigned target data type. (interpretation in days since 1990-1-1)	SINT_TO_DATE
	STRING	X	The value is converted to a character string. The character string is shown preceded by a sign. If the permitted length of the character string is violated, the enable output ENO is set to "0".	SINT_TO_STRING, S_CONV, VAL_STRG
	WSTRING	X		SINT_TO_WSTRING

Source	Target	Conversion	Explanation	Mnemonics of the instruction
	CHAR[1)]	X	The bit pattern of the source value is converted and transferred to the target data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF). Enable output ENO is set to "0" if a negative value is converted to an unsigned target data type.	SINT_TO_CHAR
	WCHAR[1)]	X		SINT_TO_WCHAR
x: Conversion possible - : Conversion not possible [1)] Bit strings (BYTE, WORD, DWORD) and data type CHAR are first extended to the necessary width including sign, and then the bits are copied. The source type determines the interpretation.

Explicit conversion of DINT

Options for explicit conversion

The following table shows the options and instructions for explicit conversion of the DINT data type:

Source	Target	Conversion	Explanation	Mnemonics of the instruction
DINT	BOOL	X	The following scenarios are possible: • If the source is "0", the target data type is also "0" and enable output ENO is "1". • If only the LSB (Least Significant Bit) "1" is set in the source value, the target data type is also "1" and enable output ENO is "1". • If bit is not equal to LSB in the source value, the target data type is set according to LSB and enable output ENO is "0".	DINT_TO_BOOL
	BYTE[1)]	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type. If a negative value is converted to an unsigned target data type, the enable output ENO is set to "0".	DINT_TO_BYTE
	WORD[1)]	X		DINT_TO_WORD
	DWORD[1)]	X		DINT_TO_DWORD
	SINT	X	The bit pattern of the source value is converted and transferred to the target data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF)). If a negative value is converted to an unsigned target data type, the enable output ENO is set to "0".	DINT_TO_SINT
	USINT	X		DINT_TO_USINT
	INT	X		DINT_TO_INT
	UINT	X		DINT_TO_UINT
	UDINT	X		DINT_TO_UDINT
	REAL	X	The value is converted to the format of the target data type (the value "-1", for example, is converted with the instruction "Convert value" (CONVERT) to the value "-1.0").	DINT_TO_REAL, NORM_X
	LREAL	X		DINT_TO_LREAL, NORM_X
	TIME	X	The value is transferred to the target data type and interpreted as milliseconds.	DINT_TO_TIME, T_CONV
	DTL	-	No explicit conversion	-
	TOD	X	The bit pattern of the source value is converted and transferred to the target data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF)). If a negative value is converted to an unsigned target data type, the enable output ENO is set to "0". (interpretation in milliseconds since 0:0)	DINT_TO_TOD
	DATE	X	The bit pattern of the source value is converted and transferred to the target data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF)). If a negative value is converted to an unsigned target	DINT_TO_DATE

Source	Target	Conversion	Explanation	Mnemonics of the instruction
			data type, the enable output ENO is set to "0". (interpretation in days since 1990-1-1)	
	STRING	X	The value is converted to a character string. The character string is shown preceded by a sign. If the permitted length of the character string is violated, the enable output ENO is set to "0".	DINT_TO_STRING, S_CONV, VAL_STRG
	WSTRING	X		DINT_TO_WSTRING
	CHAR[1)]	X	The bit pattern of the source value is converted and transferred to the target data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF)). If a negative value is converted to an unsigned target data type, the enable output ENO is set to "0".	DINT_TO_CHAR
	WCHAR[1)]	X		DINT_TO_WCHAR
	BCD32	X	The value to be converted has type DINT and is accepted as an integer with a value between –999999 and +9999999. The result is available after conversion as a BCD-coded number of the type DWORD. The enable output is set to "0" in the event of overflow. A real conversion takes place. If the value is outside the target area, a synchronous error is not triggered, but rather only the status bit OV is set.	DINT_TO_BCD32
	BCD32_DWORD	X		DINT_TO_BCD32_DWORD

x: Conversion possible

- : Conversion not possible

[1)] Bit strings (BYTE, WORD, DWORD) and data type CHAR are first extended to the necessary width including sign, and then the bits are copied. The source type determines the interpretation.

Explicit conversion of UDINT

Options for explicit conversion

The following table shows the options and instructions for explicit conversion of the UDINT data type:

Source	Target	Conversion	Explanation	Mnemonics of the instruction
UDINT	BOOL	X	The following scenarios are possible: • If the source is "0", the target data type is also "0" and enable output ENO is "1". • If only the LSB (Least Significant Bit) "1" is set in the source value, the target data type is also "1" and enable output ENO is "1". • If bit is not equal to LSB in the source value, the target data type is set according to LSB and enable output ENO is "0".	UDINT_TO_BOOL
	BYTE[1)]	X	The bit pattern of the source value is transferred unchanged to the target data type. If bits are lost in the process, the enable output ENO is set to "0".	UDINT_TO_BYTE
	WORD[1)]	X		UDINT_TO_WORD
	DWORD[1)]	X		UDINT_TO_DWORD
	SINT	X		UDINT_TO_SINT
	USINT	X		UDINT_TO_USINT
	INT	X		UDINT_TO_INT
	UINT	X		UDINT_TO_UINT
	DINT	X	The bit pattern of the source value is transferred unchanged to the target data type. If the sign bit is changed during the conversion, the enable output ENO is set to "0".	UDINT_TO_DINT
	REAL	X	The value is converted to the format of the target data type (the value "1", for example, is converted with the instruction "Convert value" (CONVERT) to the value "1.0").	UDINT_TO_REAL, NORM_X
	LREAL	X		UDINT_TO_LREAL, NORM_X
	TIME	X	The bit pattern of the source value is transferred unchanged right-justified and interpreted as milliseconds to the target data type.	UDINT_TO_TIME
	DTL	-	No explicit conversion	-
	TOD	X	The bit pattern of the source value is converted and transferred to the target data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF). Enable output ENO is set to "0" if a negative value is converted to an unsigned target data type. (interpretation in milliseconds since 0:0; check for 24h limit)	UDINT_TO_TOD, T_CONV
	DATE	X	The bit pattern of the source value is converted and transferred to the target data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF). Enable output	UDINT_TO_DATE

Source	Target	Conversion	Explanation	Mnemonics of the instruction
			ENO is set to "0" if a negative value is converted to an unsigned target data type. (interpretation in days since 1990-1-1; check for negative value)	
	STRING	X	The value is converted to a character string. If the permitted length of the character string is violated, the enable output ENO is set to "0".	UDINT_TO_STRING, S_CONV, VAL_STRG
	WSTRING	X		UDINT_TO_WCHAR
	CHAR[1)]	X	The bit pattern of the source value is transferred unchanged to the target data type. The enable output ENO is set to "0" in the event of overflow.	UDINT_TO_CHAR
	WCHAR[1)]	X		UDINT_TO_WCHAR
x: Conversion possible - : Conversion not possible [1)] Bit strings (BYTE, WORD, DWORD, LWORD) and the data type CHAR are first extended to the necessary width (the non-existent sign is replaced with zeros) and then the bits are copied. The source type determines the interpretation.

11.5.17 Data type conversion for S7-300, S7-400

11.5.17.1 Overview of data type conversion

Introduction

If you combine several operands in an instruction, you must make sure that the data types are compatible. This also applies when you assign or supply block parameters. If the operands are not of the same data type, a conversion has to be carried out.

There are two options for conversion:

- Implicit conversion
  Implicit conversion is supported by the programming languages LAD, FBD, SCL and GRAPH. Implicit conversion is not possible in the STL programming language.
- Explicit conversion

Note

Converting bit strings to SCL

All bit strings (BYTE, WORD, DWORD and LWORD) are handled like the corresponding unsigned integers (USINT, UINT, UDINT and ULINT) in expressions. Therefore, implicit conversion from DWORD to REAL is carried out like a conversion from UDINT to REAL, for example.

Implicit conversion

Implicit conversion is executed automatically if the data types of the operands are compatible. This compatibility test can be carried out according to strict or less strict criteria:

- With IEC check
  The following rules apply in the LAD, FBD and GRAPH programming languages when the IEC check has been set:
  - The only data types for which implicit conversion is possible are BYTE and WORD.
  - The bit length of the source data type may not exceed the bit length of the target data type. A WORD data type operand, for example, cannot be specified at a parameter at which the BYTE data type is expected.

  The following rules apply in the SCL programming language when the IEC check has been set:
  - Implicit conversion of bit strings into other data types is not possible. A WORD data type operand, for example, cannot be specified at a parameter at which the INT data type is expected.
  - The bit length of the source data type may not exceed the bit length of the target data type. A WORD data type operand, for example, cannot be specified at a parameter at which the BYTE data type is expected.
- Without IEC check (default setting)
  The following rules apply in the LAD, FBD and GRAPH programming languages when the IEC check has not been set:
  - Implicit conversion of data types BYTE, WORD, DWORD, INT, DINT, TIME, S5TIME, TOD, DATE and CHAR is possible.
  - The bit length of the source data type may not exceed the bit length of the target data type. A DWORD data type operand, for example, cannot be specified at a parameter at which the WORD data type is expected.

  The following rules apply in the SCL programming language when the IEC check has not been set:
  - Bit strings can be implicitly converted into other data types. A WORD data type operand can, for example, be given at a parameter at which the WORD data type is expected.
  - Bit strings cannot be implicitly converted into floating-point numbers. A WORD data type operand, for example, cannot be specified at a parameter at which the REAL data type is expected.
  - Bit strings can only be implicitly converted into the data types TIME, TOD, DATE and CHAR if these have the same bit length. A DWORD data type operand, for example, cannot be specified at a parameter at which the DATE data type is expected.
  - The bit length of the source data type may not exceed the bit length of the target data type. A DINT data type operand, for example, cannot be specified at a parameter at which the INT data type is expected.
  - The bit length of an operand entered at in-out parameters must be the same as the programmed bit length for the parameter in question.

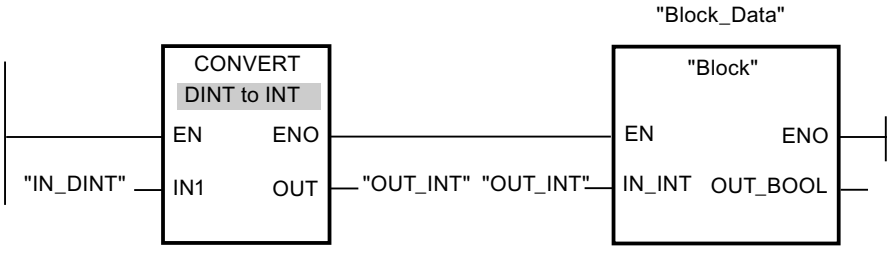
Explicit conversion

If the operands are not compatible and implicit conversion is therefore not possible, you can use an explicit conversion instruction. You can find the conversion instructions in the "Instructions" task card.

Any overflow will be displayed on the ENO enable output. An overflow occurs, for example, if the value of the source data type is greater than the value of the target data type.

You can find additional information on explicit conversion under "See also".

The following figure shows an example in which explicit data type conversion must be carried out:



The "Block" function block expects a tag of the INT data type at the "IN_INT" input parameter. The value of the "IN_DINT" tag has therefore to the converted first from DINT to INT. Conversion is performed if the value of the "IN_DINT" tag is within the admissible value range for the INT data type. Otherwise an overflow is reported. However, a conversion takes place even in the event of an overflow, but the values are truncated and the ENO enable output is set to "0".

Explicit conversion (Page 2171)

11.5.17.2 Implicit conversion

Setting and disabling the IEC check

The data types of the operands used are checked for compatibility. This compatibility test can be carried out according to criteria that are more or less strict. If "IEC check" is activated, stricter criteria are applied.

You can set the IEC check centrally for all new blocks of the project or for individual blocks.

Setting IEC check for new blocks

To set the IEC check for all new blocks in the project, proceed as follows:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. Select the "PLC programming > General" group in the area navigation.
3. Select or clear the "IEC check" check box in the "Default settings for new blocks" group.
   The IEC check is enabled or disabled for all new blocks in the program.

Setting IEC check for a block

To set the IEC check for a block, proceed as follows:

1. Open the block.
2. Open the "Properties" tab in the inspector window.
3. Select the "Attributes" group in the area navigation.
4. Select or clear the "IEC check" check box.
   The IEC check is enabled or disabled for this block. The setting is stored together with the project.

Explicit conversion of TIME

Options for explicit conversion

The following table shows the options and instructions for the explicit conversion of the TIME data type:

Source	Target	Conversion	Explanation	Mnemonics of the instruction
TIME	BOOL	-	No explicit conversion	-
	BYTE	-		
	WORD	-		
	DWORD	X	The bit pattern of the source value is transferred unchanged to the destination data type. The result of conversion shows the duration in milliseconds.	CONVERT
	INT	-	No explicit conversion	-
	DINT	X	The bit pattern of the source value is transferred unchanged to the destination data type. The result of conversion shows the duration in milliseconds.	T_CONV, CONVERT
	REAL	-	No explicit conversion	-
	S5TIME	X	The value is converted to the destination data type format. The enable output ENO is set to "0" in the event of overflow.	T_CONV, CONVERT
	DT	-	No explicit conversion	-
	TOD	-		
	DATE	-		
	STRING	-		
	CHAR	-		
x: Conversion possible - : Conversion not possible

Explicit conversion of STRING

Options for explicit conversion

The following table shows the options and instructions for the explicit conversion of the STRING data type:

Source	Target	Conversion	Explanation	Mnemonics of the instruction
STRING	BOOL	-	No explicit conversion	-
	BYTE	-		
	WORD	-		
	DWORD	-		
	INT	X	Conversion begins with the first character in the character string (STRING) and stops at the end of the string or at the first inadmissible character. The following characters are admissible for conversion: • Digit • Sign • Dot The first character in the character string may be a sign (+, -) or a digit. Leading spaces are ignored. The dot is used as separation for the conversion of floating-point numbers. The exponential notation "e" or "E" is not permitted. The comma as thousand separator to the left of the decimal point is permitted but is ignored. If the layout of the character string is invalid for the conversion or an overflow occurs, then the enable output ENO will be set to "0".	S_CONV, CONVERT
	DINT	X		
	REAL	X		
	TIME	-	No explicit conversion	-
	S5TIME	-		
	DT	-		
	TOD	-		
	DATE	-		
	CHAR	X	The first character in the character string (STRING) is transferred to the target data type. The value "0" is written to the target data type if the character string is empty.	S_CONV, CONVERT
x: Conversion possible - : Conversion not possible

Additional conversion functions

Additional explicit conversion functions

Additional options for explicit conversion in SCL

The following table shows the additional options and operations for explicit conversion in SCL:

Source	Target	Explanation	Mnemonics of the instruction
WORD	BLOCK_DB	The bit pattern of WORD is interpreted as a data block number.	WORD_TO_BLOCK_DB
BLOCK_DB	WORD	The data block number is interpreted as a bit pattern of WORD.	BLOCK_DB_TO_WORD

11.6 Instructions

11.6.1 General parameters of the instructions

11.6.1.1 Meaning of the parameters REQ, RET_VAL and BUSY with asynchronous instructions

Asynchronous instructions

For instructions that work asynchronously, the function is executed with several calls.

Identification of the job

If you use asynchronous instructions to trigger a process interrupt, output control commands to DP slaves, start a data transfer, or abort a non-configured connection with one of the SFCs listed above and then call the same SFC again before the current job is completed, then the reaction of the SFC will depend on whether the second call involves the same job.

Parameter REQ

The input parameter REQ (request) is used solely to start the job:

- If you call the instruction for a job that is not currently active, the job is started with REQ = 1 (case 1).
- If a particular job has been started and not yet completed and you call the instruction again to perform the same job (for example, in a cyclic interrupt OB), then REQ is not evaluated by the instruction (case 2).

Parameter RET_VAL and BUSY

The output parameters RET_VAL and BUSY indicate the status of the job.

Pay attention to the note in section: Evaluating errors with output parameter RET_VAL (Page 2195)

- In case 1 (first call with REQ=1), the input parameter will be entered in RET_VALW#16#7001 if system resources are available and supply is correct. BUSY will be set.
  If the required system resources are currently being used or the input parameters have errors, the corresponding error code is entered in RET_VAL and BUSY has the value 0.
- In case 2 (interim call) W#16#7002 will be entered in RET_VAL (this corresponds to a warning: Job still being processed!), and BUSY will be set.
- The following applies to the last call for a job:
  - For instruction "DPNRM_DG (Page 3139)", the number of data in bytes will entered as integer in RET_VAL in case there are no errors in data transmission. BUSY has the value "0" in this case.
    If there is an error, then the error information will be entered in RET_VAL and you should not evaluate BUSY in this case.
  - For all other instructions, "0" will be entered in RET_VAL if the job was executed without errors and BUSY has the value "0" in this case. If there is an error, the error code is entered in RET_VAL and BUSY has the value "0" in this case.

Note

If the first and last call coincide, the reaction is the same for RET_VAL and BUSY as described for the last call.

Overview

The following table provides you with an overview of the relationships explained above. In particular, it shows the possible values of the output parameters if the execution of the job is not completed after an instruction call has been completed.

Note

Following every call, you must evaluate the relevant output parameters in your program.

Relationship between call, REQ, RET_VAL and BUSY during execution of a "running" job.

Number of the call	Type of call	REQ	RET_VAL	BUSY
1	First call	1	W#16#7001	1
			Error code	0
2 to (n - 1)	Intermediate call	irrelevant	W#16#7002	1
n	Last call	irrelevant	W#16#0000, if no errors have occurred.	0
			Error code if errors occurred	0

11.6.1.2 Evaluating errors with output parameter RET_VAL

Types of error information

An executed instruction indicates in the user program whether or not the CPU was able to execute the function of the instruction successfully.

You can obtain information about any errors that occurred in two ways:

- In the BR bit of the status word
- in the output parameter RET_VAL (return value).

Note

Before evaluating the output parameters specific to an instruction, you should always follow the steps below:

- First, evaluate the BR bit of the status word.
- Then check the output parameter RET_VAL.

If the BR bit indicates that an error has occurred or if RET_VAL contains a general error code, you should not evaluate the instruction-specific output parameters.

Error information in the return value

An instruction indicates that an error occurred during its execution by entering the value "0" in the binary result bit (BR) of the status word. Some instructions provide an additional error code at an output parameter known as the return value (RET_VAL). If a general error is entered in the output parameter RET_VAL (see below for explanation), this is only indicated by the value "0" in the BR bit of the status word.

The return value is of the data type integer (INT). The relationship of the return value to the value "0" indicates whether or not an error occurred during execution of the function.

CPU execution of the instruction	BR	Return value	Sign of the integer
With error(s)	0	less than "0"	negative (sign bit is "1")
Without error	1	greater than or equal to "0"	positive (sign bit is "0")

Reacting to error information

There are two types of error codes in RET_VAL:

- A general error code that all instructions can output and
- A specific error code that an instruction can output and which relates to its specific function.

You can write your program so that it reacts to the errors that occur during execution of an instruction. This way you prevent further errors occurring as a result of the first error.

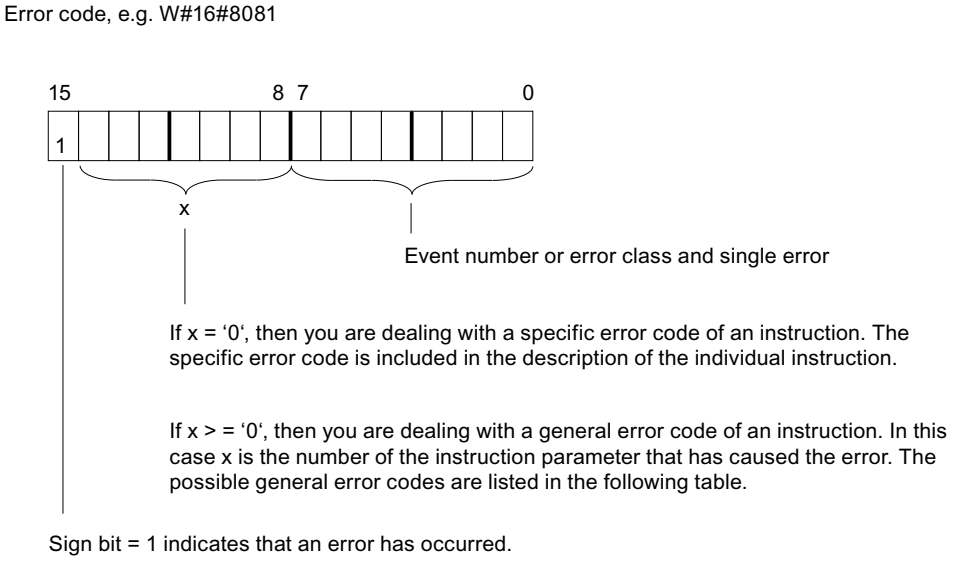
General and specific error information

The return value (RET_VAL) of an instruction provides one of the two following types of error codes:

- A general error code that relates to errors that can occur in any instruction.
- A specific error code that relates only to the particular instruction.

Even though the data type of the output parameter RET_VAL is an integer (INT), the error codes for the instruction are grouped according to hexadecimal values. If you want to examine a return value and compare the value with the error codes listed in this documentation, then display the error code in hexadecimal format.

The figure below shows the structure of a system function error code in hexadecimal format.

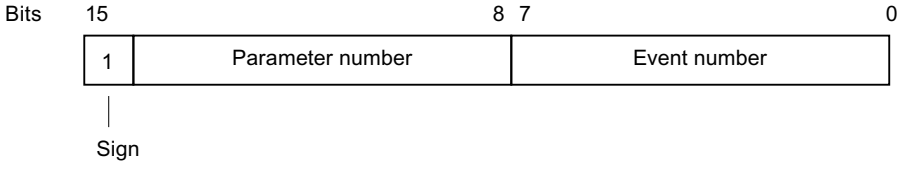


General error information

The general error code indicates errors that can occur in all instructions. A general error code consists of the following two numbers:

- A parameter number from 1 to 111, where 1 indicates the first parameter of the called instruction, 2 the second parameter, and so forth.
- An event number from 0 to 127. The event number indicates that a synchronous error occurred.

The following table lists the codes for general errors and an explanation of each error.



Note

If a general error code was entered in RET_VAL, then the following situations are possible:

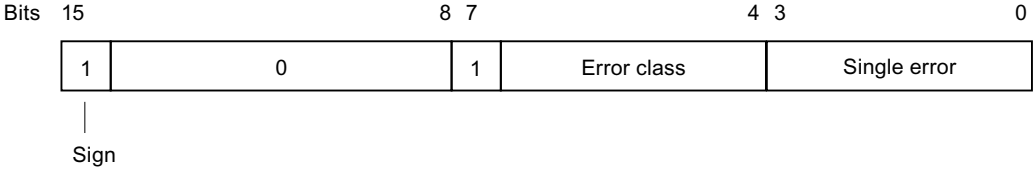
- The action associated with the instruction may have been started or already completed.
- A specific instruction error may have occurred when the action was performed. As a result of a general error that occurred later, the specific error could, however, no longer be indicated.

Specific error information

Some instructions have a return value that provides an error code specific for the instruction. A specific error code indicates errors that can occur only in specific instructions.

A specific error code consists of the following two numbers:

- An error class from 0 to 7.
- An error number from 0 to 15.



General error codes

The following table explains the general error codes of a return value. The error code is shown in hexadecimal format. The letter x in each code number is simply a place holder and represents the number of the system function parameter that caused the error.

General error codes

Error code (W#16#...)	Explanation
8x7F	Internal error This error code indicates an internal error at parameter x.
8x01	Illegal syntax ID at an VARIANT parameter
8x22	Range length error when reading a parameter.
8x23	Range length error when writing a parameter. This error code indicates that the parameter x is located either entirely or partly outside the range of an address, or that the length of a bit range is not a multiple of 8 with an VARIANT parameter.
8x24	Range error when reading a parameter.
8x25	Range error when writing a parameter. This error code indicates that the parameter x is located in a range that is illegal for the system function. Refer to the descriptions of the individual functions for information about the illegal ranges.

Error code (W#16#...)	Explanation
8x26	The parameter contains a timer cell number that is too high. This error code indicates that the timer cell specified in parameter x does not exist.
8x27	The parameter contains a counter cell number that is too high (counter number error). This error code indicates that the counter cell specified in parameter x does not exist.
8x28	Alignment error when reading a parameter.
8x29	Alignment error when writing a parameter. This error code indicates that the reference to parameter x is an operand with bit address that is not equal to 0.
8x30	The parameter is located in a read-only global DB.
8x31	The parameter is located in a read-only instance DB. This error code indicates that parameter x is located in a read-only data block. If the data block was opened by the system function itself, the system function always returns the value W#16#8x30.
8x32	The parameter contains a DB number that is too high (DB number error).
8x34	The parameter contains an FC number that is too high (FC number error).
8x35	The parameter contains an FB number that is too high (FB number error). This error code indicates that parameter x contains a block number higher than the highest permitted number.
8x3A	The parameter contains the number of a DB that is not loaded.
8x3C	The parameter contains the number of an FC that is not loaded.
8x3E	The parameter contains the number of an FB that is not loaded.
8x42	An access error occurred while the system was attempting to read a parameter from the peripheral input area.
8x43	An access error occurred while the system was attempting to write a parameter to the peripheral output area.
8x44	Error in the nth (n > 1) read access after an error occurred.
8x45	Error in the nth (n > 1) write access after an error occurred. This error code indicates that access to the required parameter is denied.

11.6.2 Basic instructions

11.6.2.1 LAD

Bit logic operations

---| |---: Normally open contact

Description

The activation of the normally open contact depends on the signal state of the associated operand. When the operand has signal state "1", the normally open contact closes and the signal state at the output is set to the signal state of the input.

When the operand has signal state "0", the normally open contact is not activated and the signal state at the output of the instruction is reset to "0".

Two or more normally open contacts are linked bit-by-bit by AND when connected in series. With a series connection, power flows when all contacts are closed.

The normally open contacts are linked by OR when connected in parallel. With a parallel connection, power flows when one of the contacts is closed.

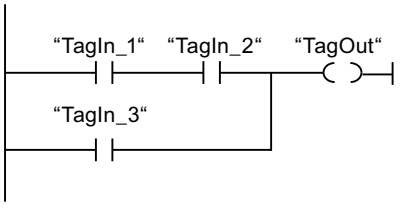
Parameter

The following table shows the parameters of the instruction:

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand>	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Operand whose signal state is queried.

Example

The following example shows how the instruction works:



The "TagOut" operand is set when one of the following conditions is fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The operand "TagIn_3" has the signal state "1".

Example of controlling room temperature (Page 3868)

---| / |---: Normally closed contact

Description

The activation of the normally closed contact depends on the signal state of the associated operand. When the operand has signal state "1", the normally closed contact opens and the signal state at the output of the instruction is reset to "0".

When the operand has signal state "0", the normally closed contact is not enabled and the signal state of the input is transferred to the output.

Two or more normally closed contacts are linked bit-by-bit by AND when connected in series. With a series connection, power flows when all contacts are closed.

The normally closed contacts are linked by OR when connected in parallel. With a parallel connection, power flows when one of the contacts is closed.

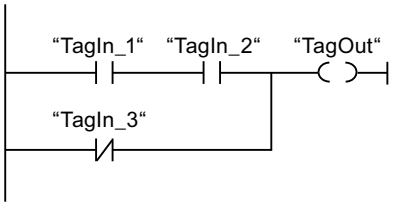
Parameter

The following table shows the parameters of the instruction:

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand>	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Operand whose signal state is queried.

Example

The following example shows how the instruction works:



The "TagOut" operand is set when one of the following conditions is fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The operand "TagIn_3" has the signal state "0".

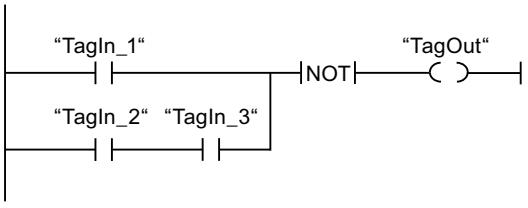
--|NOT|--: Invert RLO

Description

You use the "Invert RLO" instruction to invert the signal state of the result of logic operation (RLO). If the signal state is "1" at the input of the instruction, the output of the instruction has signal state "0". If the signal state is "0" at the input of the instruction, the output has the signal state "1".

Example

The following example shows how the instruction works:



Operand "TagOut" is reset when one of the following conditions is fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The signal state of the operands "TagIn_2" and "TagIn_3" is "1".

---( )---: Assignment

Description

You can use the "Assignment" instruction to set the bit of a specified operand. If the result of logic operation (RLO) at the input of the coil has signal state "1", the specified operand is set to signal state "1". If the signal state is "0" at the input of the coil, the bit of the specified operand is reset to "0".

The instruction does not influence the RLO. The RLO at the input of the coil is sent directly to the output.

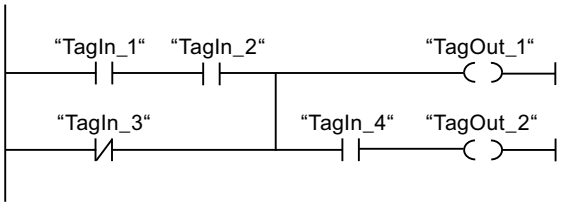
Parameter

The following table shows the parameters of the "Assignment" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand>	Output	BOOL	I, Q, M, D, L	Operand to which the RLO is assigned.

Example

The following example shows how the instruction works:



The "TagOut_1" operand is set when one of the following conditions is fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The signal state of the operand "TagIn_3" is "0".

The "TagOut_2" operand is set when one of the following conditions is fulfilled:

- Operands "TagIn_1", "TagIn_2", and "TagIn_4" have signal state "1".
- The signal state of the "TagIn_3" operand is "0" and the signal state of the "TagIn_4" operand is "1".

See also

Overview of the valid data types (Page 1908)

Example of detecting the fill level of a storage area (Page 3864)

Example of controlling room temperature (Page 3868)

--(/)--: Negate assignment

Description

The "Negate assignment" instruction inverts the result of logic operation (RLO) and assigns it to the specified operand. When the RLO at the input of the coil is "1", the operand is reset. When the RLO at the input of the coil is "0", the operand is set to signal state "1".

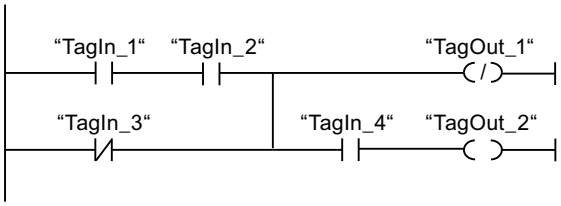
Parameter

The following table shows the parameters of the "Negate assignment" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand>	Output	BOOL	I, Q, M, D, L	Operand to which the RLO is assigned.

Example

The following example shows how the instruction works:



Operand "TagOut_1" is reset when one of the following conditions is fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The signal state of the operand "TagIn_3" is "0".

See also

Overview of the valid data types (Page 1908)

---(R)---: Reset output

Description

You can use the "Reset output" instruction to reset the signal state of a specified operand to "0".

The instruction is only executed if the result of logic operation (RLO) at the input of the coil is "1". If power flows to the coil (RLO = "1"), the specified operand is reset to "0". If the RLO at the input of the coil is "0" (no signal flow to the coil), the signal state of the specified operand remains unchanged.

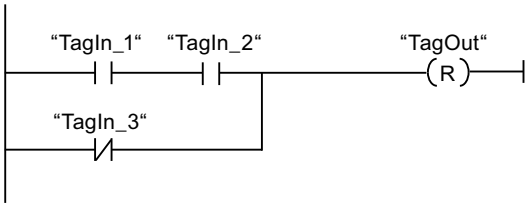
Parameter

The following table shows the parameters of the "Reset output" instruction:

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand>	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Operand that is reset when RLO = "1".

Example

The following example shows how the instruction works:



Operand "TagOut" is reset when one of the following conditions is fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The signal state of the operand "TagIn_3" is "0".

See also

Overview of the valid data types (Page 1908)

Example of controlling a conveyor belt (Page 3861)

Example of detecting the direction of a conveyor belt (Page 3863)

---(S)---: Set output

Description

You can use the "Set output" instruction to set the signal state of a specified operand to "1".

The instruction is only executed if the result of logic operation (RLO) at the input of the coil is "1". If power flows to the coil (RLO = "1"), the specified operand is set to "1". If the RLO at the input of the coil is "0" (no signal flow to the coil), the signal state of the specified operand remains unchanged.

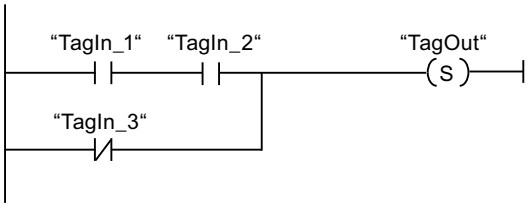
Parameter

The following table shows the parameters of the "Set output" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand>	Output	BOOL	I, Q, M, D, L	Operand which is set with RLO = "1".

Example

The following example shows how the instruction works:



The "TagOut" operand is set when one of the following conditions is fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The signal state of the operand "TagIn_3" is "0".

Example of detecting the direction of a conveyor belt (Page 3863)

SET_BF: Set bit field

Description

You use the instruction "Set bit field" to set multiple bits starting from a certain address.

You determine the number of bits to be set using the value of <Operand1>. The address of the first bit to be set is defined by <Operand2>. If the value of <Operand1> is greater than the number of bits in a selected byte, then the bits of the next byte will be set. The bits remain set until they are explicitly reset, for example, by another instruction.

The instruction is only executed if the result of logic operation (RLO) at the input of the coil is "1". If the RLO at the input of the coil is "0", the instruction does not execute.

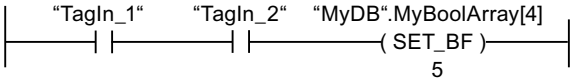
Parameter

The following table shows the parameters of the "Set bit field" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand2>	Output	BOOL	I, Q, M In the case of a DB or an IDB, an element of an ARRAY[..] of BOOL	Pointer to the first bit to be set.
<Operand1>	Input	UINT	Constant	Number of bits to be set.

Example

The following example shows how the instruction works:



If the operands "TagIn_1" and "TagIn_2" have the signal state "1", 5 bits are set starting at the address of the operand "MyDB".MyBoolArray[4]

See also

Overview of the valid data types (Page 1908)

RESET_BF: Reset bit field

Description

You use the "Reset bit field" instruction to reset several bits starting from a certain address.

You specify the number of bits to be reset using the value of <Operand1>. The address of the first bit to be reset is specified by <Operand2>. If the value of <Operand1> is greater than the number of bits in a selected byte, the bits of the next byte will be reset. The bits remain reset until they are explicitly set, for example, by another instruction.

The instruction is only executed if the result of logic operation (RLO) at the input of the coil is "1". If the RLO at the input of the coil is "0", the instruction does not execute.

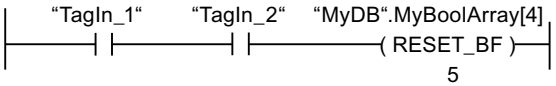
Parameter

The following table shows the parameters of the "Reset bit field" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand2>	Output	BOOL	I, Q, M In the case of a DB or an IDB, an element of an ARRAY[..] of BOOL	Pointer to the first bit to be reset.
<Operand1>	Input	UINT	Constant	Number of bits to be reset.

Example

The following example shows how the instruction works:



If the operands "TagIn_1" and "TagIn_2" have the signal state "1", 5 bits are reset starting at the address of the operand "MyDB".MyBoolArray[4]

See also

Overview of the valid data types (Page 1908)

SR: Set/reset flip-flop

Description

Use the instruction "Set/reset flip-flop" to set or reset the bit of the specified operand, depending on the signal state of the inputs S and R1. If the signal state is "1" at input S and "0" at input R1, the specified operand is set to "1". If the signal state is "0" at input S and "1" at input R1, the specified operand will be reset to "0".

Input R1 takes priority over input S. When the signal state is "1" on both inputs S and R1, the signal state of the specified operand is reset to "0".

The instruction is not executed if the signal state at the two inputs S and R1 is "0". The signal state of the operand then remains unchanged.

The current signal state of the operand is transferred to output Q and can be queried there.

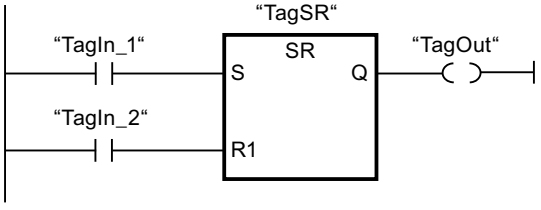
Parameter

The following table shows the parameters of the "Set/reset flip-flop" instruction:

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
S	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable setting
R1	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable reset-ting
<Operand>	InOut	BOOL	I, Q, M, D, L	I, Q, M, D, L	Operand that is set or reset.
Q	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Signal state of the operand

Example

The following example shows how the instruction works:



The operands "TagSR" and "TagOut" are set when the following conditions are fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The operand "TagIn_2" has the signal state "0".

The operands "TagSR" and "TagOut" are reset when one of the following conditions is fulfilled:

- The operand "TagIn_1" has signal state "0" and the operand "TagIn_2" has signal state "1".
- The operands "TagIn_1" and "TagIn_2" have signal state "1".

RS: Reset/set flip-flop

Description

You can use the "Reset/set flip-flop" instruction to reset or set the bit of a specified operand based on the signal state of the inputs R and S1. If the signal state is "1" at input R and "0" at input S1, the specified operand will be reset to "0". If the signal state is "0" at input R and "1" at input S1, the specified operand is set to "1".

Input S1 takes priority over input R. When the signal state is "1" at both inputs R and S1, the signal state of the specified operand is set to "1".

The instruction is not executed if the signal state at the two inputs R and S1 is "0". The signal state of the operand then remains unchanged.

The current signal state of the operand is transferred to output Q and can be queried there.

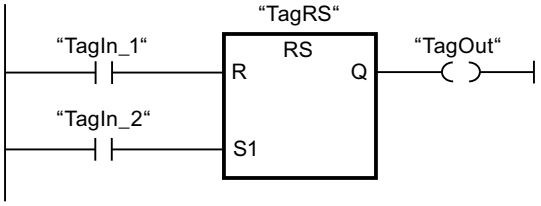
Parameter

The following table shows the parameters of the "Reset/set flip-flop" instruction:

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
R	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable reset-ting
S1	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable setting
<Operand>	InOut	BOOL	I, Q, M, D, L	I, Q, M, D, L	Operand that is reset or set.
Q	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Signal state of the operand

Example

The following example shows how the instruction works:



The operands "TagRS" and "TagOut" are reset when the following conditions are fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The operand "TagIn_2" has the signal state "0".

The operands "TagRS" and "TagOut" are set when one of the following conditions is fulfilled:

- The operand "TagIn_1" has signal state "0" and the operand "TagIn_2" has signal state "1".
- The operands "TagIn_1" and "TagIn_2" have signal state "1".

Overview of the valid data types (Page 1908)

--|P|--: Scan operand for positive signal edge

Description

You can use the "Scan operand for positive signal edge" instruction to determine if there is a "0" to "1" change in the signal state of a specified operand (<Operand1>). The instruction compares the current signal state of <Operand1> with the signal state of the previous scan that is saved in an edge memory bit (<Operand2>). If the instruction detects a change in the result of logic operation (RLO) from "0" to "1", there is a positive, rising edge.

If a positive edge is detected, the output of the instruction has the signal state "1". In all other cases, the signal state at the output of the instruction is "0".

Specify the operand to be queried (<Operand1>) in the operand placeholder above the instruction. Specify the edge memory bit (<Operand2>) in the operand placeholder below the instruction.

Note

The address of the edge memory bit must not be used more than once in the program, otherwise the bit memory is overwritten. This step influences the edge evaluation and the result is therefore no longer unique. The memory area of the edge memory bit must be located in a DB (static area for FB) or in the bit memory area.

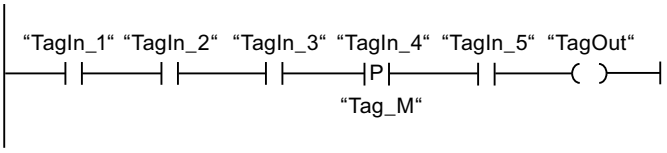
Parameter

The following table shows the parameters of the "Scan operand for positive signal edge" instruction:

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand1>	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Signal to be scanned
<Operand2>	InOut	BOOL	I, Q, M, D, L	I, Q, M, D, L	Edge memory bit in which the signal state of the previous query is saved.

Example

The following example shows how the instruction works:



Operand "TagOut" is set when the following conditions are fulfilled:

- The operands "TagIn_1", "TagIn_2", and "TagIn_3" have signal state "1".
- There is a rising edge at operand "TagIn_4". The signal state of the previous scan is stored in the edge memory bit "Tag_M".
- The signal state of the operand "TagIn_5" is "1".

Example of detecting the direction of a conveyor belt (Page 3863)

--|N|--: Scan operand for negative signal edge

Description

You can use the "Scan operand for negative signal edge" instruction to determine if there is a "1" to "0" change in the signal state of a specified operand (<Operand1>). The instruction compares the current signal state of <Operand1> with the signal state of the previous scan that is saved in an edge memory bit <Operand2>. If the instruction detects a change in the result of logic operation (RLO) from "1" to "0", there is a negative, falling edge.

If a negative signal edge is detected, the output of the instruction has the signal state "1". In all other cases, the signal state at the output of the instruction is "0".

Specify the operand to be queried (<Operand1>) in the operand placeholder above the instruction. Specify the edge memory bit (<Operand2>) in the operand placeholder below the instruction.

Note

The address of the edge memory bit must not be used more than once in the program, otherwise the bit memory is overwritten. This step influences the edge evaluation and the result is therefore no longer unique. The memory area of the edge memory bit must be located in a DB (static area for FB) or in the bit memory area.

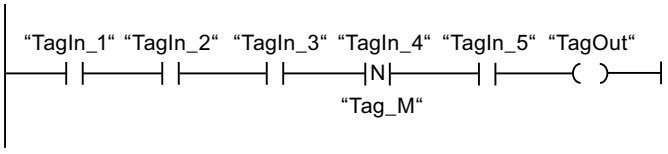
Parameter

The following table shows the parameters of the "Scan operand for negative signal edge" instruction:

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand1>	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Signal to be scanned
<Operand2>	InOut	BOOL	I, Q, M, D, L	I, Q, M, D, L	Edge memory bit in which the signal state of the previous query is saved.

Example

The following example shows how the instruction works:



Operand "TagOut" is set when the following conditions are fulfilled:

- The operands "TagIn_1", "TagIn_2", and "TagIn_3" have signal state "1".
- There is a negative signal edge at operand "TagIn_4". The signal state of the previous scan is stored in the edge memory bit "Tag_M".
- The signal state of the operand "TagIn_5" is "1".

Overview of the valid data types (Page 1908)

--(P)--: Set operand on positive signal edge

Description

You can use the "Set operand on positive signal edge" instruction to set a specified operand (<Operand1>) when there is a "0" to "1" change in the result of logic operation (RLO). The instruction compares the current RLO with the RLO from the previous query, which is saved in the edge memory bit (<Operand2>). If the instruction detects a change in the RLO from "0" to "1", there is a positive signal edge.

When a positive signal edge is detected, <Operand1> is set to signal state "1" for one program cycle. In all other cases, the operand has the signal state "0".

Specify the operand to be set (<Operand1>) in the operand placeholder above the instruction. Specify the edge memory bit (<Operand2>) in the operand placeholder below the instruction.

Note

The address of the edge memory bit must not be used more than once in the program, otherwise the bit memory is overwritten. This step influences the edge evaluation and the result is therefore no longer unique. The memory area of the edge memory bit must be located in a DB (static area for FB) or in the bit memory area.

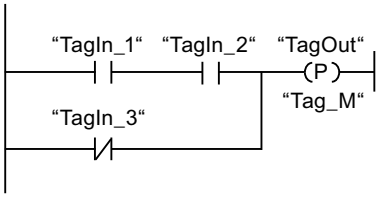
Parameter

The following table shows the parameters of the "Set operand on positive signal edge" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand1>	Output	BOOL	I, Q, M, D, L	Operand which is set by a positive edge.
<Operand2>	InOut	BOOL	I, Q, M, D, L	Edge memory bit

Example

The following example shows how the instruction works:



Operand "TagOut" is set for one program cycle, when the signal state at the input of the coil switches from "0" to "1" (positive signal edge). In all other cases, the operand "TagOut" has the signal state "0".

See also

Overview of the valid data types (Page 1908)

--(N)--: Set operand on negative signal edge

Description

You can use the "Set operand on negative signal edge" instruction to set a specified operand (<Operand1>) when there is a "1" to "0" change in the result of logic operation (RLO). The instruction compares the current RLO with the RLO from the previous query, which is saved in the edge memory bit (<Operand2>). If the instruction detects a change in the RLO from "1" to "0", there is a negative edge.

When a negative signal edge is detected, <Operand1> is set to signal state "1" for one program cycle. In all other cases, the operand has the signal state "0".

Specify the operand to be set (<Operand1>) in the operand placeholder above the instruction. Specify the edge memory bit (<Operand2>) in the operand placeholder below the instruction.

Note

The address of the edge memory bit must not be used more than once in the program, otherwise the bit memory is overwritten. This step influences the edge evaluation and the result is therefore no longer unique. The memory area of the edge memory bit must be located in a DB (static area for FB) or in the bit memory area.

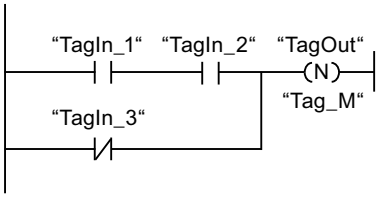
Parameter

The following table shows the parameters of the "Set operand on negative signal edge" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand1>	Output	BOOL	I, Q, M, D, L	Operand which is set by a negative edge.
<Operand2>	InOut	BOOL	I, Q, M, D, L	Edge memory bit

Example

The following example shows how the instruction works:



Operand "TagOut" is set for one program cycle, when the signal state at the input of the coil switches from "1" to "0" (negative signal edge). In all other cases, the operand "TagOut" has the signal state "0".

Overview of the valid data types (Page 1908)

P_TRIG: Scan RLO for positive signal edge

Description

Use the "Scan RLO for positive signal edge" instruction to query a "0" to "1" change in the signal state of the result of logic operation (RLO). The instruction compares the current signal state of the RLO with the signal state of the previous query, which is saved in an edge memory bit (<operand>). If the instruction detects a change in the RLO from "0" to "1", there is a positive signal edge.

If a positive edge is detected, the output of the instruction has the signal state "1". In all other cases, the signal state at the output of the instruction is "0".

Note

The address of the edge memory bit must not be used more than once in the program, otherwise the bit memory is overwritten. This step influences the edge evaluation and the result is therefore no longer unique. The memory area of the edge memory bit must be located in a DB (static area for FB) or in the bit memory area.

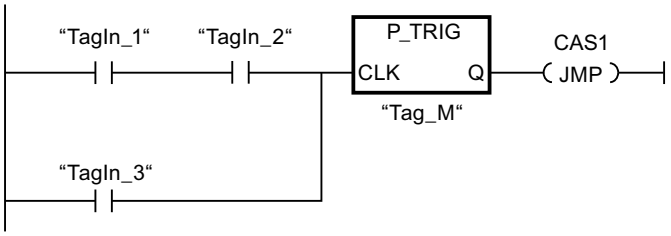
Parameter

The following table shows the parameters of the "Scan RLO for positive signal edge" instruction:

Parameter	Declaration	Data type	Memory area	Description
CLK	Input	BOOL	I, Q, M, D, L	Current RLO
<Operand>	InOut	BOOL	M, D	Edge memory bit in which the RLO of the previous query is saved.
Q	Output	BOOL	I, Q, M, D, L	Result of edge evaluation

Example

The following example shows how the instruction works:



The RLO of the previous query is saved in the edge memory bit "Tag_M". If a "0" to "1" change is detected in the signal state of the RLO, the program jumps to jump label CAS1.

See also

Overview of the valid data types (Page 1908)

N_TRIG: Scan RLO for negative signal edge

Description

Use the "Scan RLO for negative signal edge" instruction to query a "1" to "0" change in the signal state of the result of logic operation (RLO). The instruction compares the current signal state of the RLO with the signal state of the previous query, which is saved in an edge memory bit (<operand>). If the instruction detects a change in the RLO from "1" to "0", there is a negative edge.

If a negative signal edge is detected, the output of the instruction has the signal state "1". In all other cases, the signal state at the output of the instruction is "0".

Note

The address of the edge memory bit must not be used more than once in the program, otherwise the bit memory is overwritten. This step influences the edge evaluation and the result is therefore no longer unique. The memory area of the edge memory bit must be located in a DB (static area for FB) or in the bit memory area.

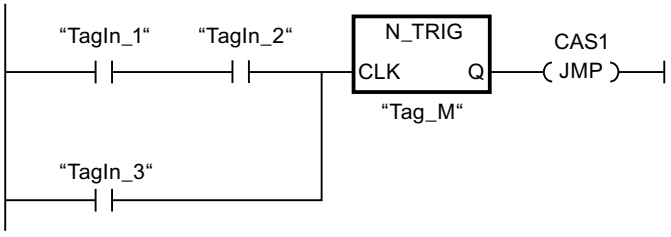
Parameter

The following table shows the parameters of the "Scan RLO for negative signal edge" instruction:

Parameters	Declaration	Data type	Memory area	Description
CLK	Input	BOOL	I, Q, M, D, L	Current RLO
<Operand>	InOut	BOOL	M, D	Edge memory bit in which the RLO of the previous query is saved.
Q	Output	BOOL	I, Q, M, D, L	Result of edge evaluation

Example

The following example shows how the instruction works:



The RLO of the previous query is saved in the edge memory bit "Tag_M". If a "1" to "0" change is detected in the signal state of the RLO, the program jumps to jump label CAS1.

See also

Overview of the valid data types (Page 1908)

R_TRIG: Detect positive signal edge

Description

With the "Detect positive signal edge" instruction, you can detect a state change from "0" to "1" at the CLK input. The instruction compares the current value at the CLK input with the state of the previous query (edge memory bit) that is saved in the specified instance. If the instruction detects a state change at the CLK input from "0" to "1", a positive signal edge is generated at the Q output, i.e., the output has the value TRUE or "1" for exactly one cycle.

In all other cases, the signal state at the output of the instruction is "0".

When you insert the instruction in the program, the "Call options" dialog opens automatically. In this dialog you can specify whether the edge memory bit is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface.

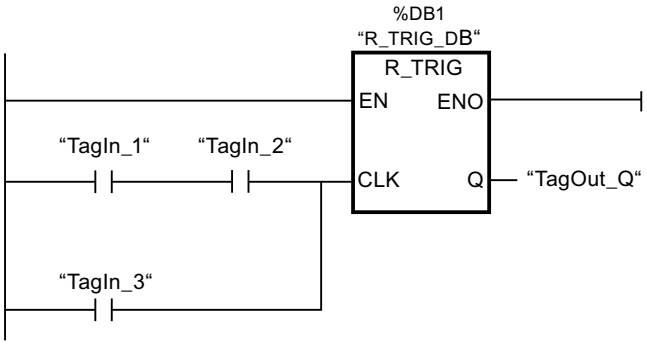
Parameter

The following table shows the parameters of the "Detect positive signal edge" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
CLK	Input	BOOL	I, Q, M, D, L or constant	Incoming signal, the edge of which is to be queried.
Q	Output	BOOL	I, Q, M, D, L	Result of edge evaluation

Example

The following example shows how the instruction works:



The previous state of the tag at the CLK input is stored in the "R_TRIG_DB" tag. If a change in the signal state from "0" to "1" is detected in the "TagIn_1" and "TagIn_2" operands or in the "TagIn_3" operand, the "TagOut_Q" output has signal state "1" for one cycle.

See also

Overview of the valid data types (Page 1908)

F_TRIG: Detect negative signal edge

Description

With the "Detect negative signal edge" instruction, you can detect a state change from "1" to "0" at the CLK input. The instruction compares the current value at the CLK input with the state of the previous query (edge memory bit) that is saved in the specified instance. If the instruction detects a state change at the CLK input from "1" to "0", a negative signal edge is generated at the Q output, i.e., the output has the value TRUE or "1" for exactly one cycle.

In all other cases, the signal state at the output of the instruction is "0".

When you insert the instruction in the program, the "Call options" dialog opens automatically. In this dialog you can specify whether the edge memory bit is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface.

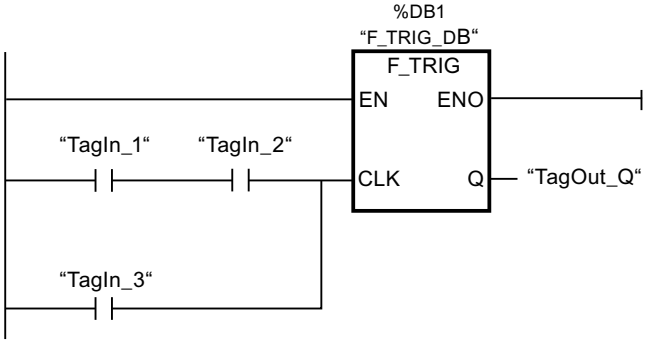
Parameter

The following table shows the parameters of the "Detect negative signal edge" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
CLK	Input	BOOL	I, Q, M, D, L or constant	Incoming signal, the edge of which is to be queried.
Q	Output	BOOL	I, Q, M, D, L	Result of edge evaluation

Example

The following example shows how the instruction works:



The previous state of the tag at the CLK input is stored in the "F_TRIG_DB" tag. If a change in the signal state from "1" to "0" is detected in the "TagIn_1" and "TagIn_2" operands or in the "TagIn_3" operand, the "TagOut_Q" output has signal state "1" for one cycle.

Overview of the valid data types (Page 1908)

Timers

TP: Generate pulse

Description

You can use the "Generate pulse" instruction to set the output Q for a programmed duration. The instruction is started when the result of logic operation (RLO) at input IN changes from "0" to "1" (positive signal edge). The programmed time PT begins when the instruction starts. Output Q is set for the duration PT, regardless of the subsequent course of the input signal. Even if a new positive signal edge is detected, the signal state at the output Q is not affected as long as the PT time duration is running.

You can scan the current time value at the ET output. The time value starts at T#0s and ends when the value of duration PT is reached. When the duration PT is reached and the signal state at input IN is "0", the ET output is reset.

Each call of the "Generate pulse" instruction must be assigned to an IEC timer in which the instruction data is stored.

Note

If the timer is not called in the program because it is skipped, for example, the ET output returns a constant value as soon as the timer has expired.

For S7-1200 CPU

An IEC timer is a structure of the data type IEC_TIMER or TP_TIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TP_TIME, TP_LTIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

An IEC timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TP_TIME or TP_LTIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TP_TIME, TP_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the IEC timer is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

The instruction data is updated both when the instruction is called and also each time the outputs Q or ET are accessed.

The execution of the "Generate pulse" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

Parameters

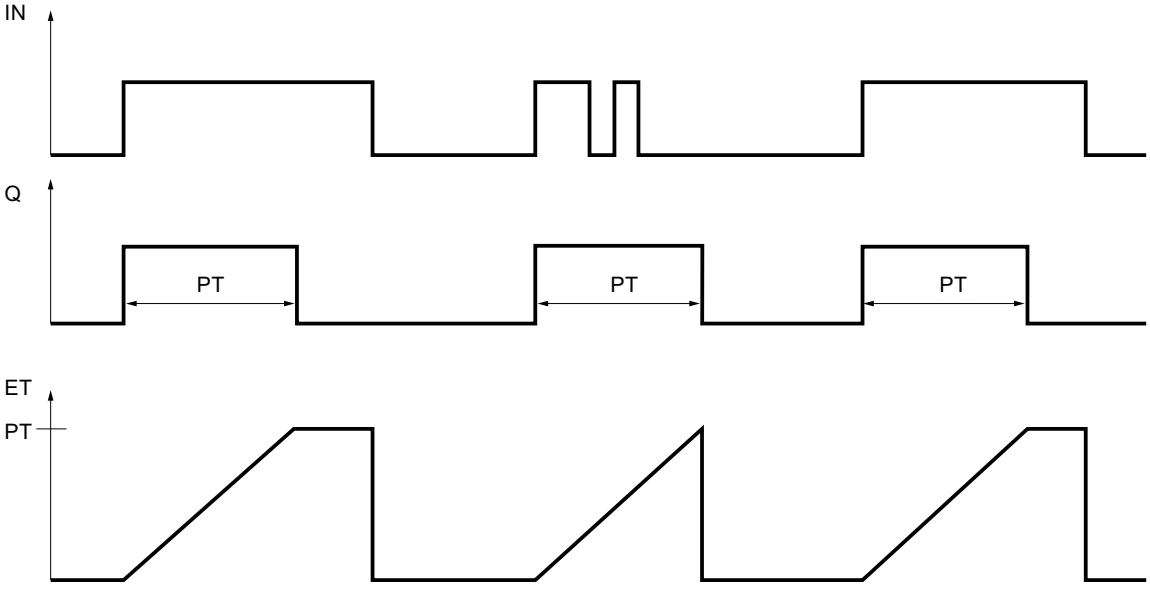
The following table shows the parameters of the "Generate pulse" instruction:

Parameter	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Start input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	I, Q, M, D, L, P or constant	Duration of the pulse The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Pulse output
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L	I, Q, M, D, L, P	Current time value

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Generate pulse" instruction:



See also

Overview of the valid data types (Page 1908)

Example of controlling room temperature (Page 3868)

TON: Generate on-delay

Description

You can use the "Generate on-delay" instruction to delay setting of the Q output by the programmed duration PT. The instruction is started when the result of logic operation (RLO) at input IN changes from "0" to "1" (positive signal edge). The programmed time PT begins when the instruction starts. When the duration PT expires, the output Q has the signal state "1". Output Q remains set as long as the start input is still "1". When the signal state at the start input changes from "1" to "0", the Q output is reset. The timer function is started again when a new positive signal edge is detected at the start input.

The current time value can be queried at the ET output. The time value starts at T#0s and ends when the value of duration PT is reached. The ET output is reset as soon as the signal state at the IN input changes to "0".

Each call of the "Generate on-delay" instruction must be assigned to an IEC timer in which the instruction data is stored.

Note

If the timer is not called in the program because it is skipped, for example, the ET output returns a constant value as soon as the timer has expired.

For S7-1200 CPU

An IEC timer is a structure of the data type IEC_TIMER or TON_TIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TON_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

An IEC timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TON_TIME or TON_LTIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TON_TIME, TON_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the IEC timer is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

The instruction data is updated both when the instruction is called and also each time the outputs Q or ET are accessed.

The execution of the "Generate on-delay" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

Parameters

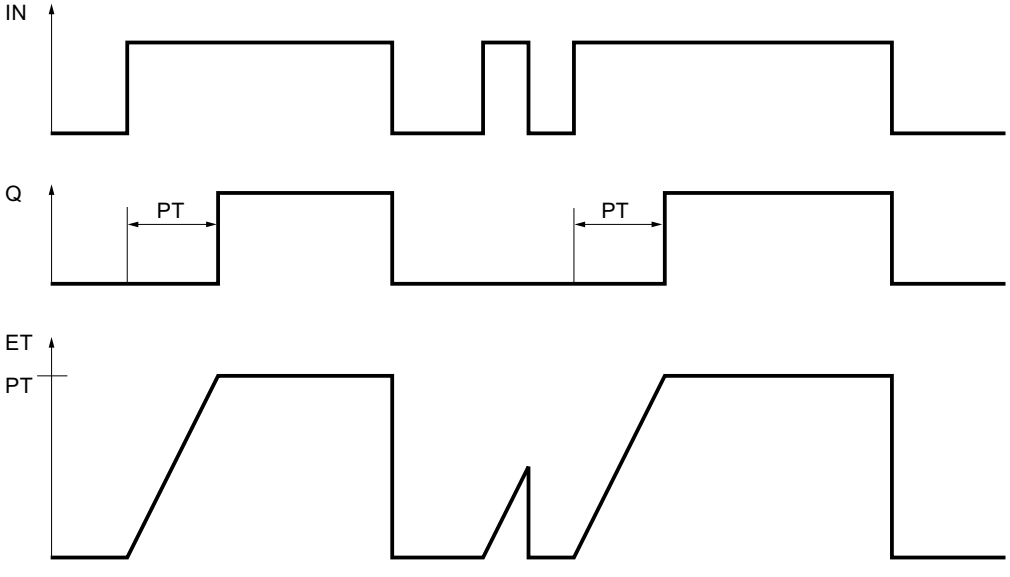
The following table shows the parameters of the "Generate on-delay" instruction:

Parameter	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Start input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	I, Q, M, D, L, P or constant	Duration of the on-delay The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Output that is set when the time PT expires.
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L	I, Q, M, D, L, P	Current time value

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Generate on-delay" instruction:



See also

Overview of the valid data types (Page 1908)

TOF: Generate off-delay

Description

You can use the "Generate off-delay" instruction to delay resetting of the Q output by the programmed duration PT. The Q output is set when the result of logic operation (RLO) at input IN changes from "0" to "1" (positive signal edge). When the signal state at input IN changes back to "0", the programmed time PT starts. Output Q remains set as long as the duration PT is running. When duration PT expires, the Q output is reset. If the signal state at input IN changes to "1" before the PT time duration expires, the timer is reset. The signal state at the output Q continues to be "1".

The current time value can be queried at the ET output. The time value starts at T#0s and ends when the value of duration PT is reached. When the time duration PT expires, the ET output remains set to the current value until the IN input changes back to "1". If input IN switches to "1" before the duration PT has expired, the ET output is reset to the value T#0s.

Each call of the "Generate off-delay" instruction must be assigned to an IEC timer in which the instruction data is stored.

Note

If the timer is not called in the program because it is skipped, for example, the ET output returns a constant value as soon as the timer has expired.

For S7-1200 CPU

An IEC timer is a structure of the data type IEC_TIMER or TOF_TIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TOF_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

An IEC timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TOF_TIME or TOF_LTIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TOF_TIME, TOF_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the IEC timer is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, you will find it

in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

The instruction data is updated both when the instruction is called and also each time the outputs Q or ET are accessed.

The execution of the "Generate off-delay" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

Parameters

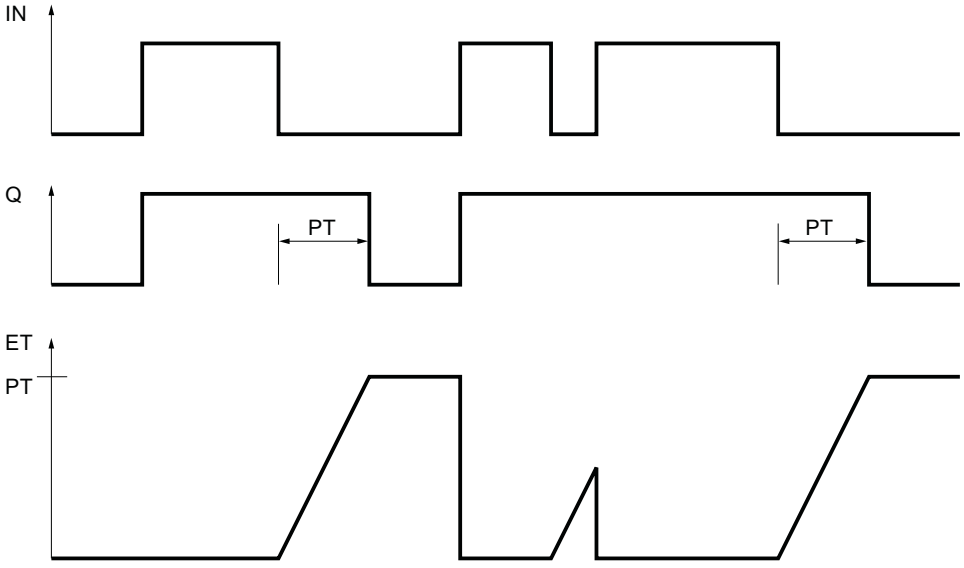
The following table shows the parameters of the "Generate off-delay" instruction:

Parameter	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Start input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	I, Q, M, D, L, P or constant	Duration of the off delay The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Output that is reset when the timer PT expires.
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L	I, Q, M, D, L, P	Current time value

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Generate off-delay" instruction:



See also

Overview of the valid data types (Page 1908)

TONR: Time accumulator

Description

The "Time accumulator" instruction is used to accumulate time values within a period set by the PT parameter. When the signal state at input IN changes from "0" to "1" (positive signal edge), the instruction is executed and the duration PT starts. While the duration PT is running, the time values are accumulated that are recorded when the IN input has signal state "1". The accumulated time is written to output ET and can be queried there. When the duration PT expires, the output Q has signal state "1". The Q parameter remains set to "1", even when the signal state at the IN parameter changes from "1" to "0" (negative signal edge).

The R input resets the outputs ET and Q regardless of the signal state at the start input.

Each call of the "Time accumulator" instruction must be assigned to an IEC timer in which the instruction data is stored.

For S7-1200 CPU

An IEC timer is a structure of the data type IEC_TIMER or TONR_TIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TONR_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

An IEC timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TONR_TIME or TONR_LTIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TONR_TIME, TONR_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

When you insert the instruction in the program, the "Call options" dialog opens automatically, in which you can specify whether the IEC timer is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

The instruction data is updated both when the instruction is called and also each time the outputs Q or ET are accessed.

The execution of the Time accumulator" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

Parameters

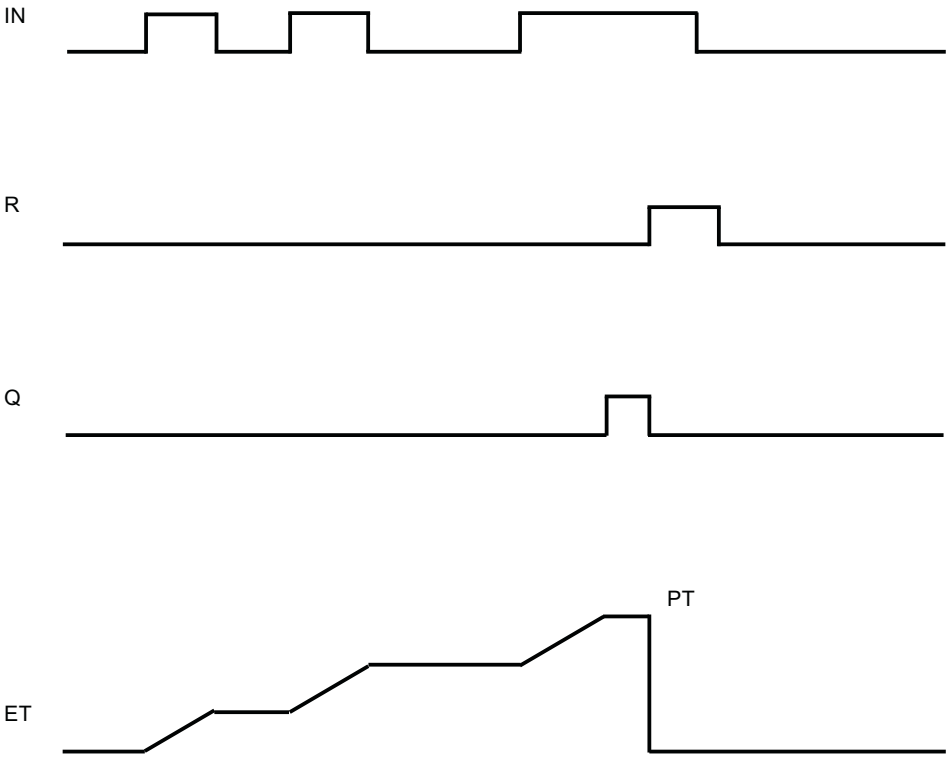
The following table shows the parameters of the "Time accumulator" instruction:

Parameter	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Start input
R	Input	BOOL	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L, P, or constant	Reset input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	I, Q, M, D, L, P, or constant	Maximum duration of time recording The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Output that is set when the time PT expires.
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L	I, Q, M, D, L, P	Accumulated time

You can find additional information on valid data types under "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Time accumulator" instruction:



See also

Overview of the valid data types (Page 1908)

---(TP)---: Start pulse timer

Description

Use the "Start pulse timer" instruction to start an IEC timer with a specified duration as pulse. The IEC timer is started when the result of logic operation (RLO) changes from "0" to "1" (positive signal edge). The IEC timer runs for the specified duration regardless of any subsequent changes in the RLO. The run of the IEC timer is also not affected by the detection of a new positive signal edge. As long as the IEC timer is running, the querying of the timer status for "1" returns the signal state "1". When the IEC timer has expired, the timer status returns the signal state "0".

Note

You can start and query the IEC timer at various execution levels, as each querying of the outputs Q or ET updates the IEC_TIMER structure.

For S7-1200 CPU

The instruction "Start pulse timer" stores its data in a structure of the data type IEC_TIMER or TP_TIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TP_LTIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

The instruction "Start pulse timer" stores its data in a structure of the data type IEC_TIMER, IEC_LTIMER, TP_TIME or TP_LTIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TP_TIME, TP_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

The instruction data is updated both when the instruction is called and also each time the assigned timer is accessed.

The current timer status is stored in the Q structure component of the IEC timer. You can use a normally open contact to query timer status for "1" or a normally closed contact for "0". The query on Q or ET (for example, "MyTimer".Q or "MyTimer".ET) updates the IEC_TIMER structure.

The execution of the "Start pulse timer" instruction assumes a preceding logic operation. It can be placed only at the end of the network.

Parameter

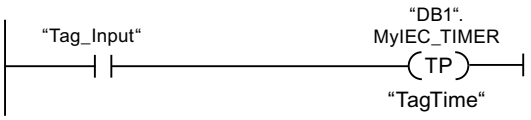
The following table shows the parameters of the "Start pulse timer" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Time duration>	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	Duration with which the IEC timer runs.
<IEC timer>	InOut	IEC_TIMER, TP_TIME	IEC_TIMER, IEC_LTIMER, TP_TIME, TP_LTIME	D, L	IEC timer that is started.

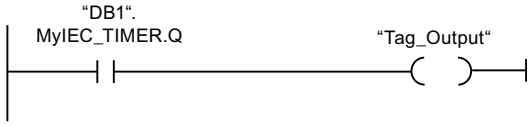
For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "Start pulse timer" instruction is executed when the signal state of the operand "Tag_Input" changes from "0" to "1". The timer "DB1".MyIEC_TIMER is started for the time stored in the operand "TagTime".



As long as the timer "DB1". MyIEC_TIMER is running, the timer status ("DB1".MyIEC_TIMER.Q) has signal state "1" and the operand "Tag_Output" is set. When the IEC timer has expired, the signal state of the time status changes back to "0" and the "Tag_Output" operand is reset.

See also

Overview of the valid data types (Page 1908)

---(TON)---: Start on-delay timer

Description

Use the "Start on-delay timer" instruction to start an IEC timer with a specified duration as on-delay. The IEC timer is started when the result of logic operation (RLO) changes from "0" to "1" (positive signal edge). The IEC timer runs for the specified time. The output returns the signal state "1" if the RLO at the input of the instruction has the signal state "1". If the RLO changes to "0" before the time expires, the IEC timer is reset. In this case, querying the timer status for "1" returns signal state "0". The IEC timer restarts when the next positive signal edge is detected at the input of the instruction.

Note

You can start and query the IEC timer at various execution levels, as each querying of the outputs Q or ET updates the IEC_TIMER structure.

For S7-1200 CPU

The instruction "Start on-delay timer" stores its data in a structure of the data type IEC_TIMER or TON_TIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TON_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

The "Start on-delay timer" instruction stores its data in a structure of the data type IEC_TIMER, IEC_LTIMER, TON_TIME or TON_LTIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TON_TIME, TON_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

The instruction data is updated both when the instruction is called and also each time the assigned timer is accessed.

The current timer status is stored in the ET structure component of the IEC timer. You can use a normally open contact to query timer status for "1" or a normally closed contact for "0". The query on Q or ET (for example, "MyTimer".Q or "MyTimer".ET) updates the IEC_TIMER structure.

The execution of the "Start on-delay timer" instruction assumes a preceding logic operation. It can be placed only at the end of the network.

Parameter

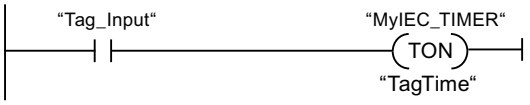
The following table shows the parameters of the "Start on-delay timer" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Time duration>	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	Duration with which the IEC timer runs.
<IEC timer>	InOut	IEC_TIMER, TON_TIME	IEC_TIMER, IEC_LTIMER, TON_TIME, TON_LTIME	D, L	IEC timer that is started.

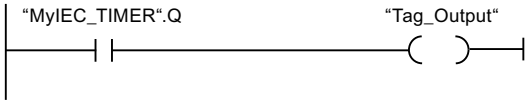
For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "Start on-delay timer" instruction is executed when the signal state of the operand "Tag_Input" changes from "0" to "1". The "MyIEC_TIMER timer is started for the time stored in the "TagTime" operand.



If the timer "MyIEC_TIMER" has expired and the operand "Tag_Input" has the signal state "1", querying the timer status ("MyIEC_TIMER).Q) returns signal state "1" and the "Tag_Output" operand is set. When the signal state of the operand "Tag_Input" changes to "0", the querying of the timer status returns the signal state "0" and the operand "Tag_Output" is reset.

See also

Overview of the valid data types (Page 1908)

---(TOF)---: Start off-delay timer

Description

Use the "Start off-delay timer" instruction to start an IEC timer with a specified duration as on-delay. The query of the timer status for "1" returns the signal state "0" if the result of logic operation (RLO) at the input of the instruction has the signal state "1". When the RLO changes from "1" to "0" (negative signal edge), the IEC timer starts with the specified time. The timer status remains at signal state "1" as long as the IEC timer is running. When the timer has run out and the RLO at the input of the instruction has the signal state "0", the timer status is set to the signal state "0". If the RLO changes to "1" before the time expires, the IEC timer is reset and the timer status remains at signal state "1".

Note

You can start and query the IEC timer at various execution levels, as each querying of the outputs Q or ET updates the IEC_TIMER structure.

For S7-1200 CPU

The instruction "Start off-delay timer" stores its data in a structure of the data type IEC_TIMER or TOF_TIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TOF_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

The "Start off-delay timer" instruction stores its data in a structure of the data type IEC_TIMER, IEC_LTIMER, TOF_TIME or TOF_LTIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TOF_TIME, TOF_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

The instruction data is updated both when the instruction is called and also each time the assigned timer is accessed.

The current timer status is stored in the ET structure component of the IEC timer. You can use a normally open contact to query timer status for "1" or a normally closed contact for "0". The query on Q or ET (for example, "MyTimer".Q or "MyTimer".ET) updates the IEC_TIMER structure.

The execution of the "Start off-delay timer" instruction assumes a preceding logic operation. It can be placed only at the end of the network.

Parameters

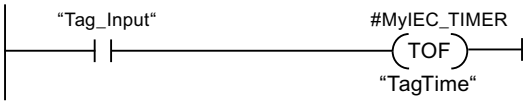
The following table shows the parameters of the "Start off-delay timer" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Time duration>	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	Duration with which the IEC timer runs.
<IEC timer>	InOut	IEC_TIMER, TOF_TIME	IEC_TIMER, IEC_LTIMER, TOF_TIME, TOF_LTIME	D, L	IEC timer that is started.

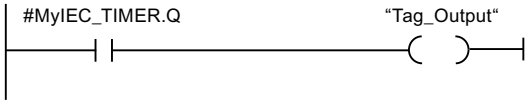
For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "Start off-delay timer" instruction is executed when the signal state of the operand "Tag_Input" changes from "1" to "0". The timer #MyIEC_TIMER is started for the time stored in the operand "TagTime".



As long as timer #MyIEC_TIMER is running, the query of the time status (#MyIEC_TIMER.Q) returns the signal state "1" and operand "Tag_Output" is set. If the timer has expired and the operand "Tag_Input" has the signal state "0", the query of the timer status returns the signal state "0". If the signal state of the operand "Tag_Input" changes to "1" before timer #MyIEC_TIMER expires, the timer is reset. When the signal state of the operand "Tag_Input" is "1", the query of the timer status returns the signal state "1".

See also

Overview of the valid data types (Page 1908)

---(TONR)---: Time accumulator

Description

You can use the "Time accumulator" instruction to record how long the signal is at the input of instruction "1". The instruction is started when the result of logic operation (RLO) changes from "0" to "1" (positive signal edge). The time is recorded as long at the RLO is "1". If the RLO changes to "0", the instruction is halted. If the RLO changes back to "1", the time recording is continued. The query of the timer status for "1" returns the signal state "1" if the recorded time exceeds the value of the specified duration and the RLO at the input of coil is "1".

The timer status and the currently expired timer can be reset to "0" using the "Reset timer" instruction.

Note

You can start and query the IEC timer at various execution levels, as each querying of the outputs Q or ET updates the IEC_TIMER structure.

For S7-1200 CPU

The "Time accumulator" instruction stores its data in a structure of the data type IEC_TIMER or TONR_TIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TONR_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

The "Time accumulator" instruction stores its data in a structure of the data type IEC_TIMER, IEC_LTIMER, TONR_TIME or TONR_LTIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TONR_TIME, TONR_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

The instruction data is updated both when the instruction is called and also each time the assigned timer is accessed.

The current timer status is stored in the ET structure component of the IEC timer. You can use a normally open contact to query timer status for "1" or a normally closed contact for "0". The query on Q or ET (for example, "MyTimer".Q or "MyTimer".ET) updates the IEC_TIMER structure.

The execution of the Time accumulator" instruction requires a preceding logic operation. It can be placed only at the end of the network.

Parameter

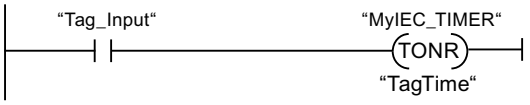
The following table shows the parameters of the "Time accumulator" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Time duration>	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	Duration with which the IEC timer runs.
<IEC timer>	InOut	IEC_TIMER, TONR_TIME	IEC_TIMER, IEC_LTIMER, TONR_TIME, TONR_LTIME	D, L	IEC timer that is started.

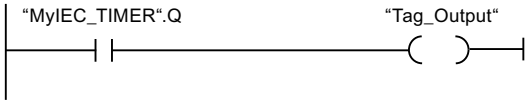
For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "Time accumulator" instruction executes on a positive signal edge in the RLO. The time is recorded as long as the operand "Tag_Input" has the signal state "1".



If the recorded time exceeds the value of the operand "TagTime", then the query of the timer status ("MyIEC_TIMER".Q) will return the signal state "1" and the operand "Tag_Output" will be set.

See also

Overview of the valid data types (Page 1908)

---(RT)---: Reset timer

Description

You can use the "Reset timer" instruction to reset an IEC timer to "0". The instruction is only executed if the result of logic operation (RLO) at the input of the coil is "1". If current is flowing to the coil (RLO is "1"), the structure components of the timer in the specified data block are reset to "0". If the RLO at the input of the instruction is "0", the timer remains unchanged.

The instruction does not influence the RLO. The RLO at the input of the coil is sent directly to the output of the coil.

You assign the "Reset timer" instruction an IEC timer that has been declared in the program.

The instruction data is updated only when the instruction is called and not each time the assigned IEC timer is accessed. Querying the data is only identical from the call of the instruction to the next call of the instruction.

Parameters

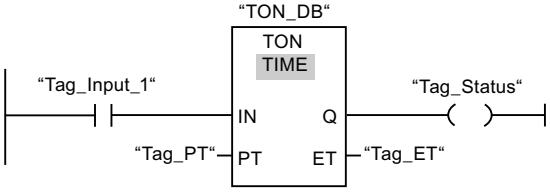
The following table shows the parameters of the "Reset timer" instruction":

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<IEC timer>	Output	IEC_TIMER, TP_TIME, TON_TIME, TOF_TIME, TONR_TIME	IEC_TIMER, IEC_LTIMER, TP_TIME, TP_LTIME, TON_TIME, TON_LTIME, TOF_TIME, TOF_LTIME, TONR_TIME, TONR_LTIME	D, L	IEC timer that is reset.

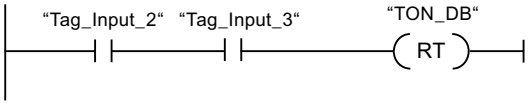
For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "Generate on-delay" instruction executes when the signal state of the "Tag_Input_1" operand changes from "0" to "1". The timer stored in the "TON_DB" instance data block starts running for the time duration specified by operand "Tag_PT".



If operands "Tag_Input_2" and "Tag_Input_3" have the signal state "1", the "Reset timer" instruction is executed and the timer stored in the "TON_DB" data block.

See also

Overview of the valid data types (Page 1908)

---(PT)---: Load time duration

Description

You can use the "Load time duration" instruction to set the time for an IEC timer. The instruction is executed in every cycle when the result of logic operation (RLO) at the input of the instruction has the signal state "1". The instruction writes the specified time to the structure of the specified IEC timer.

Note

If the specified IEC timer is running while the instruction executes, the instruction overwrites the current time of the specified IEC timer. This can change the timer status of the IEC timer.

You assign an IEC timer declared in the program to the "Load time duration" instruction.

The instruction data is updated only when the instruction is called and each time the assigned IEC timer is accessed. The query on Q or ET (for example, "MyTimer".Q or "MyTimer".ET) updates the IEC_TIMER structure.

Parameter

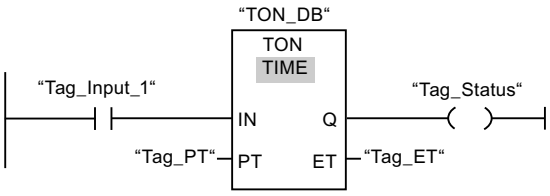
The following table shows the parameters of the "Load time duration" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Time duration>	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	Duration with which the IEC timer runs.
<IEC timer>	Output	IEC_TIMER, TP_TIME, TON_TIME, TOF_TIME, TONR_TIME	IEC_TIMER, IEC_LTIMER, TP_TIME, TP_LTIME, TON_TIME, TON_LTIME, TOF_TIME, TOF_LTIME, TONR_TIME, TONR_LTIME	D, L	IEC timer, the duration of which is set.

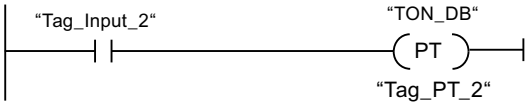
For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "Generate on-delay" instruction executes when the signal state of the "Tag_Input_1" operand changes from "0" to "1". The IEC timer stored in the instance data block "TON_DB" is started with the time duration that is specified by the operand "Tag_PT".



The "Load time duration" instruction is executed when the operand "Tag_Input_2" has the signal state "1". The instruction writes the time duration "Tag_PT_2" in the instance data block "TON_DB" and at the same time overwrites the value of the operand "Tag_PT" within the data block. The signal state of the timer status may therefore change at the next query or when "MyTimer".Q or "MyTimer".ET are accessed.

Overview of the valid data types (Page 1908)

Legacy

S_PULSE: Assign pulse timer parameters and start

Description

The "Assign pulse timer parameters and start" instruction starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at input S. The timer expires with the programmed duration (TV) as soon as the signal state at input S is "1". If the signal state at input S changes to "0" before the programmed duration expires, the timer is stopped. In this case, the signal state at output Q is "0".

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down towards zero. The time base indicates the time period with which the time value is changed. The current time value is output BI-coded at output BI and BCD-coded at output BCD.

If the timer is running and the signal state at input R changes to "1" then the current time value and the time base are also set to zero. If the timer is not running, the signal state "1" at the R input has no effect.

The "Assign pulse timer parameters and start" instruction requires a preceding logic operation for edge evaluation and can be placed within or at the end of the network.

The instruction data is updated at every access. It can therefore happen that the query of the data at the start of the cycle returns different values than at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameters

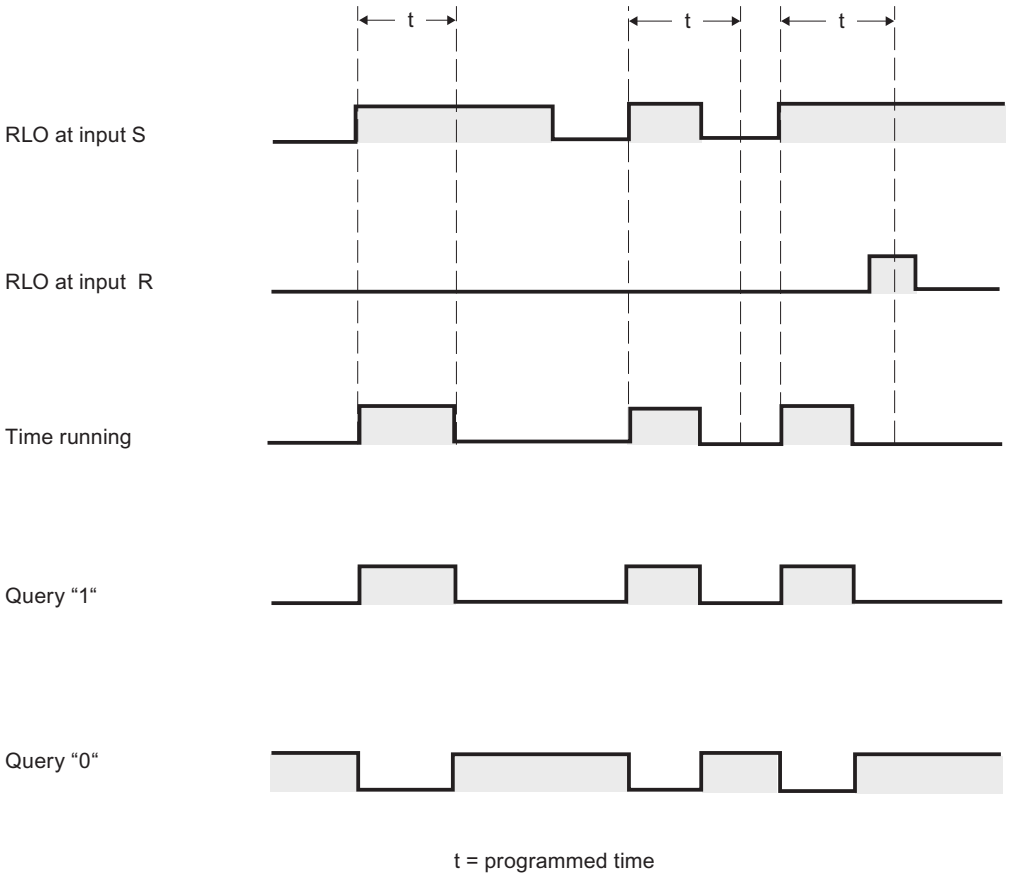
The following table shows the parameters of the instruction "Assign pulse timer parameters and start":

Parameter	Declaration	Data type	Memory area	Description
<Timer>	InOut/Input	TIMER	T	Time of the instruction The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, D, L	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Preset time value
R	Input	BOOL	I, Q, M, T, C, D, L, P or constant	Reset input
BI	Output	WORD	I, Q, M, D, L, P	Current time value (BI-coded)
BCD	Output	WORD	I, Q, M, D, L, P	Current time value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the timer

For additional information on valid data types, refer to "See also".

Pulse timing diagram

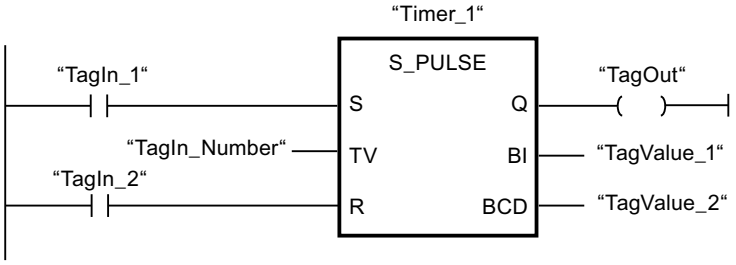
The following figure shows the pulse timing diagram of the instruction "Assign pulse timer parameters and start":



t = programmed time

Example

The following example shows how the instruction works:



The timer "Timer_1" is started when the signal state of the operand "TagIn_1" changes from "0" to "1". The timer expires with the time value of the operand "TagIn_Number" as long as the operand "TagIn_1" has the signal state "1". If the signal state of the operand "TagIn_1" changes from "1" to "0" before the timer expires, the timer "Timer_1" is stopped. The operand "TagOut" is reset to "0" in this case.

The operand "TagOut" has the signal state "1" as long as the timer is running and the operand "TagIn_1" has the signal state "1". When the timer expires or is reset, the operand "TagOut" is reset to "0".

Overview of the valid data types (Page 1908)

S_PEXT: Assign extended pulse timer parameters and start

Description

The "Assign extended pulse timer parameters and start" instruction starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at input S. The timer expires with the programmed duration (TV), even if the signal state at input S changes to "0". As long as the timer is running, the output Q has the signal state "1". When the timer expires, the output Q is reset to "0". If the signal state at input S changes from "0" to "1" while the timer is running, the timer is restarted with the duration programmed at input TV.

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down towards zero. The time base indicates the time period with which the time value is changed. The current time value is output BI-coded at output BI and BCD-coded at output BCD.

If the timer is running and the signal state at input R changes to "1" then the current time value and the time base are also set to zero. If the timer is not running, the signal state "1" at the R input has no effect.

The "Assign extended pulse timer parameters and start" instruction requires a preceding logic operation for edge evaluation and can be placed within or at the end of the network.

The instruction data is updated at every access. It can therefore happen that the query of the data at the start of the cycle returns different values than at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameter

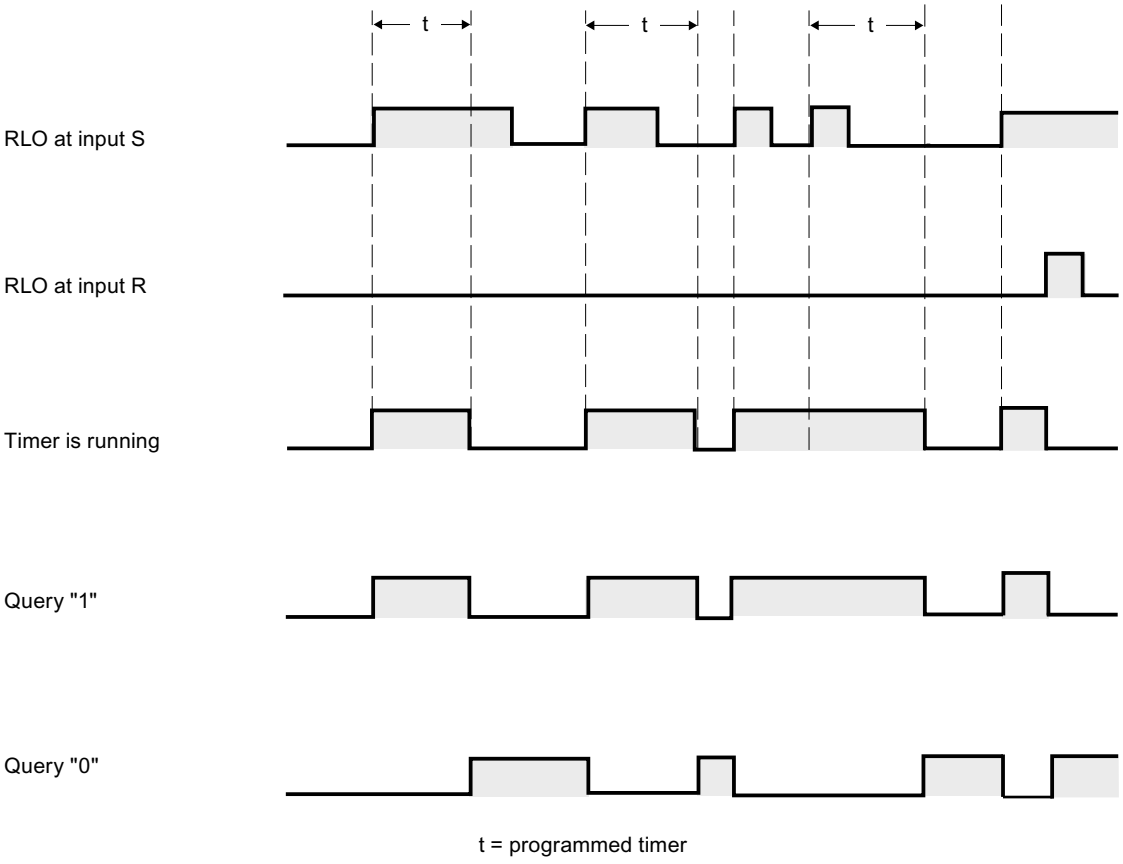
The following table shows the parameters of the instruction "Assign extended pulse timer parameters and start":

Parameter	Declaration	Data type	Memory area	Description
<Timer>	InOut/Input	TIMER	T	Time of the instruction The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, D, L	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Preset time value
R	Input	BOOL	I, Q, M, T, C, D, L, P or constant	Reset input
BI	Output	WORD	I, Q, M, D, L, P	Current time value (BI-coded)
BCD	Output	WORD	I, Q, M, D, L, P	Current time value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the timer

For additional information on valid data types, refer to "See also".

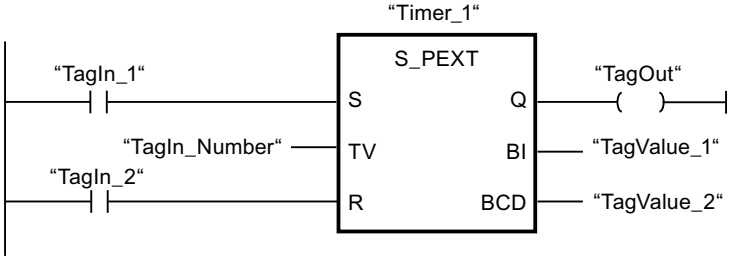
Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign extended pulse timer parameters and start" instruction:



Example

The following example shows how the instruction works:



The timer "Timer_1" is started when the signal state of the operand "TagIn_1" changes from "0" to "1". The timer expires with the time value of the operand "TagIn_Number" without being affected by a negative edge at input S. If the signal state of the operand "TagIn_1" changes from "0" to "1" before the timer expires, the timer is restarted.

The operand "TagOut" has the signal state "1" as long as the timer is running. When the timer expires or is reset, the operand "TagOut" is reset to "0".

Overview of the valid data types (Page 1908)

S_ODT: Assign on-delay timer parameters and start

Description

The "Assign on-delay timer parameters and start" instruction starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at input S. The timer expires with the programmed duration (TV) as soon as the signal state at input S is "1". If the timer expires correctly and input S still has signal state "1" then output Q returns signal state "1". If the signal state at input S changes from "1" to "0" while the timer is running, the timer is stopped. In this case, output Q is reset to signal state "0".

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down towards zero. The time base indicates the time period with which the time value is changed. The current time value is output BI-coded at output BI and BCD-coded at output BCD.

If the time is running and the signal state at input R changes from "0" to "1" then the current time value and the time base are also set to zero. In this case, the signal state at output Q is "0". The timer is reset if the signal state is "1" at the R input even if the timer is not running and the RLO at input S is "1".

Specify the timer of the instruction in the placeholder above the box. The timer must be declared with the data type TIMER.

The "Assign on-delay timer parameters and start" instruction requires a preceding logic operation for edge evaluation and can be placed within or at the end of the network.

The instruction data is updated at every access. It can therefore happen that the query of the data at the start of the cycle returns different values than at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameter

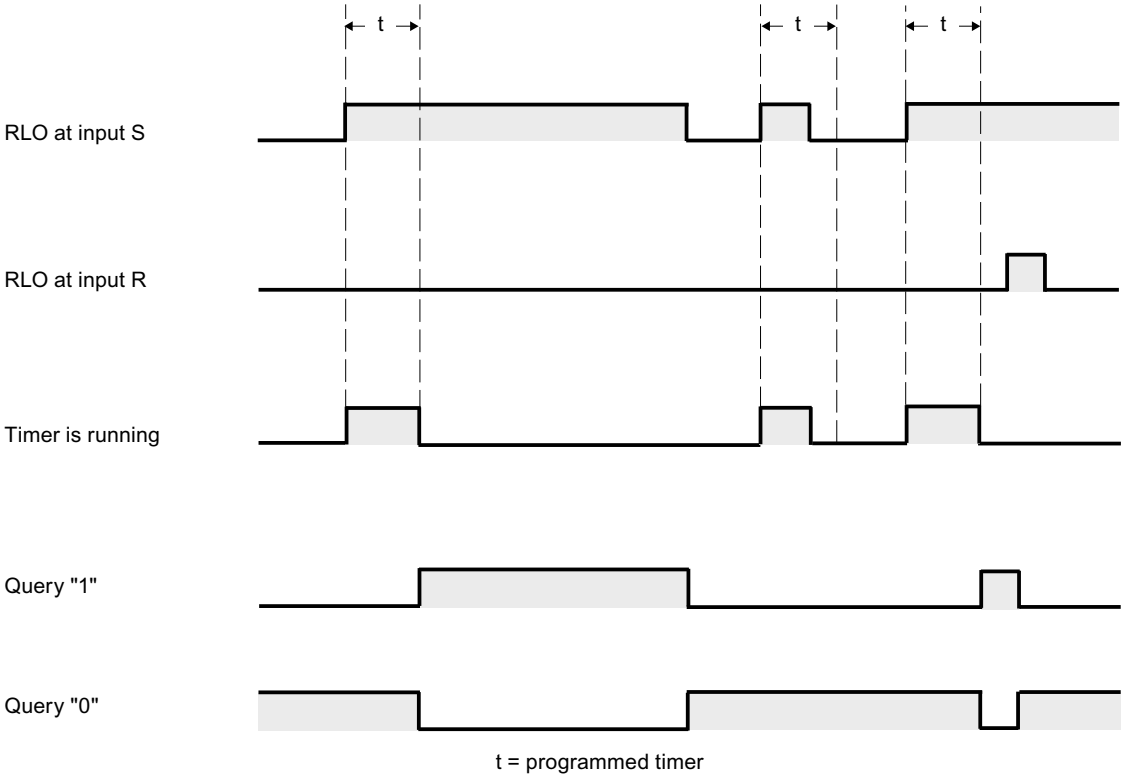
The following table shows the parameters of the "Assign on-delay timer parameters and start" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Timer>	InOut/Input	TIMER	T	Time of the instruction The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, D, L	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Preset time value
R	Input	BOOL	I, Q, M, T, C, D, L, P or constant	Reset input
BI	Output	WORD	I, Q, M, D, L, P	Current time value (BI-coded)
BCD	Output	WORD	I, Q, M, D, L, P	Current time value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the timer

For additional information on valid data types, refer to "See also".

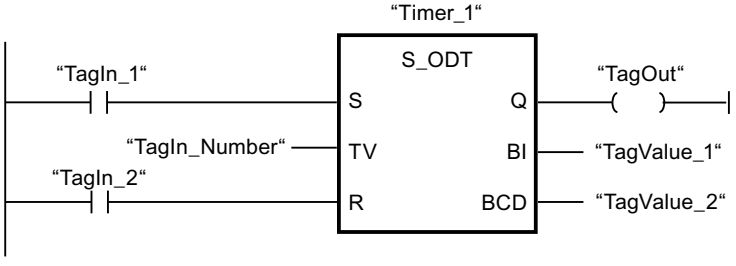
Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign on-delay timer parameters and start" instruction:



Example

The following example shows how the instruction works:



The timer "Timer_1" is started when the signal state of the operand "TagIn_1" changes from "0" to "1". The timer expires with the time value of the operand "TagIn_Number". If the timer expires and the operand has the signal state "1", the operand "TagOut" is set to "1". If the signal state of the operand "TagIn_1" changes from "1" to "0" before the timer expires, the timer is stopped. The operand "TagOut" has the signal state "0" in this case.

Overview of the valid data types (Page 1908)

S_ODTS: Assign retentive on-delay timer parameters and start

Description

The "Assign retentive on-delay timer parameters and start" instruction starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at input S. The timer expires with the programmed duration (TV), even if the signal state at input S changes to "0". If the timer expires, the "Q" output returns signal state "1" regardless of the signal state at input "S". If the signal state at input S changes from "0" to "1" while the timer is running, the timer is restarted with the duration programmed at input (TV).

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down towards zero. The time base indicates the time period with which the time value is changed. The current time value is output BI-coded at output BI and BCD-coded at output BCD.

Signal state "1" at input R resets the current time value and time base to "0" regardless of the signal state at start input S. In this case, the signal state at output Q is "0".

The "Assign retentive on-delay timer parameters and start" instruction requires a preceding logic operation for edge evaluation and can be placed within or at the end of the network.

The instruction data is updated at every access. It can therefore happen that the query of the data at the start of the cycle returns different values than at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameter

The following table shows the parameters of the "Assign retentive on-delay timer parameters and start" instruction:

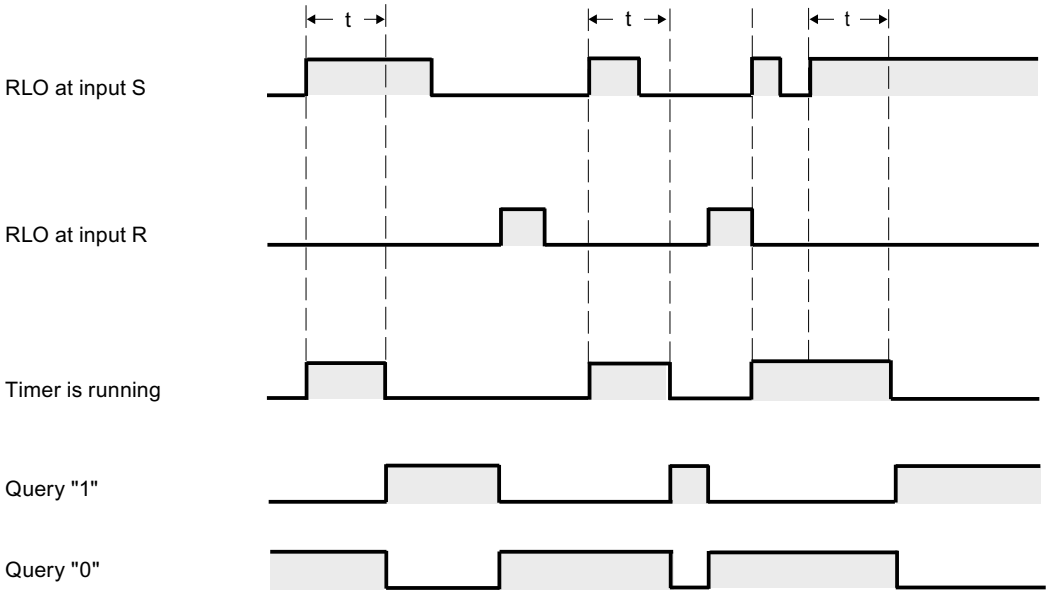
Parameter	Declaration	Data type	Memory area	Description
<Timer>	InOut/Input	TIMER	T	Time of the instruction The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, D, L	Start input

Parameter	Declaration	Data type	Memory area	Description
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Preset time value
R	Input	BOOL	I, Q, M, T, C, D, L, P or constant	Reset input
BI	Output	WORD	I, Q, M, D, L, P	Current time value (BI-coded)
BCD	Output	WORD	I, Q, M, D, L, P	Current time value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the timer

For additional information on valid data types, refer to "See also".

Pulse timing diagram

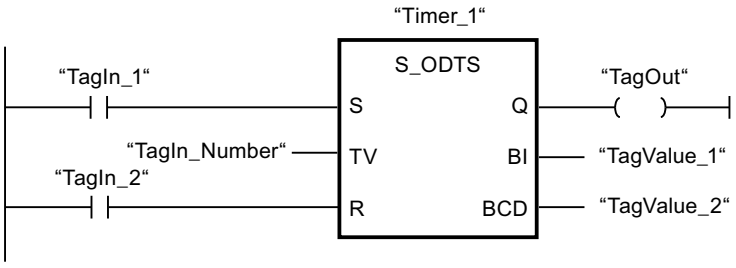
The following figure shows the pulse timing diagram of the "Assign retentive on-delay timer parameters and start" instruction:



t = programmed timer

Example

The following example shows how the instruction works:



The timer "Timer_1" is started when the signal state of the operand "TagIn_1" changes from "0" to "1". The timer expires with the time value of the operand "TagIn_Number", even if the signal state of the operand "TagIn_1" changes to "0". When the timer expires, the operand "TagOut" is set to "1". If the signal state of the operand "TagIn_1" changes from "0" to "1" while the timer is running, the timer is restarted.

Overview of the valid data types (Page 1908)

S_OFFDT: Assign off-delay timer parameters and start

Description

The "Assign off-delay timer parameters and start" instruction starts a programmed timer when a change from "1" to "0" (negative signal edge) is detected in the result of logic operation (RLO) at input S. The timer expires with the programmed duration (TV). As long as the timer is running or input S returns signal state "1", then output Q has signal state "1". When the timer expires and the signal state at input S is "0", output Q is reset to the signal state "0". If the signal state at input S changes from "0" to "1" while the timer is running, the timer is stopped. The timer is only restarted after a falling signal edge is detected at input S.

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down towards zero. The time base indicates the time period with which the time value is changed. The current time value is output BI-coded at output BI and BCD-coded at output BCD.

Signal state "1" at input R resets the current time value and time base to "0". In this case, the signal state at output Q is "0".

The "Assign off-delay timer parameters and start" instruction requires a preceding logic operation for edge evaluation and can be placed within or at the end of the network.

The instruction data is updated at every access. It can therefore happen that the query of the data at the start of the cycle returns different values than at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameter

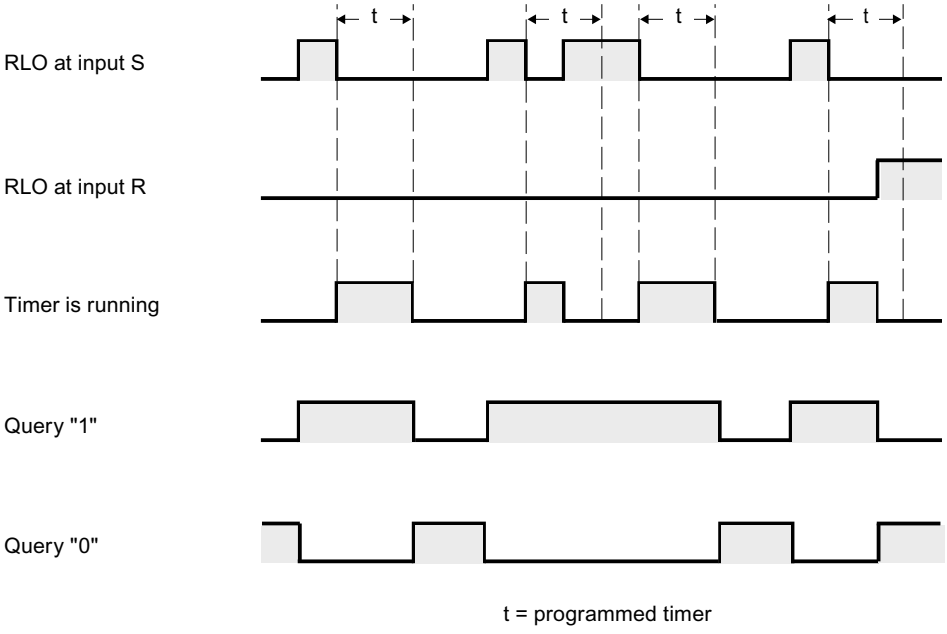
The following table shows the parameters of the "Assign off-delay timer parameters and start" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Timer>	InOut/Input	TIMER	T	Time of the instruction The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, D, L	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Preset time value
R	Input	BOOL	I, Q, M, T, C, D, L, P or constant	Reset input
BI	Output	WORD	I, Q, M, D, L, P	Current time value (BI-coded)
BCD	Output	WORD	I, Q, M, D, L, P	Current time value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the timer

For additional information on valid data types, refer to "See also".

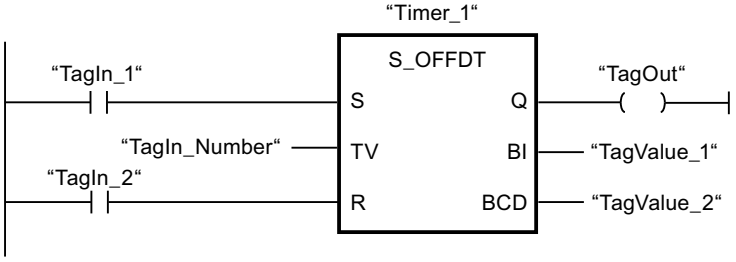
Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign off-delay timer parameters and start" instruction:



Example

The following example shows how the instruction works:



The timer "Timer_1" is started when the signal state of the operand "TagIn_1" changes from "1" to "0". The timer expires with the time value of the operand "TagIn_Number". The operand "TagOut" is set to "1" when the timer is running and when the operand "TagIn_1" has the signal state "0". If the signal state of the operand "TagIn_1" changes from "0" to "1" while the timer is running, the timer is reset.

Overview of the valid data types (Page 1908)

---(SP): Start pulse timer

Description

The "Start pulse timer" instruction starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO). The time runs with the specified duration as long as the RLO has the signal state "1". As long as the timer is running, the querying of the timer status for "1" returns the signal state "1". If there is a change from "1" to "0" in the RLO before the time value has elapsed, the timer stops. In this case, the querying of the timer status for "1" returns the signal state "0".

The duration is made up internally of a time value and a time base. When the instruction is started, the programmed time value is counted down towards zero. The time base indicates the time period with which the time value is changed.

The "Start pulse timer" instruction requires a preceding logic operation for edge evaluation and can only be placed at the right side of the network.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameters

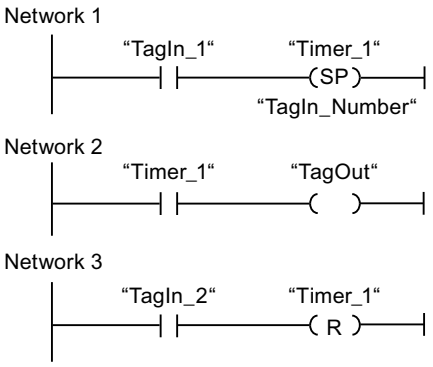
The following table shows the parameters of the "Start pulse timer" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Time duration>	Input	S5TIME, WORD	I, Q, M, D, L or constant	Duration with which the timer expires.
<Timer>	InOut/Input	TIMER	T	Timer which is started. The number of timers depends on the CPU.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The timer "Timer_1" is started when the signal state of the operand "TagIn_1" changes from "0" to "1". The timer expires with the time value of the operand "TagIn_Number" as long as the signal state of the operand "TagIn_1" is "1". If the signal state of the operand "TagIn_1" changes from "1" to "0" before the timer expires, the timer is stopped. As long as the timer is running, the operand "TagOut" has the signal state "1". A signal state change of the operand "TagIn_1" from "0" to "1" resets the timer, which stops the timer and sets the current time value to "0".

See also

Overview of the valid data types (Page 1908)

---(SE): Start extended pulse timer

Description

The "Start extended pulse timer" instruction starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO). The timer expires with the specified duration, even if the RLO changes to the signal state "0". As long as the timer is running, the querying of the timer status for "1" returns the signal state "1". If the RLO changes from "0" to "1" while the timer is running, the timer is restarted with the programmed duration. The querying of the timer status for "1" returns the signal state "0" when the timer expires.

The duration is made up internally of a time value and a time base. When the instruction is started, the programmed time value is counted down towards zero. The time base indicates the time period with which the time value is changed.

The "Start extended pulse timer" instruction requires a preceding logic operation for edge evaluation and can only be placed at the right side of the network.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameter

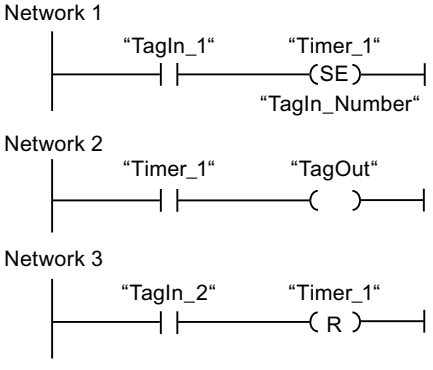
The following table shows the parameters of the "Start extended pulse timer" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Time duration>	Input	S5TIME, WORD	I, Q, M, D, L or constant	Duration with which the timer expires.
<Timer>	InOut/Input	TIMER	T	Timer which is started. The number of timers depends on the CPU.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The timer "Timer_1" is started when the signal state of the operand "TagIn_1" changes from "0" to "1". The timer expires with the time value of the operand "TagIn_Number" without being affected by a negative edge in the RLO. As long as the timer is running, the operand "TagOut" has the signal state "1". If the signal state of the operand "TagIn_1" changes from "0" to "1" before the timer expires, the timer is restarted.

See also

Overview of the valid data types (Page 1908)

---(SD): Start on-delay timer

Description

The "Start on-delay timer" instruction starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO). The timer runs for the specified duration as long as the RLO is "1". If the timer expires and the RLO still has the signal state "1", the query of the timer status for "1" returns the signal state "1". If the RLO changes from "1" to "0" while the timer is running, the timer is stopped. In this case, the querying of the timer status for "1" returns the signal state "0".

The duration is made up internally of a time value and a time base. When the instruction is started, the programmed time value is counted down towards zero. The time base indicates the time period with which the time value is changed.

The "Start on-delay timer" instruction requires a preceding logic operation for edge evaluation and can only be placed at the right side of the network.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameter

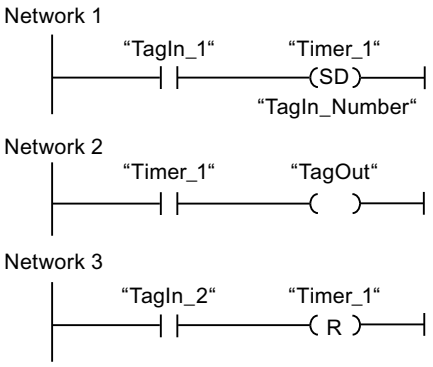
The following table shows the parameters of the "Start on-delay timer" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Time duration>	Input	S5TIME, WORD	I, Q, M, D, L or constant	Duration with which the timer expires.
<Timer>	InOut/Input	TIMER	T	Timer which is started. The number of timers depends on the CPU.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The timer "Timer_1" is started when the signal state of the operand "TagIn_1" changes from "0" to "1". The timer expires with the time value of the operand "TagIn_Number". If the timer expires and the RLO has the signal state "1", the operand "TagOut" is set to "1". If the signal state of the operand "TagIn_1" changes from "1" to "0" before the timer expires, the timer is stopped. If the signal state of the operand "TagIn_2" is "1", the timer "Timer_1" is reset, which stops the timer and sets the current time value to "0".

Overview of the valid data types (Page 1908)

---(SS): Start retentive on-delay timer

Description

The "Start retentive on-delay timer" instruction starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO). The timer expires with the specified duration, even if the RLO changes to the signal state "0". When the timer expires, the querying of the timer status for "1" returns the signal state "1". After expiry of the timer, the timer can only be restarted if it is explicitly reset.

The duration is made up internally of a time value and a time base. When the instruction is started, the programmed time value is counted down towards zero. The time base indicates the time period with which the time value is changed.

The "Start retentive on-delay timer" instruction requires a preceding logic operation for edge evaluation and can only be placed at the right side of the network.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameters

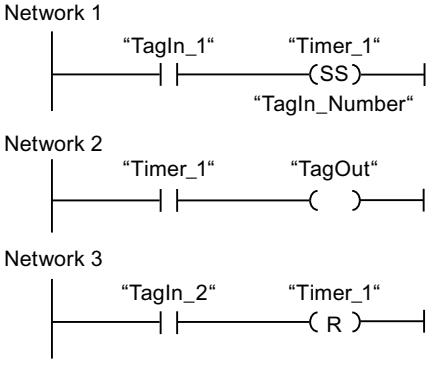
The following table shows the parameters of the "Start retentive on-delay timer" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Time duration>	Input	S5TIME, WORD	I, Q, M, D, L or constant	Duration with which the timer expires.
<Timer>	InOut/Input	TIMER	T	Timer which is started. The number of timers depends on the CPU.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The timer "Timer_1" is started when the signal state of the operand "TagIn_1" changes from "0" to "1". The timer expires with the time value of the operand "TagIn_Number". When the timer expires, the operand "TagOut" is set to "1". If the signal state of the operand "TagIn_1" changes from "0" to "1" while the timer is running, the timer is restarted. If the signal state of the operand "TagIn_2" is "1", the timer "Timer_1" is reset, which stops the timer and sets the current time value to "0".

See also

Overview of the valid data types (Page 1908)

---(SF): Start off-delay timer

Description

The "Start off-delay timer" instruction starts a programmed timer when a change from "1" to "0" (negative signal edge) is detected in the result of logic operation (RLO). The timer expires with the specified duration. As long as the timer is running, the querying of the timer status for "1" returns the signal state "1". If the RLO changes from "0" to "1" while the timer is running, the timer is reset. The timer is always restarted when the RLO changes from "1" to "0".

The duration is made up internally of a time value and a time base. When the instruction is started, the programmed time value is counted down towards zero. The time base indicates the time period with which the time value is changed.

The "Start off-delay timer" instruction requires a preceding logic operation for edge evaluation and can only be placed at the right side of the network.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameter

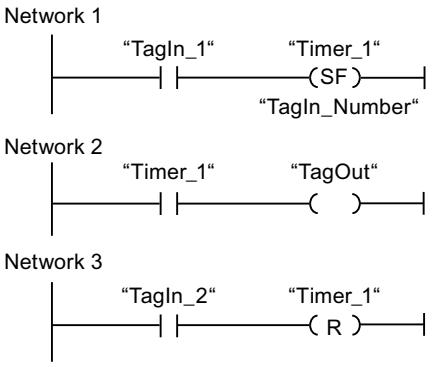
The following table shows the parameters of the "Start off-delay timer" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Time duration>	Input	S5TIME, WORD	I, Q, M, D, L or constant	Duration with which the timer expires.
<Timer>	InOut/Input	TIMER	T	Timer which is started. The number of timers depends on the CPU.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The timer "Timer_1" is started when the signal state of the operand "TagIn_1" changes from "1" to "0". The timer expires with the time value of the operand "TagIn_Number". As long as the timer is running, the operand "TagOut" is set to "1". If the signal state of the operand "TagIn_1" changes from "1" to "0" while the timer is running, the timer is restarted. If the signal state of the operand "TagIn_2" is "1", the timer "Timer_1" is reset, which stops the timer and sets the current time value to "0".

Overview of the valid data types (Page 1908)

Counter operations

CTU: Count up

Description

You can use the "Count up" instruction to increment the value at output CV. When the signal state at the CU input changes from "0" to "1" (positive signal edge), the instruction is executed and the current counter value at the CV output is incremented by one. The counter value is incremented each time a positive signal edge is detected, until it reaches the high limit for the data type specified at the output CV. When the high limit is reached, the signal state at the CU input no longer has an effect on the instruction.

You can query the counter status in the Q output. The signal state at the Q output is determined by the PV parameter. If the current counter value is greater than or equal to the value of the PV parameter, the Q output is set to signal state "1". In all other cases, the Q output has signal state "0".

The value at the CV output is reset to zero when the signal state at input R changes to "1". As long as the R input has signal state "1", the signal state at the CU input has no effect on the instruction.

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Each call of the "Count up" instruction must be assigned an IEC counter in which the instruction data is stored. An IEC counter is a structure with one of the following data types:

For S7-1200 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER	• CTU_SINT / CTU_USINT • CTU_INT / CTU_UINT • CTU_DINT / CTU_UDINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER

For S7-1500 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER	• CTU_SINT / CTU_USINT • CTU_INT / CTU_UINT • CTU_DINT / CTU_UDINT • CTU_LINT / CTU_ULINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER

You can declare an IEC counter as follows:

- Declaration of a data block of system data type IEC_<Counter> (for example, "MyIEC_COUNTER")
- Declaration as a local tag of the type CTU_<Data type> or IEC_<Counter> in the "Static" section of a block (for example #MyIEC_COUNTER)

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the IEC counter is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, it is saved to the "Program resources" folder in the "Program blocks > System blocks" path of the project tree. For additional information on this topic, refer to "See also".

When you set up the IEC counter in a separate data block (single instance), the instance data block is created by default with "optimized block access" and the individual tags are defined as retentive. For additional information on setting retentivity in an instance data block, refer to "See also".

When you set up the IEC counter as local tag (multi-instance) in a function block with "optimized block access", it is defined as retentive in the block interface.

The execution of the "Count up" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

Parameters

The following table shows the parameters of the instruction "Count up":

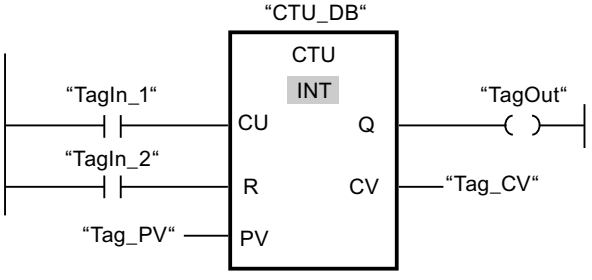
Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
CU	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Count input
R	Input	BOOL	I, Q, M, D, L, P, or constant	I, Q, M, T, C, D, L, P or constant	Reset input
PV	Input	Integers	I, Q, M, D, L, P, or constant	I, Q, M, D, L, P, or constant	Value at which the output Q is set.
Q	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Counter status
CV	Output	Integers, CHAR, WCHAR, DATE	I, Q, M, D, L, P	I, Q, M, D, L, P	Current counter value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:



When the signal state of the "TagIn_1" operand changes from "0" to "1", the "Count up" instruction is executed and the current counter value of the "Tag_CV" operand is incremented by one. With each additional positive signal edge, the counter value is incremented until the high limit of the data type (INT = 32767) is reached.

The value of the PV parameter is adopted as the limit for determining the "TagOut" output. The "TagOut" output has signal state "1" as long as the current counter value is greater than or equal to the value of the "Tag_PV" operand. In all other cases, the "TagOut" output has signal state "0".

See also

Overview of the valid data types (Page 1908)

CTD: Count down

Description

You can use the "Count down" instruction to decrement the value at output CV. When the signal state at the CD input changes from "0" to "1" (positive signal edge), the instruction is executed and the current counter value at the CV output is decremented by one. Each time a positive signal edge is detected, the counter value is decremented until it reaches the low limit of the specified data type. When the low limit is reached, the signal state at the CD input no longer has an effect on the instruction.

You can query the counter status in the Q output. If the current counter value is less than or equal to zero, the Q output is set to signal state "1". In all other cases, the Q output has signal state "0".

The value at the CV output is set to the value of the PV parameter when the signal state at the LD input changes to "1". As long as the LD input has signal state "1", the signal state at the CD input has no effect on the instruction.

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Each call of the "Count down" instruction must be assigned an IEC counter in which the instruction data is stored. An IEC counter is a structure with one of the following data types:

For S7-1200 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER	• CTD_SINT / CTD_USINT • CTD_INT / CTD_UINT • CTD_DINT / CTD_UDINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER

For S7-1500 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER	• CTD_SINT / CTD_USINT • CTD_INT / CTD_UINT • CTD_DINT / CTD_UDINT • CTD_LINT / CTD_ULINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER

You can declare an IEC counter as follows:

- Declaration of a data block of system data type IEC_<Counter> (for example, "MyIEC_COUNTER")
- Declaration as a local tag of the type CTD_<Data type> or IEC_<Counter> in the "Static" section of a block (for example #MyIEC_COUNTER)

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the IEC counter is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, it is saved to the "Program resources" folder in the "Program blocks > System blocks" path of the project tree. For additional information on this topic, refer to "See also".

When you set up the IEC counter in a separate data block (single instance), the instance data block is created by default with "optimized block access" and the individual tags are defined as retentive. For additional information on setting retentivity in an instance data block, refer to "See also".

When you set up the IEC counter as local tag (multi-instance) in a function block with "optimized block access", it is defined as retentive in the block interface.

The execution of the "Count down" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

Parameters

The following table shows the parameters of the instruction "Count down":

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
CD	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Count input
LD	Input	BOOL	I, Q, M, D, L, P, or constant	I, Q, M, T, C, D, L, P or constant	Load input
PV	Input	Integers	I, Q, M, D, L, P, or constant	I, Q, M, D, L, P, or constant	Value to which the CV output is set with LD = 1.

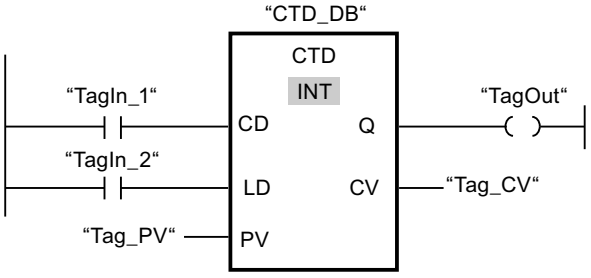
Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
Q	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Counter status
CV	Output	Integers, CHAR, WCHAR, DATE	I, Q, M, D, L, P	I, Q, M, D, L, P	Current counter value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:



When the signal state of the "TagIn_1" operand changes from "0" to "1", the instruction is executed and the value at the "Tag_CV" output is decremented by one. With each additional positive signal edge, the counter value is decremented until the low limit of the specified data type (INT = -32768) is reached.

The "TagOut" output has signal state "1" as long as the current counter value is less than or equal to zero. In all other cases, the "TagOut" output has signal state "0".

Overview of the valid data types (Page 1908)

CTUD: Count up and down

Description

You can use the "Count up and down" instruction to increment and decrement the counter value at the CV output. If the signal state at the CU input changes from "0" to "1" (positive signal edge), the current counter value is incremented by one and stored at the CV output. If the signal state at the CD input changes from "0" to "1" (positive signal edge), the counter value at the CV output is decremented by one. If there is a positive signal edge at the CU and CD inputs in one program cycle, the current counter value at the CV output remains unchanged.

The counter value can be incremented until it reaches the high limit of the data type specified at the CV output. When the high limit is reached, the counter value is no longer incremented on a positive signal edge. The counter value is no longer decremented once the low limit of the specified data type has been reached.

When the signal state at the LD input changes to "1", the counter value at the CV output is set to the value of the PV parameter. As long as the LD input has signal state "1", the signal state at the CU and CD inputs has no effect on the instruction.

The counter value is set to zero when the signal state at the R input changes to "1". As long as the R input has signal state "1", a change in the signal state of the CU, CD and LD inputs has no effect on the "Count up and down" instruction.

You can query the status of the up counter at the QU output. If the current counter value is greater than or equal to the value of the PV parameter, the QU output is set to signal state "1". In all other cases, the QU output has signal state "0".

You can query the status of the down counter at the QD output. If the current counter value is less than or equal to zero, the QD output is set to signal state "1". In all other cases, the QD output has signal state "0".

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Each call of the "Count up and down" instruction must be assigned an IEC counter in which the instruction data is stored. An IEC counter is a structure with one of the following data types:

For S7-1200 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER	• CTUD_SINT / CTUD_USINT • CTUD_INT / CTUD_UINT • CTUD_DINT / CTUD_UDINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER

For S7-1500 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER	• CTUD_SINT / CTUD_USINT • CTUD_INT / CTUD_UINT • CTUD_DINT / CTUD_UDINT • CTUD_LINT / CTUD_ULINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER

You can declare an IEC counter as follows:

- Declaration of a data block of system data type IEC_<Counter> (for example, "MyIEC_COUNTER")
- Declaration as a local tag of the type CTUD_<Data type> or IEC_<Counter> in the "Static" section of a block (for example #MyIEC_COUNTER)

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the IEC counter is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, it is saved to the "Program resources" folder in the "Program blocks > System blocks" path of the project tree. For additional information on this topic, refer to "See also".

When you set up the IEC counter in a separate data block (single instance), the instance data block is created by default with "optimized block access" and the individual tags are defined as retentive. For additional information on setting retentivity in an instance data block, refer to "See also".

When you set up the IEC counter as local tag (multi-instance) in a function block with "optimized block access", it is defined as retentive in the block interface.

The execution of the "Count up and down" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

Parameters

The following table shows the parameters of the instruction "Count up and down":

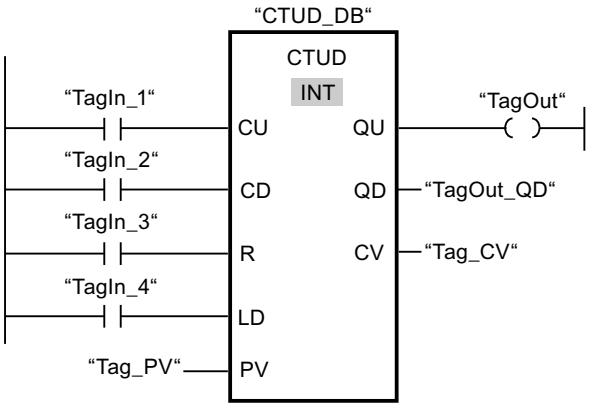
Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
CU	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Count up input
CD	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Count down input
R	Input	BOOL	I, Q, M, D, L, P, or constant	I, Q, M, T, C, D, L, P or constant	Reset input
LD	Input	BOOL	I, Q, M, D, L, P, or constant	I, Q, M, T, C, D, L, P or constant	Load input
PV	Input	Integers	I, Q, M, D, L, P, or constant	I, Q, M, D, L, P, or constant	Value at which the output QU is set. / Value to which the CV output is set with LD = 1.
QU	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Status of the up counter
QD	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Status of the down counter
CV	Output	Integers, CHAR, WCHAR, DATE	I, Q, M, D, L, P	I, Q, M, D, L, P	Current counter value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:



If the signal state at the "TagIn_1" or "TagIn_2" input changes from "0" to "1" (positive signal edge), the "Count up and down" instruction is executed. When there is a positive signal edge at the "TagIn_1" input, the current counter value is incremented by one and stored at the "Tag_CV" output. When there is a positive signal edge at the "TagIn_2" input, the counter value is decremented by one and stored at the "Tag_CV" output. When there is a positive signal edge at the CU input, the counter value is incremented until it reaches the high limit of 32767. If input CD has a positive signal edge, the counter value is decremented until it reaches the low limit of INT = -32768.

The "TagOut" output has signal state "1" as long as the current counter value is greater than or equal to the value at the "Tag_PV" input. In all other cases, the "TagOut" output has signal state "0".

The "TagOut_QD" output has signal state "1" as long as the current counter value is less than or equal to zero. In all other cases, the "TagOut_QD" output has signal state "0".

Legacy

S_CU: Assign parameters and count up

Description

You can use the "Assign parameters and count up" instruction to increment the value of a counter. If the signal state at the CU input changes from "0" to "1" (positive signal edge), the current counter value is incremented by one. The current counter value is output as a hexadecimal value at output CV and BCD-coded at output CV_BCD. The counter value can be incremented until the limit of "999" is reached. When the limit is reached, the counter value is no longer incremented on a positive signal edge.

When the signal state at input S changes from "0" to "1", the counter value is set to the value of the PV parameter. If the counter is set and if RLO at input CU is "1", the counter will count accordingly in the next scan cycle, even when no change has been detected in the signal edge.

The counter value is set to zero when the signal state at the R input changes to "1". As long as the R input has the signal state "1", processing of the signal state of the CU and S inputs has no effect on the counter value.

The signal state at output Q is "1" if the counter value is greater than zero. If the counter value is equal to zero, output Q has the signal state "0".

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

The "Assign parameters and count up" instruction requires a preceding logic operation for edge evaluation and can be placed within or at the end of the network.

Parameter

The following table shows the parameters of the "Assign parameters and count up" instruction:

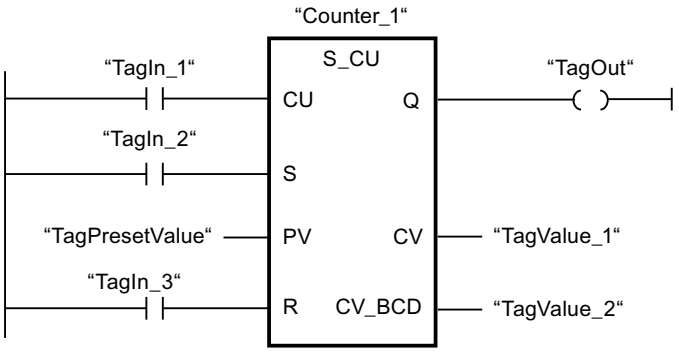
Parameter	Declaration	Data type	Memory area	Description
<Counter>	InOut/Input	COUNTER	C	Counter of the instruction The number of counters depends on the CPU.
CU	Input	BOOL	I, Q, M, D, L	Count up input
S	Input	BOOL	I, Q, M, D, L, T, C or constant	Input for presetting counter
PV	Input	WORD	I, Q, M, D, L or constant	Preset counter value (C#0 to C#999)
R	Input	BOOL	I, Q, M, D, L, T, C or constant	Reset input
CV	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (hexadecimal)

Parameter	Declaration	Data type	Memory area	Description
CV_BCD	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the counter

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



When the signal state at the "TagIn_1" input changes from "0" to "1" (positive signal edge) and the current counter value is less than "999", the counter value is incremented by one. When the signal state at input "TagIn_2" changes from "0" to "1", the counter value is set to the value of the operand "TagPresetValue". The counter value is reset to "0" when the "TagIn_3" operand has signal state "1".

The current counter value is saved as a hexadecimal value in the operand "TagValue_1" and BCD-coded in the operand "TagValue_2".

The "TagOut" output has the signal state "1" as long as the current counter value is not equal to "0".

See also

Overview of the valid data types (Page 1908)

S_CD: Assign parameters and count down

Description

You can use the "Assign parameters and count down" instruction to decrement the value of a counter. If the signal state at the CD input changes from "0" to "1" (positive signal edge), the counter value is decremented by one. The current counter value is output as a hexadecimal value at output CV and BCD-coded at output CV_BCD. The counter value is decremented until the low limit of "0" is reached. When the low limit is reached, the counter value is no longer decremented on a positive signal edge.

When the signal state at input S changes from "0" to "1", the counter value is set to the value of the PV parameter. If the counter is set and if RLO at input CD is "1", the counter will count accordingly in the next scan cycle, even when no change has been detected in the signal edge.

The counter value is set to zero when the signal state at the R input changes to "1". As long as the R input has the signal state "1", processing of the signal state of the CD and S inputs has no effect on the counter value.

The signal state at output Q is "1" if the counter value is greater than zero. If the counter value is equal to zero, output Q has the signal state "0".

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

The "Assign parameters and count down" instruction requires a preceding logic operation for edge evaluation and can be placed within or at the end of the network.

Parameter

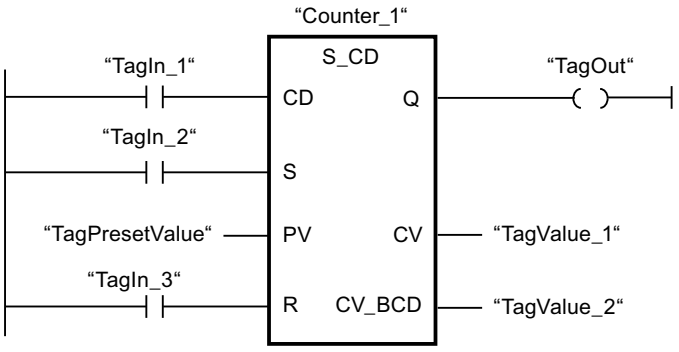
The following table shows the parameters of the "Assign parameters and count down" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Counter>	InOut/Input	COUNTER	C	Counter of the instruction The number of counters depends on the CPU.
CD	Input	BOOL	I, Q, M, D, L or constant	Count down input
S	Input	BOOL	I, Q, M, D, L, T, C or constant	Input for presetting counter
PV	Input	WORD	I, Q, M, D, L or constant	Preset counter value (C#0 to C#999)
R	Input	BOOL	I, Q, M, D, L, T, C or constant	Reset input
CV	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (hexadecimal)
CV_BCD	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the counter

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



When the signal state at the "TagIn_1" input changes from "0" to "1" (positive signal edge) and the current counter value is greater than "0", the counter value is decremented by one. When the signal state at input "TagIn_2" changes from "0" to "1", the counter value is set to the value of the operand "TagPresetValue". The counter value is reset to "0" when the "TagIn_3" operand has signal state "1".

The current counter value is saved as a hexadecimal value in the operand "TagValue_1" and BCD-coded in the operand "TagValue_2".

The "TagOut" output has the signal state "1" as long as the current counter value is not equal to "0".

Overview of the valid data types (Page 1908)

S_CUD: Assign parameters and count up / down

Description

You can use the "Assign parameters and count up / down" instruction to increment or decrement the value of a counter. If the signal state at the CU input changes from "0" to "1" (positive signal edge), the current counter value is incremented by one. If the signal state at the CD input changes from "0" to "1" (positive signal edge), the counter value is decremented by one. The current counter value is output as a hexadecimal value at output CV and BCD-coded at output CV_BCD. If there is a positive signal edge at the CU and CD inputs in one program cycle, the counter value remains unchanged.

The counter value can be incremented until the high limit of "999" is reached. When the high limit value is reached, the counter value is no longer incremented on a positive signal edge. When the low limit "0" is reached, the counter value is not decremented any further.

When the signal state at input S changes from "0" to "1", the counter value is set to the value of the PV parameter. If the counter is set and if RLO is "1" at the inputs CU and CD, the counter counts accordingly in the next scan cycle, even if no change in the signal edge was detected.

The counter value is set to zero when the signal state at the R input changes to "1". As long as the R input has the signal state "1", processing of the signal state of the CU, CD and S inputs has no effect on the counter value.

The signal state at output Q is "1" if the counter value is greater than zero. If the counter value is equal to zero, output Q has the signal state "0".

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

The "Assign parameters and count up / down" instruction requires a preceding logic operation for edge evaluation and can be placed within or at the end of the network.

Parameters

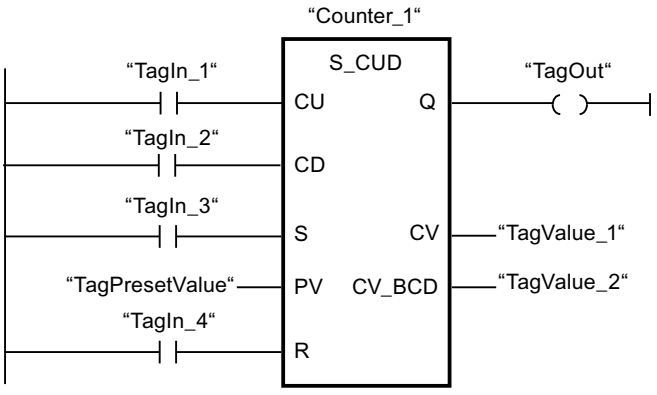
The following table shows the parameters of the "Assign parameters and count up / down" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Counter>	InOut/Input	COUNTER	C	Counter of the instruction The number of counters depends on the CPU.
CU	Input	BOOL	I, Q, M, D, L	Count up input
CD	Input	BOOL	I, Q, M, D, L, T, C or constant	Count down input
S	Input	BOOL	I, Q, M, D, L, T, C or constant	Input for presetting counter
PV	Input	WORD	I, Q, M, D, L or constant	Preset counter value (C#0 to C#999)
R	Input	BOOL	I, Q, M, D, L, T, C or constant	Reset input
BI	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (hexadecimal)
CV_BCD	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the counter

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If the signal state at the "TagIn_1"" or "TagIn_2" input changes from "0" to "1" (positive signal edge), the "Assign parameters and count up / down" instruction is executed. When there is a positive signal edge at the "TagIn_1" input and the current counter value is less than "999", the counter value is incremented by one. When there is a positive signal edge at the "TagIn_2" input and the current counter value is greater than "0", the counter value is decremented by one.

When the signal state at input "TagIn_3" changes from "0" to "1", the counter value is set to the value of the operand "TagPresetValue". The counter value is reset to "0" when the "TagIn_4" operand has signal state "1".

The current counter value is saved as a hexadecimal value in the operand "TagValue_1" and BCD-coded in the operand "TagValue_2".

The "TagOut" output has the signal state "1" as long as the current counter value is not equal to "0".

See also

Overview of the valid data types (Page 1908)

---(SC): Set counter value

Description

You can use the "Set counter value" instruction to set the value of a counter. The instruction is executed when the result of logic operation (RLO) at the input changes from "0" to "1". When the instruction is executed, the counter is set to the specified counter value.

The "Set counter value" instruction needs a preceding logic operation for the edge evaluation and can only be placed on the right edge of the network.

Parameter

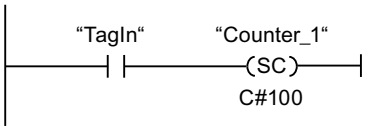
The following table lists the parameters of the "Set counter value" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Count value>	Input	WORD	I, Q, M, D, L or constant	Value with which the counter is preset in the BCD format. (C#0 to C#999)
<Counter>	InOut/Input	COUNTER	C	Counter that is preset.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



the counter "Counter_1" starts with the value "100" when the signal state of the "TagIn" operand changes from "0" to "1".

See also

Overview of the valid data types (Page 1908)

---(CU): Count up

Description

With the "Count up" instruction you can increment the value of the specified counter by one if there is a positive signal edge in the result of logic operation (RLO). The counter value can be incremented until the limit of "999" is reached. When the limit is reached, the counter value is no longer incremented on a positive signal edge.

The "Count up" instruction requires a preceding logic operation for edge evaluation and can only be placed at the right side of the network.

Parameter

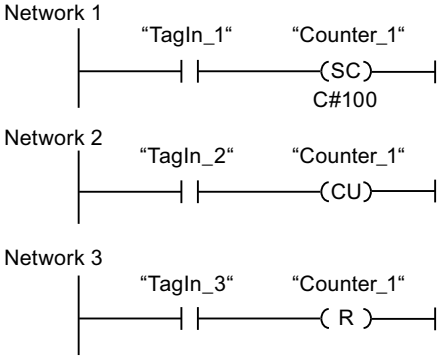
The following table shows the parameters of the "Count up" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Counter>	InOut/Input	COUNTER	C	Counter whose value is incremented.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



When the signal state of the "TagIn_1" operand changes from "0" to "1" (positive signal edge), the counter "Counter_1" is preset with the value "100".

The value of the counter "Counter_1" is incremented by one when the signal state of the operand "TagIn_2" changes from "0" to "1".

When the operand "TagIn_3" has the signal state "1", the value of the counter "Counter_1" is reset to "0".

See also

Overview of the valid data types (Page 1908)

---(CD): Count down

Description

With the "Count down" instruction you can increment the value of the specified counter by one if there is a positive signal edge in the result of logic operation (RLO). The counter value can be decremented until the limit of "0" is reached. When the limit is reached, the counter value is no longer changed on a positive signal edge.

The "Count down" instruction requires a preceding logic operation for edge evaluation and can only be placed at the right side of the network.

Parameter

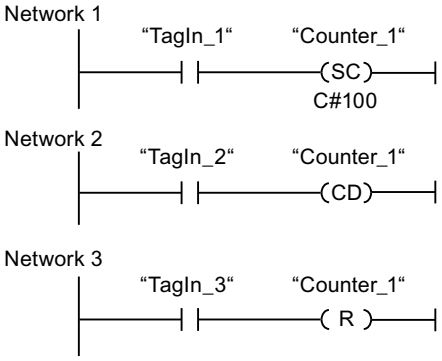
The following table shows the parameters of the "Count down" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Counter>	InOut/Input	COUNTER	C	Counter whose value is decremented.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



When the signal state of the "TagIn_1" operand changes from "0" to "1" (positive signal edge), the counter "Counter_1" is preset with the value "100".

The value of the counter "Counter_1" is decremented by one when the signal state of the operand "TagIn_2" changes from "0" to "1".

When the operand "TagIn_3" has the signal state "1", the value of the counter "Counter_1" is reset to "0".

Overview of the valid data types (Page 1908)

Comparator operations

CMP ==: Equal

Description

You can use the "Equal" instruction to determine if a first comparison value (<Operand1>) is equal to a second comparison value (<Operand2>).

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0". The RLO of the instruction is logically combined with the RLO of the entire rung as follows:

- By AND, when the comparison instruction is connected in series.
- By OR, when the comparison instruction is connected in parallel.

Specify the first comparison value (<Operand1>) at the operand placeholder above the instruction. Specify the second comparison value (<Operand2>) at the operand placeholder below the instruction.

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison.

The following table lists examples of string comparisons:

<Operand1>	<Operand2>	RLO of the instruction
'AA'	'AA'	1
'Hello World'	'HelloWorld'	0
'AA'	'aa'	0

You can also use the "Equal" instruction to compare individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

If IEC check is enabled, the operands to be compared must be of the same data type. If IEC check is not enabled, the width (length) of the operands must be the same. When floating-point numbers are compared, the operands to be compared must have the same data type regardless of the setting for the IEC Check.

Note

Comparison of floating-point numbers

If you want to compare the data types REAL or LREAL, instead of the instruction "CMP ==: Equal", use the instruction "IN_RANGE: Value within range".

Note

Comparison of the data type PORT

To be able to compare the operands of the PORT data type with the "Equal" instruction, you need to select the WORD data type from the drop-down list of the instructions box.

Parameters

The following table lists the parameters of the "Equal" instruction:

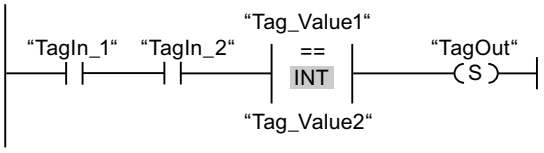
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Operand1>	Input	Bit strings, integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Bit strings, integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	First comparison value
<Operand2>	Input	Bit strings, integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Bit strings, integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	Second value to compare

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" = "Tag_Value2".

See also

Overview of the valid data types (Page 1908)

CMP <>: Not equal

Description

You can use the "Not equal" instruction to determine if a first comparison value (<Operand1>) is not equal to a second comparison value (<Operand2>).

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0". The RLO of the instruction is logically combined with the RLO of the entire rung as follows:

- By AND, when the comparison instruction is connected in series.
- By OR, when the comparison instruction is connected in parallel.

Specify the first comparison value (<Operand1>) at the operand placeholder above the instruction. Specify the second comparison value (<Operand2>) at the operand placeholder below the instruction.

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison.

The following table lists examples of string comparisons:

<Operand1>	<Operand2>	RLO of the instruction
'AA'	'aa'	1
'Hello World'	'HelloWorld'	1
'AA'	'AA'	0

You can also use the "Not equal" instruction to compare individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

If IEC check is enabled, the operands to be compared must be of the same data type. If IEC check is not enabled, the width (length) of the operands must be the same. If the floating-point numbers are being compared, the operands to be compared must be of the same data type regardless of the IEC check setting.

Note

Comparison of the data type PORT

To be able to compare the operands of the PORT data type with the "Not equal" instruction, you need to select the WORD data type from the drop-down list of the instructions box.

Parameters

The following table lists the parameters of the "Not equal" instruction:

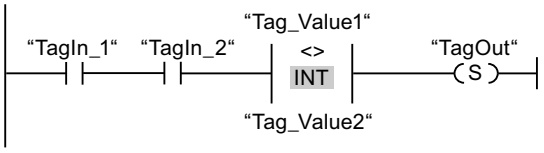
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Operand1>	Input	Bit strings, integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Bit strings, integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	First comparison value
<Operand2>	Input	Bit strings, integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Bit strings, integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	Second value to compare

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" **<>** "Tag_Value2".

See also

Overview of the valid data types (Page 1908)

CMP >=: Greater or equal

Description

You can use the "Greater or equal" instruction to determine if a first comparison value (<Operand1>) is greater than or equal to a second comparison value (<Operand2>). Both values to be compared must be of the same data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0". The RLO of the instruction is logically combined with the RLO of the entire rung as follows:

- By AND, when the comparison instruction is connected in series.
- By OR, when the comparison instruction is connected in parallel.

Specify the first comparison value (<Operand1>) at the operand placeholder above the instruction. Specify the second comparison value (<Operand2>) at the operand placeholder below the instruction.

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison. If the left part of the longer string is identical to the shorter string, the longer string is considered greater.

The following table lists examples of string comparisons:

<Operand1>	<Operand2>	RLO of the instruction
'BB'	'AA'	1
'AAA'	'AA'	1
'Hello World'	'Hello World'	1
'Hello World'	'HelloWorld'	0
'AA'	'aa'	0
'AAA'	'a'	0

You can also use the "Greater or equal" instruction to compare individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

When time values are compared, the RLO of the instruction is "1" if the point of time at <Operand1> is greater (more recent) than or equal to the point of time at <Operand2>.

Parameters

The following table lists the parameters of the "Greater or equal" instruction:

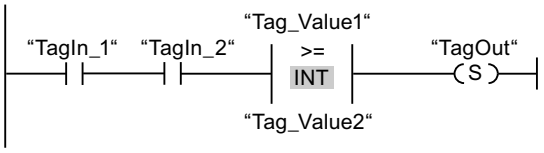
Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Operand1>	Input	Integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	First comparison value
<Operand2>	Input	Integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	Second value to compare

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" >= "Tag_Value2".

See also

Overview of the valid data types (Page 1908)

Example of detecting the fill level of a storage area (Page 3864)

CMP <=: Less or equal

Description

You can use the "Less or equal" instruction to determine if a first comparison value (<Operand1>) is less than or equal to a second comparison value (<Operand2>). Both values to be compared must be of the same data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0". The RLO of the instruction is logically combined with the RLO of the entire rung as follows:

- By AND, when the comparison instruction is connected in series.
- By OR, when the comparison instruction is connected in parallel.

Specify the first comparison value (<Operand1>) at the operand placeholder above the instruction. Specify the second comparison value (<Operand2>) at the operand placeholder below the instruction.

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison. If the left part of the longer string is identical to the shorter string, the shorter string is considered smaller.

The following table lists examples of string comparisons:

<Operand1>	<Operand2>	RLO of the instruction
'AA'	'aa'	1
'AAA'	'a'	1
'Hello World'	'Hello World'	1
'HelloWorld'	'Hello World'	0
'BB'	'AA'	0
'AAA'	'AA'	0

You can also use the "Less or equal" instruction to compare individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

When time values are compared, the RLO of the instruction is "1" if the point of time at <Operand1> is less (less recent) than or equal to the point of time at <Operand2>.

Parameters

The following table lists the parameters of the "Less or equal" instruction:

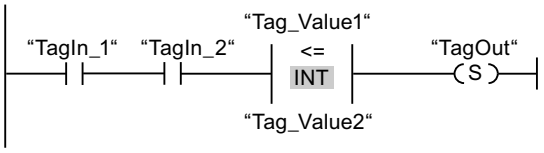
Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Operand1>	Input	Integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	First comparison value
<Operand2>	Input	Integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	Second value to compare

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" <= "Tag_Value2".

See also

Overview of the valid data types (Page 1908)

CMP >: Greater than

Description

You can use the "Greater than" instruction to determine if a first comparison value (<Operand1>) is greater than a second comparison value (<Operand2>). Both values to be compared must be of the same data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0". The RLO of the instruction is logically combined with the RLO of the entire rung as follows:

- By AND, when the comparison instruction is connected in series.
- By OR, when the comparison instruction is connected in parallel.

Specify the first comparison value (<Operand1>) at the operand placeholder above the instruction. Specify the second comparison value (<Operand2>) at the operand placeholder below the instruction.

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison. If the left part of the longer string is identical to the shorter string, the longer string is considered greater.

The following table lists examples of string comparisons:

<Operand1>	<Operand2>	RLO of the instruction
'BB'	'AA'	1
'AAA'	'AA'	1
'AA'	'aa'	0
'AAA'	'a'	0

You can also use the "Greater than" instruction to compare individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

When time values are compared, the RLO of the instruction is "1" if the point of time at <Operand1> is greater (more recent) than the point of time at <Operand2>.

Parameters

The following table lists the parameters of the "Greater than" instruction:

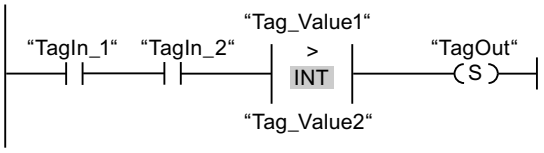
Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Operand1>	Input	Integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	First comparison value
<Operand2>	Input	Integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	Second value to compare

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" > "Tag_Value2".

See also

Overview of the valid data types (Page 1908)

CMP <: Less than

Description

You can use the "Less than" instruction to determine if a first comparison value (<Operand1>) is less than a second comparison value (<Operand2>). Both values to be compared must be of the same data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0". The RLO of the instruction is logically combined with the RLO of the entire rung as follows:

- By AND, when the comparison instruction is connected in series.
- By OR, when the comparison instruction is connected in parallel.

Specify the first comparison value (<Operand1>) at the operand placeholder above the instruction. Specify the second comparison value (<Operand2>) at the operand placeholder below the instruction.

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison. If the left part of the longer string is identical to the shorter string, the shorter string is considered smaller.

The following table lists examples of string comparisons:

<Operand1>	<Operand2>	RLO of the instruction
'AA'	'aa'	1
'AAA'	'a'	1

<Operand1>	<Operand2>	RLO of the instruction
'BB'	'AA'	0
'AAA'	'AA'	0

You can also use the "Less than" instruction to compare individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

When time values are compared, the RLO of the instruction is "1" if the point of time at <Operand1> is less (less recent) than the point of time at <Operand2>.

Parameters

The following table lists the parameters of the "Less than" instruction:

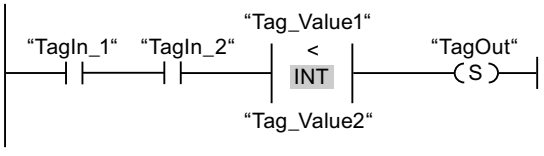
Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Operand1>	Input	Integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	First comparison value
<Operand2>	Input	Integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	Second value to compare

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" < "Tag_Value2".

Example of detecting the fill level of a storage area (Page 3864)

IN_RANGE: Value within range

Description

You can use the "Value within range" instruction to determine if the value at the VAL input is within a specific value range.

You specify the limits of the value range with the MIN and MAX inputs. The "Value within range" instruction compares the value at the VAL input with the values of the MIN and MAX inputs and sends the result to the box output. If the value at the VAL input fulfills the comparison MIN <= VAL or VAL <= MAX, the box output has the signal state "1". If the comparison is not fulfilled, the box output has the signal state "0".

If the box input has the signal state "0", the "Value within range" instruction is not executed.

The comparison function can only execute if the values to be compared are of the same data type and the box input is interconnected.

Parameters

The following table shows the parameters of the "Value within range" instruction:

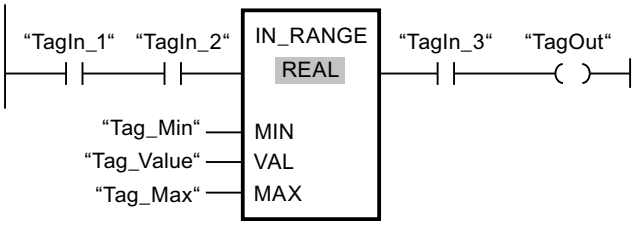
Parameter	Declaration	Data type	Memory area	Description
Box input	Input	BOOL	I, Q, M, D, L	Result of the previous logic operation
MIN	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Low limit of the value range
VAL	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Comparison value
MAX	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	High limit of the value range
Box output	Output	BOOL	I, Q, M, D, L	Result of the comparison

You can select the data type for the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also":

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The value of the operand "Tag_Value" is within the value range that is specified by the current values of the operands "Tag_Min" and "Tag_Max" (MIN <= VAL or VAL <= MAX).
- The operand "TagIn_3" has the signal state "1".

See also

Overview of the valid data types (Page 1908)

OUT_RANGE: Value outside range

Description

You can use the "Value outside range" instruction to determine if the value at the VAL input is outside a specific value range.

You specify the limits of the value range with the MIN and MAX inputs. The "Value outside range" instruction compares the value at the VAL input with the values of the MIN and MAX inputs and sends the result to the box output. If the value at the VAL input fulfills the comparison MIN > VAL or VAL > MAX, the box output has the signal state "1". The box output also has the signal state "1" if a specified operand with the REAL data type shows an invalid value.

The box output returns the signal state "0", if the value at input VAL does not satisfy the MIN > VAL or VAL > MAX condition.

If the box input has the signal state "0", the "Value outside range" instruction is not executed.

The comparison function can only execute if the values to be compared are of the same data type and the box input is interconnected.

Parameters

The following table shows the parameters of the "Value outside range" instruction:

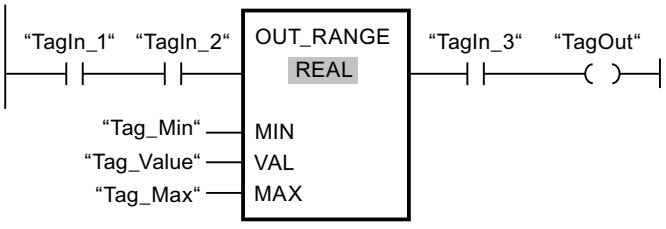
Parameter	Declaration	Data type	Memory area	Description
Box input	Input	BOOL	I, Q, M, D, L	Result of the previous logic operation
MIN	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Low limit of the value range
VAL	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Comparison value
MAX	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	High limit of the value range
Box output	Output	BOOL	I, Q, M, D, L	Result of the comparison

You can select the data type for the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The value of the operand "Tag_Value" is outside the value range that is specified by the values of the operands "Tag_Min" and "Tag_Max" (MIN > VAL or VAL > MAX).
- The operand "TagIn_3" has the signal state "1".

Overview of the valid data types (Page 1908)

----I OK I----: Check validity

Description

You can use the "Check validity" instruction to check if the value of an operand (<operand>) is a valid floating-point number. The query is started in each program cycle when the signal state at the input of the instruction is "1".

The output of the instruction has signal state "1" when the value of the operand is a valid floating-point number at the time of the query and the input of the instruction has signal state "1". In all other cases, the signal state at the output of the "Check validity" instruction is "0".

You can use the "Check validity" instruction together with the EN mechanism. If you connect the instruction box to an EN enable input, the enable input is set only when the result of the validity query of the value is positive. You can use this function to ensure that an instruction is enabled only when the value of the specified operand is a valid floating-point number.

Parameters

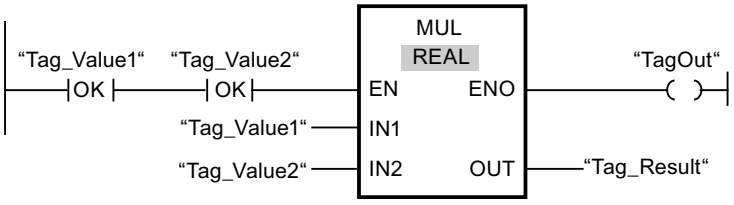
The following table shows the parameters of the "Check validity" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand>	Input	Floating-point numbers	I, Q, M, D, L	Value to be queried.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



When the values of the operands "Tag_Value1" and "Tag_Value2" show valid floating-point numbers, the "Multiply" (MUL) instruction is activated and the ENO output is set. During the execution of the "Multiply" (MUL) instruction, the value of the operand "Tag_Value1" is multiplied with the value of the operand "Tag_Value2". The product of the multiplication is then stored in the operand "Tag_Result". If the instruction is executed without errors, the ENO and "TagOut" outputs are set to signal state "1".

See also

Overview of the valid data types (Page 1908)

----| NOT_OK |----: Check invalidity

Description

You can use the "Check invalidity" instruction to check if the value of an operand (<operand>) is an invalid floating-point number. The query is started in each program cycle when the signal state at the input of the instruction is "1".

The output of the instruction has signal state "1" when the value of the operand is an invalid floating-point number at the time of the query and the input of the instruction has signal state "1". In all other cases, the signal state at the output of the "Check invalidity" instruction is "0".

Parameters

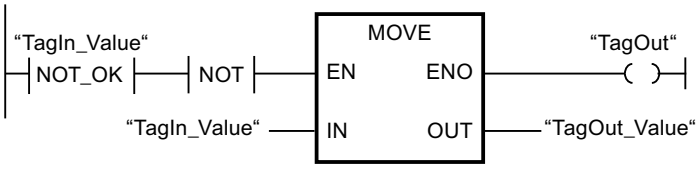
The following table shows the parameters of the "Check invalidity" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand>	Input	Floating-point numbers	I, Q, M, D, L	Value to be queried.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



When the value of operand "TagIn_Value" is an invalid floating-point number, the "Move value" (MOVE) instruction will not be executed. The "TagOut" output is reset to signal state "0".

VARIANT

EQ_Type: Compare data type for EQUAL with the data type of a tag

Description

You can use the "Compare data type for EQUAL with the data type of a tag" instruction to query the data type of a tag to which a VARIANT points. You are comparing the data type of the tag (<Operand1>), which you declared in the block interface, with the data type of a tag (<Operand2>) for "Equal to".

<Operand1> must have the VARIANT data type. <Operand2> can be an elementary data type or a PLC data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0". The RLO of the instruction is logically combined with the RLO of the entire rung as follows:

- By AND, when the comparison instruction is connected in series.
- By OR, when the comparison instruction is connected in parallel.

Specify <Operand1> at the operand placeholder above the instruction. Specify <Operand2> at the operand placeholder below the instruction.

Parameters

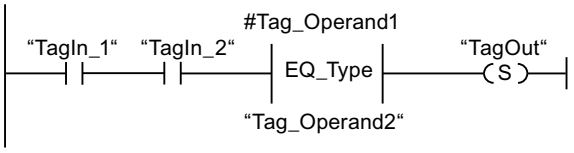
The following table lists the parameters of the "Compare data type for EQUAL with the data type of a tag" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand1>	Input	VARIANT	I, Q, M, L	First operand
<Operand2>	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY, PLC data types	I, Q, M, D, L, P	Second operand

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the "#Tag_Operand1" operand is equal to "Tag_Operand2".

Overview of the valid data types (Page 1908)

NE_Type: Compare data type for UNEQUAL with the data type of a tag

Description

You can use the "Compare data type for UNEQUAL with the data type of a tag" instruction to query which data type a tag to which a VARIANT points does not have. You are comparing the data type of the tag (<Operand1>), which you declared in the block interface, with the data type of a tag (<Operand2>) for "Not equal to".

<Operand1> must have the VARIANT data type. <Operand2> can be an elementary data type or a PLC data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0". The RLO of the instruction is logically combined with the RLO of the entire rung as follows:

- By AND, when the comparison instruction is connected in series.
- By OR, when the comparison instruction is connected in parallel.

Specify <Operand1> at the operand placeholder above the instruction. Specify <Operand2> at the operand placeholder below the instruction.

Parameters

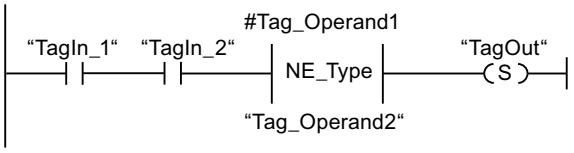
The following table lists the parameters of the "Compare data type for UNEQUAL with the data type of a tag" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand1>	Input	VARIANT	I, Q, M, L	First operand
<Operand2>	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY, PLC data types	I, Q, M, D, L, P	Second operand

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the "#Tag_Operand1" operand is not equal to "Tag_Operand2".

See also

Overview of the valid data types (Page 1908)

EQ_ElemType: Compare data type of an ARRAY element for EQUAL with the data type of a tag

Description

You can use the "Compare data type of an ARRAY element for EQUAL with the data type of a tag" instruction to query the data type of a tag to which a VARIANT points. You are comparing the data type of the tag (<Operand1>), which you declared in the block interface, with the data type of a tag (<Operand2>) for "Equal to".

<Operand1> must have the VARIANT data type. <Operand2> can be an elementary data type or a PLC data type.

If the data type of the VARIANT tag (<Operand1>) is an ARRAY, the data type of the ARRAY elements is compared.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0". The RLO of the instruction is logically combined with the RLO of the entire rung as follows:

- By AND, when the comparison instruction is connected in series.
- By OR, when the comparison instruction is connected in parallel.

Specify <Operand1> at the operand placeholder above the instruction. Specify <Operand2> at the operand placeholder below the instruction.

Parameters

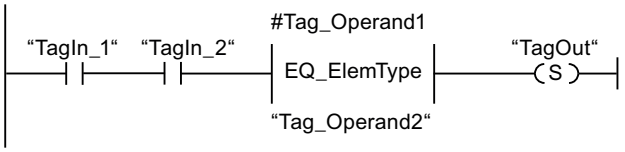
The following table lists the parameters of the "Compare data type of an ARRAY for EQUAL with the data type of a tag" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand1>	Input	VARIANT	I, Q, M, L	First operand
<Operand2>	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY, PLC data types	I, Q, M, D, L	Second operand

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the "#Tag_Operand1" operand is equal to "Tag_Operand2".

See also

Overview of the valid data types (Page 1908)

NE_ElemType: Compare data type of an ARRAY element for UNEQUAL with the data type of a tag

Description

You can use the "Compare data type of an ARRAY element for UNEQUAL with the data type of a tag" instruction to query which data type a tag does not have to which a VARIANT points. You are comparing the data type of the tag (<Operand1>), which you declared in the block interface, with the data type of a tag (<Operand2>) for "Not equal to".

<Operand1> must have the VARIANT data type. <Operand2> can be an elementary data type or a PLC data type.

If the data type of the VARIANT tag (<Operand1>) is an ARRAY, the data type of the ARRAY elements is compared.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0". The RLO of the instruction is logically combined with the RLO of the entire rung as follows:

- By AND, when the comparison instruction is connected in series.
- By OR, when the comparison instruction is connected in parallel.

Specify <Operand1> at the operand placeholder above the instruction. Specify <Operand2> at the operand placeholder below the instruction.

Parameters

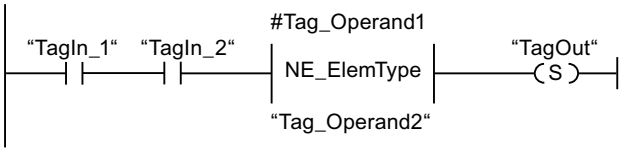
The following table lists the parameters of the "Compare data type of an ARRAY for UNEQUAL with the data type of a tag" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand1>	Input	VARIANT	I, Q, M, L	First operand
<Operand2>	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY, PLC data types	I, Q, M, D, L	Second operand

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the "#Tag_Operand1" operand is not equal to "Tag_Operand2".

See also

Overview of the valid data types (Page 1908)

IS_NULL: Check for EQUALS NULL pointer

Description

You can use the instruction "Check for EQUALS NULL pointer" to query whether the VARIANT points to a NULL pointer and therefore does not point to an object.

<Operand> must have the VARIANT data type.

Note

VARIANT tag points to an ANY pointer

If the VARIANT tag points to an ANY pointer, the instruction always returns the result RLO = "0" even if the ANY pointer is NULL.

Parameters

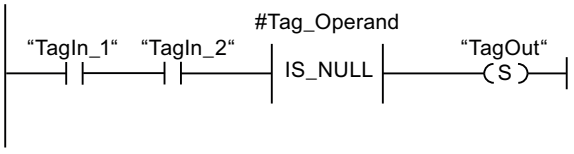
The following table shows the parameters of the "Check for EQUALS NULL pointer" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand>	Input	VARIANT	I, Q, M, L	Operand that is compared for EQUALS NULL

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the "#Tag_Operand" operand does not point to an object.

See also

Overview of the valid data types (Page 1908)

NOT_NULL: Check for UNEQUALS NULL pointer

Description

You can use the instruction "Check for UNEQUALS NULL pointer" to query whether the VARIANT does not point to a NULL pointer and therefore points to an object.

<Operand> must have the VARIANT data type.

Note

VARIANT tag points to an ANY pointer

If the VARIANT tag points to an ANY pointer, the instruction always returns the result RLO = "1" even if the ANY pointer is NULL.

Parameters

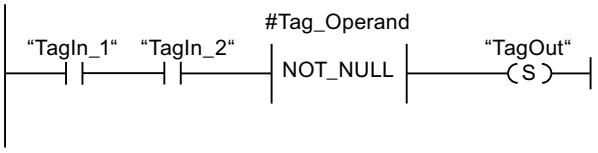
The following table shows the parameters of the "Check for UNEQUALS NULL pointer" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand>	Input	VARIANT	I, Q, M, L	Operand that is compared for UNEQUALS NULL

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the "#Tag_Operand" operand points to an object.

See also

Overview of the valid data types (Page 1908)

IS_ARRAY: Check for ARRAY

Description

You can use the "Check for ARRAY" instruction to query whether the VARIANT points to a tag of the ARRAY data type.

<Operand> must have the VARIANT data type.

Parameters

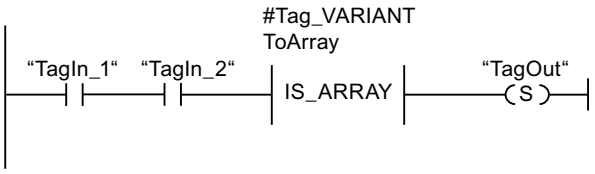
The following table shows the parameters of the "Check for ARRAY" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	VARIANT	I, Q, M, L	Operand that is queried for ARRAY

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the "#Tag_VARIANTToArray" operand has the ARRAY data type.

Overview of the valid data types (Page 1908)

Math functions

CALCULATE: Calculate

Description

The "Calculate" instruction is used to define and execute an expression for the calculation of mathematical operations or complex logic operations depending on the selected data type.

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box. Depending on the data type selected, you can combine the functions of certain instructions to perform a complex calculation. The expression to be calculated is specified via a dialog you can open via the "Calculator" icon at the top of the instruction box. The expression can contain names of input parameters and the syntax of the instructions. Operand names and operand addresses cannot be specified.

In its initial state, the instruction box contains at least 2 inputs (IN1 and IN2). The number of inputs can be extended. The inserted inputs are numbered in ascending order in the box.

The values of the inputs are used to execute the specified expression. Not all of the defined inputs have to be used in the expression. The result of the instruction is transferred to the output OUT.

Note

If one of the mathematical operations fails in the expression, no result is transferred to the output OUT and the enable output ENO returns the signal state "1".

If you use inputs in the expression that are not available in the box, they are inserted automatically. This requires that there are no gaps in the numbering of the inputs to be newly

defined in the expression. For example, you cannot use the IN4 input in the expression unless the IN3 input has been defined.

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- The EN enable input has the signal state "0".
- The result of the "Calculate" instruction is outside the range permitted for the data type specified at the OUT output.
- A floating-point number has an invalid value.
- An error occurred during execution of one of the instructions in the expression.

The following table shows the instructions that can be executed together in the expression of the instruction "Calculate", depending on the selected data type:

Data type	Instruction	Syntax	Example
Bit strings	AND: AND logic operation	AND	IN1 AND IN2 OR IN3
	OR: OR logic operation	OR	
	XOR: EXCLUSIVE OR logic operation	XOR	
	INV: Create ones complement	NOT	
	SWAP: Swap [1)]	SWAP	
Integers	ADD: Add	+	(IN1 + IN2) * IN3; (ABS(IN2)) * (ABS(IN1))
	SUB: Subtract	-	
	MUL: Multiply	*	
	DIV: Divide	/	
	MOD: Return remainder of division	MOD	
	INV: Create ones complement	NOT	
	NEG: Create twos complement	-(in1)	
	ABS: Form absolute value	ABS( )	

Data type	Instruction	Syntax	Example
Floating-point numbers	ADD: Add	+	((SIN(IN2) * SIN(IN2) + (SIN(IN3) * SIN(IN3)) / IN3)); (SQR(SIN(IN2)) + (SQR(COS(IN3)) / IN2))
	SUB: Subtract	-	
	MUL: Multiply	*	
	DIV: Divide	/	
	EXPT: Exponentiate	**	
	ABS: Form absolute value	ABS( )	
	SQR: Form square	SQR( )	
	SQRT: Form square root	SQRT( )	
	LN: Form natural logarithm	LN( )	
	EXP: Form exponential value	EXP( )	
	FRAC: Return fraction	FRAC( )	
	SIN: Form sine value	SIN( )	
	COS: Form cosine value	COS( )	
	TAN: Form tangent value	TAN( )	
	ASIN: Form arcsine value	ASIN( )	
	ACOS: Form arcosine value	ACOS( )	
	ATAN: Form arctangent value	ATAN( )	
	NEG: Create twos complement	-(in1)	
	TRUNC: Truncate numerical value	TRUNC( )	
	ROUND: Round numerical value	ROUND( )	
	CEIL: Generate next higher integer from floating-point number	CEIL( )	
	FLOOR: Generate next lower integer from floating-point number	FLOOR( )	
[1] Not possible for data type BYTE.			

Parameters

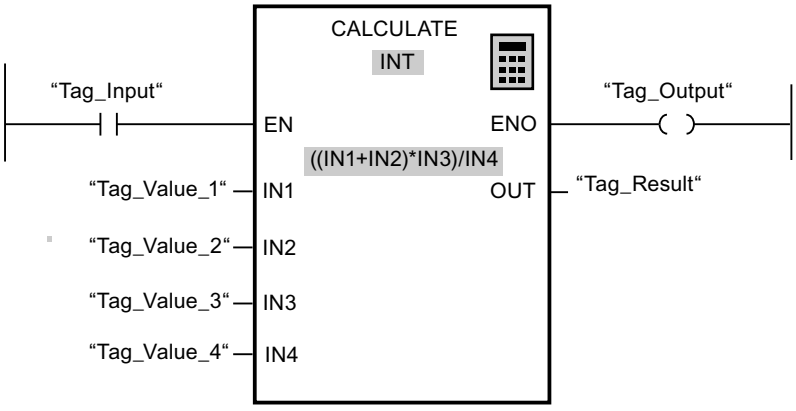
The following table shows the parameters of the "Calculate" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Bit strings, integers, floating-point numbers	I, Q, M, D, L, P or constant	First available input
IN2	Input	Bit strings, integers, floating-point numbers	I, Q, M, D, L, P or constant	Second available input
INn	Input	Bit strings, integers, floating-point numbers	I, Q, M, D, L, P or constant	Additionally inserted inputs
OUT	Output	Bit strings, integers, floating-point numbers	I, Q, M, D, L, P	Output to which the end result is to be transferred.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN1	Tag_Value_1	4
IN2	Tag_Value_2	4
IN3	Tag_Value_3	3
IN4	Tag_Value_4	2
OUT	Tag_Result	12

If the "Tag_Input" input has the signal state"1", the "Calculate" instruction is executed. The value of operand "Tag_Value_1" is added to the value of operand "Tag_Value_2". The sum is multiplied with the value of operand "Tag_Value_3". The product is divided by the value of operand "Tag_Value_4". The quotient is transferred as end result to the operand "Tag_Result" at the OUT output of the instruction. If the instruction is executed without errors, the enable output ENO and operand "Tag_Output" are set to "1".

See also

Overview of the valid data types (Page 1908)

Example of calculating an equation (Page 3867)

ADD: Add

Description

You can use the "Add" instruction to add the value at input IN1 and the value at input IN2 and query the sum at output OUT (OUT := IN1+IN2).

In its initial state, the instruction box contains at least 2 inputs (IN1 and IN2). The number of inputs can be extended. The inserted inputs are numbered in ascending order in the box. When

the instruction is executed, the values of all available input parameters are added. The sum is stored at the OUT output.

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- The enable input EN has the signal state "0".
- The result of the instruction is outside the range permitted for the data type specified at the OUT output.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Add" instruction:

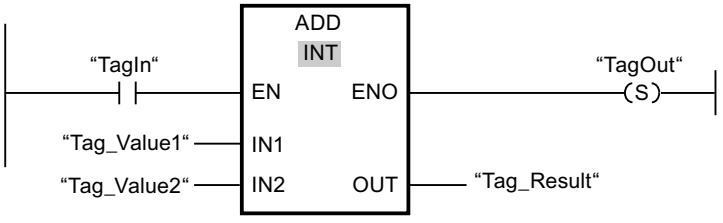
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	First number to be added
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	Second number to be added
INn	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	Optional input values that are added.
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	Sum

You can select the data type for the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also":

Example

The following example shows how the instruction works:



If operand "TagIn" has the signal state "1", the "Add" instruction is executed. The value of operand "Tag_Value1" is added to the value of operand "Tag_Value2". The result of the addition is stored in operand "Tag_Result". If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

Overview of the valid data types (Page 1908)

SUB: Subtract

Description

You can use the "Subtract" instruction to subtract the value at input IN2 from the value at input IN1 and query the difference at output OUT (OUT := IN1-IN2).

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- The EN enable input has the signal state "0".
- The result of the instruction is outside the range permitted for the data type specified at the OUT output.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Subtract" instruction:

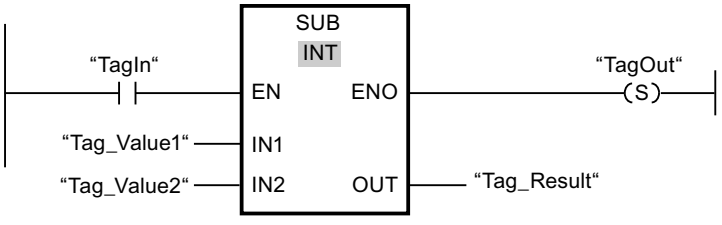
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	Minuend
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	Subtracting
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	Difference

You can select the data type for the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If operand "TagIn" has the signal state "1", the "Subtract" instruction is executed. The value of operand "Tag_Value2" is subtracted from the value of operand "Tag_Value1". The result of

the subtraction is stored in operand "Tag_Result". If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

MUL: Multiply

Description

You can use the "Multiply" instruction to multiply the value at input IN1 with the value at input IN2 and query the product at output OUT (OUT := IN1*IN2).

The number of inputs can be expanded in the instruction box. The added inputs are numbered in ascending order in the box. When the instruction is executed, the values of all available input parameters are multiplied. The product is stored at the OUT output.

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- The EN input has the signal state "0".
- The result is outside the range permitted for the data type specified at output OUT.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Multiply" instruction:

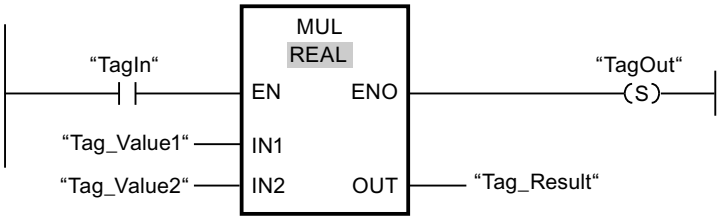
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	Multiplier
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	Number being multiplied
INn	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	Optional input values that can be multiplied.
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	Product

You can select the data type for the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If operand "TagIn" has the signal state "1", the "Multiply" instruction is executed. The value of operand "Tag_Value1" is multiplied by the value of operand "Tag_Value2". The result of the multiplication is stored in operand "Tag_Result". If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

DIV: Divide

Description

You can use the "Divide" instruction to divide the value at input IN1 by the value at input IN2 and query the quotient at output OUT (OUT := IN1/IN2).

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- The EN enable input has the signal state "0".
- The result of the instruction is outside the range permitted for the data type specified at the OUT output.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Divide" instruction:

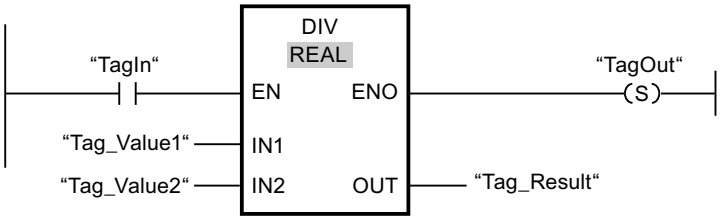
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	Dividend
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	Divisor
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	Quotient value

You can select the data type for the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If operand "TagIn" has the signal state "1", the "Divide" instruction is executed. The value of operand "Tag_Value1" is divided by the value of operand "Tag_Value2". The division result is stored in operand "Tag_Result". If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

MOD: Return remainder of division

Description

You can use the "Return remainder of division" instruction to divide the value at input IN1 by the value at input IN2 and query the remainder of division at output OUT.

Parameters

The following table shows the parameters of the "Return remainder of division" instruction:

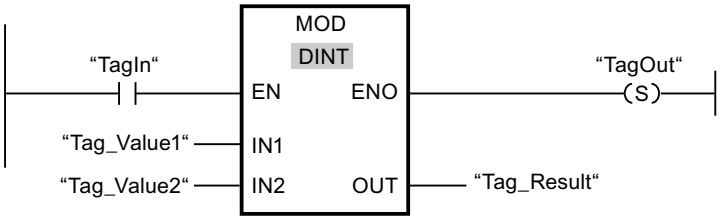
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Integers	I, Q, M, D, L, P, or constant	Dividend
IN2	Input	Integers	I, Q, M, D, L, P, or constant	Divisor
OUT	Output	Integers	I, Q, M, D, L, P	Remainder of division

You can select the data type of the instruction from the "<Auto ???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If operand "TagIn" has the signal state "1", the "Return remainder of division" instruction is executed. The value of operand "Tag_Value1" is divided by the value of operand "Tag_Value2". The remainder of division is stored in operand "Tag_Result". If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

NEG: Create twos complement

Description

You can use the "Create twos complement" instruction to change the sign of the value at the IN input and query the result at the OUT output. If there is a positive value at input IN, for example, the negative equivalent of this value is sent to output OUT.

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- The EN enable input has the signal state "0".
- The result of the instruction is outside the range permitted for the data type specified at the OUT output.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Create twos complement" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output

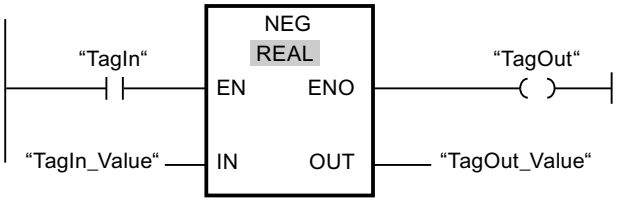
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	SINT, INT, DINT, floating-point numbers	SINT, INT, DINT, LINT, floating-point numbers	I, Q, M, D, L, P or constant	Input value
OUT	Output	SINT, INT, DINT, floating-point numbers	SINT, INT, DINT, LINT, floating-point numbers	I, Q, M, D, L, P	Twos complement of the input value

You can select the data type for the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If operand "TagIn" has the signal state "1", the "Create twos complement" instruction is executed. The sign of the value at input "TagIn_Value" is changed and the result is provided at "TagOut_Value" output. If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

INC: Increment

Description

You can use the "Increment" instruction to change the value of the operand at the IN/OUT parameter to the next higher value and query the result. The "Increment" instruction is only started when the signal state at the EN enable input is "1". If no overflow error occurs during the execution, the ENO enable output also has the signal state "1".

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- The EN enable input has the signal state "0".
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Increment" instruction:

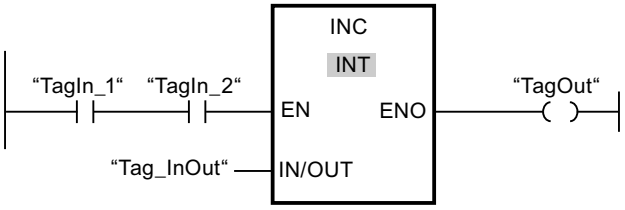
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN/OUT	InOut	Integers	I, Q, M, D, L	Value to be incremented.

You can select the data type for the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If operands "TagIn_1" and "TagIn_2" have the signal state "1", the value of operand "Tag_InOut" is incremented by one and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

DEC: Decrement

Description

You can use the "Decrement" instruction to change the value of the operand at the IN/OUT parameter to the next lower value and query the result. The "Decrement" instruction is only started when the signal state at the EN enable input is "1". If the range of values of the selected data type is not exceeded during processing, the ENO output also has the signal state "1".

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- The EN enable input has the signal state "0".
- A floating-point number has an invalid value.

Parameter

The following table shows the parameters of the "Decrement" instruction:

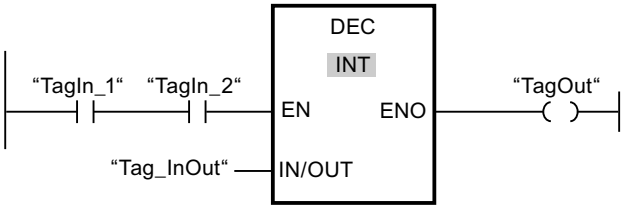
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN/OUT	InOut	Integers	I, Q, M, D, L	Value to be decremented.

You can select the data type for the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If operands "TagIn_1" and "TagIn_2" have the signal state "1", the value of operand "Tag_InOut" is decremented by one and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

ABS: Form absolute value

Description

You can use the "Form absolute value" instruction to calculate the absolute value of the value specified at input IN. The result of the instruction is sent to the OUT output and can be queried there.

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- The EN enable input has the signal state "0".
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Form absolute value" instruction:

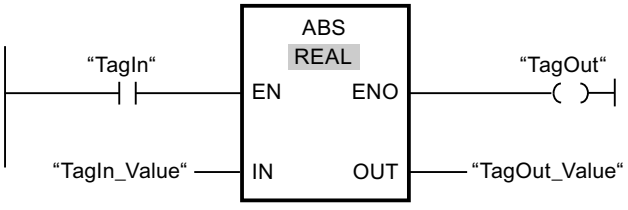
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
IN	Input	SINT, INT, DINT, floating-point numbers	SINT, INT, DINT, LINT, floating-point numbers	I, Q, M, D, L, P or constant	Input value
OUT	Output	SINT, INT, DINT, floating-point numbers	SINT, INT, DINT, LINT, floating-point numbers	I, Q, M, D, L, P	Absolute value of the input value

You can select the data type for the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	TagIn_Value	-6.234
OUT	TagOut_Value	6.234

If operand "TagIn" has the signal state "1", the "Form absolute value" instruction is executed. The instruction calculates the absolute value of the value at input "TagIn_Value" and sends the result to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

MIN: Get minimum

Description

The "Get minimum" instruction compares the values at the available inputs and writes the lowest value to the OUT output. The number of inputs can be expanded at the instruction box by additional inputs. The inputs are numbered in ascending order in the box.

A minimum of two and a maximum of 100 inputs must be specified for the execution of the instruction.

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- Enable input EN has the signal state "0".
- The implicit conversion of the data types fails during execution of the instruction.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Get minimum" instruction:

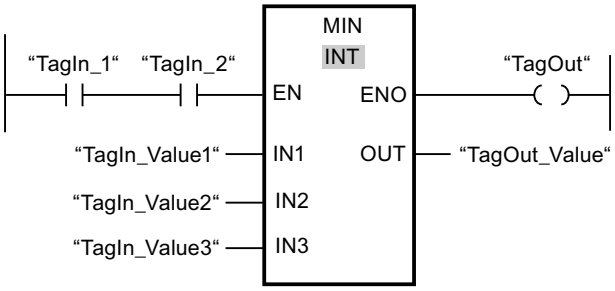
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	First input value
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P, or constant	Second input value
INn	Input	Integers, floating-point numbers	I, Q, M, D, L, P, or constant	Additionally inserted inputs whose values are to be compared
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	Result
When the IEC check is not activated, you can also use tags of the data type TIME, LTIME, TOD, LTOD, DATE and LDT by selecting an equally long bit string or integer as data type of the instruction (e.g. instead of TIME => DINT, UDINT or DWORD = 32 bit)				

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN1	TagIn_Value1	12222
IN2	TagIn_Value2	14444
IN3	TagIn_Value3	13333
OUT	TagOut_Value	12222

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. The instruction compares the values of the specified operands and copies the lowest value ("TagIn_Value1") to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

MAX: Get maximum

Description

The "Get maximum" instruction compares the values at the available inputs and writes the highest value to the OUT output. The number of inputs can be expanded at the instruction box by additional inputs. The inputs are numbered in ascending order in the box.

A minimum of two and a maximum of 100 inputs must be specified for the execution of the instruction.

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- Enable input EN has the signal state "0".
- The implicit conversion of the data types fails during execution of the instruction.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Get maximum" instruction:

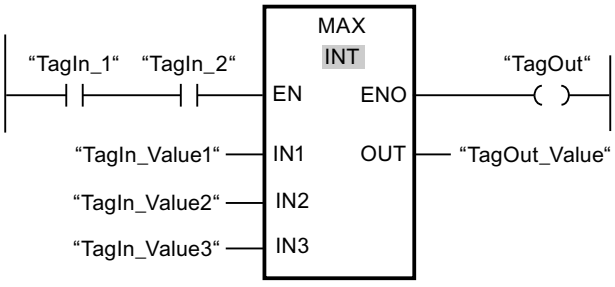
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers	I, Q, M, D, L, P, or constant	First input value
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P, or constant	Second input value
INn	Input	Integers, floating-point numbers	I, Q, M, D, L, P, or constant	Additionally inserted inputs whose values are to be compared
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	Result
When the IEC check is not activated, you can also use tags of the data type TIME, LTIME, TOD, LTOD, DATE and LDT by selecting an equally long bit string or integer as data type of the instruction. (e.g. instead of TIME => DINT, UDINT or DWORD = 32 bit)				

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN1	TagIn_Value1	12222
IN2	TagIn_Value2	14444
IN3	TagIn_Value3	13333
OUT	TagOut_Value	14444

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. The instruction compares the values of the specified operands and copies the highest value ("TagIn_Value2") to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

LIMIT: Set limit value

Description

You can use the "Set limit value" instruction to limit the value at input IN to the values at the inputs MN and MX. If the value at the IN input meets the condition MN <= IN <= MX, it is copied to the OUT output. If the condition is not fulfilled and the input value IN is below the low limit MN, the output OUT is set to the value of the MN input. If the MX high limit is exceeded, the OUT output is set to the value of the MX input.

If the value at the MN input is greater than at the MX input, the result is undefined and the enable output ENO is "0".

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- Enable input EN has the signal state "0".
- The specified tags are not of the same data type.
- An operand has an invalid value.
- The value at the MN input is greater than the value of the MX input.

Parameters

The following table shows the parameters of the "Set limit value" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
MN	Input	Integers, floating-point numbers, TIME, TOD, DATE	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P or constant	Low limit
IN	Input	Integers, floating-point numbers, TIME, TOD, DATE	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P or constant	Input value
MX	Input	Integers, floating-point numbers, TIME, TOD, DATE	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P or constant	High limit

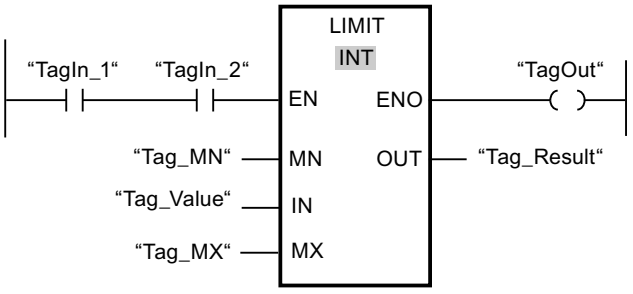
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
OUT	Output	Integers, floating-point numbers, TIME, TOD, DATE	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	Result
The data types TOD, LTOD, DATE, and LDT can only be used if the IEC test is not enabled.					

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
MN	Tag_MN	12000
IN	Tag_Value	8000
MX	Tag_MX	16000
OUT	Tag_Result	12000

If operands "TagIn_1" and "TagIn_2" have the signal state "1", the "Set limit value" instruction is executed. The value of operand "Tag_Value" is compared with the values of operands "Tag_MN" and "Tag_MX". Since the value of operand "Tag_Value" is less than the low limit, the value of operand "Tag_MN" is copied to the "Tag_Result" output. If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

SQR: Form square

Description

The instruction "Form square" is used to square the value of a floating-point number at input IN and to write the result to output OUT.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.

Parameters

The following table shows the parameters of the instruction "Form square":

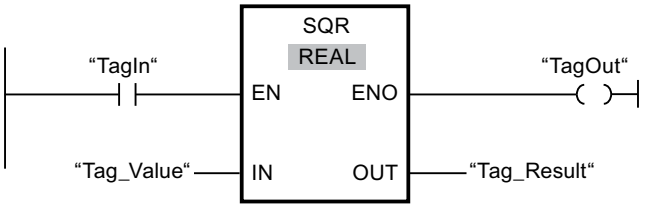
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Input value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Square of the input value

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	Tag_Value	5.0
OUT	Tag_Result	25.0

If the operand "TagIn" has the signal state "1", the "Form square" instruction is executed. The instruction squares the value of the operand "Tag_Value" and sends the result to output "Tag_Result". If no errors occur during the execution of the instruction, the output "TagOut" is set.

See also

Overview of the valid data types (Page 1908)

SQRT: Form square root

Description

The instruction "Form square root" is used form the square root from the value of the floating-point number at input IN and to write the result to output OUT. The instruction has a positive result if the input value is greater than zero. If input values are less than zero, output OUT returns an invalid floating-point number. If the value at input IN is "0", the result is also "0".

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.
- The value at input IN is negative.

Parameters

The following table shows the parameters of the instruction "Form square root":

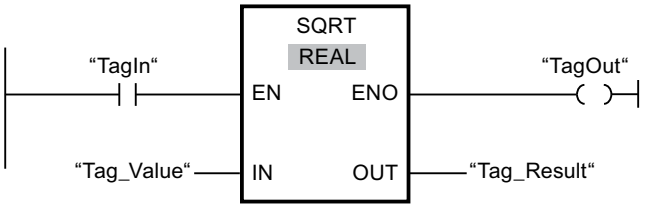
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Input value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Square root of the input value

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	Tag_Value	25.0
OUT	Tag_Result	5.0

If the operand "TagIn" has the signal state "1", the "Form square root" instruction is executed. The instruction calculates the square root of the operand "Tag_Value" and sends the result to output "Tag_Result". If no errors occur during the execution of the instruction, the output "TagOut" is set.

See also

Overview of the valid data types (Page 1908)

LN: Form natural logarithm

Description

You can use the "Form natural logarithm" instruction to calculate the natural logarithm to base e (e = 2.718282) of the value at input IN. The result is sent to output OUT and can be queried there. The instruction has a positive result if the input value is greater than zero. If input values are less than zero, output OUT returns an invalid floating-point number.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.
- The value at input IN is negative.

Parameters

The following table shows the parameters of the instruction "Form natural logarithm":

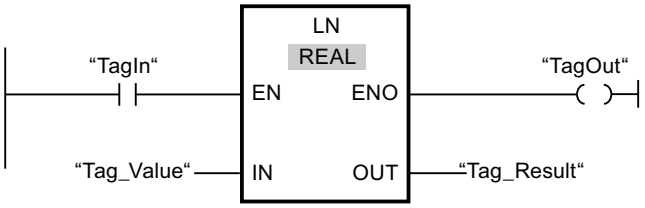
Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Input value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Natural logarithm of the input value

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If the operand "TagIn" has the signal state "1", the "Form natural logarithm" instruction is executed. The instruction forms the natural logarithm of the value at input "Tag_Value" and sends the result to output "Tag_Result". If no errors occur during the execution of the instruction, the output "TagOut" is set.

See also

Overview of the valid data types (Page 1908)

EXP: Form exponential value

Description

You can use the "Form exponential value" instruction to calculate the exponent from the base e (e = 2.718282) and the value specified at input IN. The result is provided at output OUT and can be queried there (OUT = e^{IN}).

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.

Parameters

The following table shows the parameters of the instruction "Form exponential value":

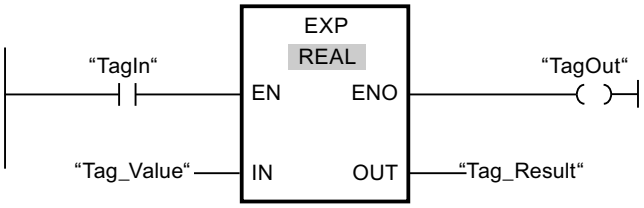
Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Input value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Exponential value of input value IN

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If the operand "TagIn" has the signal state "1", the "Form exponential value" instruction is executed. The instruction forms the exponent from base e and the value of the operand "Tag_Value" and sends the result to output "Tag_Result". If no errors occur during the execution of the instruction, the output "TagOut" is set.

See also

Overview of the valid data types (Page 1908)

SIN: Form sine value

Description

Use the "Form sine value" instruction to calculate the sine of the angle. The size of the angle is specified in radians at the IN input. The result of the instruction is sent to the OUT output and can be queried there.

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- The EN enable input has the signal state "0".
- The value at the IN input is not a valid floating-point number.

Parameters

The following table shows the parameters of the "Form sine value" instruction:

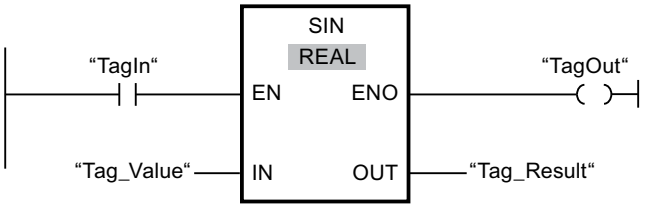
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	Size of angle in radians
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Sine of the specified angle

You can select the data type for the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	Tag_Value	+1.570796 (π/2)
OUT	Tag_Result	1.0

If operand "TagIn" has the signal state "1", the "Form sine value" instruction is executed. The instruction calculates the sine of the angle specified at the "Tag_Value" input and stores the result in the "Tag_Result" output. If the instruction is executed without errors, the "TagOut" output is set.

Overview of the valid data types (Page 1908)

COS: Form cosine value

Description

Use the "Form cosine value" instruction to calculate the cosine of the angle. The size of the angle is specified in radians at the IN input. The result of the instruction is sent to the OUT output and can be queried there.

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- The EN enable input has the signal state "0".
- The value at the IN input is not a valid floating-point number.

Parameters

The following table shows the parameters of the "Form cosine value" instruction:

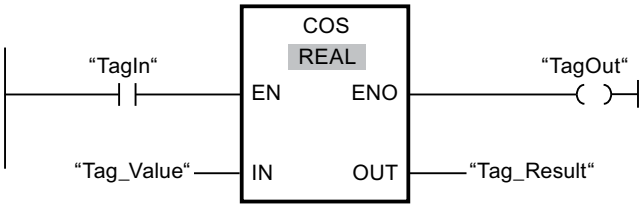
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	Size of angle in radians
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Cosine of the specified angle

You can select the data type for the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	Tag_Value	+1.570796 (π/2)
OUT	Tag_Result	0

If operand "TagIn" has the signal state "1", the "Form cosine value" instruction is executed. The instruction calculates the cosine of the angle specified at the "Tag_Value" input and stores the result in the "Tag_Result" output. If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

TAN: Form tangent value

Description

Use the "Form tangent value" instruction to calculate the tangent of the angle. The size of the angle is specified in radians at the IN input. The result of the instruction is sent to the OUT output and can be queried there.

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- The EN enable input has the signal state "0".
- The value at the IN input is not a valid floating-point number.

Parameters

The following table shows the parameters of the "Form tangent value" instruction:

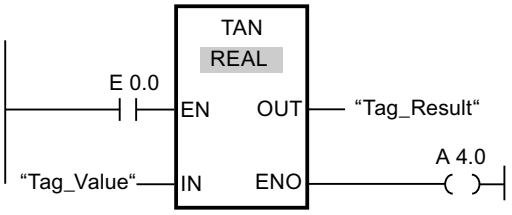
Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	Size of angle in radians
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Tangent of the specified angle

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	Tag_Value	+3.141593 (π)
OUT	Tag_Result	0

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction calculates the tangent of the angle specified at the "Tag_Value" input and stores the result in the "Tag_Result" output. If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

ASIN: Form arcsine value

Description

You can use the "Form arcsine value" instruction to calculate the size of the angle from the arcsine value specified at input IN, which corresponds to this value. Only valid floating-point numbers within the range -1 to +1 can be specified at the IN input. The calculated angle size is output in radians at the OUT output and can range in value from -π/2 to +π/2.

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- The EN enable input has the signal state "0".
- The value at the IN input is not a valid floating-point number.
- The value at the IN input is outside the permitted value range (-1 to +1).

Parameters

The following table shows the parameters of the "Form arcsine value" instruction:

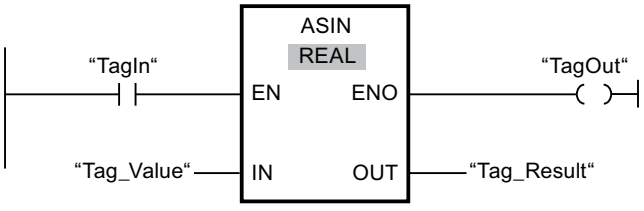
Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	Sine value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Size of angle in radians

You can select the data type for the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Value	1.0
OUT	Tag_Result	+1.570796 (π/2)

If operand "TagIn" has the signal state "1", the "Form arcsine value" instruction is executed. The instruction calculates the size of the angle corresponding to the sine value at the "Tag_Value" input. The result of the instruction is stored in the "Tag_Result" output. If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

ACOS: Form arccosine value

Description

You can use the "Form arccosine value" instruction to calculate the size of the angle from the cosine value specified at input IN, which corresponds to this value. Only valid floating-point numbers within the range -1 to +1 can be specified at the IN input. The calculated angle size is output in radians at the OUT output and can range in value from 0 to +π.

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- The EN enable input has the signal state "0".
- The value at the IN input is not a valid floating-point number.
- The value at the IN input is outside the permitted value range (-1 to +1).

Parameters

The following table shows the parameters of the "Form arccosine value" instruction:

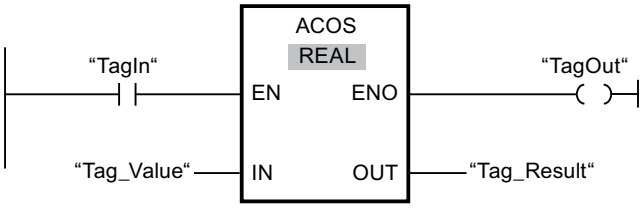
Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	Cosine value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Size of angle in radians

You can select the data type for the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Value	0
OUT	Tag_Result	+1.570796 (π/2)

If operand "TagIn" has the signal state "1", the "Form arccosine value" instruction is executed. The instruction calculates the size of the angle corresponding to the cosine value at the "Tag_Value" input. The result of the instruction is stored in the "Tag_Result" output. If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

ATAN: Form arctangent value

Description

You can use the "Form arctangent value" instruction to calculate the size of the angle from the tangent value specified at input IN, which corresponds to this value. It is only permitted to specify valid floating-point numbers (or -NaN/+NaN) at input IN. The calculated angle size is output in radians at the OUT output and can range in value from -π/2 to +π/2.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.

Parameters

The following table shows the parameters of the instruction "Form arctangent value":

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output

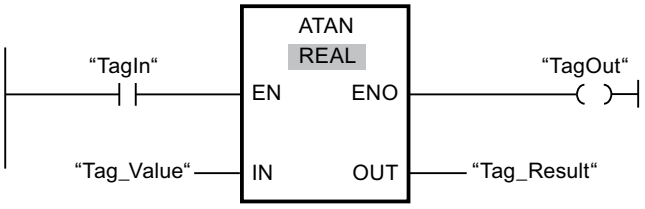
Parameters	Declaration	Data type	Memory area	Description
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Tangent value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Size of angle in radians

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Value	1.0
OUT	Tag_Result	+0.785398 (π/4)

If the operand "TagIn" has the signal state "1", the "Form arctangent value" instruction is executed. The instruction calculates the size of the angle corresponding to the tangent value at input "Tag_Value". The result of the instruction is stored at output "Tag_Result". If no errors occur during the execution of the instruction, the output "TagOut" is set.

Overview of the valid data types (Page 1908)

Invalid floating-point numbers (Page 1927)

FRAC: Return fraction

Description

You can use the "Return fraction" instruction to determine the decimal places of the value at the IN input. The result of the query is stored at the OUT output and can be queried there. If, for example, the IN input has the value 123.4567, the OUT output returns the value 0.4567.

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- The EN enable input has the signal state "0".
- The value at input IN is not a valid floating-point number.

Parameters

The following table shows the parameters of the "Return fraction" instruction:

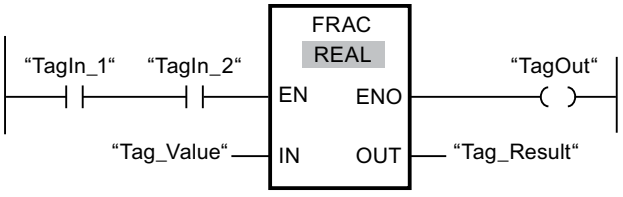
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	Value, whose decimal places are to be determined.
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Decimal places of the value at the IN input

You can select the data type for the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	Tag_Value	2.555
OUT	Tag_Result	0.555

If operands "TagIn_1" and "TagIn_2" have the signal state "1", the "Return fraction" instruction is started. The decimal places from the value of operand "Tag_Value" are copied to operand "Tag_Result". If the instruction is executed without errors, the ENO output has the signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

EXPT: Exponentiate

Description

You can use the "Exponentiate" instruction to raise the value at the IN1 input to a power specified with the value at the IN2 input. The result of the instruction is provided at the OUT output and can be queried there (OUT =$IN1^{IN2}$).

The IN1 input can only be assigned valid floating-point numbers. Integers can also be assigned to the IN2 input.

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- The EN enable input has the signal state "0".
- Errors occur during execution of the instruction, for example, an overflow occurs.

Parameters

The following table shows the parameters of the "Exponentiate" instruction:

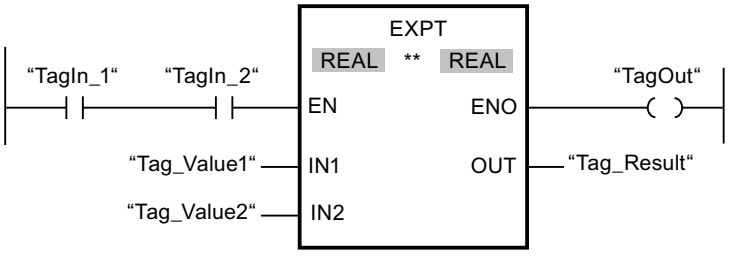
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Floating-point numbers	I, Q, M, D, L, P or constant	Base value
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	Value with which the base value is exponentiated
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Result

You can select the data type for the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If operands "TagIn_1" and "TagIn_2" have the signal state "1", the "Exponentiate" instruction is started. The value of operand "Tag_Value1" is raised to a power specified with the value of operand "Tag_Value2". The result is stored in the "Tag_Result" output. If the instruction is

executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

Overview of the valid data types (Page 1908)

Move operations

MOVE: Move value

Description

You use the "Move value" instruction to transfer the content of the operand at the IN input to the operand at the OUT1 output. The transfer is always made in the direction of ascending address.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The data type at the IN parameter does not correspond to the specified data type at the OUT1 parameter.

The following table lists the possible transfers for the S7-1200 CPU series:

Source (IN)	Destination (OUT1)	
	With IEC check	Without IEC check
BYTE	BYTE, WORD, DWORD	BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT, TIME, DATE ,TOD, CHAR

IEC_UL-COUNTER	IEC_ULCOUNTER	IEC_ULCOUNTER

[1)] You can also use the "Move value" instruction to transfer individual characters of a string to operands of the CHAR or WCHAR data type. The number of the character to be transferred is specified in square brackets next to the operand name. "MyString[2]", for example, transfers the second character of the "MyString" string. The transfer of the operand of the data type CHAR or WCHAR to the individual character of a string is also possible. You can also replace a specific character of a string with the character of another string.

[2)] Transferring entire arrays (ARRAY) is possible only when the array components of the operands at input IN and at output OUT1 are of the same data type.

If the bit length of the data type at input IN exceeds the bit length of the data type at output OUT1, the higher-order bits of the source value are lost. If the bit length of the data type at input IN is less than the bit length of the data type at output OUT1, the higher-order bits of the destination value will be overwritten with zeros.

In its initial state, the instruction box contains 1 output (OUT1). The number of outputs can be extended. The added outputs are numbered in ascending order on the box. During the execution of the instruction, the content of the operand at the input IN is transferred to all available outputs. The instruction box cannot be extended if structured data types (DTL, STRUCT, ARRAY) or characters of a string are transferred.

You can also use the "Move block" (MOVE_BLK) and "Move block uninterruptible" (UMOVE_BLK) instructions to move operands of the ARRAY data type. Operand of the data type STRING or WSTRING can be copied with the instruction "Move character string" (S_MOVE).

Parameter

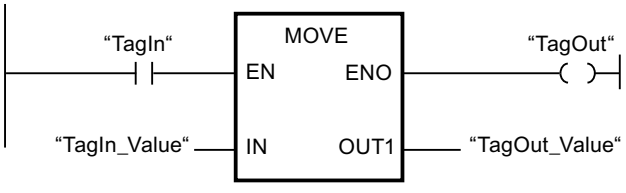
The following table lists the parameters of the "Move value" instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers, floating-point numbers, timers, date and time, CHAR, WCHAR, STRUCT, ARRAY, IEC data types, PLC data type (UDT)	Bit strings, integers, floating-point numbers, timers, date and time, CHAR; WCHAR, STRUCT, ARRAY, TIMER, COUNTER, IEC data type, PLC data type (UDT)	I, Q, M, D, L or constant	Source value
OUT1	Output	Bit strings, integers, floating-point numbers, timers, date and time, CHAR, WCHAR, STRUCT, ARRAY, IEC data types, PLC data type (UDT)	Bit strings, integers, floating-point numbers, timers, date and time, CHAR; WCHAR, STRUCT, ARRAY, TIMER, COUNTER, IEC data type, PLC data type (UDT)	I, Q, M, D, L	Operands to which in the source value is transferred.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	TagIn_Value	0011 1111 1010 1111
OUT1	TagOut_Value	0011 1111 1010 1111

If the operand "TagIn" has the signal state "1", the "Move value" instruction is executed. The instruction copies the contents of operand "TagIn_Value" to operand "TagOut_Value" and sets output "TagOut" to signal state "1".

Overview of the valid data types (Page 1908)

MOVE_BLK: Move block (Page 2344)

UMOVE_BLK: Move block uninterruptible (Page 2350)

S_MOVE: Move character string (Page 3001)

Deserialize: Deserialize

Description

You can use the "Deserialize" instruction to convert the sequential representation of a PLC data type (UDT) back to a PLC data type and to fill its entire contents.

The memory area in which the sequential representation of a PLC data type is located must have the ARRAY of BYTE data type and be declared with standard access. The capacity of the standard memory area is 64 KB. Make sure that there is enough memory space prior to the conversion.

The instruction enables you to convert multiple sequential representations of converted PLC data types back to their original state step-by-step.

If you only want to convert back a single sequential representation of a PLC data type (UDT), you can also use the instruction "TRCV: Receive data via communication connection".

Note

Applies to CPUs of the S7-1500 series

For a block with the block property "Optimized block access", the bit has a length of 1 byte.

Parameters

The following table shows the parameters of the "Deserialize" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
SRC_ARRAY	Input	VARIANT	I, Q, M, L	Global data block in which the generated data stream is stored
DEST_VARIABLE	InOut	VARIANT	I, Q, M, L	Tag in which the returned converted PLC data type (UDT) is stored

Parameters	Declaration	Data type	Memory area	Description
POS	InOut	DINT	I, Q, M, D, L	Number of bytes that the converted PLC data types use. The POS parameter is calculated zero-based.
RET_VAL	Output	INT	I, Q, M, D, L	Error information

For additional information on valid data types, refer to "See also".

Parameter RET_VAL

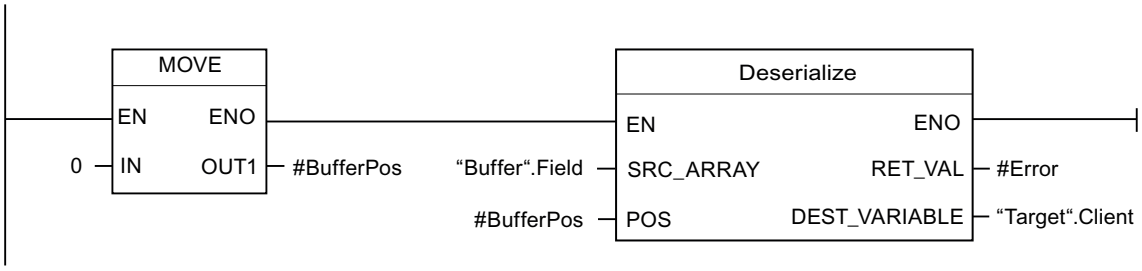
The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B0	The memory areas for the SRC_ARRAY and DEST_VARIABLE parameters overlap.
8136	The data block at the DEST_VARIABLE parameter is not a block with standard access.
8150	The VARIANT data type at the SRC_ARRAY parameter contains no value.
8151	Code generation error at the SRC_ARRAY parameter
8153	There is not enough free memory available at the SRC_ARRAY parameter.
8250	The VARIANT data type at the DEST_VARIABLE parameter contains no value.
8251	Code generation error at the DEST_VARIABLE parameter
8254	Invalid data type at the DEST_VARIABLE parameter
8382	The value at parameter POS is outside the limits of the array.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

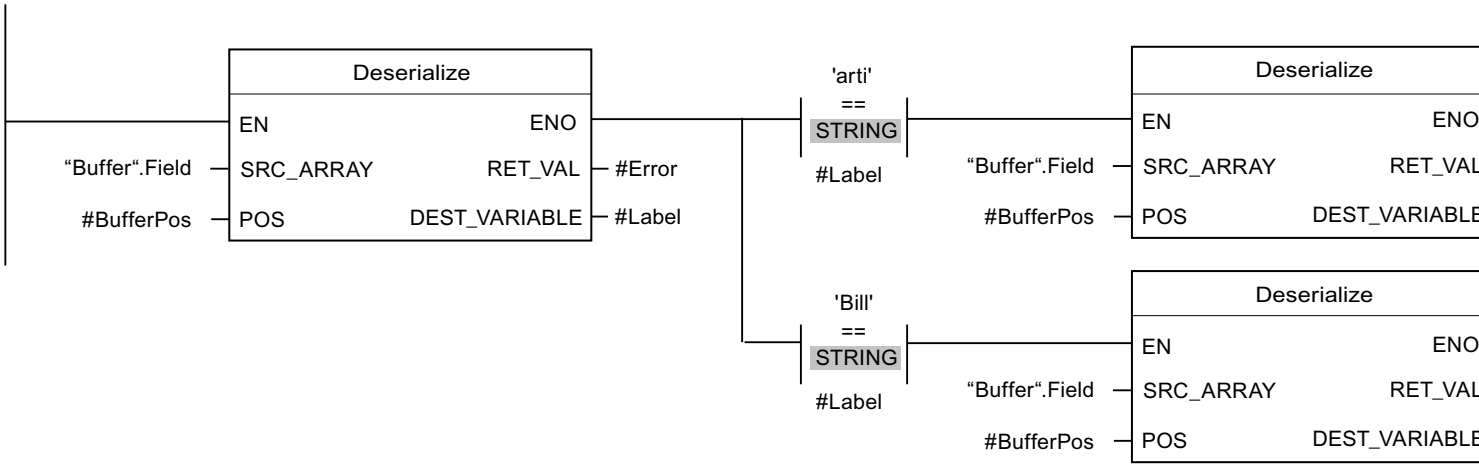
The following example shows how the instruction works:

Network 1:



The "Move value" instruction moves the value "0" to the "#BufferPos" operand. The "Deserialize" instruction deserializes the sequential representation of the customer data from the "Buffer" data block and writes it to the "Target" data block. The number of bytes used by the converted customer data is stored in the "#BufferPos" operand.

Network 2:



The "Deserialize" instruction deserializes the sequential representation of the separator sheet, which was saved with the sequential representation after the customer data, from the "Buffer" data block and writes the characters to the "#Label" operand. The characters are compared using comparison instructions "arti" and "Bill". If the comparison for "arti" = TRUE, these are article data that have been deserialized and written to the "Target" data block. If the comparison for "Bill" = TRUE, these are billing data that have been deserialized and written to the "Target" data block.

The following table shows the declaration of the operands:

Operand	Data type	Declaration
DeliverPos	INT	In the "Input" section of the block interface
BufferPos	DINT	In the "Temp" section of the block interface
Error	INT	In the "Temp" section of the block interface
Label	STRING[4]	In the "Temp" section of the block interface

The following table shows the declarations of the PLC data types:

Name of the PLC data types	Name	Data type
Article	Number	DINT
	Declaration	STRING
	Colli	INT
Client	Title	INT
	First name	STRING[10]
	Surname	STRING[10]

The following table shows the declaration of the data blocks:

Name of the data blocks	Name	Data type
Target	Client	"Client" (PLC data type)
	Article	Array[0..10] of "Article" (PLC data type)
	Bill	Array[0..10] of INT
Buffer	Field	Array[0..294] of BYTE

See also

Overview of the valid data types (Page 1908)

PLC data types (Page 1954)

Serialize: Serialize

Description

You can use the "Serialize" instruction to convert several PLC data types (UDT) to a sequential representation without losing parts of their structure.

You can use the instruction to cache multiple structured data from your program in a buffer, which is preferably in a global data block, and send it to another CPU. The memory area in which the converted PLC data types are stored must have the ARRAY of BYTE data type and be declared with standard access. The capacity of the standard memory area is 64 KB. Make sure that there is enough memory space prior to the conversion.

The operand at the POS parameter contains information about the number of bytes used by the converted PLC data types.

If you want to send a single PLC data type (UDT), you can directly call the instruction "TSEND: Send data via communication connection".

Note

Applies to CPUs of the S7-1500 series

For a block with the block property "Optimized block access", the bit has a length of 1 byte.

Parameters

The following table shows the parameters of the instruction "Serialize":

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
SRC_VARIABLE	Input	VARIANT	I, Q, M, L	PLC data type (UDT) that is converted to sequential representation.

Parameters	Declaration	Data type	Memory area	Description
DEST_ARRAY	InOut	VARIANT	I, Q, M, L	Data block in which the generated data stream is stored.
POS	InOut	DINT	I, Q, M, D, L	Number of bytes that the converted PLC data types use. The POS parameter is calculated zero-based.
RET_VAL	Output	INT	I, Q, M, D, L	Error information

For additional information on valid data types, refer to "See also".

Parameter RET_VAL

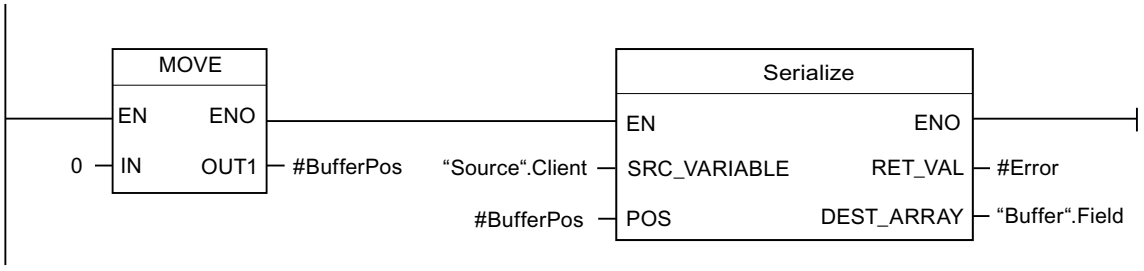
The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B0	The memory areas for the SRC_VARIABLE and DEST_ARRAY parameters overlap.
8150	The VARIANT data type at the SRC_VARIABLE parameter contains no value.
8152	Code generation error at the SRC_VARIABLE parameter
8236	The data block at the DEST_ARRAY parameter is not a block with standard access.
8250	The VARIANT data type at the DEST_ARRAY parameter contains no value.
8252	Code generation error at the DEST_ARRAY parameter
8253	There is not enough free memory available at the DEST_ARRAY parameter.
8254	Invalid data type at the DEST_ARRAY parameter
8382	The value at parameter POS is outside the limits of the array.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

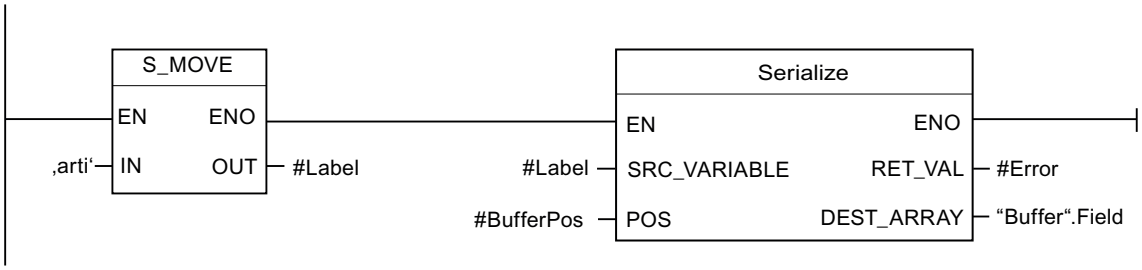
The following example shows how the instruction works:

Network 1:



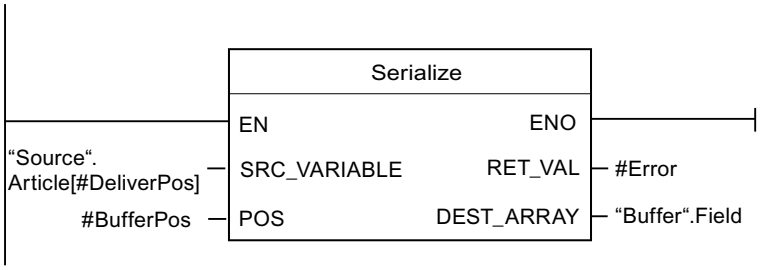
The "Move value" instruction moves the value "0" to the "#BufferPos" operand. The "Serialize" instruction serializes the customer data from the "Source" data block and writes it in sequential representation to the "Buffer" data block. The number of bytes used by the sequential representation is stored in the "#BufferPos" operand.

Network 2:



A kind of separator sheet is inserted now to make it easier to deserialize the sequential representation later. The "Move string" instruction moves the "arti" characters to the "#Label" operand. The "Serialize" instruction writes these characters after the customer data to the "Buffer" data block. The number of bytes that the characters need is added to the number already stored in the "#BufferPos" operand.

Network 3:



The "Serialize" instruction serializes the data of a specific article, which is calculated in runtime, from the "Source" data block and writes it in sequential representation to the "Buffer" data block after the "arti" characters.

The following table shows the declaration of the operands:

Operand	Data type	Declaration
DeliverPos	INT	In the "Input" section of the block interface
BufferPos	DINT	In the "Temp" section of the block interface
Error	INT	In the "Temp" section of the block interface
Label	STRING[4]	In the "Temp" section of the block interface

The following table shows the declarations of the PLC data types:

Name of the PLC data types	Name	Data type
Article	Number	DINT
	Declaration	STRING
	Colli	INT

Name of the PLC data types	Name	Data type
Client	Title	INT
	First name	STRING[10]
	Surname	STRING[10]

The following table shows the declaration of the data blocks:

Name of the data blocks	Name	Data type
Source	Client	"Client" (PLC data type)
	Article	Array[0..10] of "Article" (PLC data type)
Buffer	Field	Array[0..294] of BYTE

MOVE_BLK: Move block

Description

You can use the "Move block" instruction to move the content of a memory area (source area) to another memory area (destination area). The number of elements to be moved to the destination area is specified at input COUNT. The width of the elements to be moved is defined by the width of the element at input IN.

The instruction can only be executed if the source area and the destination area have the same data type.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- More data is moved than is made available at input IN or output OUT.

When a ARRAY of BOOL is copied, the enable output ENO for an overflow is set to "1" until the byte limit of the ARRAY structure is exceeded. If the byte limit of the ARRAY structure is exceeded by the value at the COUNT input, the ENO enable output is reset to "0".

Parameters

The following table lists the parameters of the "Move block" instruction:

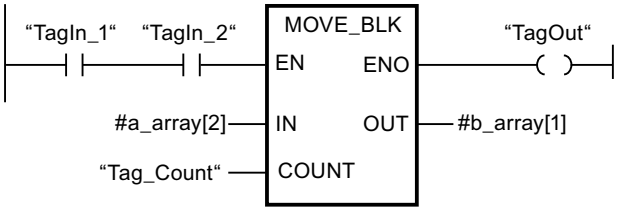
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN [1]	Input	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	The first element of the source area that is being copied
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P, or constant	Number of elements to be moved from the source area to the destination area.
OUT [1]	Output	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	The first element of the destination area to which the contents of the source area are being copied
[1] The specified data types can only be used as elements of an ARRAY structure.					

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	a_array[2]	The data type of the a_array operand is Array [0..5] of INT. It consists of six elements of data type INT.
COUNT	Tag_Count	3
OUT	b_array[1]	The data type of the b_array operand is Array [0..6] of INT. It consists of seven elements of data type INT.

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the "Move block" instruction is executed. Starting from the third element, the instruction selects three INT elements from the #a_array tag and copies their contents to the #b_array output tag, beginning with the second element. If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

MOVE_BLK_VARIANT: Move block

Description

You can use the "Move block" instruction to move the content of a memory area (source area) to another memory area (destination area). You can copy a complete ARRAY or elements of an ARRAY to another ARRAY of the same data type. The size (number of elements) of source and destination ARRAY may be different. You can copy multiple or single elements within an ARRAY.

When you use the instruction at the time to the block is created, the ARRAY does not yet have to be known, as the source and the designation are transferred per VARIANT.

Counting at the parameters SRC_INDEX and DEST_INDEX always begins with the low limit "0", regardless of the later declaration of the ARRAY.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- More data is copied than is made available.

Note

VARIANT in connection with BOOL data type

If you want to interconnect a parameter of data type VARIANT (source or destination area) with a tag of data type BOOL or an ARRAY of BOOL, you have the following options:

1. You can address it symbolically
   Example: Parameter SRC: "Data_block".myArray
2. You can address it with help of ANY pointer. However, you must note that the specified length of the area must be dividable by 8, or the instruction will otherwise not be executed.
   Example: Parameter SRC: P#DB123.DBX456.0 BOOL 1000

Parameters

The following table lists the parameters of the "Move block" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output

Parameter	Declaration	Data type	Memory area	Description
SRC	Input	VARIANT (which points to an ARRAY or an individual ARRAY element), ARRAY of <Data_type>	I, Q, M, L	Source block from which to copy
COUNT	Input	UDINT	I, Q, M, D, L or constant	Number of elements which are copied Assign the value "1" to the parameter COUNT, if no ARRAY is specified at parameter SRC or at Parameter DEST.
SRC_INDEX	Input	DINT	I, Q, M, D, L or constant	• The SRC_INDEX parameter is calculated zero-based. If an ARRAY is specified at parameter SRC, the integer at parameter SRC_INDEX specifies the first element within the source area from which it is to be copied. Independent of the declared ARRAY limits. • If no ARRAY is specified at parameter SRC or only one single element of an ARRAY is specified, then assign the value "0" at parameter SRC_INDEX.
DEST_INDEX	Input	DINT	I, Q, M, D, L or constant	• The DEST_INDEX parameter is calculated zero-based. If an ARRAY is specified at parameter DEST, the integer at parameter DEST_INDEX specifies the first element within the destination area to it is to be copied. Independent of the declared ARRAY limits. • If no ARRAY is specified at parameter DEST, then assign the value "0" at parameter DEST_INDEX.
DEST	Output [1)]	VARIANT	I, Q, M, L	Destination area into which the contents of the source block are copied.

Parameter	Declaration	Data type	Memory area	Description
RET_VAL	Output	INT	I, Q, M, D, L	Error information: If an error occurs during execution of the instruction, an error code is output at the RET_VAL parameter.
1) The DEST parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

For additional information on valid data types, refer to "See also".

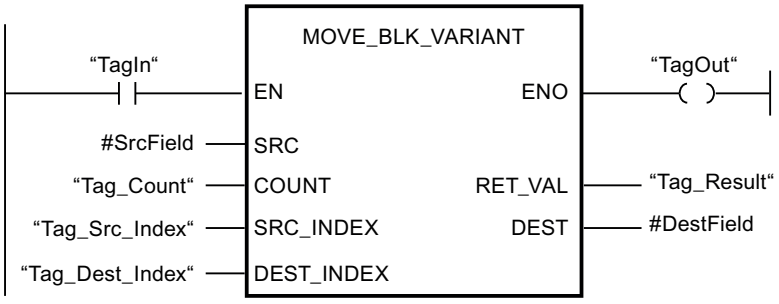
Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	Data types do not correspond
8151	Access to the SRC parameter is not possible.
8152	The operand at the SRC parameter is not typed.
8153	Code generation error at the SRC parameter
8154	The operand at the SRC parameter has the data type BOOL.
8281	The COUNT parameter has an invalid value
8382	The value at the SRC_INDEX parameter is outside the limits of the VARIANT.
8383	The value at parameter SRC_INDEX is outside the high limit of the ARRAY.
8482	The value at the DEST_INDEX parameter is outside the limits of the VARIANT.
8483	The value at parameter DEST_INDEX is outside the high limit of the ARRAY.
8534	The DEST parameter is write protected
8551	Access to the DEST parameter is not possible.
8552	The operand at the DEST parameter is not typed.
8553	Code generation error at the DEST parameter
8554	The operand at the DEST parameter has the data type BOOL.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Declaration in the block interface	Operand	Value
SRC	Input	#SrcField	The local operand #SrcField uses a PLC data type that was still unknown at the time when the block was programmed. (ARRAY[0..10] of "MOVE_UDT"
COUNT	Input	Tag_Count	2
SRC_INDEX	Input	Tag_Src_Index	3
DEST_INDEX	Input	Tag_Dest_Index	3
DEST	InOut	#DestField	The local operand #DestField uses a PLC data type that was still unknown at the time when the block was programmed. (ARRAY[10..20] of "MOVE_UDT"

If the operand "TagIn" has the signal state "1", the "Move block" instruction is executed. Two elements are copied from the source area, beginning from the fourth element of the ARRAY of UDT, to the destination area. The copies are inserted in the ARRAY of UDT starting from the fourth element. If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

UMOVE_BLK: Move block uninterruptible

Description

You can use the "Move block uninterruptible" instruction to move the content of a memory area (source area) to another memory area (destination area). The number of elements to be moved to the destination area is specified with the COUNT parameter. The width of the elements to be moved is defined by the width of the element at input IN.

The instruction can only be executed if the source area and the destination area have the same data type.

Note

The move operation cannot be interrupted by other operating system activities. This is why the interrupt reaction times of the CPU increase during the execution of the "Move block uninterruptible" instruction.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- More data is moved than is made available at input IN or output OUT.

When a ARRAY of BOOL is copied, the enable output ENO for an overflow is set to "1" until the byte limit of the ARRAY structure is exceeded. If the byte limit of the ARRAY structure is exceeded by the value at the COUNT input, the ENO enable output is reset to "0".

You can use the "Move block uninterruptible" instruction to move a maximum of 16 KB. Note the CPU-specific restrictions for this.

Parameters

The following table shows the parameters of the "Move block uninterruptible" instruction:

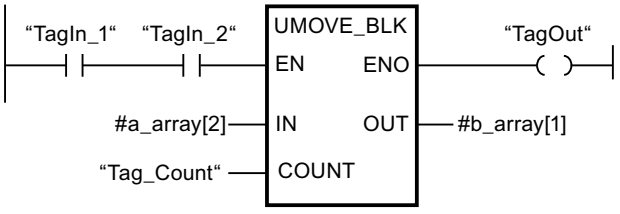
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
IN [1)]	Input	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	The first element of the source area that is being copied
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P, or constant	Number of elements to be moved from the source area to the destination area.

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
OUT [1]	Output	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	The first element of the destination area to which the contents of the source area are being copied
[1] The specified data types can only be used as elements of an ARRAY structure.					

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	a_array[2]	The data type of the a_array operand is Array [0..5] of INT. It consists of six elements of data type INT.
COUNT	Tag_Count	3
OUT	b_array[1]	The data type of the b_array operand is Array [0..6] of INT. It consists of seven elements of data type INT.

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the "Move block uninterruptible" instruction is executed. Starting from the third element, the instruction selects three INT elements from the #a_array tag and copies their contents to the #b_array output tag, beginning with the second element. The move operation cannot be interrupted by other operating system activities. If the instruction is executed without errors, the ENO output has the signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

FILL_BLK: Fill block

Description

You can use the "Fill block" instruction to fill a memory area (destination area) with the value of the IN input. The destination area is filled beginning with the address specified at the OUT output. The number of repeated move operations is specified with the COUNT parameter. When the instruction is executed, the value at the input IN is selected and moved to the destination area as often as specified by the value of the COUNT parameter.

The instruction can only be executed if the source area and the destination area have the same data type.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- More data is moved than is made available at input IN or output OUT.

When a ARRAY of BOOL is copied, the enable output ENO for an overflow is set to "1" until the byte limit of the ARRAY structure is exceeded. If the byte limit of the ARRAY structure is exceeded by the value at the COUNT input, the ENO enable output is reset to "0".

Parameters

The following table shows the parameters of the "Fill block" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
IN [1]	Input	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	I, Q, M, D, L, P, or constant	Element used to fill the destination area
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P, or constant	Number of repeated move operations
OUT [2]	Output	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	Address in destination area from which filling starts.

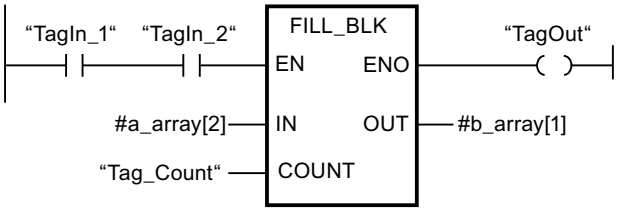
[1] The specified data types can also be used as elements of an ARRAY structure.

[2] The specified data types can only be used as elements of an ARRAY structure.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	a_array[2]	The data type of the a_array operand is Array [0..5] of INT. It consists of six elements of data type INT.
COUNT	Tag_Count	3
OUT	b_array[1]	The data type of the b_array operand is Array [0..6] of INT. It consists of seven elements of data type INT.

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the "Fill block" instruction is executed. The instruction copies the third element (#a_array[2]) of the #a_array tag three times to the #b_array output tag. If the instruction is executed without errors, the ENO and "TagOut" enable outputs are set to signal state "1".

Overview of the valid data types (Page 1908)

UFILL_BLK: Fill block uninterruptible

Description

You can use the "Fill block uninterruptible" instruction to fill a memory area (destination area) with the value of the IN input without interruption. The destination area is filled beginning with the address specified at the OUT output. The number of repeated move operations is specified with the COUNT parameter. When the instruction is executed, the value at the input IN is selected and moved to the destination area as often as specified by the value of the COUNT parameter.

The instruction can only be executed if the source area and the destination area have the same data type.

Note

The move operation cannot be interrupted by other operating system activities. This is why the alarm reaction times of the CPU increase during the execution of the "Fill block uninterruptible" instruction.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- More data is moved than is made available at input IN or output OUT.

When a ARRAY of BOOL is copied, the enable output ENO for an overflow is set to "1" until the byte limit of the ARRAY structure is exceeded. If the byte limit of the ARRAY structure is exceeded by the value at the COUNT input, the ENO enable output is reset to "0".

You can use the "Fill block uninterruptible" instruction to move a maximum of 16 KB. Note the CPU-specific restrictions for this.

Parameters

The following table shows the parameters of the "Fill block uninterruptible" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
IN [1]	Input	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	I, Q, M, D, L, P, or constant	Element used to fill the destination area.
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P, or constant	Number of repeated move operations
OUT [2]	Output	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	Address in destination area from which filling begins.

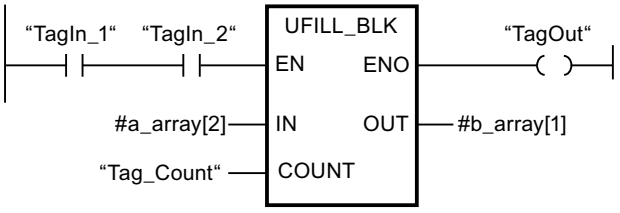
[1] The specified data types can also be used as elements of an ARRAY structure.

[2] The specified data types can only be used as elements of an ARRAY structure.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	a_array[2]	The data type of the a_array operand is Array [0..5] of INT. It consists of six elements of data type INT.
COUNT	Tag_Count	3
OUT	b_array[1]	The data type of the b_array operand is Array [0..6] of INT. It consists of seven elements of data type INT.

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the "Fill block uninterruptible" instruction is executed. The instruction copies the third element (#a_array[2]) of the #a_array tag three times to the #b_array output tag. The move operation cannot be interrupted by other operating system activities. If the instruction is executed without errors, the ENO and "TagOut" enable outputs are set to signal state "1".

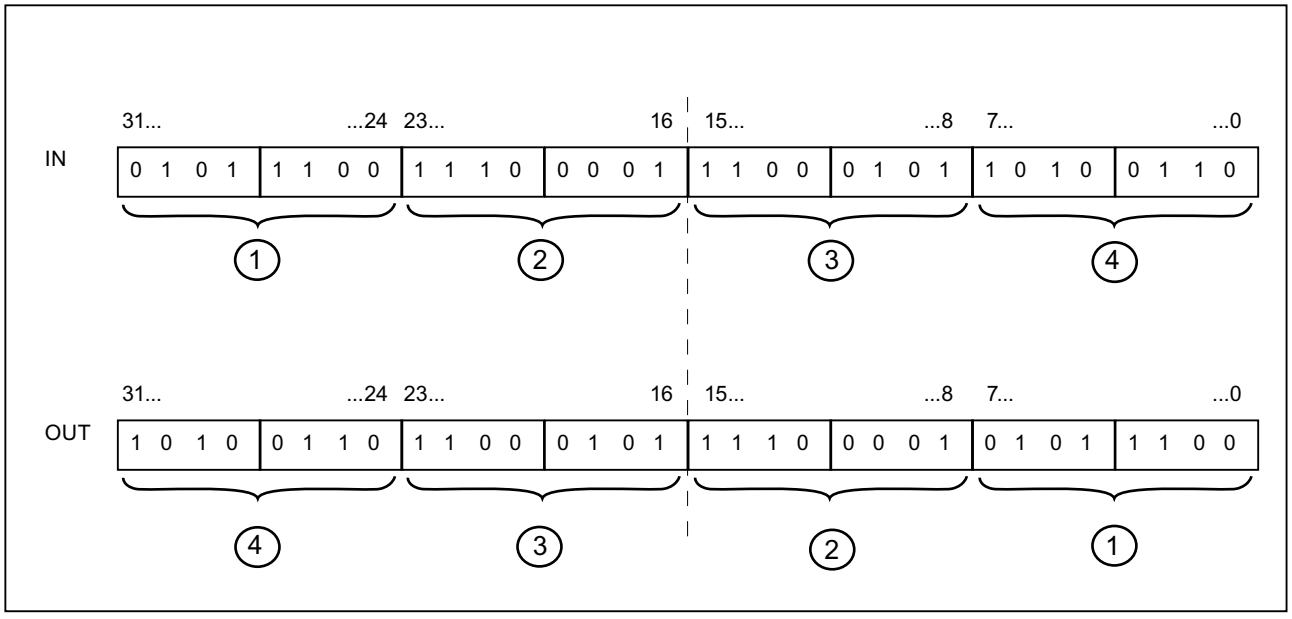
Overview of the valid data types (Page 1908)

SWAP: Swap

Description

You can use the "Swap" instruction to change the order of the bytes at input IN and query the result at output OUT.

The following figure shows how the bytes of an operand of the DWORD data type are swapped using the "Swap" instruction:



Parameter

The following table lists the parameters of the "Swap" instruction:

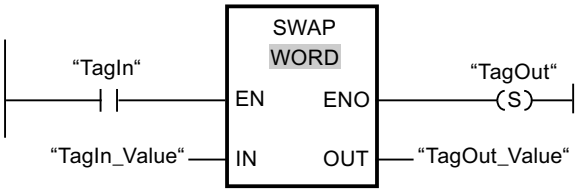
Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
IN	Input	WORD, DWORD	WORD, DWORD, LWORD	I, Q, M, D, L or, P constant	Operand whose bytes are swapped.
OUT	Output	WORD, DWORD	WORD, DWORD, LWORD	I, Q, M, D, L, P	Result

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	TagIn_Value	0000 1111 0101 0101
OUT	TagOut_Value	0101 0101 0000 1111

If operand "TagIn" has the signal state "1", the "Swap" instruction is executed. The order of the bytes is changed and stored in operand "TagOut_Value".

Overview of the valid data types (Page 1908)

ARRAY DB

ReadFromArrayDB: Read from array data block

Description

The "Read from array data block" instruction is used to read data from an ARRAY data block and write it to a destination area.

An ARRAY data block is a data block that consists of exactly one ARRAY of [Data type]. The elements of the ARRAY can be PLC data type or any other elementary data type. The counting at the ARRAY always begins with the low limit "0", regardless of the later declaration of the ARRAY.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- If an error occurs during the execution of the instruction.

Parameters

The following table shows the parameters of the "Read from array data block" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
DB	Input	DB_ANY	I, Q, M, D, L	Data block that is read
INDEX	Input	DINT	I, Q, M, D, L, P, or constant	Element that is read
VALUE	Output [1)]	VARIANT	I, Q, M, L	Value that is read and output

Parameter	Declaration	Data type	Memory area	Description
RET_VAL	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output at the RET_VAL parameter.
1) The VALUE parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

For additional information on valid data types, refer to "See also".

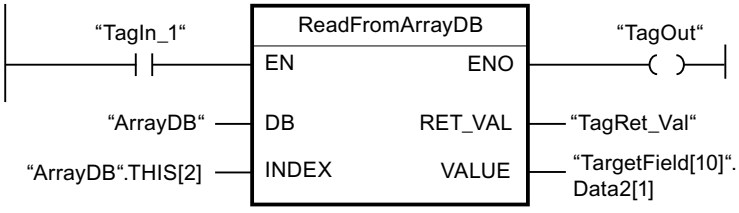
Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
80B5	The copying was interrupted.
8132	The data block does not exist, is too short, write protected, or is located in load memory.
8135	The ARRAY data block contains invalid values.
8154	The data block has the incorrect data type.
8282	The value at parameter INDEX is outside the limits of the ARRAY.
8450	The data type VARIANT at parameter VALUE provides the value "0".
8452	Code generation error
8453	The size of the VALUE parameter does not match the element length in the ARRAY data block.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
DB	ArrayDB	The data type of the "ArrayDB" operand is Array [0 to 10] of INT.
INDEX	ArrayDB.THIS[2]	Third element of the "ArrayDB"
VALUE	TargetField[10].Data2[1]	The data type of the "Target-Field" operand is Array [10 to 20] of "MOVE_UDT".

If the "TagIn1" operand has the signal state "1", the "Read from the array data block" instruction is executed. The third element is read from "ArrayDB" and written to the "TargetField[10].Data2[1]" operand. If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

Overview of the valid data types (Page 1908)

Using ARRAY data blocks (Page 239)

WriteToArrayDB: Write to array data block

Description

The instruction "Write to array data block" is used to write data to an ARRAY data block.

An ARRAY data block is a data block that consists of exactly one ARRAY of [Data type]. The elements of the ARRAY can be PLC data type or any other elementary data type. The counting at the ARRAY always begins with the low limit "0", regardless of the later declaration of the ARRAY.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- If an error occurs during the execution of the instruction.

Parameters

The following table shows the parameters of the "Write to array data block" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
DB	Input	DB_ANY	I, Q, M, D, L	Data block to which data is written
INDEX	Input	DINT	I, Q, M, D, L, P, or constant	Element in the DB to which data is written

Parameter	Declaration	Data type	Memory area	Description
VALUE	Input	VARIANT	I, Q, M, L	Value to be written
RET_VAL	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output at the RET_VAL parameter.

For additional information on valid data types, refer to "See also".

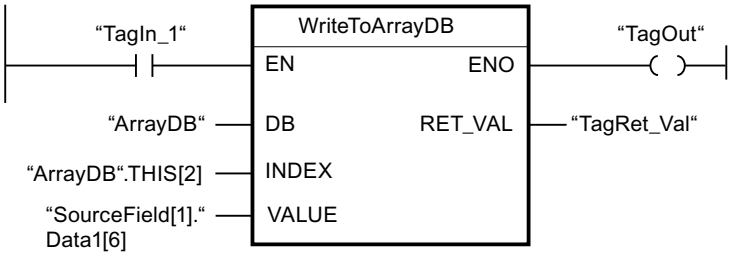
Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
80B5	The copying was interrupted.
8132	The data block does not exist, is too short, or is located in load memory.
8134	The data block is write protected.
8135	The data block is not an ARRAY data block.
8154	The data block has the incorrect data type.
8282	The value at parameter INDEX is outside the limits of the ARRAY.
8350	The data type VARIANT at parameter VALUE provides the value "0".
8352	Code generation error
8353	The size of the VALUE parameter does not match the element length in the ARRAY data block.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
DB	ArrayDB	The data type of the "ArrayDB" operand is Array [0 to 10] of INT.
INDEX	ArrayDB.THIS[2]	Third element of the "ArrayDB"
VALUE	SourceField[1].Data1[6]	The data type of the "Source-Field" operand is Array [0 to 10] of "MOVE_UDT".

If the "TagIn1" operand has the signal state "1", the "Write to ARRAY data block" instruction is executed. From the "SourceField" operand, the "Data1[6]" element from the second element is written to the "ArrayDB". The third element is written to the "ArrayDB". If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

Using ARRAY data blocks (Page 239)

ReadFromArrayDBL: Read from array data block in load memory

Description

The instruction "Read from array data block in load memory" is used to read data from an ARRAY data block in the load memory.

An ARRAY data block is a data block that consists of exactly one ARRAY of [Data type]. The elements of the ARRAY can be PLC data type or any other elementary data type. The counting at the ARRAY always begins with the low limit "0", regardless of the later declaration of the ARRAY.

If the ARRAY data block has been designated with the block attribute "Only store in load memory", it will only be stored in the load memory.

The instruction is executed when a positive signal edge is detected at the REQ parameter. The BUSY parameter then has the signal state "1". The instruction is terminated if a negative signal edge is detected at the BUSY parameter. The DONE parameter has the signal state "1" for one program cycle and the read value is output at the VALUE parameter within this cycle. With all other program cycles, the value at the VALUE parameter is not changed.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, it is saved to the "Program resources" folder in the "Program blocks > System blocks" path of the project tree. For additional information on this topic, refer to "See also".

Note

The ARRAY data block must be created with the "Optimized" block property.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- If an error occurs during the execution of the instruction.

Parameters

The following table lists the parameters of the "Read from array data block in load memory" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = "1": Begin with the reading of the ARRAY DB
DB	Input	DB_ANY	I, Q, M, D, L	Data block that is read
INDEX	Input	DINT	I, Q, M, D, L, P, or constant	Element that is read
VALUE	InOut	VARIANT	I, Q, M, L	Value that is read and output No local constants or tags from the TEMP section must be used.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = "1": The array DB is still being read
DONE	Output	BOOL	I, Q, M, D, L	DONE = "1": The instruction was executed successfully
ERROR	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during the execution of the instruction, an error code is output at the ERROR parameter.

For additional information on valid data types, refer to "See also".

ERROR parameter

The following table shows the meaning of the values of the ERROR parameter:

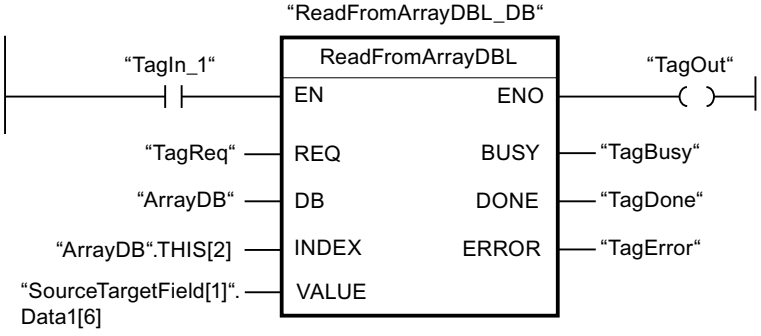
Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
8230	The data block number is incorrect.
8231	The data block does not exist.
8232	The data block is too short, or is not located in load memory.
8235	The data block is not an ARRAY DB.
8254	The data block has the incorrect data type.

Error code* (W#16#...)	Explanation
8382	The value at parameter INDEX is outside the limits of the ARRAY.
8750	The data type VARIANT at parameter VALUE provides the value "0".
8751	Code generation error
8752	Code generation error
8753	The size of the VALUE parameter does not match the element length in the ARRAY data block.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

You can find descriptions of the error codes triggered by the instructions "READ_DBL: Read from data block in the load memory" and "WRIT_DBL: Write to data block in the load memory" under "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
REQ	TagReq	BOOL
DB	ArrayDB	The data type of the "ArrayDB" operand is Array [0 to 10] of INT.
INDEX	ArrayDB.THIS[2]	Third element of the "ArrayDB"
VALUE	SourceTargetField[1].Data1[6]	The data type of the "SourceTargetField" operand is Array [0 to 10] of "MOVE_UDT".
BUSY	TagBusy	BOOL
DONE	TagDone	BOOL

If the "TagIn1" operand has the signal state "1" and a positive edge is detected at the "TagReq"operand, the "Read from ARRAY data block in load memory" instruction is executed. The third element is read from "ArrayDB" and written to the "SourceTargetField[1].Data1[6]" operand. As soon as a negative signal edge is detected at the "TagBusy" operand, the instruction is terminated and the value at the VALUE parameter is no longer changed. If the instruction is executed without errors, the ENO enable output has the signal state "1" and the

"TagOut" output is set. After the instruction has been processed, the "TagDone" operand the signal state "1".

WRIT_DBL: Write to data block in the load memory (Page 3353)

Using ARRAY data blocks (Page 239)

WriteToArrayDBL: Write to array data block in load memory

Description

The instruction "Write to array data block in load memory" is used to write data to an ARRAY data block in the load memory.

An ARRAY data block is a data block that consists of exactly one ARRAY of [Data type]. The elements of the ARRAY can be PLC data type or any other elementary data type. The counting at the ARRAY always begins with the low limit "0", regardless of the later declaration of the ARRAY.

If the ARRAY data block has been designated with the block attribute "Only store in load memory", it will only be stored in the load memory.

The instruction is executed when a positive signal edge is detected at the REQ parameter. The BUSY parameter then has the signal state "1". If a negative signal edge is detected at the BUSY parameter, the instruction is terminated and the value at the VALUE parameter is written to the data block. The DONE parameter then has the signal state "1" for one program cycle.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, it is saved to the "Program resources" folder in the "Program blocks > System blocks" path of the project tree. For additional information on this topic, refer to "See also".

Note

The ARRAY data block must be created with the "Optimized" block property.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- If an error occurs during the execution of the instruction.

Parameters

The following table lists the parameters of the "Write to array data block in load memory" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = "1": Start writing to the array DB
DB	Input	DB_ANY	I, Q, M, D, L	Data block to which data is written
INDEX	Input	DINT	I, Q, M, D, L, P, or constant	Element in the DB to which data is written
VALUE	Input	VARIANT	I, Q, M, L	Value to be written No local constants or tags from the TEMP section must be used.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = "1": The array DB is still being written
DONE	Output	BOOL	I, Q, M, D, L	DONE = "1": The instruction was executed successfully
ERROR	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during the execution of the instruction, an error code is output at the ERROR parameter.

For additional information on valid data types, refer to "See also".

ERROR parameter

The following table shows the meaning of the values of the ERROR parameter:

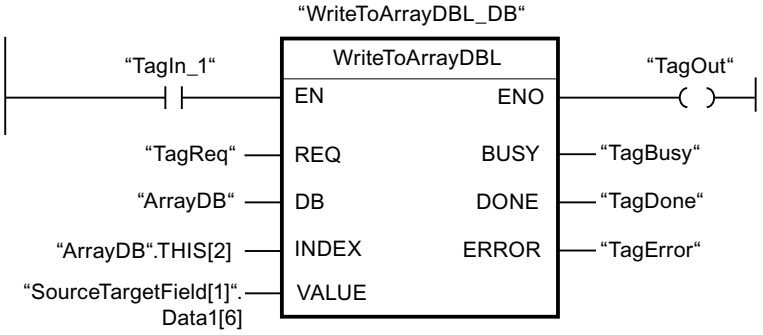
Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
8230	The data block number is incorrect.
8231	The data block does not exist.
8232	The data block is too short, or is not located in load memory.
8234	The data block is write protected.
8235	The data block is not an ARRAY DB.
8254	The data block has the incorrect data type.
8382	The value at parameter INDEX is outside the limits of the ARRAY.
8750	The data type VARIANT at parameter VALUE provides the value "0".
8751	Code generation error
8752	Code generation error

Error code* (W#16#...)	Explanation
8753	The size of the VALUE parameter does not match the element length in the ARRAY data block.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

You can find descriptions of the error codes triggered by the instructions "READ_DBL: Read from data block in the load memory" and "WRIT_DBL: Write to data block in the load memory" under "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
REQ	TagReq	BOOL
DB	ArrayDB	The data type of the "ArrayDB" operand is Array [0 to 10] of INT.
INDEX	ArrayDB.THIS[2]	Third element of the "ArrayDB"
VALUE	SourceTargetField[1].Data1[6]	The data type of the "SourceTargetField" operand is Array [0 to 10] of "MOVE_UDT".
BUSY	TagBusy	BOOL
DONE	TagDone	BOOL

If the "TagIn1" operand has the signal state "1" and a positive edge is detected at the "TagReq"operand, the "Write to ARRAY data block in load memory" instruction is executed. As soon as a negative signal edge is detected at the "TagBusy" operand, the instruction is terminated and the value at the VALUE parameter is written in the third element in the "ArrayDB". If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set. After the instruction has been processed, the "TagDone" operand the signal state "1".

VARIANT

VariantGet: Read out VARIANT tag value

Description

You can use the "Read out VARIANT tag value" instruction to read the value of the tag to which the VARIANT at the SRC parameter points and write it in the tag at the DST parameter.

The SRC parameter has the VARIANT data type. Any data type except for VARIANT can be specified at the DST parameter.

The data type of the tag at the DST parameter must match the data type to which the VARIANT points.

Note

To copy structures and ARRAYs, you can use the "MOVE_BLK_VARIANT: Move block" instruction. For additional information, refer to "See also".

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The data types do not correspond. (No value is transferred.)

Parameter

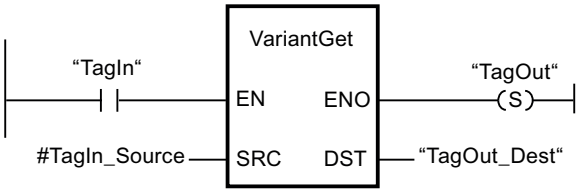
The following table lists the parameters of the instruction "Read out VARIANT tag value":

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
SRC	Input	VARIANT	I, Q, M, L	Tag to be read
DST	Output	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY elements, PLC data types	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If the "TagIn" operand has signal state "1", the instruction is executed. The value of the tag to which the VARIANT at the "#TagIn_Source" operand points, is read and written to the "TagOut_Dest" operand.

See also

Overview of the valid data types (Page 1908)

VARIANT (Page 1951)

MOVE_BLK_VARIANT: Move block (Page 2346)

VariantPut: Write VARIANT tag value

Description

You can use the "Write VARIANT tag value" instruction to write the value of the tag at the SRC parameter to the tag at the DST parameter to which the VARIANT points.

The DST parameter has the VARIANT data type. Any data type except for VARIANT can be specified at the SRC parameter.

The data type of the tag at the SRC parameter must match the data type to which the VARIANT points.

Note

To copy structures and ARRAYs, you can use the "MOVE_BLK_VARIANT: Move block" instruction. For additional information, refer to "See also".

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The data types do not correspond. (No value is transferred.)

Parameters

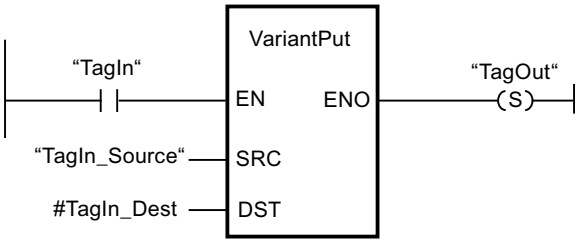
The following table lists the parameters of the instruction "Write VARIANT tag value":

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
SRC	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY elements, PLC data types	I, Q, M, D, L	Tag to be read
DST	Input	VARIANT	I, Q, M, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If the "TagIn" operand has signal state "1", the instruction is executed. The value of the "TagIn_Source" operand is written to the tag to which the VARIANT at the #TagIn_Dest operand points.

See also

Overview of the valid data types (Page 1908)

VARIANT (Page 1951)

MOVE_BLK_VARIANT: Move block (Page 2346)

CountOfElements: Get number of ARRAY elements

Description

You can use the "Get number of ARRAY elements" instruction to query how many ARRAY elements a tag pointing to an VARIANT has.

If it is a one-dimensional ARRAY, the difference between the high and low limit +1 is output as a result. If it is a multi-dimensional ARRAY, the product of all dimensions is output as the result.

The IN parameter must have the VARIANT data type.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The VARIANT tag is not an ARRAY. (The result is "0".)

If the VARIANT points to an ARRAY of BOOL, the fill elements are also included in the count. (For example, 8 is returned for an ARRAY[0..1] of BOOL)

Parameters

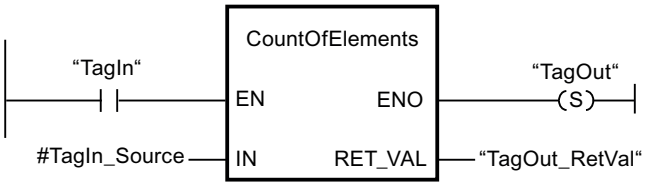
The following table shows the parameters of the "Get number of ARRAY elements" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	VARIANT	I, Q, M, L	Tag to be queried
RET_VAL	Output	UDINT	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If the "TagIn" operand has the signal state "1", the "Get number of ARRAY elements" instruction is executed. The number of ARRAY elements of the tag to which the VARIANT at the "#TagIn_Source" operand points is read and output at the "TagOut_RetVal" operand.

Legacy

FieldRead: Read field

Description

You can use the "Read field" instruction to read out a specific component from the field specified at input MEMBER and transfer its content to the tag at output VALUE. You specify the index of the field component to be read at input INDEX. Specify the first component of the field from which reading is to occur at input MEMBER.

The data types of the field component at parameter MEMBER, the index and the tags at parameter VALUE must correspond to the data type of the instruction "Read field" because implicit conversion is not possible.

Enable output ENO has signal state "0" if one of the following conditions applies:

- Enable input EN has signal state "0".
- The field component specified at input INDEX is not defined in the field specified at output MEMBER.
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the instruction "Read field":

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
INDEX	Input	DINT	DINT	I, Q, M, D, L, P, or constant	Index of field component whose content is read out

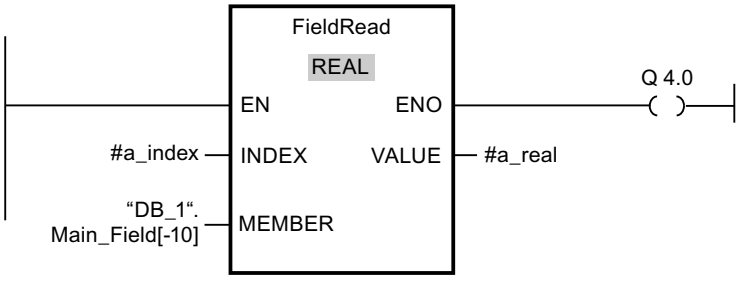
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
MEMBER	Input	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR and WCHAR as components of an ARRAY tag	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, LTOD, CHAR and WCHAR as components of an ARRAY tag	D, L	First component of the field from which reading occurs.
VALUE	Output	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, LTOD CHAR, WCHAR	I, Q, M, D, L, P	Operand to which the content of the field component is transferred

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Tag	Value
INDEX	a_index	4
MEMBER	"DB_1".Main_Field[-10]	First component of the "Main_Field[-10..10] of REAL" field in the data block "DB_1"
VALUE	a_real	Component with index 4 of the "Main_Field[-10..10] of REAL" field

The field component with index 4 is read from the "Main_Field[-10...10] of REAL" field and written to the "a_real" tag. The field component to be read is specified by the value at input INDEX.

See also

Overview of the valid data types (Page 1908)

FieldWrite: Write field

Description

The "Write field" instruction is used to transfer the content of the tag at the VALUE input to a specific component of the field at the MEMBER output. You can use the value at the INDEX input to specify the index of the field component that is described. At the MEMBER output, enter the first component of the field which is to be written to.

The data types of the field component at parameter MEMBER, the index and the tags at parameter VALUE must correspond to the data type of the instruction "Read field" because implicit conversion is not possible.

Enable output ENO has signal state "0" if one of the following conditions applies:

- Enable input EN has signal state "0".
- The field component specified at the input INDEX is not defined in the field specified at the output MEMBER.
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the instruction "Write field":

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
INDEX	Input	DINT	DINT	I, Q, M, D, L, P, or constant	Index of the field component that is being written with the content of VALUE.

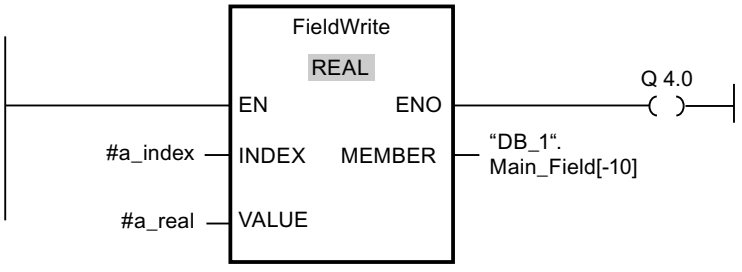
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
VALUE	Input	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, LTOD, CHAR, WCHAR	I, Q, M, D, L, P, or constant	Operand whose content is copied.
MEMBER	Output	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR and WCHAR as components of an ARRAY tag	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, LTOD, CHAR and WCHAR as components of an ARRAY tag	D, L	First component of the field to which the content of VALUE is written.

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
INDEX	a_index	4
VALUE	a_real	10.54
MEMBER	"DB_1".Main_Field[-10]	First component of the "Main_Field[-10..10] of REAL" field in the data block "DB_1"

The value "10.54" of the "a_real" tag is written to the field component with index 4 of the "Main_Field[-10..10] of REAL" field. The index of the field component to which the content of the tag "a_real" is transferred is specified by the value at the input INDEX.

Overview of the valid data types (Page 1908)

BLKMOV: Move block

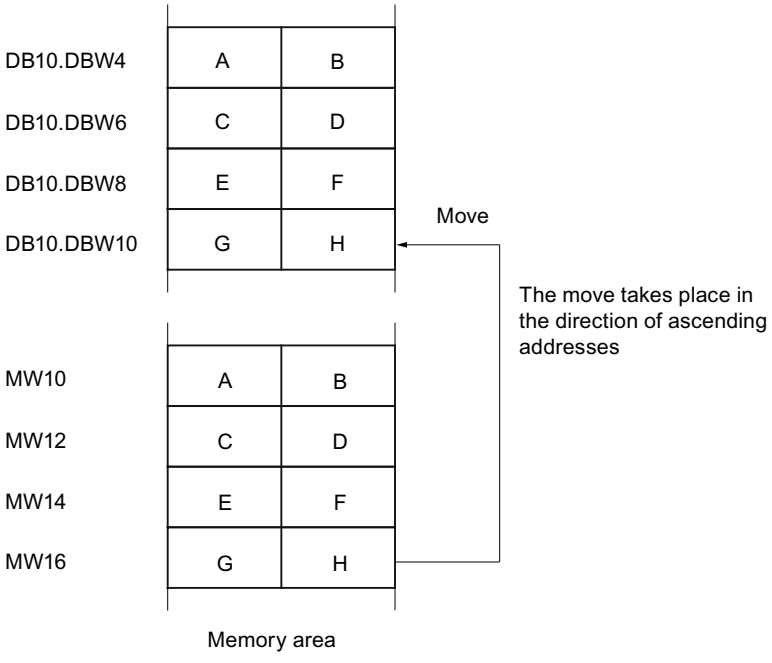
Description

You can use the "Move block" instruction to move the content of a memory area (source area) to another memory area (destination area). The move operation takes place in the direction of ascending addresses. You use VARIANT to define the source and destination areas.

Note

The tags of the instruction can only be used in data blocks in which the "Optimized block access" attribute is not set. If the tag with the retentivity setting "Set in IDB" has been declared, you can also use the tags "with optimized access".

The following figure shows the principle of the move operation:



Consistency of source and destination data

Make sure that the source data remain unchanged during the execution of the "Move block" instruction. Otherwise, consistency of the destination data cannot be guaranteed.

Interruptibility

There is no limit to the nesting depth.

Memory areas

You can use the "Move block" instruction to move the following memory areas:

- Areas of a data block
- Bit memory
- Process image input
- Process image output

General rules for moving

The source and destination areas must not overlap. If the source and destination areas have different lengths, only the length of the smaller area will be moved.

If the source area is smaller than the destination area, the entire source area will be written to the destination area. The remaining bytes of the destination area remain unchanged.

If the destination area is smaller than the source area, the entire destination area will be written. The remaining bytes of the source area are ignored.

If a block of data type BOOL is moved, the tag must be addressed absolutely and the specified length of the area must be divisible by 8, otherwise the instruction cannot be executed.

Rules for moving character strings

You can use the "Move block" instruction to also move source and destination areas of the STRING data type. If only the source area is STRING data type, the characters will be moved that are actually contained in the character string. Information on the actual and maximum length is also written to the destination area. If the source and destination area are both STRING data type, the current length of the character string in the destination area is set to the number of characters actually moved.

If you want to move the information on the maximum and actual length of a character string, specify the areas in bytes in the SRCBLK and DSTBLK parameters.

Parameters

The following table shows the parameters of the "Move block" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
SRCBLK	Input	VARIANT	I, Q, M, L, P	Specifies the memory area to be moved (source area).
RET_VAL	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during the execution of the instruction, an error code is output at the RET_VAL parameter.

Parameter	Declaration	Data type	Memory area	Description
DSTBLK	Output 1)	VARIANT	I, Q, M, L, P	Specifies the memory area to which the block is to be moved (destination area).
1) The DSTBLK parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

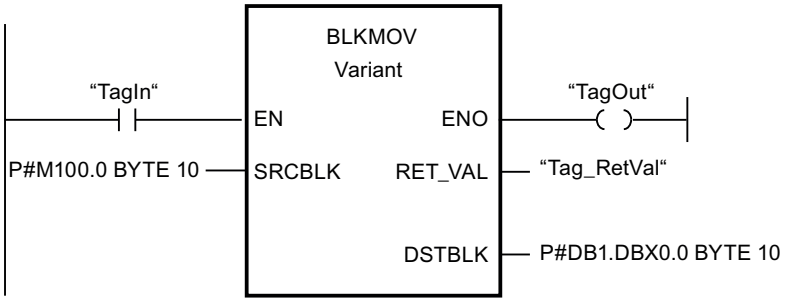
Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
8092	The source or target area is only available in the load memory.
8152	The WSTRING, WCHAR and BOOL data types are not supported at the SRCBLK parameter.
8352	The WSTRING, WCHAR and BOOL data types are not supported at the DSTBLK parameter.
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:



If the "TagIn" operand has signal state "1", the instruction is executed. The instruction copies 10 bytes starting from MB100 and writes them to DB1. If an error occurs during the move operation, its error code is output in the "Tag_RetVal" tag.

Overview of the valid data types (Page 1908)

GET_ERR_ID: Get error ID locally (Page 2417)

UBLKMOV: Move block uninterruptible

Description

You can use the "Move block uninterruptible" instruction to move the content of a memory area (source area) to another memory area (destination area). The move operation takes place in the direction of ascending addresses. You use VARIANT to define the source and destination areas.

The move operation cannot be interrupted by other operating system activities. As a result, the interrupt reaction time of the CPU can increase during the execution of the "Move block uninterruptible" instruction.

Note

The tags of the instruction can only be used in data blocks in which the "Optimized block access" attribute is not set. If the tag with the retentivity setting "Set in IDB" has been declared, you can also use the tags "with optimized access".

Memory areas

You can use the "Move block uninterruptible" instruction to move the following memory areas:

- Areas of a data block
- Bit memory
- Process image input
- Process image output

General rules for moving

The source and destination areas must not overlap during the execution of the "Move block uninterruptible" instruction. If the source area is smaller than the destination area, the entire source area will be written to the destination area. The remaining bytes of the destination area remain unchanged.

If the destination area is smaller than the source area, the entire destination area will be written. The remaining bytes of the source area are ignored.

If a source or destination area defined as a formal parameter is smaller than a destination or source area specified in the SRCBLK or DSTBLK parameter, no data is transferred.

If a block of data type BOOL is moved, the tag must be addressed absolutely and the specified length of the area must be divisible by 8, otherwise the instruction cannot be executed.

You can use the "Move block uninterruptible" instruction to move a maximum of 16 KB. Note the CPU-specific restrictions for this.

Rules for moving character strings

You can use the "Move block uninterruptible" instruction to also move source and destination areas of the STRING data type. If only the source area is STRING data type, the characters will be moved that are actually contained in the character string. Information on the actual and maximum length are not written in the destination area. If the source and destination area are both STRING data type, the current length of the character string in the destination area is set to the number of characters actually moved. If areas of the STRING data type are moved, specify "1" as area length.

Parameters

The following table shows the parameters of the "Move block uninterruptible" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
SRCBLK	Input	VARIANT	I, Q, M, L, P	Specifies the memory area to be moved (source area).
RET_VAL	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output at the RET_VAL parameter.
DSTBLK	Output [1)]	VARIANT	I, Q, M, L, P	Specifies the memory area to which the block is to be moved (destination area).
1) The DSTBLK parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

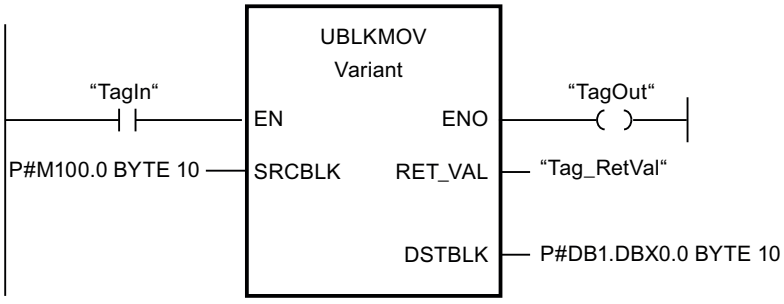
Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
8091	The source or destination area is located in the load memory only.
8152	The WSTRING, WCHAR and BOOL data types are not supported at the SRCBLK parameter.
8352	The WSTRING, WCHAR and BOOL data types are not supported at the DSTBLK parameter.
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:



If the "TagIn" operand has signal state "1", the instruction is executed. The instruction copies 10 bytes starting from MB100 and writes them to DB1. If an error occurs during the move operation, its error code is output in the "Tag_RetVal" tag.

GET_ERR_ID: Get error ID locally (Page 2417)

FILL: Fill block

Description

You can use the "Fill block" instruction to fill a memory area (destination area) with the content of another memory area (source area). The "Fill block" instruction moves the content of the source area to the destination area until the destination area is completely written. The move operation takes place in the direction of ascending addresses.

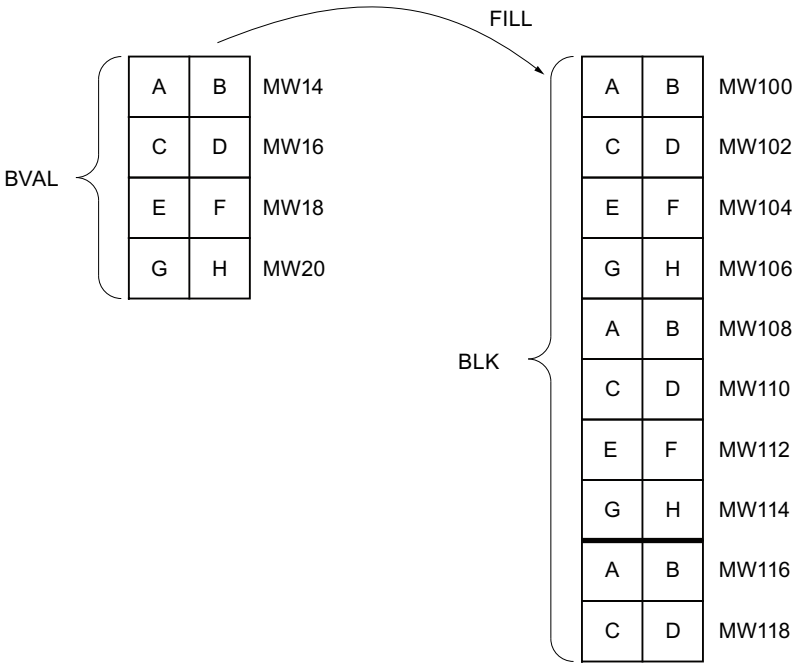
You use VARIANT to define the source and destination areas.

Note

The tags of the instruction can only be used in data blocks in which the "Optimized block access" attribute is not set. If the tag with the retentivity setting "Set in IDB" has been declared, you can also use the tags "with optimized access".

For blocks with the "Optimized block access" attribute, you can use the "FILL_BLK instruction. Fill block" instruction.

The following figure shows the principle of the move operation:



Example: The contents of the range MW100 to MW118 are to be preassigned with the contents of the memory words MW14 to MW20.

Consistency of source and destination data

Note that while the instruction "Fill block" is being executed, the source data remains unchanged; otherwise the consistency of the destination data cannot be guaranteed.

Memory areas

You can use the "Fill block" instruction to move the following memory areas:

- Areas of a data block
- Bit memory
- Process image input
- Process image output

General rules for moving

The source and destination areas must not overlap. If the destination area to be preset is not an integer multiple of the length of the input parameter BVAL, the destination area is nevertheless written up to the last byte.

If the destination area to be preset is smaller than the source area, the function only copies as much data as can be written to the destination area.

If the destination or source area actually present is smaller than the assigned memory area for the source or destination area (BVAL, BLK parameters), no data is transferred.

If the ANY pointer (source or destination) is of the data type BOOL, it must be addressed absolutely and the length specified must be divisible by 8; otherwise the instruction is not executed.

If the destination area is STRING data type, the instruction writes the entire string including the administration information.

Parameters

The following table shows the parameters of the "Fill block" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
BVAL	Input	VARIANT	I, Q, M, L, P	Specification of the memory area (source area), the content of which is used to fill the destination area at the BLK parameter.
RET_VAL	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output at the RET_VAL parameter.
BLK	Output 1)	VARIANT	I, Q, M, L, P	Specification of the memory area that will be filled with the content of the source area.
1) The BLK parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

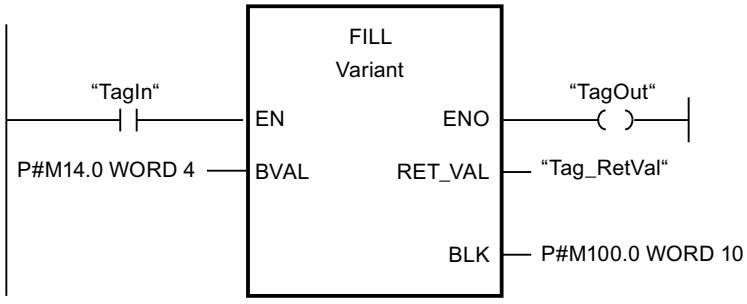
Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
8092	The source or destination area is located in the load memory only.
8152	The WSTRING, WCHAR and BOOL data types are not supported at the BVAL parameter.
8352	The WSTRING, WCHAR and BOOL data types are not supported at the BLK parameter.
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:



If the "TagIn" operand has signal state "1", the instruction is executed. The instruction copies the source area from MW14 to MW20 and fills the destination area from MW100 to MW118 with the content of the 4 words contained in the memory area in the BVAL parameter.

Conversion operations

CONVERT: Convert value

Description

The "Convert value" instruction reads the content of the IN parameter and converts it according to the data types selected in the instruction box. The converted value is provided at output OUT.

For information on possible conversions, refer to the "Explicit conversion" section at "See also".

Enable output ENO has signal state "0" if one of the following conditions applies:

- Enable input EN has signal state "0".
- Errors, such as an overflow, occur during execution.

Conversion options for bit strings

BYTE and WORD bit strings cannot be selected in the instruction box. However, it is possible to specify an operand of data type DWORD or LWORD at a parameter of the instruction if the lengths of the input and output operands match. The operand is then interpreted by the data type of a bit string according to the data type of the input or output parameter and is implicitly converted. For example, the data type DWORD is interpreted as DINT/UDINT and LWORD is interpreted as LINT/ULINT. These conversion options are also available to you when "IEC check" is activated.

Note

For CPUs of the S7-1500 series: The data types DWORD and LWORD can only be converted to or from data type REAL or LREAL.

Parameters

The following table shows the parameters of the "Convert value" instruction:

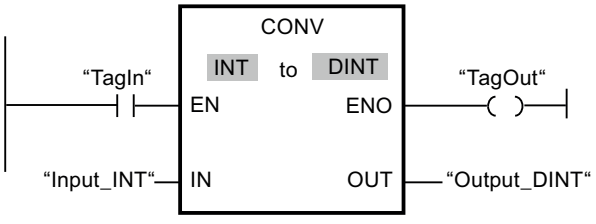
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers, floating-point numbers, CHAR, WCHAR, BCD16, BCD32	I, Q, M, D, L, P, or constant	Value to be converted.
OUT	Output	Bit strings, integers, floating-point numbers, CHAR, WCHAR, BCD16, BCD32	I, Q, M, D, L, P	Result of the conversion

You can select the data types of the instruction from the "???" drop-down lists of the instruction box.

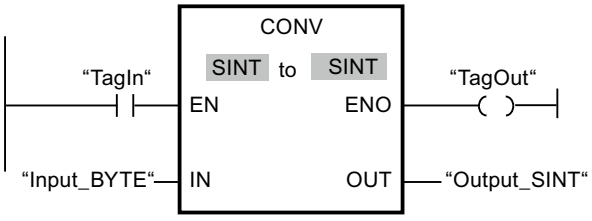
You can find additional information on valid data types under "See also".

Examples

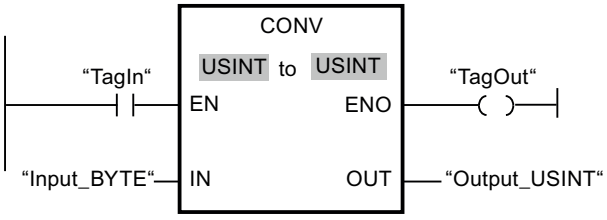
The following example shows the conversion of an integer (16 bit) to another integer (32 bit):



The following example shows the conversion of a byte (8 bit) to the integer SINT (8 bit):



The following example shows the conversion of a byte (8 bit) to the unsigned integer USINT (8 bit):



The conversions are possible because the two operands have the same length.

Data type conversion for S7-1200: (Page 2091)

ROUND: Round numerical value

Description

You can use the "Round numerical value" instruction to round the value at input IN to the nearest integer. The instruction interprets the value at input IN as a floating-point number and converts this to an integer of data type DINT. If the input value is exactly between an even and odd number, the even number is selected. The result of the instruction is sent to the OUT output and can be queried there.

Enable output ENO has signal state "0" if one of the following conditions applies:

- Enable input EN has signal state "0".
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the "Round numerical value" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output

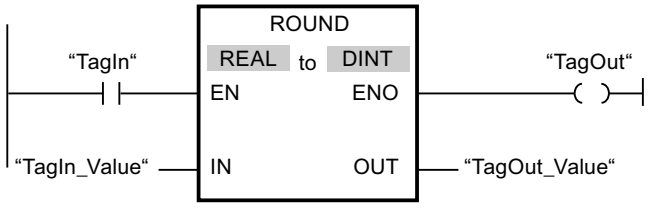
Parameter	Declaration	Data type	Memory area	Description
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Input value to be rounded.
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	Result of rounding

You can select the data type for the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value	
IN	TagIn_Value	1.50000000	-1.50000000
OUT	TagOut_Value	2	-2

If the "TagIn" operand has signal state "1", the instruction is executed. The floating-point number at input "TagIn_Value" is rounded to the nearest even integer and sent to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

Overview of the valid data types (Page 1908)

CEIL: Generate next higher integer from floating-point number

Description

You can use the "Generate next higher integer from floating-point number" instruction to round the value at input IN to the next higher integer. The instruction interprets the value at the IN input as a floating-point number and converts this number to the next higher integer. The result of the instruction is sent to the OUT output and can be queried there. The output value can be greater than or equal to the input value.

Enable output ENO has signal state "0" if one of the following conditions applies:

- Enable input EN has signal state "0".
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the "Generate next higher integer from floating-point number" instruction:

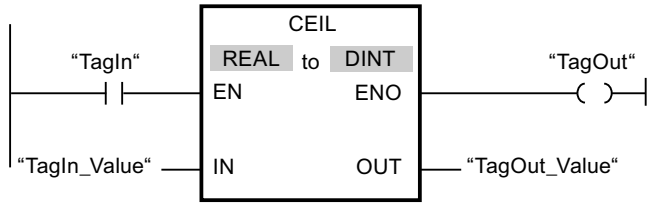
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Input value
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	Result with next higher integer

You can select the data type for the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value	
IN	TagIn_Value	0.50000000	-0.50000000
OUT	TagOut_Value	1	0

If the "TagIn" operand has signal state "1", the instruction is executed. The floating-point number at the "TagIn_Value" input is rounded to the next higher integer and sent to the "TagOut_Value" output. If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

FLOOR: Generate next lower integer from floating-point number

Description

You can use the "Generate next lower integer from floating-point number" instruction to round the value at input IN to the next lower integer. The instruction interprets the value at input IN as a floating-point number and converts this to the next lower integer. The result of the instruction is sent to the OUT output and can be queried there. The output value can be less than or equal to the input value.

Enable output ENO has signal state "0" if one of the following conditions applies:

- Enable input EN has signal state "0".
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the "Generate next lower integer from floating-point number" instruction:

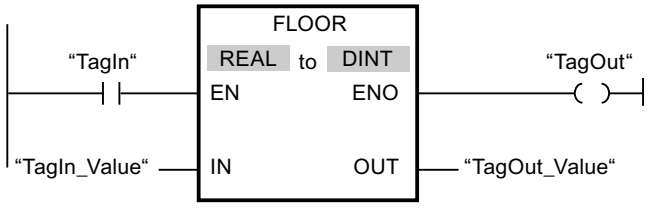
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Input value
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	Result with next lower integer

You can select the data type for the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value	
IN	TagIn_Value	0.50000000	-0.50000000
OUT	TagOut_Value	0	-1

If the "TagIn" operand has signal state "1", the instruction is executed. The floating-point number at input "TagIn_Value" is rounded to the next lower integer and sent to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

TRUNC: Truncate numerical value

Description

You can use the "Truncate numerical value" instruction to form an integer from the value at the IN input. The value at the IN input is interpreted as a floating-point number. The instruction selects only the integer part of the floating-point number and sends this to the OUT output without decimal places.

Enable output ENO has signal state "0" if one of the following conditions applies:

- Enable input EN has signal state "0".
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the "Truncate numerical value" instruction:

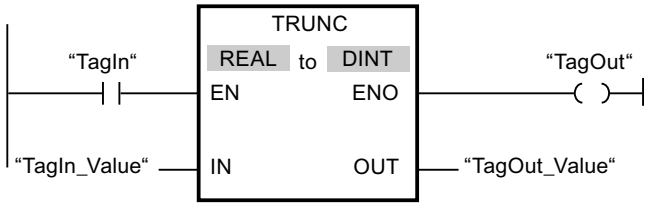
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L or constant	Input value
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L	Integer part of the input value

You can select the data type for the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value	
IN	TagIn_Value	1.50000000	-1.50000000
OUT	TagOut_Value	1	-1

If the "TagIn" operand has signal state "1", the instruction is executed. The integer part of the floating-point number at the "TagIn_Value" input is converted to an integer and sent to the "TagOut_Value" output. If the instruction is executed without errors, the "TagOut" output is set.

See also

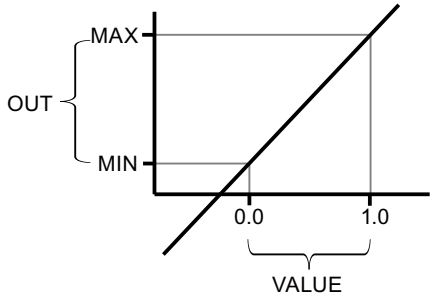
Overview of the valid data types (Page 1908)

SCALE_X: Scale

Description

You can use the "Scale" instruction to scale the value at the VALUE input by mapping it to a specified value range. When the "Scale" instruction is executed, the floating-point value at the VALUE input is scaled to the value range that was defined by the MIN and MAX parameters. The result of the scaling is an integer, which is stored in the OUT output.

The following figure shows an example of how values can be scaled:



The "Scale" instruction works with the following equation:

OUT = [VALUE * (MAX – MIN)] + MIN

Enable output ENO has signal state "0" if one of the following conditions applies:

- Enable input EN has signal state "0".
- The value at the MIN input is greater than or equal to the value at the MAX input.
- The value of a specified floating-point number is outside the range of the normalized numbers according to IEEE-754.
- An overflow occurs.
- The value at the VALUE input is NaN (Not a Number = result of an invalid arithmetic operation).

Note

For more information on the converting of analog values, refer to the respective manual.

Parameters

The following table shows the parameters of the "Scale" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
MIN	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Low limit of the value range

Parameter	Declaration	Data type	Memory area	Description
VALUE	Input	Floating-point numbers	I, Q, M, D, L or constant	Value to be scaled. If you enter a constant, you must declare it.
MAX	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	High limit of the value range
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L	Result of scaling

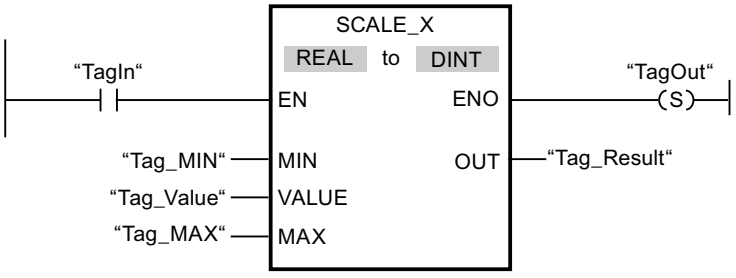
You can select the data types of the instruction from the "???" drop-down lists of the instruction box.

You can find additional information on valid data types under "See also".

For additional information on declaring constants, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
MIN	Tag_MIN	10
VALUE	Tag_Value	0.5
MAX	Tag_MAX	30
OUT	Tag_Result	20

If the "TagIn" operand has signal state "1", the instruction is executed. The value at the "Tag_Value" input is scaled to the range of values defined by the values at the "Tag_MIN" and "Tag_MAX" inputs. The result is stored in the "Tag_Result" output. If the instruction is executed without errors, the ENO enable output has signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

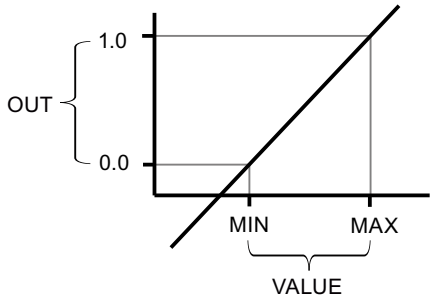
NORM_X: Normalize (Page 2393)

NORM_X: Normalize

Description

You can use the instruction "Normalize" to normalize the value of the tag at the VALUE input by mapping it to a linear scale. You can use the MIN and MAX parameters to define the limits of a value range that is applied to the scale. The result at the OUT output is calculated and stored as a floating-point number depending on the location of the value to be normalized within this value range. If the value to be normalized is equal to the value at the MIN input, the OUT output has the value "0.0". If the value to be normalized is equal to the value at input MAX, output OUT returns the value "1.0".

The following figure shows an example of how values can be normalized:



The "Normalize" instruction works with the following equation:

OUT = (VALUE – MIN) / (MAX – MIN)

Enable output ENO has signal state "0" if one of the following conditions applies:

- Enable input EN has signal state "0".
- The value at the MIN input is greater than or equal to the value at the MAX input.
- The value of a specified floating-point number is outside the range of the normalized numbers according to IEEE-754.
- The value at the VALUE input is NaN (result of an invalid arithmetic operation).

Note

For more information on the converting of analog values, refer to the respective manual.

Parameters

The following table shows the parameters of the "Normalize" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
MIN [1)]	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Low limit of the value range
VALUE [1)]	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Value to be normalized.
MAX [1)]	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	High limit of the value range
OUT	Output	Floating-point numbers	I, Q, M, D, L	Result of the normalization
[1)] If you use constants in these three parameters, you only need to declare one of them.				

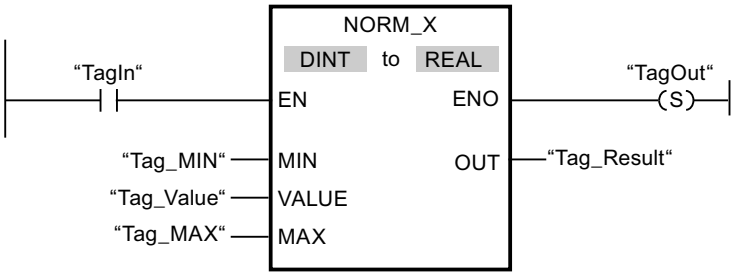
You can select the data types of the instruction from the "???" drop-down lists of the instruction box.

You can find additional information on valid data types under "See also".

For additional information on declaring constants, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
MIN	Tag_MIN	10
VALUE	Tag_Value	20
MAX	Tag_MAX	30
OUT	Tag_Result	0.5

If the "TagIn" operand has signal state "1", the instruction is executed. The value at the "Tag_Value" input is mapped to the range of values that were defined by the values at the "Tag_MIN" and "Tag_MAX" inputs. The tag value at the "Tag_Value" input is normalized to the defined value range. The result is stored as a floating-point number in the "Tag_Result" output. If the instruction is executed without errors, the ENO enable output has signal state "1" and the "TagOut" output is set.

Overview of the valid data types (Page 1908)

SCALE_X: Scale (Page 2390)

Legacy

SCALE: Scale

Description

Use the "Scale" instruction to convert the integer at the IN parameter into a floating-point number, which can be scaled in physical units between a low limit value and a high limit value. You can use the LO_LIM and HI_LIM parameters to specify the low limit and high limit of the value range to which the input value is scaled. The result of the instruction is output on the OUT parameter.

The "Scale" instruction works with the following equation:

OUT = [((FLOAT (IN) – K1)/(K2–K1)) * (HI_LIM–LO_LIM)] + LO_LIM

The values of the constants "K1" and "K2" are determined by the signal state on the BIPOLAR parameter. The following signal states are possible on the BIPOLAR parameter:

- Signal state "1": It is assumed that the value at the IN parameter is bipolar and in a value range between -27648 and 27648. In this case the "K1" constant has the value "-27648.0" and the "K2" constant the value "+27648.0".
- Signal state "0": It is assumed that the value at the IN parameter is unipolar and in a value range between 0 and 27648. In this case the "K1" constant has the value "0,0" and the "K2" constant the value "+27648.0".

When the value at the IN parameter is greater than the value of the constant "K2", the result of the instruction is set to the value of the high limit (HI_LIM) and an error is output.

When the value at the IN parameter is less than the value of the constant "K1", the result of the instruction is set to the value of the low limit value (LO_LIM) and an error is output.

When the indicated low limit value is greater than the high limit value (LO_LIM > HI_LIM), the result is scaled in reverse proportion to the input value.

Parameter

The following table shows the parameters of the "Scale" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	INT	I, Q, M, D, L, P or constant	Input value to be scaled.
HI_LIM	Input	REAL	I, Q, M, D, L, P or constant	High limit

Parameter	Declaration	Data type	Memory area	Description
LO_LIM	Input	REAL	I, Q, M, D, L, P or constant	Low limit
BIPOLAR	Input	BOOL	I, Q, M, D, L or constant	Indicates if the value at IN parameter is to be interpreted as bipolar or unipolar. The parameter can assume the following values: 1: Bipolar 0: Unipolar
OUT	Output	REAL	I, Q, M, D, L, P	Result of the instruction
RET_VAL	Output	WORD	I, Q, M, D, L, P	Error information

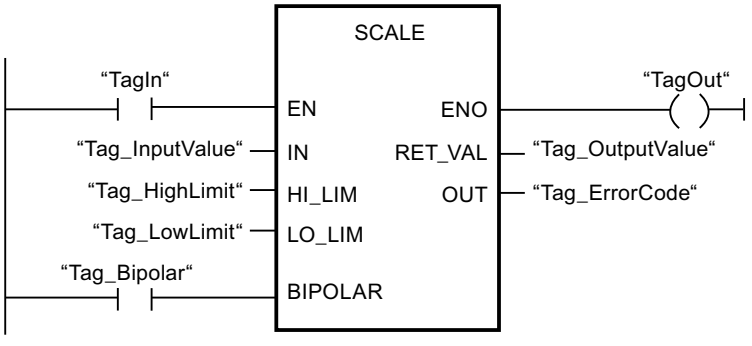
Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
0008	The value of the IN parameter is greater than the value of the constant "K2" or less than the value of the constant "K1"
General error information	See also: "GET_ERR_ID: Get error ID locally
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	Tag_InputValue	22
HI_LIM	Tag_HighLimit	100.0
LO_LIM	Tag_LowLimit	0.0
BIPOLAR	Tag_Bipolar	1
OUT	Tag_OutputValue	50.03978588
RET_VAL	Tag_ErrorCode	W#16#0000

Overview of the valid data types (Page 1908)

GET_ERR_ID: Get error ID locally (Page 2417)

UNSCALE: Unscale

Description

The "Unscale" instruction is used to unscale the floating-point number on the IN parameter into physical units between a low limit and a high limit and convert it into an integer. You can use the LO_LIM and HI_LIM parameters to specify the low limit and high limit of the value range to which the input value is unscaled. The result of the instruction is output on the OUT parameter.

The "Unscale" instruction works with the following equation:

OUT = [((IN–LO_LIM)/(HI_LIM–LO_LIM)) * (K2–K1)] + K1

The values of the constants "K1" and "K2" are determined by the signal state on the BIPOLAR parameter. The following signal states are possible on the BIPOLAR parameter:

- Signal state "1": It is assumed that the value at the IN parameter is bipolar and in a value range between -27648 and 27648. In this case the "K1" constant has the value "-27648.0" and the "K2" constant the value "+27648.0".
- Signal state "0": It is assumed that the value at the IN parameter is unipolar and in a value range between 0 and 27648. In this case the "K1" constant has the value "0.0" and the "K2" constant the value "+27648.0".

When the value at the IN parameter is greater than the value of the constant "HI_LIM", the result of the instruction is set to the value of the constant (K2) and an error is output.

When the value at the IN parameter is less than the value of the constant of the low limit (LO_LIM), the result of the instruction is set to the value of the constant (K1) and an error is output.

Parameters

The following table shows the parameters of the "Unscale" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Input	BOOL	I, Q, M, D, L	Enable output
IN	Input	REAL	I, Q, M, D, L, P or constant	Input value to be unscaled to an integer value.
HI_LIM	Input	REAL	I, Q, M, D, L, P or constant	High limit
LO_LIM	Input	REAL	I, Q, M, D, L, P or constant	Low limit
BIPOLAR	Input	BOOL	I, Q, M, D, L or constant	Indicates if the value at IN parameter is to be interpreted as bipolar or unipolar. The parameter can assume the following values: 1: Bipolar 0: Unipolar
OUT	Output	INT	I, Q, M, D, L, P	Result of the instruction
RET_VAL	Output	WORD	I, Q, M, D, L, P	Error information

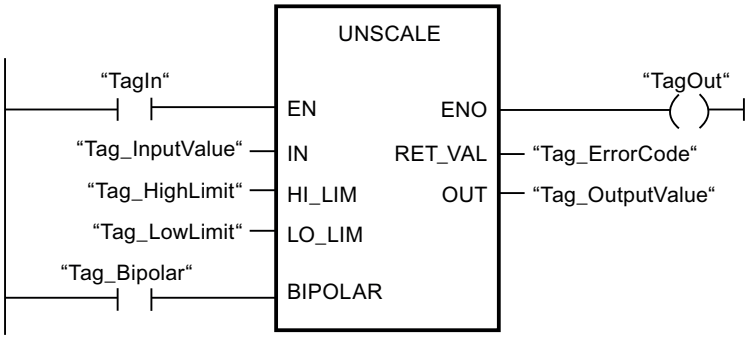
Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
0008	The value of the IN parameter is greater than the value of the high limit (HI_LIM) or less than the value of the low limit (LO_LIM).
General error information	See also: "GET_ERR_ID: Get error ID locally
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	Tag_InputValue	50.03978588
HI_LIM	Tag_HighLimit	100.0
LO_LIM	Tag_LowLimit	0.0
BIPOLAR	Tag_Bipolar	1
OUT	Tag_OutputValue	22
RET_VAL	Tag_ErrorCode	W#16#0000

Program control operations

---(JMP): Jump if RLO = 1

Description

You can use the "Jump if RLO = 1" instruction to interrupt the linear execution of the program and resume it in another network. The destination network must be identified by a jump label (LABEL). The name of this jump label is specified in the placeholder above the instruction.

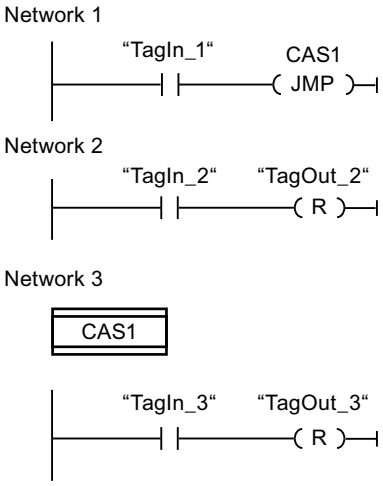
The specified jump label must be in the same block in which the instruction is executed. The name you specify can only occur once in the block. Only one jumping coil is permitted within a network.

If the result of logic operation (RLO) at the input of the instruction is "1", the jump to the network identified by the specified jump label is executed. The jump direction can be towards higher or lower network numbers.

If the condition at the input of the instruction is not fulfilled (RLO = 0), execution of the program continues in the next network.

Example

The following example shows how the instruction works:



If operand "TagIn_1" has the signal state "1", the "Jump if RLO = 1" instruction is executed. The linear execution of the program is interrupted and continues in Network 3, which is identified by the jump label CAS1. If the "TagIn_3" input has the signal state "1", the "TagOut_3" output is set.

---(JMPN): Jump if RLO = 0

Description

You can use the instruction "Jump if RLO = 0" to interrupt the linear execution of the program and resume it in another network, when the result of logic operation at the input of the instruction is "0". The destination network must be identified by a jump label (LABEL). The name of this jump label is specified in the placeholder above the instruction.

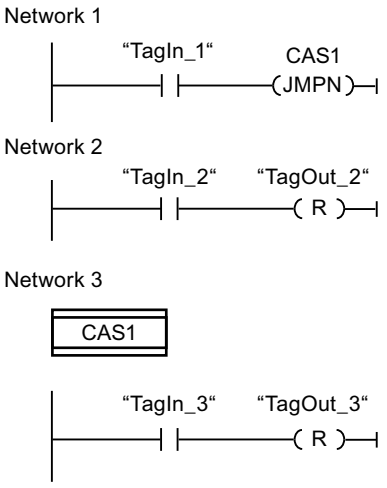
The specified jump label must be in the same block in which the instruction is executed. The name you specify can only occur once in the block. Only one jumping coil is permitted within a network.

If the result of logic operation (RLO) at the input of the instruction is "0", the jump to the network identified by the specified jump label is executed. The jump direction can be towards higher or lower network numbers.

If the result of logic operation at the input of the instruction is "1", execution of the program continues in the next network.

Example

The following example shows how the instruction works:



If operand "TagIn_1" has the signal state "0", the "Jump if RLO = 0" instruction is executed. The linear execution of the program is interrupted and continues in Network 3, which is identified by the jump label CAS1. If the "TagIn_3" input has the signal state "1", the "TagOut_3" output is set.

See also

Overview of the valid data types (Page 1908)

LABEL: Jump label

Description

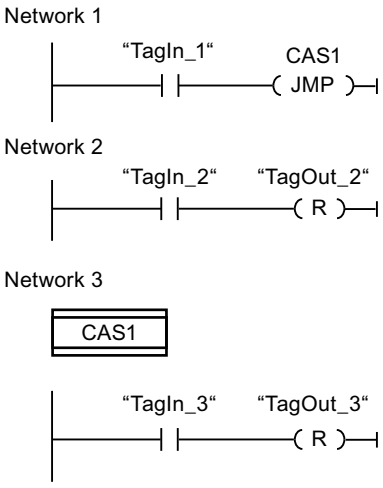
You can use a jump label to identify a destination network, in which the program execution should resume when a jump is executed.

The jump label and the instruction in which the jump label is specified must be located in the same block. The name of a jump label can only be assigned once in a block. You can declare up to 32 jump labels when you use a CPU S7-1200 and a maximum of 256 jump labels when you use a CPU S7-1500.

Only one jump label can be placed in a network. Each jump label can jump to several locations.

Example

The following example shows how the instruction works:



If operand "TagIn_1" has the signal state "1", the "Jump if RLO = 1" instruction is executed. The linear execution of the program is interrupted and continues in Network 3, which is identified by the jump label CAS1. If the "TagIn_3" input has the signal state "1", the "TagOut_3" output is set.

JMP_LIST: Define jump list

Description

You can use the "Define jump list" instruction to define several conditional jumps and continue the program execution in a specific network depending on the value of the K parameter.

You define the jumps with jump labels (LABEL), which you specify at the outputs of the instruction box. The number of outputs can be expanded in the instruction box. You can declare up to 32 outputs when you use a CPU S7-1200 and a maximum of 99 outputs when you use a CPU S7-1500.

The numbering of the outputs begins with the value "0" and continues in ascending order with each new output. Only jump labels can be specified at the outputs of the instruction. Instructions or operands cannot be specified.

The value of the K parameter specifies the number of the output and thus the jump label where the program execution is to be resumed. If the value in the K parameter is greater than the number of available outputs, the program execution is resumed in the next network of the block.

The "Define jump list" instruction is only executed if the signal state is "1" at the EN enable input.

Parameter

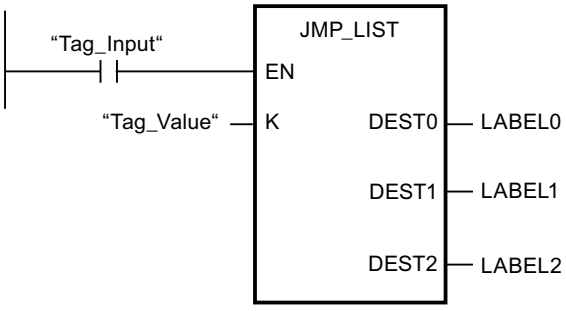
The following table shows the parameters of the "Define jump list" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
K	Input	UINT	I, Q, M, D, L or constant	Specifies the number of the output and thus the jump that is to be made.
DEST0	-	-	-	First jump label
DEST1	-	-	-	Second jump label
DESTn	-	-	-	Optional jump labels

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameters	Operand/Jump label	Value
K	Tag_Value	1
Dest0	LABEL0	Jump to the network that is identified with the jump label "LABEL0".
Dest1	LABEL1	Jump to the network that is identified with the jump label "LABEL1".
Dest2	LABEL2	Jump to the network that is identified with the jump label "LABEL2".

If operand "Tag_Input" has the signal state "1", the "Define jump list" instruction is executed. The program execution is resumed according to the value of operand "Tag_Value" in the network that is identified with the jump label "LABEL1".

Overview of the valid data types (Page 1908)

SWITCH: Jump distributor

Description

You can use the "Jump distributor" instruction to define multiple program jumps to be executed depending on the result of one or more comparison instructions.

You specify the value to be compared in the K parameter. This value is compared with the values that are provided by the various inputs. You can select the comparison method for each individual input. The availability of the various comparison instructions depends on the data type of the instruction.

The following table shows the comparison instructions that are available depending on the selected data type:

Data type		Instruction	Syntax
S7-1200	S7-1500		
Bit strings	Bit strings	Equal	==
		Not equal	<>
Integers, floating-point numbers, TIME, DATE, TOD	Integers, floating-point numbers, TIME, LTIME, DATE, TOD, LTOD, LDT	Equal	==
		Not equal	<>
		Greater or equal	>=
		Less or equal	<=
		Greater than	>
		Less than	<

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box. If you select a comparison instruction and the data type of the instruction is not yet defined, the "<???>" drop-down list only offers the data types that are permitted for the selected comparison instruction.

Execution of the instruction begins with the first comparison and runs until a comparison condition is met. If a comparison condition is met, the subsequent comparison conditions are not considered. If none of the specified comparison conditions are met, the jump at the ELSE output is executed. If no program jump is defined at the ELSE output, execution of the program continues in the next network.

The number of outputs can be expanded in the instruction box. The numbering of the outputs begins with the value "0" and continues in ascending order with each new output. Specify jump labels (LABEL) at the outputs of the instruction. Instructions or operands cannot be specified at the outputs of the instruction.

An input is automatically inserted for each additional output. The jump programmed at an output is executed if the comparison condition of the corresponding input is fulfilled.

Parameters

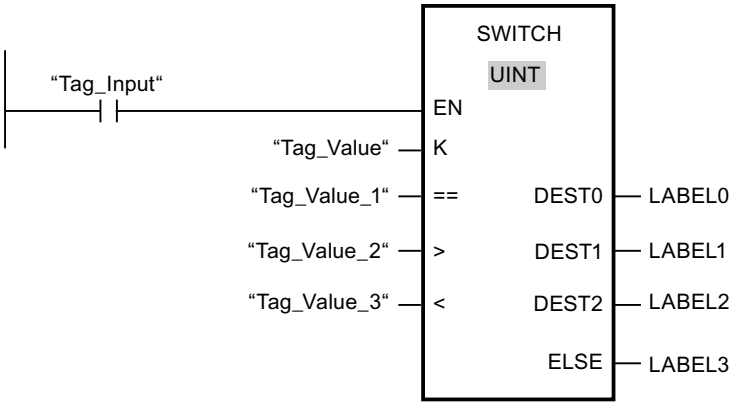
The following table shows the parameters of the "Jump distributor" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
K	Input	UINT	UINT	I, Q, M, D, L or constant	Specifies the value to be compared.
<Comparison values>	Input	Bit strings, integers, floating-point numbers, TIME, DATE, TOD	Bit strings, integers, floating-point numbers, TIME, LTIME, DATE, TOD, LTOD, LDT	I, Q, M, D, L or constant	Input value with which the value of the K parameter is compared.
DEST0	-	-	-	-	First jump label
DEST1	-	-	-	-	Second jump label
DEST(n)	-	-	-	-	Optional jump labels(n = 2 to 99)
ELSE	-	-	-	-	Program jump that is executed when none of the comparison conditions are fulfilled.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameters	Operand/Jump label	Value
K	Tag_Value	23
==	Tag_Value_1	20

Parameters	Operand/Jump label	Value
>	Tag_Value_2	21
<	Tag_Value_3	19
Dest 0	LABEL0	Jump to jump label "LABEL0", if the value of the K parameter equals 20.
Dest 1	LABEL1	Jump to jump label "LABEL1" if the value of the K parameter is greater than 21.
Dest 2	LABEL2	Jump to jump label "LABEL2", if the value of the K parameter is less than 19.
ELSE	LABEL 3	Jump to jump label "LABEL3", if the none of the comparison conditions are fulfilled.

If the operand "Tag_Input" changes to signal state "1", the instruction "Jump distributor" is executed. The execution of the program is continued in the network that is identified with the jump label "LABEL1".

Overview of the valid data types (Page 1908)

--(RET): Return

Description

You can use the "Return" instruction to stop the execution of a block. The results is three types through which the block processing can be completed.

- Without call of the "Return" instruction
  The block is exited after execution of the last network. The ENO of the function call is set to the signal state "1".
- Call of the "Return" instruction with preceding logic operation (see example)
  If the left connector has the signal state "1", the block will be exited. The ENO of the function call corresponds to the operand.
- Call of the "Return" instruction without previous logic operation
  The block is exited. The ENO of the function call corresponds to the operand.

Note

Only one jumping coil may be used in a network ("Return", "Jump if RLO=1", "Jump if RLO=0").

If the result of logic operation (RLO) at the input of the "Return" instruction is "1", program execution is terminated in the currently called block and resumed after the call function in the

calling block (for example, in the calling OB). The status (ENO) of the call function is determined by the parameter of the instruction. This can assume the following values:

- RLO
- TRUE/FALSE
- <Operand>

To set the parameter values, double-click the instruction and select the corresponding value in the drop-down list.

The following table shows the status of the call function if the "Return" instruction is programmed in a network within the called block:

RLO	Parameter value	ENO of the call function
1	RLO	1
	TRUE	1
	FALSE	0
	<Operand>	<Operand>
0	RLO	The program execution continues in the next network of the called block.
	TRUE	
	FALSE	
	<Operand>	

If an OB is completed, another block will be selected and started or executed by the priority class system:

- If the program cycle OB was completed, it will be restarted.
- If an OB is completed that has interrupted another block (for example, an alarm OB), then the interrupted block (for example, program cycle OB) will be executed.

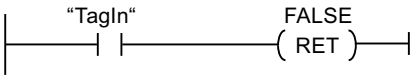
Parameters

The following table shows the parameters of the "Return" instruction:

Parameter	Declaration	Data type	Memory area	Description
Status of the calling function with RLO = 1:				
RLO	-	-		Is set to the signal status of the RLO.
TRUE	-	-		1
FALSE	-	-		0
<Operand>	Input	BOOL	I, Q, M, D, L	Signal state of the specified operand

Example

The following example shows how the instruction works:



If operand "TagIn" has the signal state "1", the "Return" instruction is executed. Program execution is terminated in the called block and continues in the calling block. The ENO enable output of the call function is reset to signal state "0".

Overview of the valid data types (Page 1908)

Runtime control

ENDIS_PW: Limit and enable password legitimation

Description

You use the "Limit and enable password legitimation" instruction to specify whether configured passwords may be legitimated or not for the CPU. You can prevent legitimated connections, even when the correct password is known.

When you call the command and the REQ parameter has the signal state "0", only the currently set state is displayed at the output parameters. If changes are made to the input parameters, these changes are not transferred to the output parameters.

If the instruction is called and REQ parameter has the signal state "1", the signal state is applied from the input parameters (F_PWD, FULL_PWD, R_PWD, HMI_PWD). FALSE means that legitimation per password is not permitted; TRUE means the password can be used.

Disable or enabling of the passwords can be allowed or prohibited individually. For example, all passwords can be prohibited, except the fail-safe password. You can thus limit access options to a small user group. The output parameters (F_PWD_ON, FULL_PWD_ON, R_PWD_ON, HMI_PWD_ON) always show the current status of the password use, regardless of the REQ parameter.

Non-configured passwords must have the TRUE signal state at the input and return the TRUE signal state at the output. The fail-safe password can only be configured for an F-CPU and, therefore, must always be interconnected with theTRUE signal state in a standard CPU. If the instruction return an error, the call remains without effect, i.e. the previous lock remains in force.

Disabled passwords can be enabled again under the following conditions:

- The CPU is reset to its factory settings.
- The front panel of the S7-1500 CPU supports a dialog that allows you to navigate to the appropriate menu in which the passwords can be enabled again.
- When you call the "Limit and enable password legitimation" instruction, the input parameter of the desired password has the signal state "1".

- Set the operating mode switch to STOP. The restriction to password legitimation is re-established as soon as the switch is set back to RUN.
- Inserting an empty memory card (transfer card or program card) into S7-1200 CPU.
- The transition from POWER OFF to POWER ON disables the protection in the S7-1200 CPU. The "Limit and enable password legitimation" instruction must be called again in the program (e.g. in the startup OB).

Note

The "Limit and enable password legitimation" instruction blocks access to the HMI system, if the HMI password has not been enabled.

Note

Existing legitimized connections retain their access rights and you cannot use the "Limit and enable password legitimation" instruction to restrict them.

Preventing accidental lockout out with an S7-1500 CPU

The same setting can be made on the front panel of the S7-1500 CPU and the CPU saves the most recent setting.

To prevent accidental lockout, the protection can be disabled by setting the mode selector to STOP with an S7-1500 CPU. The protection is automatically enabled again by setting mode selector to RUN without having to call the "Limit and enable password legitimation" instruction again or taking additional actions on the front panel.

Preventing accidental lockout with an S7-1200 CPU

The protection for POWER OFF - POWER ON is disabled because a S7-1200 CPU has no operating mode switch. As a result it is possible and advisable to use certain program sequences within your program to prevent an accidental lockout.

To do this, program a time control using either a cyclic interrupt OB or a timer in the main OB (OB 1). This provides you with the option to call the "Limit and enable password legitimation" instruction again without delay in the corresponding OB (e.g. OB 1 or OB 35) after a transition from POWER OFF - POWER ON. Call the instruction in the startup OB (OB 100) in order to keep as short as possible the time window in which the application is not active and thus ensure that no restrictions exist in the password legitimation. This procedure offers you the largest possible protection against unauthorized access.

If an unintended lockout occurs you can skip the call in the startup OB (for example, by querying an input parameter) and have the set time (for example 10 seconds to 1 minute), to establish a connection to the CPU before the lock becomes active again.

If you have set no timer in your program code and are locked out, insert an empty transfer card or empty program card into the CPU. The empty transfer card or program card deletes the internal load memory of the CPU. You must then load the user program again from STEP 7 in the CPU.

Procedure for lost passwords with an S7-1200 CPU

If you have lost the password for a password-protected S7-1200 CPU, delete the password-protected program with an empty transfer card or program card. The empty transfer card or program card deletes the internal load memory of the CPU. You can then load a new user program from STEP 7 Basic in the CPU.

Warning

Inserting empty transfer card

When you insert a transfer card in a CPU during runtime, the CPU goes to STOP mode. If operating states are unstable, controllers may fail and thus cause the uncontrolled operation of the controlled devices. This leads to an unforeseen operation of the automation system which can cause deadly or serious injuries and/or damage to property.

After you remove the transfer card the content of the transfer card is in the internal load memory. Make sure at this point that the card contains no program.

Warning

Inserting empty program card

When you insert a program card in a CPU during runtime, the CPU goes to STOP mode. If operating states are unstable, controllers may fail and thus cause the uncontrolled operation of the controlled devices. This leads to an unforeseen operation of the automation system which can cause deadly or serious injuries and/or damage to property.

Make sure that the program card is empty. The internal load memory is copied to the empty program card. The internal load memory is empty after the removal of the formerly empty program card.

You must remove the transfer card or program card before you put the CPU into RUN mode.

Effects of password use on the operating modes

The following table shows what effects the password use by means of the "Limit and enable password legitimation" instruction has on the operating modes and the corresponding user actions.

Action	Password protection by means of the instruction
Basic state after • Operating mode switch to STOP • Reset memory manually (PG, switch, change of MC (Motion Control)) • Reset to factory setting	Not activated (no restrictions)
Basic state after POWER ON	• S7-1200-CPU: the lock is disabled and the instruction must be called again in the program (in the startup OB, for example). • S7-1500 CPU: Enabled (if a lock was activated before POWER OFF). The option of not allowing passwords is retentive.
Operating mode transition RUN/STARTUP/HOLD -> STOP (by terminating the instruction, an error or communication) or STOP -> STARTUP/RUN/HOLD	Activated Passwords still cannot be used.

Parameters

The following table shows the parameters of the "Limit and enable password legitimation" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
REQ	Input	BOOL	I, Q, M, D, L or constant	When the REQ parameter has the signal state "0", the currently set signal state of the passwords is queried.
F_PWD	Input	BOOL	I, Q, M, D, L or constant	Read/write access including fail-safe • F_PWD = "0": Do not allow password • F_PWD = "1": Allow password
FULL_PWD	Input	BOOL	I, Q, M, D, L or constant	Read/write access • FULL_PWD = "0": Do not allow password • FULL_PWD = "1": Allow password
R_PWD	Input	BOOL	I, Q, M, D, L or constant	Read access • R_PWD = "0": Do not allow password • R_PWD = "1": Allow password

Parameter	Declaration	Data type	Memory area	Description
HMI_PWD	Input	BOOL	I, Q, M, D, L or constant	HMI access • HMI_PWD = "0": Do not allow password • HMI_PWD = "1": Allow password
F_PWD_ON	Output	BOOL	I, Q, M, D, L	Read/write access including fail-safe • F_PWD_ON = "0": Password not allowed • F_PWD_ON = "1": Password allowed
FULL_PWD_ON	Output	BOOL	I, Q, M, D, L	Read/write access status • FULL_PWD_ON = "0": Password not allowed • FULL_PWD_ON = "1": Password allowed
R_PWD_ON	Output	BOOL	I, Q, M, D, L	Read-access status • R_PWD_ON = "0": Password not allowed • R_PWD_ON = "1": Password allowed
HMI_PWD_ON	Output	BOOL	I, Q, M, D, L	HMI-access status • HMI_PWD_ON = "0": Password not allowed • HMI_PWD_ON = "1": Password allowed
RET_VAL	Output	WORD	I, Q, M, D, L	Error information

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
8090	The "Limit and enable password legitimation" instruction is not supported
80D0	The password for fail-safe is not configured. With standard CPUs, the signal state must be TRUE.
80D1	The read/write access is not configured
80D2	The read access is not configured
80D3	The HMI access is not configured
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

See also

Overview of the valid data types (Page 1908)

RE_TRIGR: Restart cycle monitoring time

Description

You can use the "Restart cycle monitoring time" instruction to restart the cycle time monitoring of the CPU. The maximum cycle time then starts over again for the duration you have set in the CPU configuration.

The instruction "Restart cycle monitoring time" can be called regardless of the priority in all blocks.

If the instruction is called in a block with a higher priority, such as a hardware interrupt, diagnostic error interrupt, or cyclic interrupt, the instruction is not executed and the ENO enable output is set to signal state "0".

The "Restart cycle monitoring time" instruction executes completely within a time span (10 times the maximum program cycle), regardless of the number of calls. Once this time has expired, the program cycle can no longer be prolonged.

Parameter

The "Restart cycle monitoring time" instruction has no parameters.

See also

Overview of the valid data types (Page 1908)

STP: Exit program

Description

You use the "Exit program" instruction to set the CPU to STOP mode and therefore to terminate the execution of the program. The effects of changing from RUN to STOP depend on the CPU configuration.

When the result of logic operation (RLO) at the input of the instruction is "1", the CPU changes to STOP mode and program execution is terminated. The signal state at the output of the instruction is not evaluated.

When the RLO is "0" at the input of the instruction, then the instruction will not be executed.

Parameters

The "Exit program" instruction has no parameters.

See also

Overview of the valid data types (Page 1908)

GET_ERROR: Get error locally

Description

The "Get error locally" instruction is used to query the occurrence of errors within a block. This is usually to access error. If the system reports an error during the processing of the block, detailed information is stored in the operand at the ERROR output for the first error to occur during the execution of the block since the last execution of the instruction.

Only operands of the "ErrorStruct" system data type can be specified at the ERROR output. The "ErrorStruct" system data type specifies the exact structure in which the information about the error is stored. Using additional instructions, you can evaluate this structure and program an appropriate response. If several errors occur in the block, the error information about the next error to occur in the instruction is output only after the first error that occurred has been remedied.

Note

The ERROR output is only changed if error information is present. To set the output back to "0" after handling an error, you have the following options:

- Declare the tag in the "Temp" section of the block interface.
- Reset the tag to "0" before calling the instruction.
- Query the enable output ENO.

The enable output ENO of the instruction "Get error locally" instruction is set only if the enable input EN returns signal state "1" and error information is present. If one of these conditions is not fulfilled, the remaining program execution is not affected by the "Get error locally" instruction.

You can find an example of how you can implement the instruction in combination with other troubleshooting options under "See also".

Note

The "Get error locally" instruction enables local error handling within a block. If "Get error locally" is inserted in the program code of a block, any predefined system reactions are ignored if errors occur.

Parameters

The following table lists the parameters of the "Get error locally" instruction:

Parameter	Declaration	Data type	Memory area	Description
ERROR	Output	ErrorStruct	D, L	Error information

Data type "ErrorStruct"

The following table lists the structure of the "ErrorStruct" data type:

Structure component		Data type	Description
ERROR_ID		WORD	Error ID
FLAGS		BYTE	Shows if an error occurred during a block call. 16#01: Error during a block call 16#00: No error during a block call
REACTION		BYTE	Default reaction: 0: Ignore (write error) 1: Continue with substitute value "0" (read error) 2: Skip instruction (system error)
CODE_ADDRESS		CREF	Information about the address and type of block
	BLOCK_TYPE	BYTE	Type of block where the error occurred: 1: OB 2: FC 3: FB
	CB_NUMBER	UINT	Number of the code block
	OFFSET	UDINT	Reference to the internal memory
MODE		BYTE	Information about the address of an operand
OPERAND_NUMBER		UINT	Operand number of the machine command
POINTER_NUMBER_LOCATION		UINT	(A) Internal pointer
SLOT_NUMBER_SCOPE		UINT	(B) Storage area in internal memory
DATA_ADDRESS		NREF	Information about the address of an operand
	AREA	BYTE	(C) Memory area: L: 16#40 – 4E, 86, 87, 8E, 8F, C0 – CE I: 16#81 Q: 16#82 M: 16#83 DB: 16#84, 85, 8A, 8B Range violations for a directly editable tag of data type DINT: 16#04
	DB_NUMBER	UINT	(D) Number of the data block
	OFFSET	UDINT	(E) Relative address of the operand

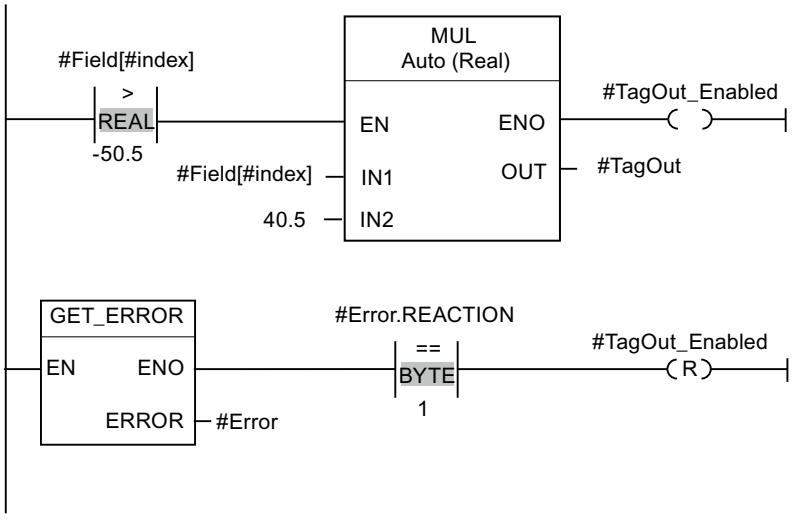
Structure component "ERROR_ID"

The following table lists the values that can be output at the structure component "ERROR_ID":

ID* (hexadecimal)	ID* (decimal)	Description
0	0	No error
2503	9475	Invalid pointer
2520	9504	Invalid STRING
2522	9506	Read error: Operand outside the valid range
2523	9507	Write error: Operand outside the valid range
2524	9508	Read error: Invalid operand
2525	9509	Write error: Invalid operand
2528	9512	Read error: Data alignment
2529	9513	Write error: Data alignment
252C	9516	Invalid pointer
2530	9520	Write error: Data block
2533	9523	Invalid pointer used
2538	9528	Access error: DB does not exist
2539	9529	Access error: Wrong DB used
253A	9530	Global data block does not exist
253C	9532	Faulty information or the function does not exist
253D	9533	System function does not exist
253E	9534	Faulty information or the function block does not exist
253F	9535	System block does not exist
2550	9552	Access error: DB does not exist
2551	9553	Access error: Wrong DB used
2575	9589	Error in the program nesting depth
2577	9591	The block property "Parameter passing via registers" is not selected.
2576	9590	Error in the local data distribution
25A0	9632	Internal error in TP
25A1	9633	Tag is write-protected
25A2	9634	Invalid numerical value of tag
2942	10562	Read error: Input
2943	10563	Write error: Output
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".		

Example

The following example shows how the instruction works:



An error occurred accessing the "#Field[#index]" tag. The enable output ENO of the "Multiply" instruction and the "#TagOut_Enabled" operand have signal state "1" despite the read/access error and the multiplication is performed with the value "0.0". If this error scenario occurs, it is recommended to program the "Get error locally" instruction after the "Multiply" instruction to get the error. The error information supplied by the "Get error locally" instruction is evaluated with the comparison instruction "Equal". If the "#Error.REACTION" structure component has the value "1", this involves a read/access error and the "#TagOut_Enabled" output is reset.

Overview of the valid data types (Page 1908)

Querying and fixing errors in the program code (Page 228)

GET_ERR_ID: Get error ID locally

Description

The "Get error ID locally" instruction is used to query the occurrence of errors within a block. This is usually to access error. If the system reports during the block processing errors within the block execution since the last execution of the instruction, the error ID of the first error that occurred in the tag is stored at the ID output.

Only operands of the WORD data type can be specified at the ID output. If several errors occur in the block, the error ID of the next error to occur in the instruction is output only after the first error that occurred has been remedied.

Note

The ID output is only changed if error information is present. To set the output back to "0" after handling an error, you have the following options:

- Declare the tag in the "Temp" section of the block interface.
- Reset the tag to "0" before calling the instruction.
- Query the enable output ENO.

The enable output ENO of the instruction "Get error ID locally" instruction is set only if the enable input EN returns signal state "1" and error information is present. If one of these conditions is not fulfilled, the remaining program execution is not affected by the "Get error ID locally" instruction.

You can find an example of how you can implement the instruction in combination with other troubleshooting options under "See also".

Note

The "Get error ID locally" instruction enables local error handling within a block. If the "Get error ID locally" instruction is inserted in the program code of a block, any predefined system reactions are ignored if errors occur.

Parameters

The following table lists the parameters of the "Get error ID locally" instruction:

Parameter	Declaration	Data type	Memory area	Description
ID	Output	WORD	I, Q, M, D, L	Error ID

ID parameter

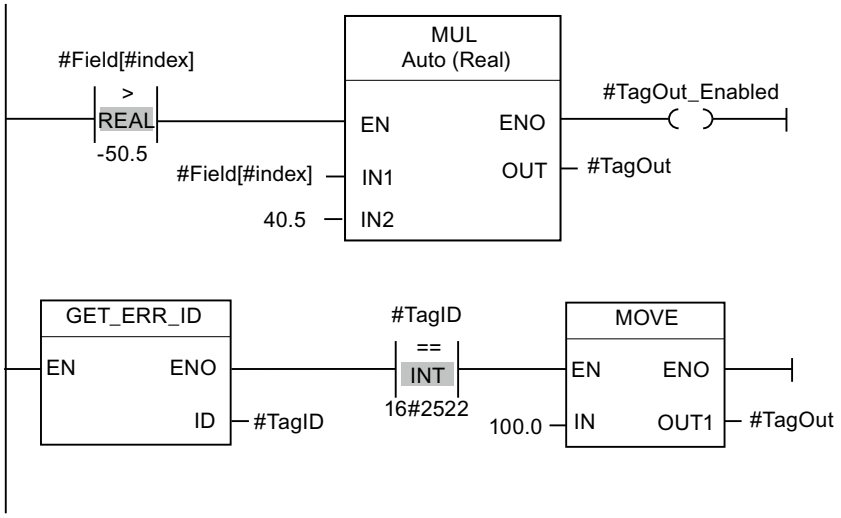
The following table lists the values that can be output at the ID parameter:

ID* (hexadecimal)	ID* (decimal)	Description
0	0	No error
2503	9475	Invalid pointer
2520	9504	Invalid STRING
2522	9506	Read error: Operand outside the valid range
2523	9507	Write error: Operand outside the valid range
2524	9508	Read error: Invalid operand
2525	9509	Write error: Invalid operand
2528	9512	Read error: Data alignment
2529	9513	Write error: Data alignment

ID* (hexadecimal)	ID* (decimal)	Description
252C	9516	Invalid pointer
2530	9520	Write error: Data block
2533	9523	Invalid pointer used
2538	9528	Access error: DB does not exist
2539	9529	Access error: Wrong DB used
253A	9530	Global data block does not exist
253C	9532	Faulty information or the function does not exist
253D	9533	System function does not exist
253E	9534	Faulty information or the function block does not exist
253F	9535	System block does not exist
2550	9552	Access error: DB does not exist
2551	9553	Access error: Wrong DB used
2575	9589	Error in the program nesting depth
2576	9590	Error in the local data distribution
2577	9591	The block property "Parameter passing via registers" is not selected.
25A0	9632	Internal error in TP
25A1	9633	Tag is write-protected
25A2	9634	Invalid numerical value of tag
2942	10562	Read error: Input
2943	10563	Write error: Output
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".		

Example

The following example shows how the instruction works:



An error occurred accessing the "#Field[#index]" tag. The enable output ENO of the "Multiply" instruction and the "#TagOut_Enabled" operand have signal state "1" despite the read/access

error and the multiplication is performed with the value "0.0". If this error scenario occurs, it is recommended to program the "Get error ID locally" instruction after the "Multiply" instruction to get the error. The error information supplied by the "Get error ID locally" instruction is evaluated with the comparison instruction "Equal". If the operand "#TagID" returns the ID 2522, this involves a read/access error and the value "100.0" is written to the "#TagOut" output.

Querying and fixing errors in the program code (Page 228)

INIT_RD: Initialize all retain data

Description

You can use the "Initialize all retain data" instruction to reset the retain data of all data blocks, bit memories and SIMATIC timers and counters at the same time. The instruction can only be executed within a startup OB because the execution would exceed the program cycle duration.

Parameter

The following table shows the parameters of the "Initialize all retain data" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
REQ	Input	BOOL	I, Q, M, D, L, T, C or constant	If the input "REQ" has the signal state "1", all retain data are reset.
RET_VAL	Output	INT	I, Q, M, D, L	Error information: If an error occurs during execution of the instruction, an error code is output at the RET_VAL parameter.

For additional information on valid data types, refer to "See also".

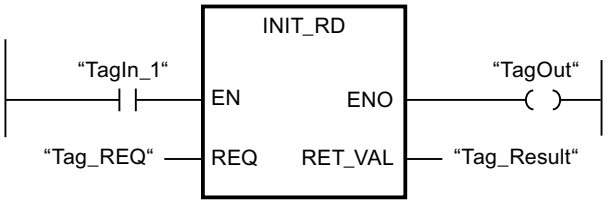
Parameters RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B5	The instruction cannot be executed because it was not programmed within a startup OB.
General error information	See also: "GET_ERR_ID: Get error ID locally
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:



If the operands "TagIn_1" and "Tag_REQ" have signal state "1", the instruction is executed. The retain data of all data blocks, bit memories and SIMATIC timers and counters are reset If the instruction is executed without errors, the ENO enable output has the signal state "1".

GET_ERR_ID: Get error ID locally (Page 2417)

WAIT: Configure time delay

Description

The "Configure time delay" instruction pauses the program execution for a specific period of time. You indicate the period of time in microseconds on the WT parameter of the instruction.

You can configure time delays from -32768 up to +32767 microseconds (µs). The smallest possible delay time depends on the respective CPU and corresponds to the execution time of the "Configure time delay" instruction.

The execution of the instruction can be interrupted by higher priority events.

The "Configure time delay" instruction returns no error information.

Parameters

The following table shows the parameters of the "Configure time delay" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
WT	Input	INT	I, Q, M, D, L, P, or constant	Time delay in microseconds (µs)

Overview of the valid data types (Page 1908)

RUNTIME: Measure program runtime

Description

The "Measure program runtime" instruction is used to measure the runtime of the entire program, individual blocks or command sequences.

If you want to measure the runtime of your entire program, call the instruction "Measure program runtime" in OB1. Measurement of the runtime is started with the first call and the output RET_VAL returns the runtime of the program after the second call. The measured runtime includes all CPU processes that can occur during the program execution, for example, interruptions caused by higher-level events or communication. The instruction "Measure program runtime" reads an internal counter of the CPU and write the value to the IN-OUT parameter MEM. The instruction calculates the current program runtime according to the internal counter frequency and writes it to output RET_VAL.

If you want to measure the runtime of individual blocks or individual command sequences, you need three separate networks. Call the instruction "Measure program runtime" in an individual network within your program. You set the starting point of the runtime measurement with this first call of the instruction. Then you call the required program block or the command sequence in the next network. In another network, call the "Measure program runtime" instruction a second time and assign the same memory to the IN-OUT parameter MEM as you did during the first call of the instruction. The "Measure program runtime" instruction in the third network reads an internal CPU counter and calculates the current runtime of the program block or the command sequence according to the internal counter frequency and writes it to the output RET_VAL.

The following applies to S7-1200 CPUs with firmware version earlier than V4.1: The Measure program runtime" instruction uses an internal high-frequency counter to calculate the time. If the counter overflows (this can occur up to once per minute), the instruction returns values <= 0.0. Ignore these runtime values.

Note

The runtime of a command sequence cannot be determined exactly, because the sequence of instructions within a command sequence is changed during optimized compilation of the program.

Parameter

The following table shows the parameters of the "Measure program runtime" instruction:

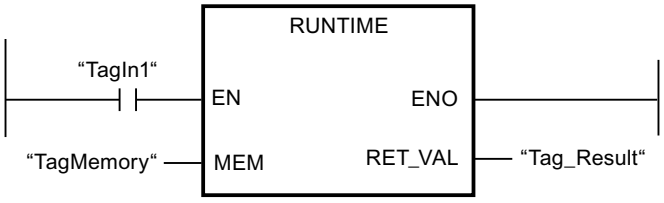
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
MEM	InOut	LREAL	I, Q, M, D, L	Saves the starting point of the runtime measurement.
RET_VAL	Output	LREAL	I, Q, M, D, L	Returns the measured runtime in seconds

For additional information on valid data types, refer to "See also".

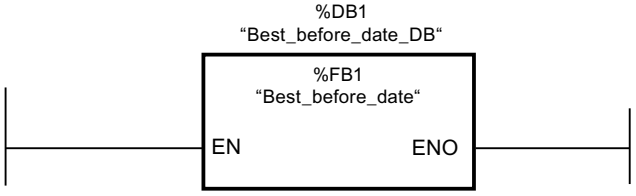
Example

The following example shows how the instruction works based on the runtime calculation of a program block:

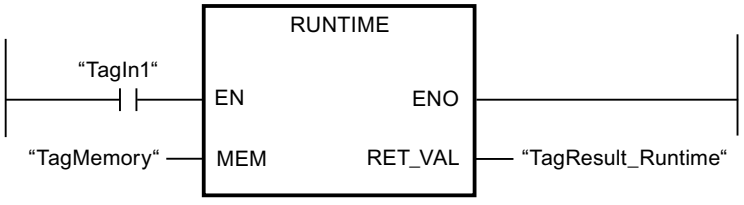
Network 1:



Network 2:



Network 3:



When the "TagIn1" operand in network 1 has the signal state "1", the instruction is executed. The starting point for the runtime measurement is set with the first call of the instruction and buffered as reference for the second call of the instruction in the "TagMemory" operand.

The "Best_before_date" program block FB1 is called in network 2.

When the FB1 program block has been executed and the "TagIn1" operand has the signal state "1", the instruction in network 3 is executed. The second call of the instruction calculates the runtime of the program block and writes the result to the output RET_VAL.

Overview of the valid data types (Page 1908)

Word logic operations

AND: AND logic operation

Description

You can use the "AND logic operation" instruction to combine the value at the IN1 input and the value at the IN2 input bit-by-bit by AND logic and query the result at the OUT output.

When the instruction is executed, bit 0 of the value at the IN1 input and bit 0 of the value at the IN2 input are logically ANDed. The result is stored in bit 0 of output OUT. The same logic operation is executed for all other bits of the specified values.

The number of inputs can be expanded in the instruction box. The added inputs are numbered in ascending order in the box. When the instruction is executed, the values of all available input parameters are combined with AND logic (ANDed). The result is stored in the OUT output.

The result bit has signal state "1" only when both of the bits in the logic operation also have signal state "1". If one of the two bits of the logic operation has signal state "0", the corresponding result bit is reset.

Parameters

The following table shows the parameters of the "AND logic operation" instruction:

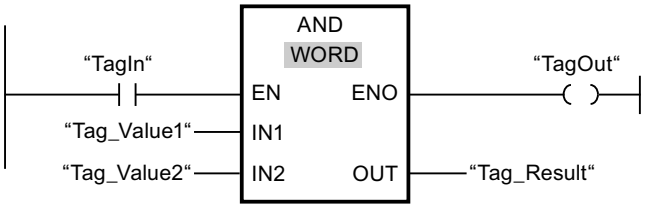
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Bit strings	I, Q, M, D, L, P, or constant	First value for logic operation
IN2	Input	Bit strings	I, Q, M, D, L, P, or constant	Second value for logic operation
INn	Input	Bit strings	I, Q, M, D, L, P, or constant	Other inputs whose values are logically combined.
OUT	Output	Bit strings	I, Q, M, D, L, P	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN1	Tag_Value1	0101 0101 0101 0101
IN2	Tag_Value2	0000 0000 0000 1111
OUT	Tag_Result	0000 0000 0000 0101

If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value1" and the value of operand "Tag_Value2" are ANDed. The result is mapped bit-for-bit and output in operand "Tag_Result". The enable output ENO and the output "TagOut" are set to signal state "1".

See also

Overview of the valid data types (Page 1908)

OR: OR logic operation

Description

You can use the "OR logic operation" instruction to combine the value at the IN1 input and the value at the IN2 input bit-by-bit by OR logic and query the result at the OUT output.

When the instruction is executed, bit 0 of the value at the IN1 input and bit 0 of the value at the IN2 input are combined by OR logic operation. The result is stored in bit 0 of output OUT. The same logic operation is executed for all bits of the specified tags.

The number of inputs can be expanded in the instruction box. The added inputs are numbered in ascending order in the box. When the instruction is executed, the values of all available input parameters are combined with OR logic (ORed). The result is stored in the OUT output.

The result bit has signal state "1" when at least one of the two bits in the logic operation has signal state "1". If both of the bits of the logic operation have signal state "0", the corresponding result bit is reset.

Parameters

The following table shows the parameters of the "OR logic operation" instruction:

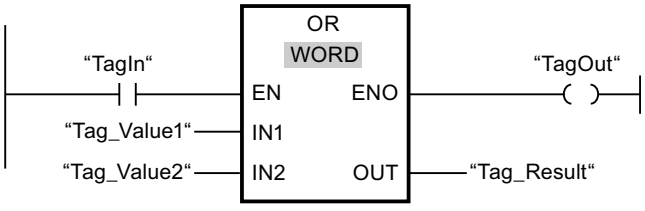
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Bit strings	I, Q, M, D, L, P, or constant	First value for logic operation
IN2	Input	Bit strings	I, Q, M, D, L, P, or constant	Second value for logic operation
INn	Input	Bit strings	I, Q, M, D, L, P, or constant	Other inputs whose values are logically combined.
OUT	Output	Bit strings	I, Q, M, D, L, P	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN1	Tag_Value1	0101 0101 0101 0101
IN2	Tag_Value2	0000 0000 0000 1111
OUT	Tag_Result	0101 0101 0101 1111

If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value1" and the value of operand "Tag_Value2" are ORed. The result is mapped bit-for-bit and output in operand "Tag_Result". The enable output ENO and the output "TagOut" are set to signal state "1".

Overview of the valid data types (Page 1908)

XOR: EXCLUSIVE OR logic operation

Description

You can use the "EXCLUSIVE OR logic operation" instruction to combine the value at the IN1 input and the value at the IN2 input bit-by-bit by EXCLUSIVE OR logic and query the result at the OUT output.

When the instruction is executed, bit 0 of the value at the IN1 input and bit 0 of the value at the IN2 input are combined by EXCLUSIVE OR logic operation. The result is stored in bit 0 of output OUT. The same logic operation is executed for all other bits of the specified value.

The number of inputs can be expanded in the instruction box. The added inputs are numbered in ascending order in the box. When the instruction is executed, the values of all available input parameters are combined with EXCLUSIVE OR logic. The result is stored in the OUT output.

The result bit has signal state "1" when one of the two bits in the logic operation has signal state "1". If both of the bits of the logic operation have signal state "1" or "0", the corresponding result bit is reset.

Parameters

The following table shows the parameters of the "EXCLUSIVE OR logic operation" instruction:

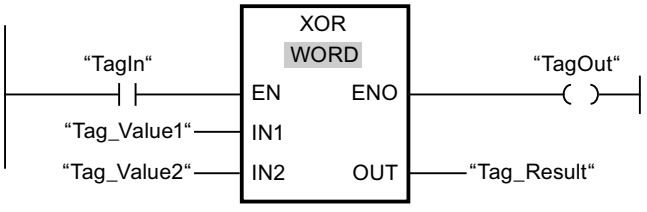
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Bit strings	I, Q, M, D, L, P, or constant	First value for logic operation
IN2	Input	Bit strings	I, Q, M, D, L, P, or constant	Second value for logic operation
INn	Input	Bit strings	I, Q, M, D, L, P, or constant	Other inputs whose values are logically combined.
OUT	Output	Bit strings	I, Q, M, D, L, P	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN1	Tag_Value1	0101 0101 0101 0101
IN2	Tag_Value2	0000 0000 0000 1111
OUT	Tag_Result	0101 0101 0101 1010

If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value1" and the value of operand "Tag_Value2" are combined by EXCLUSIVE OR logic. The result is mapped bit-for-bit and output in operand "Tag_Result". The enable output ENO and the output "TagOut" are set to signal state "1".

See also

Overview of the valid data types (Page 1908)

INVERT: Create ones complement

Description

You can use the instruction "Create ones complement" to invert the signal status of the bits at input IN. When the instruction is processed, the value at input IN is linked to EXCLUSIVE OR by a hexadecimal mask (W#16#FFFF for 16-bit numbers or DW#16#FFFF FFFF for 32-bit number). This inverts the signal state of the individual bits that are then stored at output OUT.

Parameters

The following table shows the parameters of the instruction "Create ones complement":

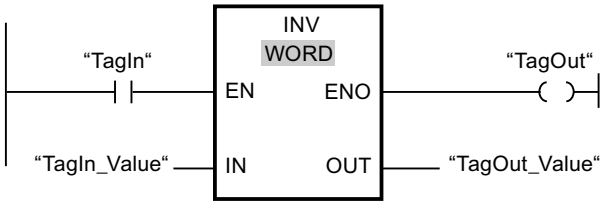
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers	I, Q, M, D, L, P, or constant	Input value
OUT	Output	Bit strings, integers	I, Q, M, D, L, P	Ones complement of the value at input IN

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value	
IN	TagIn_Value	W#16#000F	W#16#7E
OUT	TagOut_Value	W#16#FFF0	W#16#81

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction inverts the signal state of the individual bits at input "TagIn_Value" and writes the result to output "TagOut_Value". The enable output ENO and the output "TagOut" are set to signal state "1".

See also

Overview of the valid data types (Page 1908)

DECO: Decode

Description

You can use the "Decode" instruction to set a bit in the output value that is specified by the input value.

The "Decode" instruction reads the value at the IN input and sets the bit in the output value whose bit position corresponds to the read value. The other bits in the output value are filled with zeroes. When the value at the IN input is greater than 31, a modulo 32 instruction is executed.

Parameters

The following table shows the parameters of the "Decode" instruction:

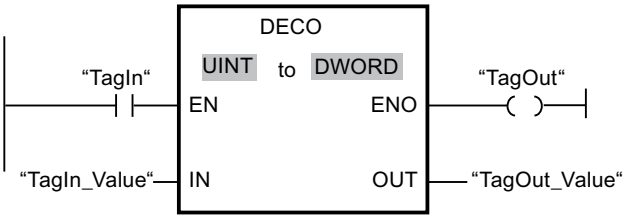
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	UINT	I, Q, M, D, L, P, or constant	Position of the bit in the output value which is set.
OUT	Output	Bit strings	I, Q, M, D, L, P	Output value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

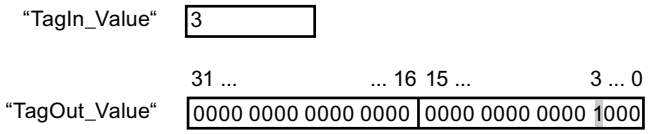
You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:



The following figure shows how the instruction works using specific operand values:



If the "TagIn" operand has signal state "1", the instruction is executed. The instruction reads bit number "3" from the value of the operand "TagIn_Value" at the input and sets the third bit to the value of the operand "TagOut_Value" at the output.

If the instruction is executed without errors, the ENO enable output has signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

ENCO: Encode

Description

You can use the "Encode" instruction to read the bit number of the least significant bit in the input value and to send it to the OUT output.

The "Encode" instruction selects the least significant bit of the value at the IN input and writes its bit number to the tag in the OUT output.

Parameters

The following table shows the parameters of the "Encode" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output

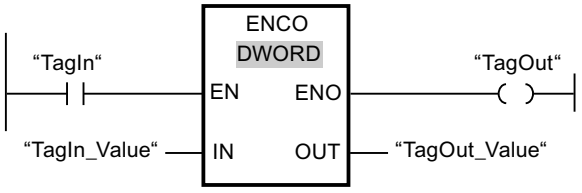
Parameter	Declaration	Data type	Memory area	Description
IN	Input	Bit strings	I, Q, M, D, L, P, or constant	Input value
OUT	Output	INT	I, Q, M, D, L, P	Output value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

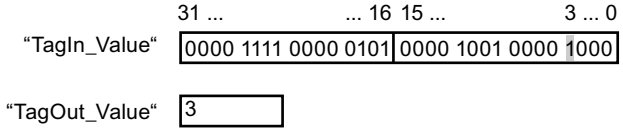
You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:



The following figure shows how the instruction works using specific operand values:



If the "TagIn" operand has signal state "1", the instruction is executed. The instruction selects the least significant bit at the "TagIn_Value" input and writes bit position "3" to the tag in the "TagOut_Value" output.

If the instruction is executed without errors, the ENO enable output has signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

SEL: Select

Description

Depending on a switch (G input), the "Select" instruction selects one of the inputs, IN0 or IN1 and copies its content to the OUT output. When the input G has signal state "0", the value at the input IN0 is moved. When the input G has signal state "1", the value at the input IN1 is moved to the output OUT.

All tags at all parameters must have the same data type.

Parameters

The following table shows the parameters of the "Select" instruction:

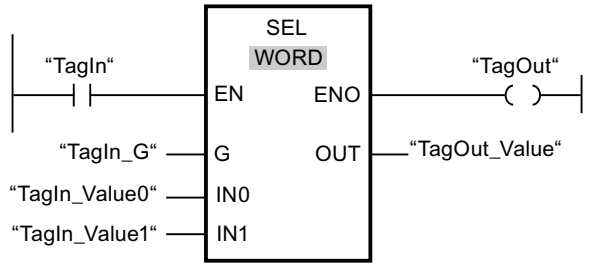
Parameter	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
G	Input	BOOL	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L, T, C or constant	Switch
IN0	Input	Bit strings, integers, floating-point numbers, timers, TOD, CHAR, WCHAR, DATE	Bit strings, integers, floating-point numbers, timers, TOD, LTOD, LDT, CHAR, WCHAR, DATE	I, Q, M, D, L, P, or constant	I, Q, M, D, L, P, or constant	First input value
IN1	Input	Bit strings, integers, floating-point numbers, timers, TOD, CHAR, WCHAR, DATE	Bit strings, integers, floating-point numbers, timers, TOD, LTOD, LDT, CHAR, WCHAR, DATE	I, Q, M, D, L, P, or constant	I, Q, M, D, L, P, or constant	Second input value
OUT	Output	Bit strings, integers, floating-point numbers, timers, TOD, CHAR, WCHAR, DATE	Bit strings, integers, floating-point numbers, timers, TOD, LTOD, LDT, CHAR, WCHAR, DATE	I, Q, M, D, L, P	I, Q, M, D, L, P	Result

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value	
G	TagIn_G	0	1
IN0	TagIn_Value0	W#16#0000	W#16#4C
IN1	TagIn_Value1	W#16#FFFF	W#16#5E
OUT	TagOut_Value	W#16#0000	W#16#5E

If the "TagIn" operand has signal state "1", the instruction is executed. Based on the signal state at the "TagIn_G" input, the value at the "TagIn_Value0" or "TagIn_Value1" input is selected and moved to the "TagOut_Value" output. If the instruction is executed without errors, the enable output ENO has signal state "1" and the output "TagOut" is set.

See also

Overview of the valid data types (Page 1908)

MUX: Multiplex

Description

You can use the instruction "Multiplex" to copy the content of a selected input to output OUT. The number of selectable inputs of the instruction box can be expanded. You can declare a maximum of 32 inputs.

The inputs are numbered automatically in the box. Numbering starts at IN0 and is incremented continuously with each new input. You can use the K parameter to define the input whose content is to be copied to the OUT output. If the value of the parameter K is greater than the number of available inputs, the content of the ELSE parameter is copied to the OUT output and the ENO enable output is assigned the signal state "0".

The "Multiplex" instruction can only be executed if the tags have the same data type in all inputs and in the OUT output. The K parameter is an exception, since only integers can be specified for it.

The enable output ENO is reset if one of the following conditions applies:

- Enable input EN has signal state "0".
- The input at the K parameter is located outside the available inputs. This applies regardless of whether the ELSE input is used. The value at the OUT output remains changed.
- Errors occurred during execution of the instruction.

Parameters

The following table shows the parameters of the "Multiplex" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
K	Input	Integers	Integers	I, Q, M, D, L, P, or constant	Specifies the input whose content is to be copied. • If K = 0 => Parameter IN0 • If K = 1 => Parameter IN1, etc.
IN0	Input	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P, or constant	First input value
IN1	Input	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P, or constant	Second input value

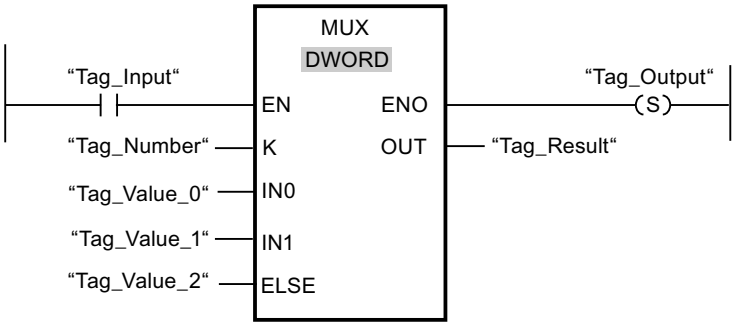
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
INn	Input	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P, or constant	Optional input values
ELSE	Input	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P, or constant	Specifies the value to be copied when K > n.
OUT	Output	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	Output to which the value is to be copied.

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
K	Tag_Number	1
IN0	Tag_Value_0	DW#16#00000000
IN1	Tag_Value_1	DW#16#003E4A7D
ELSE	Tag_Value_2	DW#16#FFFF0000
OUT	Tag_Result	DW#16#003E4A7D

If the "Tag_Input" operand has signal state "1", the instruction is executed. Depending on the value of the operand "Tag_Number", the value at input "Tag_Value_1" is copied and assigned to the operand at output "Tag_Result". If the instruction is executed without errors, the "ENO" and "Tag_Output" enable outputs are set.

See also

Overview of the valid data types (Page 1908)

DEMUX: Demultiplex

Description

You can use the instruction "Demultiplex" to copy the content of the input IN to a selected output. The number of selectable outputs can be extended in the instruction box. The outputs are numbered automatically in the box. Numbering starts at OUT0 and continues consecutively with each new output. You can use the K parameter to define the output to which the content of the IN input is to be copied. The other outputs are not changed. If the value of the parameter K is greater than the number of available outputs, then the content of input IN in the parameter ELSE and the enable output ENO will be assigned to the signal state "0".

The instruction "Demultiplex" can only be executed if the tags at the input IN and at all outputs are of the same data type. The K parameter is an exception, since only integers can be specified for it.

The enable output ENO is reset if one of the following conditions applies:

- Enable input EN has signal state "0".
- The value of the K parameter is greater than the number of available outputs.
- Errors occurred during execution of the instruction.

Parameters

The following table shows the parameters of the instruction "Demultiplex":

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
K	Input	Integers	Integers	I, Q, M, D, L, P, or constant	Specifies the output to which the input value (IN) is copied. • If K = 0 => Parameter OUT0 • If K = 1 => Parameter OUT1, etc.
IN	Input	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P, or constant	Input value
OUT0	Output	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	First output

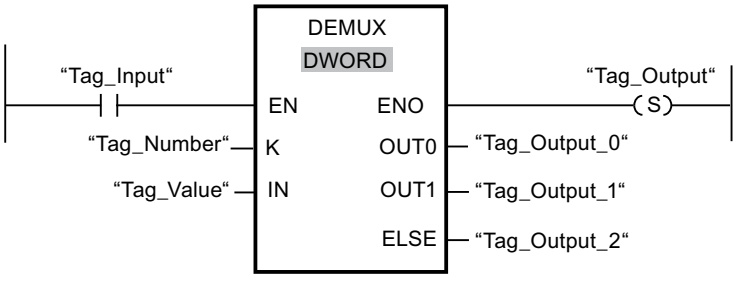
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
OUT1	Output	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	Second output
OUTn	Output	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	Optional outputs
ELSE	Output	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	Output to which the input value (IN) at K > n is copied.

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on available data types, refer to "See also".

Example

The following example shows how the instruction works:



The following tables show how the instruction works using specific operand values:

Table 11-24 Input values of the "Demultiplex" instruction before network execution

Parameter	Operand	Values	
K	Tag_Number	1	4
IN	Tag_Value	DW#16#FFFFFFFF	DW#16#003E4A7D

Table 11-25 Output values of the "Demultiplex" instruction after network execution

Parameter	Operand	Values	
OUT0	Tag_Output_0	Unchanged	Unchanged
OUT1	Tag_Output_1	DW#16#FFFFFFFF	Unchanged
ELSE	Tag_Output_2	Unchanged	DW#16#003E4A7D

If the "Tag_Input" has signal state "1", the instruction is executed. Depending on the value of the operand "Tag_Number", the value at input "IN" is copied to the corresponding output.

Overview of the valid data types (Page 1908)

Shift and rotate

SHR: Shift right

Description

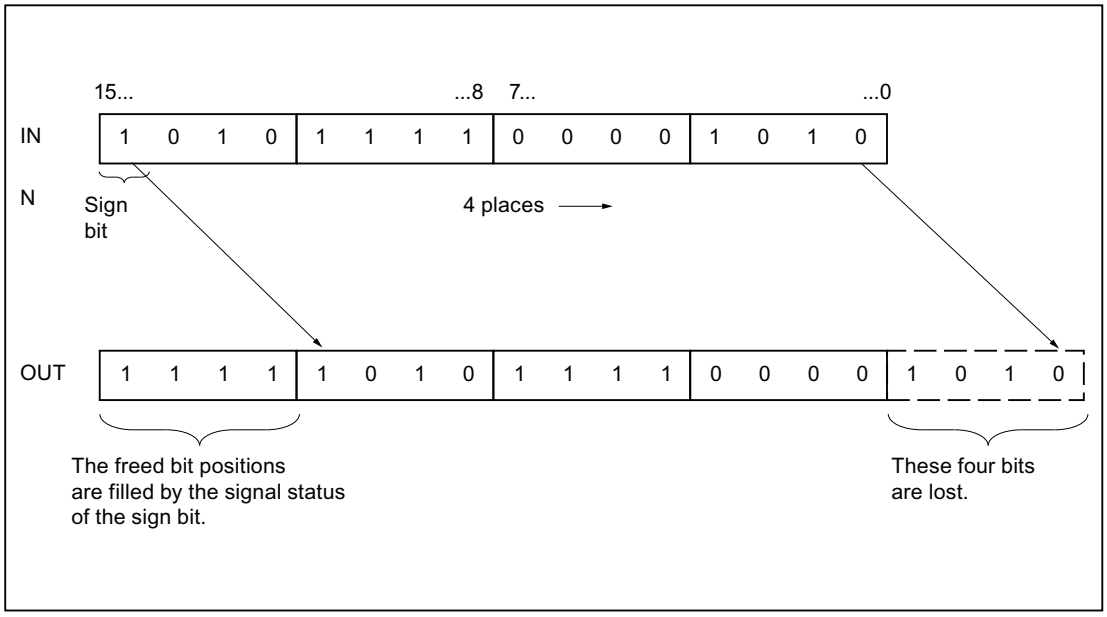
You can use the "Shift right" instruction to shift the content of the operand at the input IN bit-by-bit to the right and query the result at the OUT output. You use the N parameter to specify the number of bit positions by which the specified value is to be shifted.

When the value at the N parameter is "0", the value at the IN input is copied to the operand at the OUT output.

When the value at the N parameter is greater than the number of available bit positions, the operand value at the IN input is shifted by the available number of bit positions to the right.

The freed bit positions in the left area of the operand are filled by zeroes when values without signs are shifted. If the specified value has a sign, the free bit positions are filled with the signal state of the sign bit.

The following figure show how the content of an operand of integer data type is shifted four bit positions to the right:



Parameters

The following table shows the parameters of the instruction "Shift right":

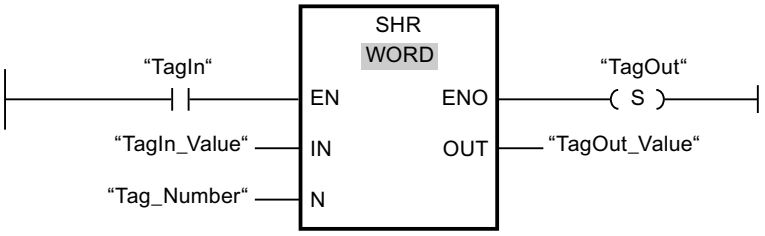
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L or constant	Value to be shifted
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L or constant	Number of bit positions by which the value is shifted
OUT	Output	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Result of the instruction

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	TagIn_Value	0011 1111 1010 1111
N	Tag_Number	3
OUT	TagOut_Value	0000 0111 1111 0101

If operand "TagIn" has the signal state "1", the "Shift right" instruction is executed. The content of operand "TagIn_Value" is shifted three bit positions to the right. The result is sent to the "TagOut_Value" output. If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

Overview of the valid data types (Page 1908)

SHL: Shift left

Description

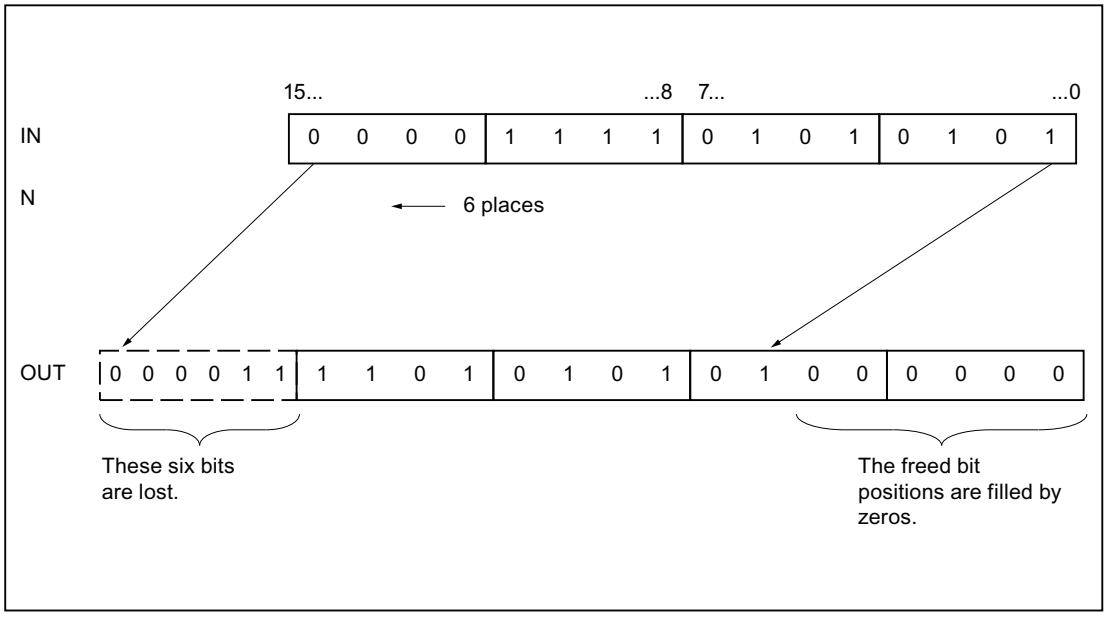
You can use the "Shift left" instruction to shift the content of the operand at the input IN bit-by-bit to the left and query the result at the OUT output. You use the N parameter to specify the number of bit positions by which the specified value is to be shifted.

When the value at the N parameter is "0", the value at the IN input is copied to the operand at the OUT output.

When the value at the N parameter is greater than the number of available bit positions, the operand value at the IN input is shifted by the available number of bit positions to the left.

The bit positions in the right part of the operand freed by shifting are filled with zeros.

The following figure shows how the content of an operand of the WORD data type is shifted by six bit positions to the left:



Parameters

The following table shows the parameters of the instruction "Shift left":

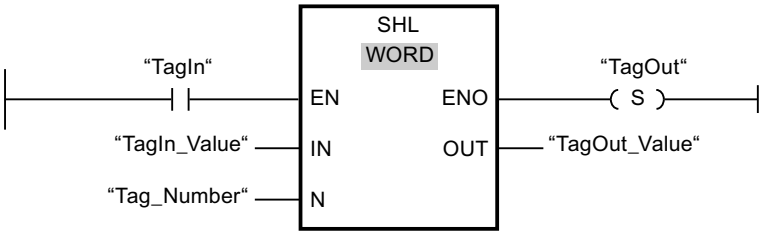
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L or constant	Value to be shifted
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L or constant	Number of bit positions by which the value is shifted
OUT	Output	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Result of the instruction

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	TagIn_Value	0011 1111 1010 1111
N	Tag_Number	4
OUT	TagOut_Value	1111 1010 1111 0000

If operand "TagIn" has the signal state "1", the "Shift left" instruction is executed. The content of operand "TagIn_Value" is shifted four bit positions to the left. The result is sent to the "TagOut_Value" output. If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

Overview of the valid data types (Page 1908)

ROR: Rotate right

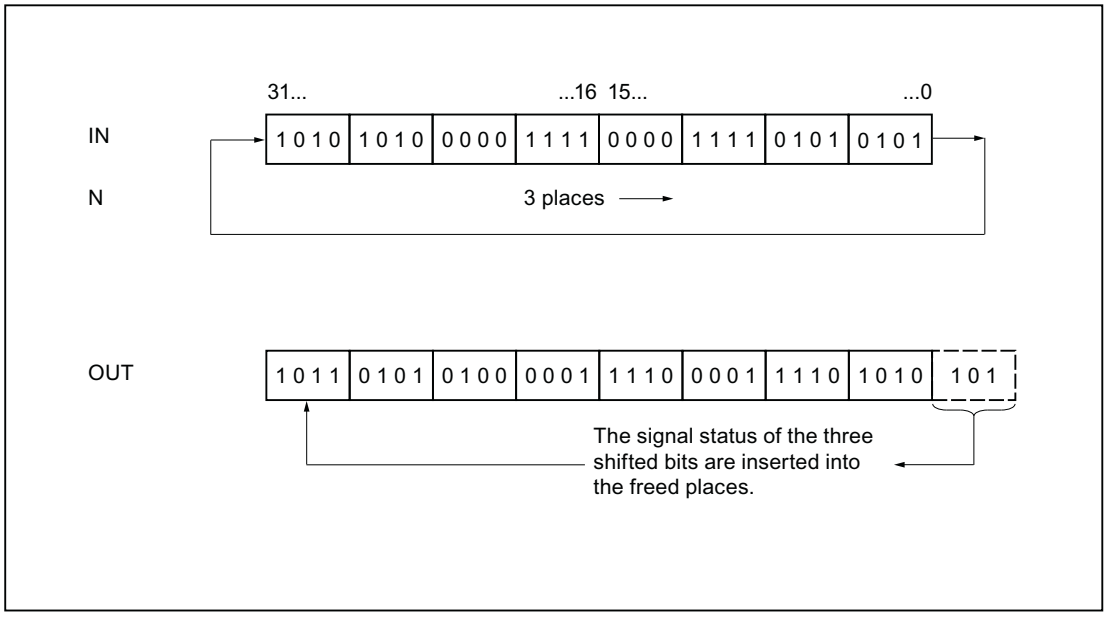
Description

You can use the "Rotate right" instruction to rotate the content of the operand at the input IN bit-by-bit to the right and query the result at the OUT output. You use the N parameter to specify the number of bit positions by which the specified value is to be rotated. The bit positions freed by rotating are filled with the bit positions that are pushed out.

When the value at the N parameter is "0", the value at the IN input is copied to the operand at the OUT output.

If the value at the parameter N is greater than the number of available bit positions, the operand value at input IN is nevertheless rotated by the specified number of bit positions.

The following figure shows how the content of an operand of DWORD data type is rotated three positions to the right:



Parameters

The following table shows the parameters of the instruction "Rotate right":

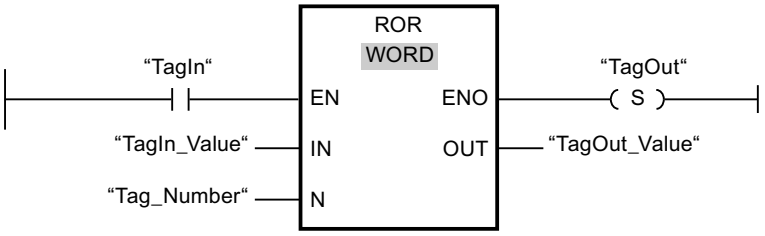
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L or constant	Value to be rotated
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L or constant	Number of bit positions by which the value is rotated
OUT	Output	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Result of the instruction

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	TagIn_Value	0000 1111 1001 0101
N	Tag_Number	5
OUT	TagOut_Value	1010 1000 0111 1100

If operand "TagIn" has the signal state "1", the "Rotate right" instruction is executed. The content of operand "TagIn_Value" is rotated five bit positions to the right. The result is sent to the "TagOut_Value" output. If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

ROL: Rotate left

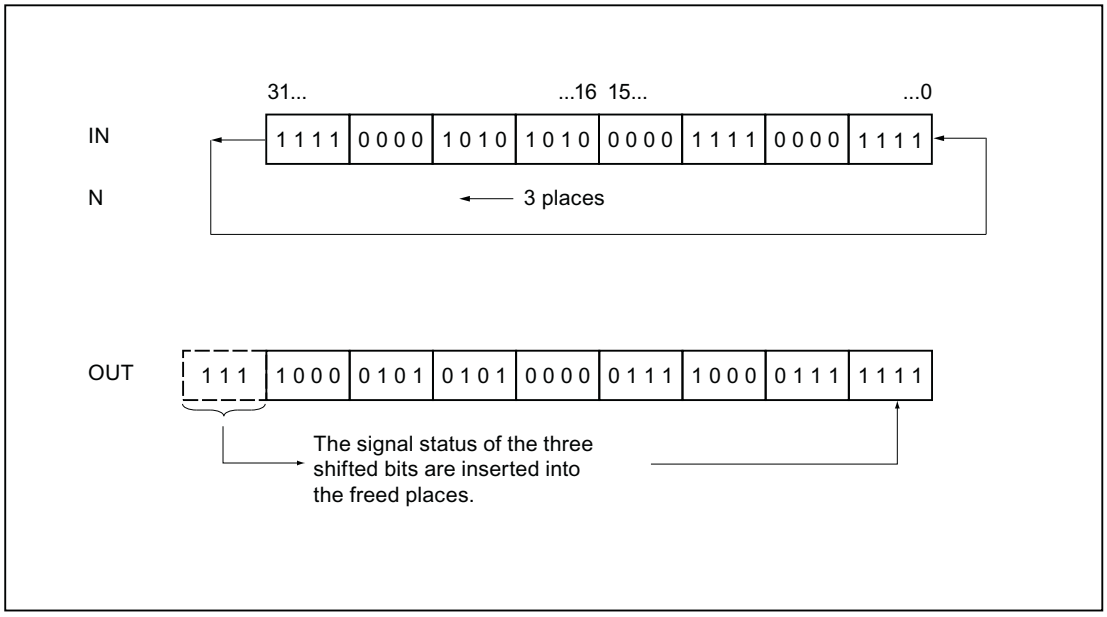
Description

You can use the "Rotate left" instruction to rotate the content of the operand at the input IN bit-by-bit to the left and query the result at the OUT output. You use the N parameter to specify the number of bit positions by which the specified value is to be rotated. The bit positions freed by rotating are filled with the bit positions that are pushed out.

When the value at the N parameter is "0", the value at the IN input is copied to the operand at the OUT output.

If the value at the parameter N is greater than the number of available bit positions, the operand value at input IN is nevertheless rotated by the specified number of bit positions.

The following figure shows how the content of an operand of DWORD data type is rotated three positions to the left:



Parameters

The following table shows the parameters of the instruction "Rotate left":

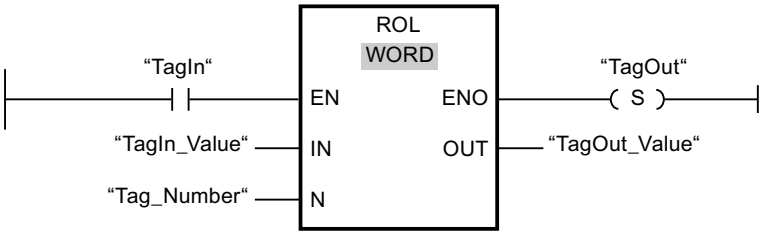
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L or constant	Value to be rotated
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L or constant	Number of bit positions by which the value is rotated
OUT	Output	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Result of the instruction

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	TagIn_Value	1010 1000 1111 0110
N	Tag_Number	5
OUT	TagOut_Value	0001 1110 1101 0101

If input "TagIn" has the signal state "1", the instruction "Rotate left" is executed. The content of operand "TagIn_Value" is rotated five bit positions to the left. The result is sent to the "TagOut_Value" output. If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

DRUM: Implement sequencer

Description

You can use the "Implement sequencer" instruction to assign the programmed values of the OUT_VAL parameter of the corresponding step to the programmed output bits (OUT1 to OUT16) and the output word (OUT_WORD). The specific step must thereby satisfy the conditions of the programmed enable mask on the S_MASK parameter while the instruction remains at this step. The instruction advances to the next step if the event for the step is true and the programmed time for the current step elapses, or if the value at the JOG parameter changes from "0" to "1". The instruction is reset if the signal state on the RESET parameter changes to "1". The current step is hereby equated to the preset step (DSP).

The amount of time spent on a step is determined by the product of the preset timebase (DTBP) and the preset counter value (S_PRESET) for each step. At the start of a new step, this calculated value is loaded into the DCC parameter, which contains the time remaining for the current step. If, for example the value at the DTBP parameter is "2" and the preset value for the first step is "100" (100 ms), the DCC parameter has the value "200" (200 ms).

A step can be programmed with a timer value, an event, or both. Steps that have an event bit and the timer value "0" advance to the next step as soon as the signal state of the event bit is

"1". Steps that are programmed only with a timer value start the time immediately. Steps that are programmed with an event bit and a timer value greater than "0" start the time when the signal state of the event bit is "1". The event bits are initialized with a signal state of "1".

When the sequencer is on the last programmed step (LST_STEP) and the time for this step has expired, the signal state on the Q parameter is set to "1"; otherwise it is set to "0". When the parameter Q is set, the instruction remains on the step until it is reset.

In the configurable mask (S_MASK), you can select the individual bits in the output word (OUT_WORD) and set or reset the output bits (OUT1 to OUT16) by means of the output values (OUT_VAL). If a bit of the configurable mask has signal state "1", the OUT_VAL value sets or resets the corresponding bit. If the signal state of a bit of the configurable mask is "0", the corresponding bit is left unchanged. All the bits of the configurable mask for all 16 steps are initialized with a signal state of "1".

The output bit at the OUT1 parameter corresponds to the least significant bit of the output word (OUT_WORD). The output bit at the OUT16 parameter corresponds to the most significant bit of the output word (OUT_WORD).

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, it is saved to the "Program resources" folder in the "Program blocks > System blocks" path of the project tree. For additional information on this topic, refer to "See also".

Parameters

The following table shows the parameters of the "Implement sequencer" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
RESET	Input	BOOL	I, Q, M, D, L or constant	The signal state "1" indicates the reset condition.
JOG	Input	BOOL	I, Q, M, D, L or constant	When the signal state changes from "0" to "1", the instruction advances to the next step.
DRUM_EN	Input	BOOL	I, Q, M, D, L or constant	The signal state "1" causes the sequencer to advance based on the event and time criteria.
LST_STEP	Input	BYTE	I, Q, M, D, L or constant	Number of the last programmed step.
EVENT(i), 1 ≤ i ≤ 16	Input	BOOL	I, Q, M, D, L or constant	Event bit (i); Initial signal state is "1".
OUT(j), 1 ≤ j ≤ 16	Output	BOOL	I, Q, M, D, L	Output bit (j)
Q	Output	BOOL	I, Q, M, D, L	The signal state "1" indicates that the time for the last step has elapsed.

Parameter	Declaration	Data type	Memory area	Description
OUT_WORD	Output	WORD	I, Q, M, D, L, P	Word address to which the sequencer writes the output values.
ERR_CODE	Output	WORD	I, Q, M, D, L, P	Error information
JOG_HIS	Static	BOOL	I, Q, M, D, L	JOG parameter history bit
EOD	Static	BOOL	I, Q, M, D, L or constant	The signal state "1" indicates that the time for the last step has elapsed.
DSP	Static	BYTE	I, Q, M, D, L, P, or constant	Preset step of the sequencer
DSC	Static	BYTE	I, Q, M, D, L, P, or constant	Current step of the sequencer
DCC	Static	DWORD	I, Q, M, D, L, P, or constant	Current numerical value of the sequencer
DTBP	Static	WORD	I, Q, M, D, L, P, or constant	Preset timebase of the sequencer
PrevTime	Static	TIME	I, Q, M, D, L or constant	Previous system time
S_PRESET	Static	ARRAY[1..16] of WORD	I, Q, M, D, L or constant	Preset count for each step [1 to 16]; where 1 clock pulse = 1 ms.
OUT_VAL	Static	ARRAY[1..16, 0..15] of BOOL	I, Q, M, D, L or constant	Output values for each step [1 to 16, 0 to 15].
S_MASK	Static	ARRAY[1..16, 0..15] of BOOL	I, Q, M, D, L or constant	Configurable mask for each step [1 to 16, 0 to 15]. Initial signal states are "1".

For additional information on valid data types, refer to "See also".

Parameter ERR_CODE

The following table shows the meaning of the values of the ERR_CODE parameter:

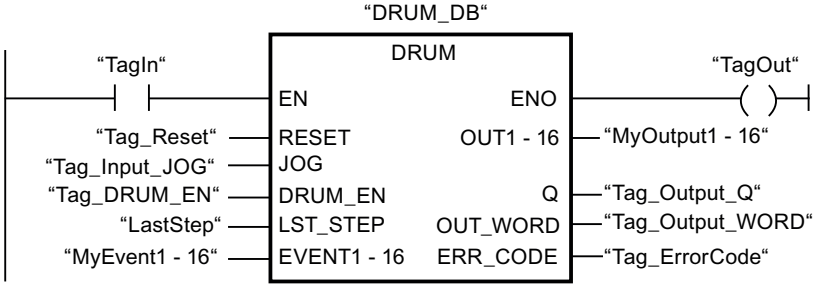
ERR_CODE*	Explanation
W#16#0000	No error
W#16#000B	The value at the LST_STEP parameter is less than 1 or greater than 16.
W#16#000C	The value at the DSC parameter is less than 1 or greater than the value of the LST_STEP parameter.
W#16#000D	The value at the DSP parameter is less than 1 or greater than the value of the LST_STEP parameter.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

In the following example the instruction advances from step 1 to step 2. The output bits (OUT1 to OUT16) and the output word (OUT_WORD) are set according to the mask configured for step 2 and the values of the OUT_VAL parameter.

Note

You can initialize static parameters in the data block.



The following tables show how the instruction works using specific values.

Before processing

In this example, the following values are used for initializing the input parameters:

Parameter	Operand	Address	Value
RESET	Tag_Reset	M0.0	FALSE
JOG	Tag_Input_JOG	M0.1	FALSE
DRUM_EN	Tag_Input_DrumEN	M0.2	TRUE
LST_STEP	Tag_Number_LastStep	MB1	B#16#08
EVENT2	MyTag_Event_2	M20.0	FALSE
EVENT4	MyTag_Event_4	M20.1	FALSE
EVENT6	MyTag_Event_6	M20.2	FALSE
EVENT8	MyTag_Event_8	M20.3	FALSE
EVENT10	MyTag_Event_10	M20.4	FALSE
EVENT12	MyTag_Event_12	M20.5	FALSE
EVENT14	MyTag_Event_14	M20.6	FALSE
EVENT16	MyTag_Event_16	M20.7	FALSE

The following values are saved in the "DRUM_DB" instance data block of the instruction:

Parameter	Address	Value
JOG_HIS	DBX12.0	FALSE
EOD	DBX12.1	FALSE
DSP	DBB13	W#16#0001
DSC	DBB14	W#16#0001
DCC	DBD16	DW#16#0000000A

Parameter	Address	Value
DTBP	DBW20	W#16#0001
S_PRESET[1]	DBW26	W#16#0064
S_PRESET[2]	DBW28	W#16#00C8
OUT_VAL[1,0]	DBX58.0	TRUE
OUT_VAL[1,1]	DBX58.1	TRUE
OUT_VAL[1,2]	DBX58.2	TRUE
OUT_VAL[1,3]	DBX58.3	TRUE
OUT_VAL[1,4]	DBX58.4	TRUE
OUT_VAL[1,5]	DBX58.5	TRUE
OUT_VAL[1,6]	DBX58.6	TRUE
OUT_VAL[1,7]	DBX58.7	TRUE
OUT_VAL[1,8]	DBX59.0	TRUE
OUT_VAL[1,9]	DBX59.1	TRUE
OUT_VAL[1,10]	DBX59.2	TRUE
OUT_VAL[1,11]	DBX59.3	TRUE
OUT_VAL[1,12]	DBX59.4	TRUE
OUT_VAL[1,13]	DBX59.5	TRUE
OUT_VAL[1,14]	DBX59.6	TRUE
OUT_VAL[1,15]	DBX59.7	TRUE
OUT_VAL[2,0]	DBX60.0	FALSE
OUT_VAL[2,1]	DBX60.1	FALSE
OUT_VAL[2,2]	DBX60.2	FALSE
OUT_VAL[2,3]	DBX60.3	FALSE
OUT_VAL[2,4]	DBX60.4	FALSE
OUT_VAL[2,5]	DBX60.5	FALSE
OUT_VAL[2,6]	DBX60.6	FALSE
OUT_VAL[2,7]	DBX60.7	FALSE
OUT_VAL[2,8]	DBX61.0	FALSE
OUT_VAL[2,9]	DBX61.1	FALSE
OUT_VAL[2,10]	DBX61.2	FALSE
OUT_VAL[2,11]	DBX61.3	FALSE
OUT_VAL[2,12]	DBX61.4	FALSE
OUT_VAL[2,13]	DBX61.5	FALSE
OUT_VAL[2,14]	DBX61.6	FALSE
OUT_VAL[2,15]	DBX61.7	FALSE
S_MASK[2,0]	DBX92.0	FALSE
S_MASK[2,1]	DBX92.1	TRUE
S_MASK[2,2]	DBX92.2	TRUE
S_MASK[2,3]	DBX92.3	TRUE
S_MASK[2,4]	DBX92.4	TRUE
S_MASK[2,5]	DBX92.5	FALSE
S_MASK[2,6]	DBX92.6	TRUE
S_MASK[2,7]	DBX92.7	TRUE

Parameter	Address	Value
S_MASK[2,8]	DBX93.0	FALSE
S_MASK[2,9]	DBX93.1	FALSE
S_MASK[2,10]	DBX93.2	TRUE
S_MASK[2,11]	DBX93.3	TRUE
S_MASK[2,12]	DBX93.4	TRUE
S_MASK[2,13]	DBX93.5	TRUE
S_MASK[2,14]	DBX93.6	FALSE
S_MASK[2,15]	DBX93.7	TRUE

The output parameters are set to the following values before the execution of the instruction:

Parameter	Operand	Address	Value
Q	Tag_Output_Q	M6.0	FALSE
OUTWORD	Tag_OutputWord	MW8	W#16#FFFF
OUT1	MyTag_Output_1	M4.0	TRUE
OUT2	MyTag_Output_2	M4.1	TRUE
OUT3	MyTag_Output_3	M4.2	TRUE
OUT4	MyTag_Output_4	M4.3	TRUE
OUT5	MyTag_Output_5	M4.4	TRUE
OUT6	MyTag_Output_6	M4.5	TRUE
OUT7	MyTag_Output_7	M4.6	TRUE
OUT8	MyTag_Output_8	M4.7	TRUE
OUT9	MyTag_Output_9	M5.0	TRUE
OUT10	MyTag_Output_10	M5.1	TRUE
OUT11	MyTag_Output_11	M5.2	TRUE
OUT12	MyTag_Output_12	M5.3	TRUE
OUT13	MyTag_Output_13	M5.4	TRUE
OUT14	MyTag_Output_14	M5.5	TRUE
OUT15	MyTag_Output_15	M5.6	TRUE
OUT16	MyTag_Output_16	M5.7	TRUE

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameter	Operand	Address	Value
OUT1	MyTag_Output_1	M4.0	TRUE
OUT2	MyTag_Output_2	M4.1	FALSE
OUT3	MyTag_Output_3	M4.2	FALSE
OUT4	MyTag_Output_4	M4.3	FALSE
OUT5	MyTag_Output_5	M4.4	FALSE
OUT6	MyTag_Output_6	M4.5	TRUE
OUT7	MyTag_Output_7	M4.6	FALSE

Parameter	Operand	Address	Value
OUT8	MyTag_Output_8	M4.7	FALSE
OUT9	MyTag_Output_9	M5.0	TRUE
OUT10	MyTag_Output_10	M5.1	TRUE
OUT11	MyTag_Output_11	M5.2	FALSE
OUT12	MyTag_Output_12	M5.3	FALSE
OUT13	MyTag_Output_13	M5.4	FALSE
OUT14	MyTag_Output_14	M5.5	FALSE
OUT15	MyTag_Output_15	M5.6	TRUE
OUT16	MyTag_Output_16	M5.7	FALSE
Q	Tag_Output_Q	M6.0	FALSE
OUTWORD	Tag_OutputWord	MW8	W#16#4321
ERR_CODE	Tag_ErrorCode	MW10	W#16#0000

The following values are changed in the instance data block "DRUM_DB" of the instruction after the execution of the instruction:

Parameter	Address	Value
JOG_HIS	DBX12.0	FALSE
EOD	DBX12.1	FALSE
DSC	DBB14	W#16#0002
DCC	DBD16	DW#16#000000C8

Overview of the valid data types (Page 1908)

DCAT: Discrete control-timer alarm

Description

The instruction "Discrete control-timer alarm" is used to accumulate the time from the point at which the CMD parameter issued the command to open or close. The time is accumulated until the preset time (PT) is exceeded or the information is received that the device was opened or closed (O_FB or C_FB) within the specified time. If the preset time is exceeded before the information on the opening or closing of the device is received, the corresponding alarm is activated. If the signal state of the command input changes state before the preset time, the time is restarted.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

The "Discrete control-timer alarm" instruction has the following reactions to the input conditions:

- When the signal state of the CMD parameter changes from "0" to "1", the signal states of the parameters Q, CMD_HIS, ET (only if ET < PT), OA and CA are influenced as follows:
  - The parameters Q and CMD_HIS are set to "1".
  - The parameters ET, OA and CA are reset to "0".
- When the signal state of the parameter CMD changes from "1" to "0", the parameters Q, ET (only if ET < PT), OA, CA and CMD_HIS are reset to "0".
- When the signal state of the parameters CMD and CMD_HIS is "1" and the parameter O_FB is set to "0", the time difference (ms) since the last execution of the instruction is added to the value at the parameter ET. If the value of the parameter ET exceeds the value of the parameter PT, the signal state on the parameter OA is set to "1". If the value of the ET parameter does not exceed the value of the parameter PT, the signal state on the parameter OA is reset to "0". The value at the parameter CMD_HIS is reset to the value of the parameter CMD.
- If the signal state of the CMD, CMD_HIS and O_FB parameters are set to "1" and the parameter C_FB has the value "0", the signal state of the parameter OA is set to "0". The value of the parameter ET is set to the value of the parameter PT. If the signal state of the O_FB parameter changes to "0", the alarm is set the next time the instruction is executed. The value of the parameter CMD_HIS is set to the value of the parameter CMD.
- If the parameters CMD, CMD_HIS and C_FB have the value "0", the time difference (ms) since the last execution of the instruction is added to the value of the parameter ET. If the value of the ET parameter exceeds the value of the parameter PT, the signal state of the parameter CA is reset to "1". If the value at the parameter PT is not exceeded, the parameter CA has the signal state "0". The value of the parameter CMD_HIS is set to the value of the parameter CMD.
- If the parameters CMD, CMD_HIS and O_FB have the signal state "0" and the parameter C_FB is set to "1", the parameter CA is set to "0". The value of the parameter ET is set to the value of the parameter PT. If the signal state of the C_FB parameter changes to "0", the alarm is set the next time the instruction is executed. The value of the parameter CMD_HIS is set to the value of the parameter CMD.
- If the parameters O_FB and C_FB simultaneously have the signal state "1", the signal states of both alarm outputs are set to "1".

The "Discrete control-timer alarm" instruction returns no error information.

Parameters

The following table shows the parameters of the "Discrete control-timer alarm" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
CMD	Input	BOOL	I, Q, M, D, L or constant	The signal state "0" indicates a "close" command. The signal state "1" indicates the "open" command.

Parameter	Declaration	Data type	Memory area	Description
O_FB	Input	BOOL	I, Q, M, D, L or constant	Feedback input when opening
C_FB	Input	BOOL	I, Q, M, D, L or constant	Feedback input when closing
Q	Output	BOOL	I, Q, M, D, L	Shows the status of the parameter CMD
OA	Output	BOOL	I, Q, M, D, L	Alarm output when opening
CA	Output	BOOL	I, Q, M, D, L	Alarm output when closing
ET	Static	DINT	D, L or constant	Currently elapsed time, where one clock pulse = 1 ms
PT	Static	DINT	D, L or constant	Preset timer value, where one clock pulse = 1 ms
PREV_TIME	Static	DWORD	D, L or constant	Previous system time
CMD_HIS	Static	BOOL	D, L or constant	CMD history bit

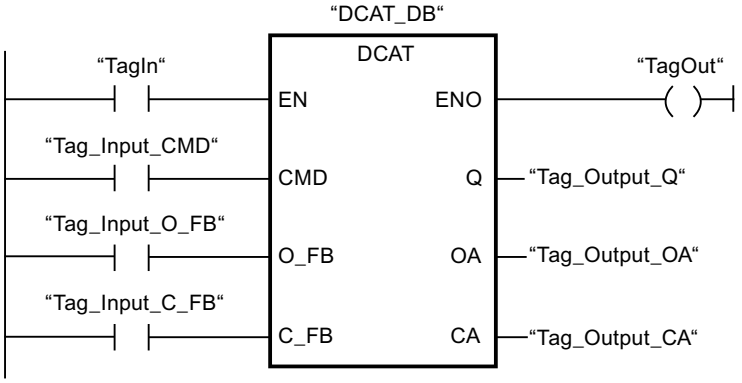
For additional information on valid data types, refer to "See also".

Example

In the following example the parameter CMD changes from "0" to "1". After the execution of the instruction the parameter Q is set to "1" and the two alarm outputs OA and CA have the signal state "0". The parameter CMD_HIS of the instance data block is set to the signal state "1" and the parameter ET is reset to "0".

Note

You can initialize static parameters in the data block.



The following tables show how the instruction works using specific values.

Before processing

In this example, the following values are used for the input and output parameters:

Parameter	Operand	Value
CMD	Tag_Input_CMD	TRUE
O_FB	Tag_Input_O_FB	FALSE
C_FB	Tag_Input_C_FB	FALSE
Q	Tag_Output_Q	FALSE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE

The following values are saved in the instance data block "DCAT_DB" of the instruction:

Parameter	Address	Value
ET	DBD4	L#12
PT	DBD8	L#222
CMD_HIS	DBX16.0	FALSE

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameter	Operand	Value
Q	Tag_Output_Q	TRUE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE

The following values are saved in the instance data block "DCAT_DB" of the instruction:

Parameter	Address	Value
ET	DBD4	L#0
CMD_HIS	DBX16.0	TRUE

Overview of the valid data types (Page 1908)

MCAT: Motor control-timer alarm

Description

The instruction "Motor control-timer alarm" is used to accumulate the time from the point in time as of which one of the command inputs (open or close) is activated. The time is accumulated until the preset time is exceeded or the relevant feedback input indicates that the device has executed the requested operation within the specified time. If the preset time is exceeded before the feedback is received, the corresponding alarm is triggered.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single

instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

Execution of the "Motor control-timer alarm" instruction

The following table shows the reactions of the "Motor control-timer alarm" instruction to the various input conditions:

Input parameters								Output parameters								
ET	O_HIS	C_HIS	O_CMD	C_CMD	S_CMD	O_FB	C_FB	OO	CO	OA	CA	ET	O_HIS	C_HIS	Q	Status
X	1	1	X	X	X	X	X	0	0	1	1	PT	0	0	0	Alarm
X	X	X	X	X	X	1	1	0	0	1	1	PT	0	0	0	Alarm
X	X	X	X	X	1	X	X	0	0	0	0	X	0	0	1	Stop
X	X	X	1	1	X	X	X	0	0	0	0	X	0	0	1	Stop
X	0	X	1	0	0	X	X	1	0	0	0	0	1	0	1	Start opening
<PT	1	0	X	0	0	0	X	1	0	0	0	INC	1	0	1	Open
X	1	0	X	0	0	1	0	0	0	0	0	PT	1	0	1	Opened
>=PT	1	0	X	0	0	0	X	0	0	1	0	PT	1	0	0	Opening alarm
X	X	0	0	1	0	X	X	0	1	0	0	0	0	1	1	Start closing
<PT	0	1	0	X	0	X	0	0	1	0	0	INC	0	1	1	Close
X	0	1	0	X	0	0	1	0	0	0	0	PT	0	1	1	Closed
>=PT	0	1	0	X	0	X	0	0	0	0	1	PT	0	1	0	Closing alarm
X	0	0	0	0	0	X	X	0	0	0	0	X	0	0	1	Stopped

Legend:	
INC	Add the time difference (ms) since the last processing of the FB to ET
PT	PT is set to the same value as ET
X	Cannot be used
<PT	ET < PT
>=PT	ET >= PT

If the input parameters O_HIS and C_HIS both have the signal state "1", they are immediately set to signal state "0". In this case, the last row in the table (X) mentioned above is valid. Because it is therefore no longer possible to check whether the input parameters O_HIS and C_HIS have the signal state "1", the output parameters are set as follows in this case:

OO = FALSE

CO = FALSE

OA = FALSE

CA = FALSE

ET = PT

Q = TRUE

The "Motor control-timer alarm" instruction returns no error information.

Parameters

The following table shows the reactions of the "Motor control-timer alarm" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
O_CMD	Input	BOOL	I, Q, M, D, L or constant	"Open" command input
C_CMD	Input	BOOL	I, Q, M, D, L or constant	"Close" command input
S_CMD	Input	BOOL	I, Q, M, D, L or constant	"Stop" command input
O_FB	Input	BOOL	I, Q, M, D, L or constant	Feedback input when opening
C_FB	Input	BOOL	I, Q, M, D, L or constant	Feedback input when closing
OO	Output	BOOL	I, Q, M, D, L	"Open" output
CO	Output	BOOL	I, Q, M, D, L	"Close" output
OA	Output	BOOL	I, Q, M, D, L	Alarm output when opening
CA	Output	BOOL	I, Q, M, D, L	Alarm output when closing
Q	Output	BOOL	I, Q, M, D, L	The signal state "0" indicates an error condition.
ET	Static	DINT	D, L or constant	Currently elapsed time, where one clock pulse = 1 ms
PT	Static	DINT	D, L or constant	Preset timer value, where one clock pulse = 1 ms
PREV_TIME	Static	DWORD	D, L or constant	Previous system time
O_HIS	Static	BOOL	D, L or constant	"Open" history bit
C_HIS	Static	BOOL	D, L or constant	"Close" history bit

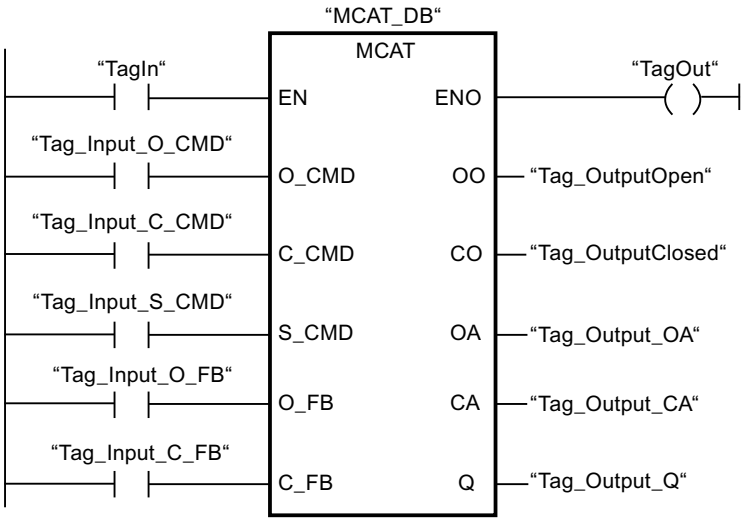
For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

Note

You can initialize static parameters in the data block.



The following tables show how the instruction works using specific values.

Before processing

In this example, the following values are used for the input and output parameters:

Parameter	Operand	Value
O_CMD	Tag_Input_O_CMD	TRUE
C_CMD	Tag_Input_C_CMD	FALSE
S_CMD	Tag_Input_S_CMD	FALSE
O_FB	Tag_Input_O_FB	FALSE
C_FB	Tag_Input_C_FB	FALSE
OO	Tag_OutputOpen	FALSE
CO	Tag_OutputClosed	FALSE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE
Q	Tag_Output_Q	FALSE

The following values are saved in the instance data block "MCAT_DB" of the instruction:

Parameter	Address	Value
ET	DBD4	L#2
PT	DBD8	L#22
O_HIS	DBX16.0	TRUE
C_HIS	DBX16.1	FALSE

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameter	Operand	Value
OO	Tag_OutputOpen	TRUE
CO	Tag_OutputClosed	FALSE

Parameter	Operand	Value
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE
Q	Tag_Output_Q	TRUE

The following values are saved in the instance data block "MCAT_DB" of the instruction:

Parameter	Address	Value
ET	DBD4	L#0
O_HIS	DBX16.0	TRUE
CMD_HIS	DBX16.1	FALSE

Overview of the valid data types (Page 1908)

IMC: Compare input bits with the bits of a mask

Description

The instruction "Compare input bits with the bits of a mask" is used to compare the signal state of up to 16 programmed input bits (IN_BIT0 to IN_BIT15) with the corresponding bits of a mask. Up to 16 steps with masks can be programmed. The value of the IN_BIT0 parameter is compared with the value of the mask CMP_VAL[x,0], with "x" indicating the step number. On the CMP_STEP parameter, you specify the step number of the mask that is used for the comparison. All programmed values are compared in the same manner. Unprogrammed input bits or unprogrammed bits of the mask have the default signal state FALSE.

If a match is found in the comparison, the signal state of the OUT parameter is set to "1". Otherwise, the OUT parameter is set to "0".

If the value of the CMP_STEP parameter is greater than 15, the instruction is not executed. An error message is output at the ERR_CODE parameter.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

Parameters

The following table shows the parameters of the "Compare input bits with the bits of a mask" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output

Parameter	Declaration	Data type	Memory area	Description
IN_BIT0	Input	BOOL	I, Q, M, D, L or constant	Input bit 0 is compared with bit 0 of the mask.
IN_BIT1	Input	BOOL	I, Q, M, D, L or constant	Input bit 1 is compared with bit 1 of the mask.
IN_BIT2	Input	BOOL	I, Q, M, D, L or constant	Input bit 2 is compared with bit 2 of the mask.
IN_BIT3	Input	BOOL	I, Q, M, D, L or constant	Input bit 3 is compared with bit 3 of the mask.
IN_BIT4	Input	BOOL	I, Q, M, D, L or constant	Input bit 4 is compared with bit 4 of the mask.
IN_BIT5	Input	BOOL	I, Q, M, D, L or constant	Input bit 5 is compared with bit 5 of the mask.
IN_BIT6	Input	BOOL	I, Q, M, D, L or constant	Input bit 6 is compared with bit 6 of the mask.
IN_BIT7	Input	BOOL	I, Q, M, D, L or constant	Input bit 7 is compared with bit 7 of the mask.
IN_BIT8	Input	BOOL	I, Q, M, D, L or constant	Input bit 8 is compared with bit 8 of the mask.
IN_BIT9	Input	BOOL	I, Q, M, D, L or constant	Input bit 9 is compared with bit 9 of the mask.
IN_BIT10	Input	BOOL	I, Q, M, D, L or constant	Input bit 10 is compared with bit 10 of the mask.
IN_BIT11	Input	BOOL	I, Q, M, D, L or constant	Input bit 11 is compared with bit 11 of the mask.
IN_BIT12	Input	BOOL	I, Q, M, D, L or constant	Input bit 12 is compared with bit 12 of the mask.
IN_BIT13	Input	BOOL	I, Q, M, D, L or constant	Input bit 13 is compared with bit 13 of the mask.
IN_BIT14	Input	BOOL	I, Q, M, D, L or constant	Input bit 14 is compared with bit 14 of the mask.
IN_BIT15	Input	BOOL	I, Q, M, D, L or constant	Input bit 15 is compared with bit 15 of the mask.
CMP_STEP	Input	BYTE	I, Q, M, D, L, P or constant	The step number of the mask used for the comparison.
OUT	Output	BOOL	I, Q, M, D, L	The signal state "1" indicates that a match was found. The signal state "0" indicates that a match was found.
ERR_CODE	Output	WORD	I, Q, M, D, L, P	Error information
CMP_VAL	Static	ARRAY OF WORD	I, Q, M, D, L or constant	Comparison masks [0 to 15, 0 to 15]: The first number of the index is the step number and the second number is the bit number of the mask.

For additional information on valid data types, refer to "See also".

Parameters ERR_CODE

The following table shows the meaning of the values of the ERR_CODE parameter:

Error code* (W#16#...)	Explanation
0000	No error
000A	The value at the CMP_STEP parameter is greater than 15.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".

Overview of the valid data types (Page 1908)

SMC: Compare scan matrix

Description

The "Compare scan matrix" instruction is used to compare the signal state of up to 16 programmed input bits (IN_BIT0 to IN_BIT15) with the corresponding bits of the comparison masks for each step. Processing starts at step 1 and is continued until the last programmed step (LAST) or until a match is found. The input bit of the IN_BIT0 parameter is compared with the value of the mask CMP_VAL[x,0], with "x" indicating the step number. All programmed values are compared in the same manner. If a match is found the signal state of the OUT parameter is set to "1" and the step number with the matching mask is written in the OUT_STEP parameter. Unprogrammed input bits or unprogrammed bits of the mask have the default signal state FALSE. If more than one step has a matching mask, only the first one found is indicated in the OUT_STEP parameter. If no match is found, the signal state of the OUT parameter is set to "0". In this case the value at the OUT_STEP parameter is greater by "1" than the value of the LAST parameter.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

Parameters

The following table shows the parameters of the "Compare scan matrix" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN_BIT0	Input	BOOL	I, Q, M, D, L or constant	Input bit 0 is compared with bit 0 of the mask.

Parameter	Declaration	Data type	Memory area	Description
IN_BIT1	Input	BOOL	I, Q, M, D, L or constant	Input bit 1 is compared with bit 1 of the mask.
IN_BIT2	Input	BOOL	I, Q, M, D, L or constant	Input bit 2 is compared with bit 2 of the mask.
IN_BIT3	Input	BOOL	I, Q, M, D, L or constant	Input bit 3 is compared with bit 3 of the mask.
IN_BIT4	Input	BOOL	I, Q, M, D, L or constant	Input bit 4 is compared with bit 4 of the mask.
IN_BIT5	Input	BOOL	I, Q, M, D, L or constant	Input bit 5 is compared with bit 5 of the mask.
IN_BIT6	Input	BOOL	I, Q, M, D, L or constant	Input bit 6 is compared with bit 6 of the mask.
IN_BIT7	Input	BOOL	I, Q, M, D, L or constant	Input bit 7 is compared with bit 7 of the mask.
IN_BIT8	Input	BOOL	I, Q, M, D, L or constant	Input bit 8 is compared with bit 8 of the mask.
IN_BIT9	Input	BOOL	I, Q, M, D, L or constant	Input bit 9 is compared with bit 9 of the mask.
IN_BIT10	Input	BOOL	I, Q, M, D, L or constant	Input bit 10 is compared with bit 10 of the mask.
IN_BIT11	Input	BOOL	I, Q, M, D, L or constant	Input bit 11 is compared with bit 11 of the mask.
IN_BIT12	Input	BOOL	I, Q, M, D, L or constant	Input bit 12 is compared with bit 12 of the mask.
IN_BIT13	Input	BOOL	I, Q, M, D, L or constant	Input bit 13 is compared with bit 13 of the mask.
IN_BIT14	Input	BOOL	I, Q, M, D, L or constant	Input bit 14 is compared with bit 14 of the mask.
IN_BIT15	Input	BOOL	I, Q, M, D, L or constant	Input bit 15 is compared with bit 15 of the mask.
OUT	Output	BOOL	I, Q, M, D, L	The signal state "1" indicates that a match was found. The signal state "0" indicates that no match was found.
ERR_CODE	Output	WORD	I, Q, M, D, L, P	Error information
OUT_STEP	Output	BYTE	I, Q, M, D, L, P	Contains the step number with the matching mask or the step number which is greater by "1" than the value of the LAST parameter, provided no match is found.

Parameter	Declaration	Data type	Memory area	Description
LAST	Static	BYTE	I, Q, M, D, L, P or constant	Specifies the step number of the last step to be scanned for a matching mask.
CMP_VAL	Static	ARRAY OF WORD	I, Q, M, D, L or constant	Comparison masks [0 to 15, 0 to 15]: The first number of the index is the step number and the second number is the bit number of the mask.

For additional information on valid data types, refer to "See also".

Parameters ERR_CODE

The following table shows the meaning of the values of the ERR_CODE parameter:

Error code* (W#16#...)	Explanation
0000	No error
000E	The value at the LAST parameter is greater than 15.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".

Overview of the valid data types (Page 1908)

LEAD_LAG: Lead and lag algorithm

Description

The "Lead and lag algorithm" instruction is used to process signals with an analog tag. The gain value at the GAIN parameter must be greater than zero. The result of the instruction "Lead and lag algorithm" is calculated using the following equation:

$$OUT = \left[\frac{LG\_TIME}{LG\_TIME + SAMPLE\_T}\right] PREV\_OUT + GAIN \left[\frac{LD\_TIME + SAMPLE\_T}{LG\_TIME + SAMPLE\_T}\right] IN - GAIN \left[\frac{LD\_TIME}{LG\_TIME + SAMPLE\_T}\right] * PREV\_IN$$

The "Lead and lag algorithm" instruction supplies plausible results only when processing is in fixed program cycles. The same units must be specified for the LD_TIME, LG_TIME, and SAMPLE_T parameters. At LG_TIME > 4 + SAMPLE_T, the instruction approaches the following function:

OUT = GAIN * ((1 + LD_TIME * s) / (1 + LG_TIME * s)) * IN

When the value of the GAIN parameter is less than or equal to zero, the calculation is not performed and an error information is output on the ERR_CODE parameter.

You can use the "Lead and lag algorithm" instruction in conjunction with loops as a compensator in dynamic feed-forward control. The instruction consists of two operations. The

"Lead" operation shifts the phase of the OUT output so that the output leads the input. The "Lag" operation, on the other hand, shifts the output so that the output lags behind the input. Because the "Lag" operation is equivalent to an integration, it can be used as a noise suppressor or as a low-pass filter. The "Lead" operation is equivalent to a differentiation and can therefore be used as a high-pass filter. The two operations together (Lead and Lag) result in the output phase lagging behind the the input at lower frequencies and leading it at higher frequencies. This means that the "Lead and lag algorithm" instruction can be used as a band pass filter.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

Parameters

The following table shows the parameters of the "Lead and lag algorithm" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	REAL	I, Q, M, D, L, P or constant	The input value of the current sample time (cycle time) to be processed. Constants can also be specified on the IN parameter.
SAMPLE_T	Input	INT	I, Q, M, D, L, P or constant	Sample time Constants can also be specified on the SAMPLE_T parameter.
OUT	Output	REAL	I, Q, M, D, L	Result of the instruction
ERR_CODE	Output	WORD	I, Q, M, D, L	Error information
LD_TIME	Static	REAL	I, Q, M, D, L, P or constant	Lead time in the same unit as sample time.
LG_TIME	Static	REAL	I, Q, M, D, L, P or constant	Lag time in in the same unit as sample time.
GAIN	Static	REAL	I, Q, M, D, L, P or constant	Gain as % / % (the ratio of the change in output to a change in input as a steady state).

Parameter	Declaration	Data type	Memory area	Description
PREV_IN	Static	REAL	I, Q, M, D, L, P or constant	Previous input
PREV_OUT	Static	REAL	I, Q, M, D, L, P or constant	Previous output

For additional information on valid data types, refer to "See also".

Parameter ERR_CODE

The following table shows the meaning of the values of the ERR_CODE parameter:

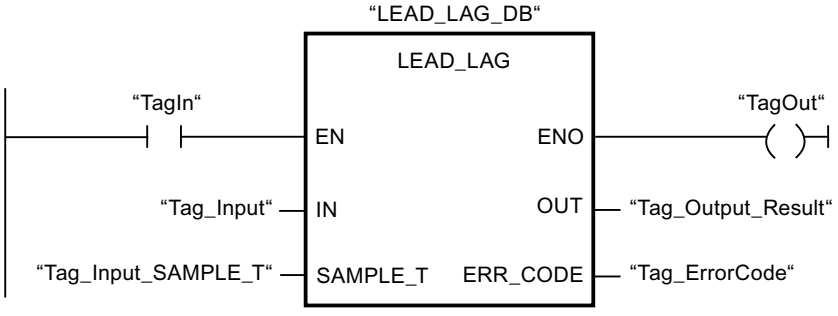
Error code* (W#16#...)	Explanation
0000	No error
0009	The value at the GAIN parameter is less than or equal to zero.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For additional information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

Note

You can initialize static parameters in the data block.



The following table shows how the instruction works using specific operand values:

Before processing

In this example the following values are used for the input parameters:

Parameter	Operand	Value
IN	Tag_Input	2.0
SAMPLE_T	Tag_InputSampleTime	10

The following values are saved in the instance data block "LEAD_LAG_DB" of the instruction:

Parameter	Address	Value
LD_TIME	DBD12	2.0
LG_TIME	DBD16	2.0
GAIN	DBD20	1.0
PREV_IN	DBD24	6.0
PREV_OUT	DBD28	6.0

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameter	Operand	Value
OUT	Tag_Output_Result	2.0

The following values are saved in the instance data block "LEAD_LAD_DB" of the instruction:

Parameter	Operand	Value
PREV_IN	DBD24	2.0
PREV_OUT	DBD28	2.0

Overview of the valid data types (Page 1908)

SEG: Create bit pattern for seven-segment display

Description

The instruction "Create bit pattern for seven-segment display" is used to convert each of the four hexadecimal digits of the specified source word (IN) into an equivalent bit pattern for a seven-segment display. The result of the instruction is output in the double word on the OUT parameter.

The following relation exists between the hexadecimal digits and the assignment of the 7 segments (a, b, c, d, e, f, g):

Input digit (Binary)	Assignment of the segments - g f e d c b a	Display (Hexadecimal)	Seven-segment display
0000	00111111	0	0001	00000110	1	
0010	01011011	2	
0011	01001111	3	
0100	01100110	4	
0101	01101101	5	
0110	01111101	6	
0111	00000111	7	
1000	01111111	8	
1001	01100111	9	
1010	01110111	A	
1011	01111100	B	
1100	00111001	C	
1101	01011110	D	
1110	01111001	E	
1111	01110001	F	

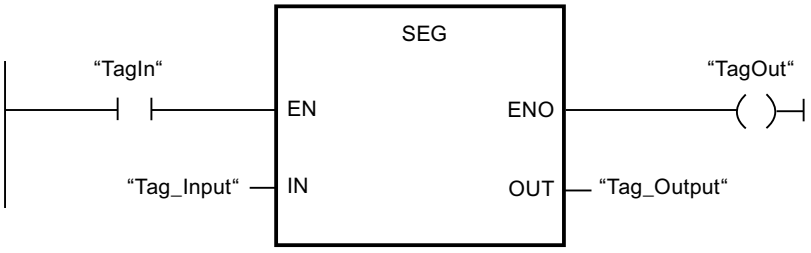
Parameter

The following table shows the parameters of the "Create bit pattern for seven-segment display" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	WORD	I, Q, M, D, L, P or constant	Source word with four hexadecimal digits
OUT	Output	DWORD	I, Q, M, D, L, P	Bit pattern for the seven-segment display

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value	
Hexadecimal	Binary		
IN	Tag_Input	W#16#1234	0001 0010 0011 0100
OUT	Tag_Output	DW#16065B4F66	000 00110 0101 1011 0100 1111 0110 0110 Display: 1234

BCDCPL: Create tens complement

Description

You can use the "Create tens complement" instruction to create the tens complement of a seven-digit BCD number specified in the IN parameter. This instruction uses the following mathematical formula to calculate:

10000000 (as BCD)

– 7-digit BCD value

Tens complement (as BCD)

Parameters

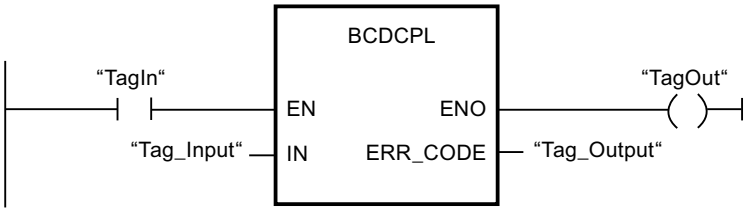
The following table shows the parameters of the "Create tens complement" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output

Parameter	Declaration	Data type	Memory area	Description
IN	Input	Bit strings	I, Q, M, D, L, P or constant	7-digit BCD number
ERR_CODE	Output	DWORD	I, Q, M, D, L, P	Result of the instruction

Example

The following example shows how the instruction works:



The following table shows how the instruction functions using specific values:

Parameter	Operand	Value*
IN	Tag_Input	DW#16#01234567
ERR_CODE	Tag_Output	DW#16#08765433
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".

BITSUM: Count number of set bits

Description

The "Count number of set bits" instruction is used to count the number of bits of an operand that is set to the signal state "1". The operand whose bits are to be counted is specified on the IN parameter. The result of the instruction is output on the RET_VAL parameter.

Parameters

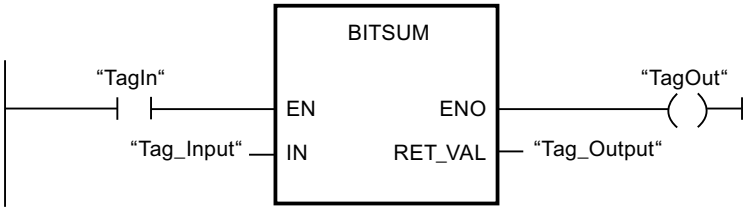
The following table shows the parameters of the "Count number of set bits" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output

Parameter	Declaration	Data type	Memory area	Description
IN	Input	DWORD	I, Q, M, D, L, P or constant	Operand whose set bits are counted
RET_VAL	Output	INT	I, Q, M, D, L, P	Number of bits to be set

Example

The following example shows how the instruction works:



The following table shows how the instruction functions using specific values:

Parameter	Operand	Value*
IN	Tag_Input	DW#16#12345678
RET_VAL	Tag_Output	W#16#000D (13 Bits)
*The error codes can be displayed as integer or hexadecimal value in the program editor. For additional information on toggling display formats, refer to "See also".

11.6.2.2 FBD

Bit logic operations

&: AND logic operation

Description

You can use the instruction "AND logic operation" to query the signal states of two or more specified operands and evaluate them according to the AND truth table.

If the signal state of all the operands is "1", then the condition is fulfilled and the instruction returns the result "1". If the signal state of one of the operands is "0", then the condition is not fulfilled and the instruction generates the result "0".

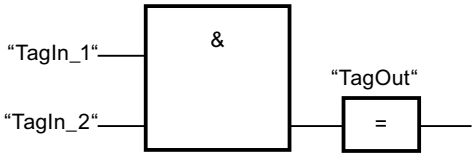
Parameters

The following table shows the parameters of the instruction "AND logic operation":

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand>	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	The operand indicates the bit whose signal state will be queried.

Example

The following example shows how the instruction works:



Output "TagOut" is set, when the signal state of the operands "TagIn_1" and "TagIn_2" is "1" and reset when the state of the operands "TagIn_1" and "TagIn_2" is "0".

>=1: OR logic operation

Description

You can use the instruction "OR logic operation" to query the signal states of two or more specified operands and evaluate them according to the OR truth table.

If the signal state of one of the operands is "1", then the condition is fulfilled and the instruction returns the result "1". If the signal state of all the operands is "0", then the condition is not fulfilled and the instruction generates the result "0".

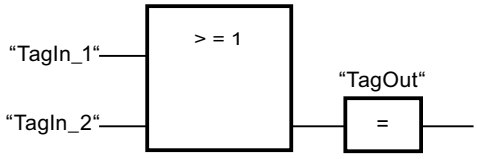
Parameters

The following table shows the parameters of the instruction "OR logic operation":

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand>	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	The operand indicates the bit whose signal state will be queried.

Example

The following example shows how the instruction works:



Output "TagOut" is set, when the signal state of the operands "TagIn_1" or "TagIn_2" is "1".

OR truth table

Results of the logic operation

The following table shows the results that arise from the OR logic operation of two operands:

Signal state of the first operand	Signal state of the second operand	Result of the logic operation
1	0	1
0	1	1
1	1	1
0	0	0

See also

>=1: OR logic operation (Page 2473)

Overview of the valid data types (Page 1908)

X: EXCLUSIVE OR logic operation

Description

You can use the "EXCLUSIVE OR logic operation" instruction to query the result of a signal state query according to the EXCLUSIVE OR truth table.

With an "EXCLUSIVE OR logic operation" instruction, the signal state is "1" when the signal state of one of the two specified operands is "1". When more than two operands are queried, the common RLO is "1" if an odd number of the queried operands returns the result "1".

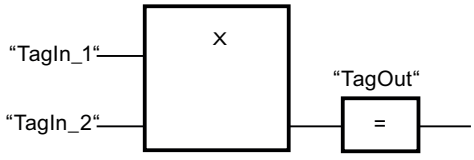
Parameters

The following table shows the parameters of the instruction "EXCLUSIVE OR logic operation":

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand>	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	The operand indicates the bit whose signal state will be queried.

Example

The following example shows how the instruction works:



Output "TagOut" is set when the signal state of the operands "TagIn_1" and "TagIn_2" is "1". When both operands return the signal state "1" or "0", the output "TagOut" is reset.

EXCLUSIVE OR truth table

Results of the logic operation

The following table shows the results that arise from the EXCLUSIVE OR logic operation of two operands:

Signal state of the first operand	Signal state of the second operand	Result of the logic operation
1	0	1
0	1	1
1	1	0
0	0	0

The following table shows the results that arise from the EXCLUSIVE OR logic operation of three operands:

Signal state of the first operand	Signal state of the second operand	Signal state of the third operand	Result of the logic operation
1	0	0	1
0	1	1	0
0	1	0	1
1	0	1	0
0	0	1	1
1	1	0	0
1	1	1	1
0	0	0	0

Insert input

Description

The "Insert input" instruction is used to add an input to the box of one of the following instructions:

- "AND logic operation"
- "OR logic operation"
- "EXCLUSIVE OR logic operation"

You can query the signal state of several operands by the extension of an instruction box.

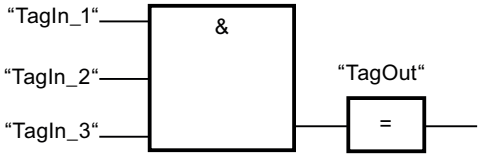
Parameters

The following table shows the parameters of the "Insert input" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand>	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	The operand indicates the bit whose signal state will be queried.

Example

The following example shows how the instruction works:



The box of the "AND logic operation" instruction was extended by an additional input at which the signal state of the operand "TagIn_3" is queried. The "TagOut" output is set, when the operands "TagIn_1" and "TagIn_2" and "TagIn_3" return signal state "1".

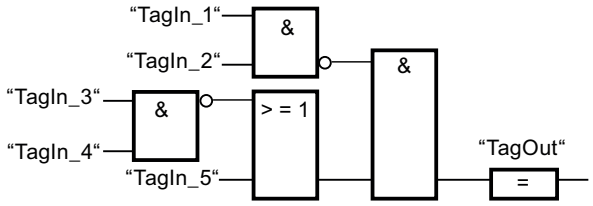
Invert RLO

Description

You use the "Invert RLO" instruction to invert the signal state of the result of logic operation (RLO).

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The input "TagIn_1" and/or "TagIn_2" has signal state "0".
- The input "TagIn_3" and/or "TagIn_4" has signal state "0" or the input "TagIn_5" has signal state "1".

Example of controlling room temperature (Page 3879)

=: Assignment

Description

You can use the instruction "Assignment" to set the bit of a specified operand. If the result of logic operation (RLO) at the box input has the signal state "1", the specified operand is set to signal state "1". If the signal state at the box input is "0", the bit of the specified operand is reset to "0".

The instruction does not influence the RLO. The RLO at the box input is assigned directly to the operand above the assignment box.

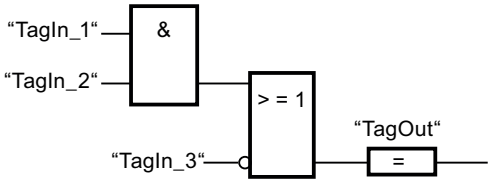
Parameters

The following table shows the parameters of the instruction "Assignment":

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Output	BOOL	I, Q, M, D, L	Operand to which the RLO is assigned.

Example

The following example shows how the instruction works:



The operand "TagOut" is set at the output of the "Assignment" instruction when one of the following conditions is fulfilled:

- The inputs "TagIn_1" and "TagIn_2" have the signal state "1".
- The signal state at the input "TagIn_3" is "0".

See also

Overview of the valid data types (Page 1908)

Example of detecting the fill level of a storage area (Page 3874)

Example of controlling room temperature (Page 3879)

/=: Negate assignment

Description

The instruction "Negate assignment" inverts the result of logic operation (RLO) and assigns this to the operand above the box. If the RLO at the input of the box is "1", the binary operand is reset. If the RLO at the input of the box is "0", the operand is set to signal state "1".

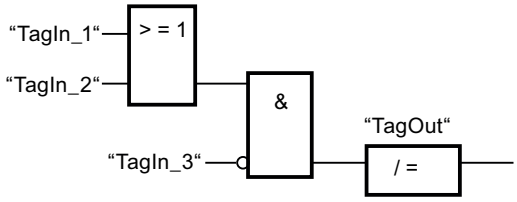
Parameters

The following table shows the parameters of the instruction "Negate assignment":

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Output	BOOL	I, Q, M, D, L	Operand to which the negated RLO is assigned.

Example

The following example shows how the instruction works:



The operand "TagOut" is reset when the following conditions are fulfilled:

- The operand "TagIn_1" or "TagIn_2" has the signal state "1".
- The operand "TagIn_3" has the signal state "0".

See also

Overview of the valid data types (Page 1908)

R: Reset output

Description

You can use the "Reset output" instruction to reset the signal state of a specified operand to "0".

The instruction is only executed if the result of logic operation (RLO) at the box input is "1". If the box input has the signal state "1", the specified operand is reset to "0". If there is an RLO of "0" at the box input, the signal state of the specified operand remains unchanged.

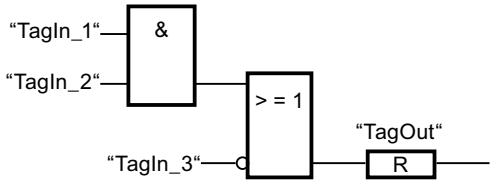
Parameters

The following table shows the parameters of the "Reset output" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand>	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Operand that is reset if RLO = "1".

Example

The following example shows how the instruction works:



Operand "TagOut" is reset when one of the following conditions is fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The operand "TagIn_3" has the signal state "0".

See also

Example of controlling a conveyor belt (Page 3871)

Overview of the valid data types (Page 1908)

S: Set output

Description

You can use the instruction "Set output" to set the signal state of a specified operand to "1".

The instruction is only executed if the result of logic operation (RLO) at the box input is "1". If the box input has the signal state "1", the specified operand is set to "1". If there is an RLO of "0" at the box input, the signal state of the specified operand remains unchanged.

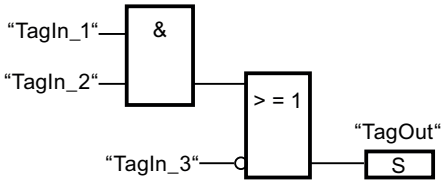
Parameters

The following table shows the parameters of the instruction "Set output":

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Output	BOOL	I, Q, M, D, L	Operand which is set with RLO = "1".

Example

The following example shows how the instruction works:



The "TagOut" operand is set when one of the following conditions is fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The operand "TagIn_3" has the signal state "0".

Example of detecting the direction of a conveyor belt (Page 3872)

SET_BF: Set bit field

Description

You can use the instruction "Set bit field" to set multiple bits starting from a certain address.

You can use the input N to define the number of bits to be set. The address of the first bit to be set is defined by (<Operand>). If the value of the N input is greater than the number of bits in a selected byte, the bits of the next byte are set. The bits remain set until they are explicitly reset, for example, by another instruction.

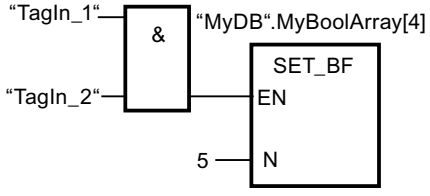
Parameters

The following table shows the parameters of the instruction "Set bit field":

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
N	Input	UINT	Constant	Constant	Number of bits to be set
<Operand>	Output	BOOL	I, Q, M With a DB or an IDB, an element of an ARRAY[..] of BOOL	I, Q, M With a DB or an IDB, an element of an ARRAY[..] of BOOL	Pointer to the first bit to be set.

Example

The following example shows how the instruction works:



If the operands "TagIn_1" and "TagIn_2" have the signal state "1", 5 bits are set starting at the address of the operand "MyDB".MyBoolArray[4].

See also

Overview of the valid data types (Page 1908)

RESET_BF: Reset bit field

Description

You can use the instruction "Reset bit field" to reset several bits starting from a certain address.

You can use the value of the N input to define the number of bits to be reset. The address of the first bit to be reset is defined by (<Operand>). If the value of the input N is greater than the number of bits in a selected byte, the bits of the next byte are reset. The bits remain reset until they are explicitly set, for example, by another instruction.

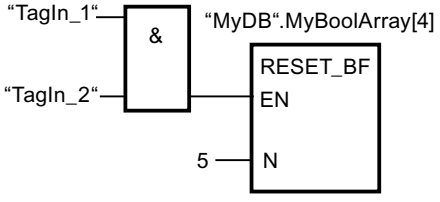
Parameters

The following table shows the parameters of the instruction "Reset bit field":

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
N	Input	UINT	Constant	Constant	Number of bits to be reset.
<Operand>	Output	BOOL	I, Q, M With a DB or an IDB, an element of an ARRAY[..] of BOOL	I, Q, M With a DB or an IDB, an element of an ARRAY[..] of BOOL	Pointer to the first bit to be reset.

Example

The following example shows how the instruction works:



If the operands "TagIn_1" and "TagIn_2" have the signal state "1", 5 bits are reset starting at the address of the operand "MyDB".MyBoolArray[4].

See also

Overview of the valid data types (Page 1908)

SR: Set/reset flip-flop

Description

You can use the "Set/reset flip-flop" instruction to set or reset the bit of a specified operand based on the signal state of the inputs S and R1. If the signal state is "1" at input S and "0" at input R1, the specified operand is set to "1". If the signal state is "0" at input S and "1" at input R1, the specified operand will be reset to "0".

Input R1 takes priority over input S. When the signal state is "1" on both inputs S and R1, the signal state of the specified operand is reset to "0".

The instruction is not executed if the signal state at the two inputs S and R1 is "0". The signal state of the operand then remains unchanged.

The current signal state of the operand is transferred to output Q and can be queried there.

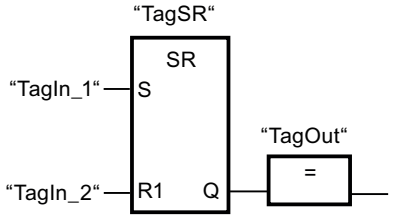
Parameters

The following table shows the parameters of the "Set/reset flip-flop" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
S	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable setting
R1	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable resetting
<Operand>	InOut	BOOL	I, Q, M, D, L	I, Q, M, D, L	Operand that is set or reset
Q	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Signal state of the operand

Example

The following example shows how the instruction works:



The operands "TagSR" and "TagOut" are set when the following conditions are fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The operand "TagIn_2" has the signal state "0".

The operands "TagSR" and "TagOut" are reset when one of the following conditions is fulfilled:

- The operand "TagIn_1" has signal state "0" and the operand "TagIn_2" has signal state "1".
- The operands "TagIn_1" and "TagIn_2" have signal state "1".

See also

Overview of the valid data types (Page 1908)

RS: Reset/set flip-flop

Description

You can use the "Reset/set flip-flop" instruction to reset or set the bit of a specified operand based on the signal state of the inputs R and S1. If the signal state is "1" at input R and "0" at input S1, the specified operand will be reset to "0". If the signal state is "0" at input R and "1" at input S1, the specified operand is set to "1".

Input S1 takes priority over input R. When the signal state is "1" at both inputs R and S1, the signal state of the specified operand is set to "1".

The instruction is not executed if the signal state at the two inputs R and S1 is "0". The signal state of the operand then remains unchanged.

The current signal state of the operand is transferred to output Q and can be queried there.

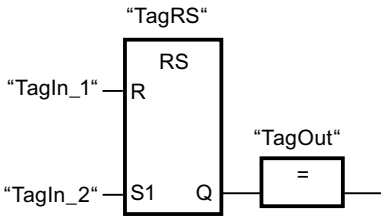
Parameters

The following table shows the parameters of the "Reset/set flip-flop" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
R	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable resetting
S1	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable setting
<Operand>	InOut	BOOL	I, Q, M, D, L	I, Q, M, D, L	Operand that is reset or set.
Q	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Signal state of the operand

Example

The following example shows how the instruction works:



The operands "TagRS" and "TagOut" are reset when the following conditions are fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The operand "TagIn_2" has the signal state "0".

The operands "TagRS" and "TagOut" are set when the following conditions are fulfilled:

- The operand "TagIn_1" has signal state "0" and the operand "TagIn_2" has signal state "1".
- The operands "TagIn_1" and "TagIn_2" have signal state "1".

See also

Overview of the valid data types (Page 1908)

P: Scan operand for positive signal edge

Description

You can use the "Scan operand for positive signal edge" instruction to determine whether there is a "0" to "1" change in the signal state of a specified operand (<Operand1>). The instruction compares the current signal state of <Operand1> with the signal state of the previous scan, which is saved in an edge memory bit (<Operand2>). If the instruction detects a change in the result of logic operation (RLO) from "0" to "1", there is a positive, rising edge.

If a rising edge is detected, the output of the instruction has the signal state "1". In all other cases, the signal state at the output of the instruction is "0".

Specify the operand to be queried (<Operand1>) in the operand placeholder above the instruction. Specify the edge memory bit (<Operand2>) in the operand placeholder below the instruction.

Note

The address of the edge memory bit must not be used more than once in the program, otherwise the memory bit is overwritten. This would influence edge evaluation and the result would no longer be unequivocal. The memory area of the edge memory bit has to be located in a DB (static area for FB) or in the bit memory area.

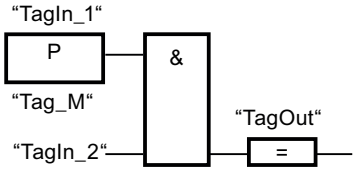
Parameters

The following table shows the parameters of the "Scan operand for positive signal edge" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand1>	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Signal to be scanned
<Operand2>	InOut	BOOL	I, Q, M, D, L	I, Q, M, D, L	Edge memory bit in which the signal state of the previous scan is saved.

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- There is a rising edge at input "TagIn_1".
- The signal state of the operand "TagIn_2" is "1".

Overview of the valid data types (Page 1908)

Example of detecting the direction of a conveyor belt (Page 3872)

N: Scan operand for negative signal edge

Description

You can use the "Scan operand for negative signal edge" instruction to determine whether there is a "1" to "0" change in the signal state of a specified operand (<Operand1>). The instruction compares the current signal state of <Operand1> with the signal state of the previous scan, which is saved in an edge memory bit (<Operand2>). If the instruction detects a change in the result of logic operation (RLO) from "1" to "0", there is a negative, falling edge.

If a falling edge is detected, the output of the instruction has the signal state "1". In all other cases, the signal state at the output of the instruction is "0".

Specify the operand to be queried (<Operand1>) in the operand placeholder above the instruction. Specify the edge memory bit (<Operand2>) in the operand placeholder below the instruction.

Note

The address of the edge memory bit must not be used more than once in the program, otherwise the memory bit is overwritten. This would influence edge evaluation and the result would no longer be unequivocal. The memory area of the edge memory bit has to be located in a DB (static area for FB) or in the bit memory area.

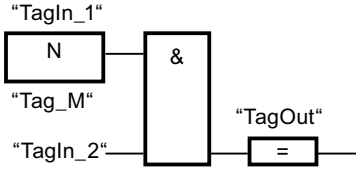
Parameters

The following table shows the parameters of the "Scan operand for negative signal edge" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand1>	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Signal to be scanned
<Operand2>	InOut	BOOL	I, Q, M, D, L	I, Q, M, D, L	Edge memory bit in which the signal state of the previous scan is saved.

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- There is a falling edge at input "TagIn_1".
- The signal state of the operand "TagIn_2" is "1".

See also

Overview of the valid data types (Page 1908)

P=: Set operand on positive signal edge

Description

You can use the instruction "Set operand on positive signal edge" to set a specified operand (<Operand2>) when there is a "0" to "1" change in the result of logic operation (RLO). The instruction compares the current RLO with the RLO from the previous query, which is saved in the edge memory bit (<Operand1>). If the instruction detects a change in the result of logic operation (RLO) from "0" to "1", there is a positive, rising edge.

When a positive edge is detected, <Operand2> is set to signal state "1" for one program cycle. In all other cases, the operand has the signal state "0".

You specify the operand (<Operand2>) to be set in the operand placeholder above the instruction. Specify the edge memory bit (<Operand1>) in the operand placeholder below the instruction.

Note

The address of the edge memory bit must not be used more than once in the program, otherwise the memory bit is overwritten. This would influence edge evaluation and the result would no longer be unequivocal. The memory area of the edge memory bit has to be located in a DB (static area for FB) or in the bit memory area.

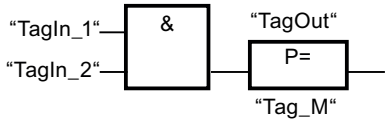
Parameters

The following table shows the parameters of the instruction "Set operand on positive signal edge":

Parameters	Declaration	Data type	Memory area	Description
<Operand2>	Output	BOOL	I, Q, M, D, L	Operand which is set when there is a positive signal edge.
<Operand1>	InOut	BOOL	I, Q, M, D, L	Edge memory bit

Example

The following example shows the parameters of the instruction:



The "TagOut" output is set for one program cycle, when the signal state at the input of the instruction box switches from "0" to "1" (positive signal edge). In all other cases, the "TagOut" output has signal state "0".

See also

Overview of the valid data types (Page 1908)

N=: Set operand on negative signal edge

Description

You can use the instruction "Set operand on negative signal edge" to set a specified operand (<Operand1>) when there is a "1" to "0" change in the result of logic operation (RLO). The instruction compares the current RLO with the RLO from the previous query, which is saved in the edge memory bit (<Operand2>). If the instruction detects a change in the result of logic operation (RLO) from "1" to "0", there is a negative, falling edge.

When a negative edge is detected, <Operand1> is set to signal state "1" for one program cycle. In all other cases, the operand has the signal state "0".

You specify the operand (<Operand1>) to be set in the operand placeholder above the instruction. Specify the edge memory bit (<Operand2>) in the operand placeholder below the instruction.

Note

The address of the edge memory bit must not be used more than once in the program, otherwise the memory bit is overwritten. This would influence edge evaluation and the result would no longer be unequivocal. The memory area of the edge memory bit has to be located in a DB (static area for FB) or in the bit memory area.

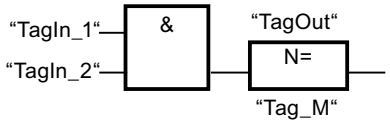
Parameters

The following table shows the parameters of the instruction "Set operand on negative signal edge":

Parameters	Declaration	Data type	Memory area	Description
<Operand1>	Output	BOOL	I, Q, M, D, L	Operand which is set when there is a negative signal edge.
<Operand2>	InOut	BOOL	I, Q, M, D, L	Edge memory bit

Example

The following example shows how the instruction works:



The operand "TagOut" is set for one program cycle if the signal state at the input of the instruction box changes from "1" to "0" (negative signal edge). In all other cases, the operand "TagOut" has the signal state "0".

See also

Overview of the valid data types (Page 1908)

P_TRIG: Scan RLO for positive signal edge

Description

Use the instruction "Scan RLO for positive signal edge" to query a "0" to "1" change in the signal state of the result of logic operation (RLO). The instruction compares the current signal state of the RLO with the signal state of the previous query, which is saved in an edge memory bit (<Operand>). If the instruction detects a change in the result of logic operation (RLO) from "0" to "1", there is a positive, rising edge.

If a rising edge is detected, the output of the instruction has the signal state "1". In all other cases, the signal state at the output of the instruction is "0".

Note

The address of the edge memory bit must not be used more than once in the program, otherwise the memory bit is overwritten. This would influence edge evaluation and the result would no longer be unequivocal. The memory area of the edge memory bit has to be located in a DB (static area for FB) or in the bit memory area.

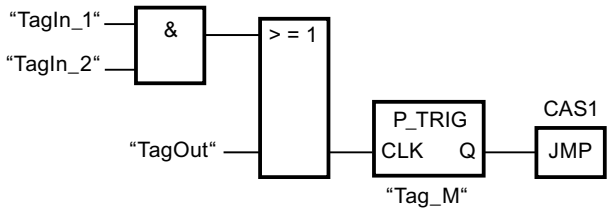
Parameters

The following table shows the parameters of the instruction "Scan RLO for positive signal edge":

Parameter	Declaration	Data type	Memory area	Description
CLK	Input	BOOL	I, Q, M, D, L	Current RLO
<Operand>	InOut	BOOL	M, D	Edge memory bit in which the RLO of the previous query is saved.
Q	Output	BOOL	I, Q, M, D, L	Result of edge evaluation

Example

The following example shows how the instruction works:



The RLO of the preceding bit logic operation is saved in the edge memory bit "Tag_M". If a "0" to "1" change is detected in the signal state of the RLO, the program jumps to jump label CAS1.

See also

Overview of the valid data types (Page 1908)

N_TRIG: Scan RLO for negative signal edge

Description

Use the instruction "Scan RLO for negative signal edge" to query a "1" to "0" change in the signal state of the result of logic operation (RLO). The instruction compares the current signal state of the RLO with the signal state of the previous query saved in the edge memory bit (<Operand>). If the instruction detects a change in the result of logic operation (RLO) from "1" to "0", there is a negative, falling edge.

If a falling edge is detected, the output of the instruction has the signal state "1". In all other cases, the signal state at the output of the instruction is "0".

Note

The address of the edge memory bit must not be used more than once in the program, otherwise the memory bit is overwritten. This would influence edge evaluation and the result would no longer be unequivocal. The memory area of the edge memory bit has to be located in a DB (static area for FB) or in the bit memory area.

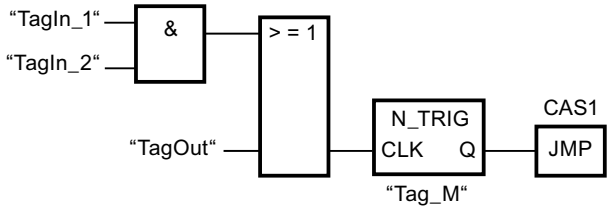
Parameters

The following table shows the parameters of the instruction "Scan RLO for negative signal edge":

Parameter	Declaration	Data type	Memory area	Description
CLK	Input	BOOL	I, Q, M, D, L	Current RLO
<Operand>	InOut	BOOL	M, D	Edge memory bit in which the RLO of the previous query is saved.
Q	Output	BOOL	I, Q, M, D, L	Result of edge evaluation

Example

The following example shows how the instruction works:



The RLO of the preceding bit logic operation is saved in the edge memory bit "Tag_M". If a "1" to "0" change is detected in the signal state of the RLO, the program jumps to jump label CAS1.

See also

Overview of the valid data types (Page 1908)

R_TRIG:Detect positive signal edge

Description

With the "Detect positive signal edge" instruction, you can detect a state change from "0" to "1" at the CLK input. The instruction compares the current value at the CLK input with the state of the previous query (edge memory bit) that is saved in the specified instance. If the instruction detects a state change at the CLK input from "0" to "1", a positive signal edge is generated at the Q output, i.e., the output has the value TRUE or "1" for exactly one cycle.

In all other cases, the signal state at the output of the instruction is "0".

When you insert the instruction in the program, the "Call options" dialog opens automatically. In this dialog you can specify whether the edge memory bit is stored in its own data block (single instance) or as a local tag (multiple instance) in the block interface.

Parameters

The following table shows the parameters of the "Detect positive signal edge" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
CLK	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L, T, C or constant	Incoming signal, the edge of which is to be queried.
Q	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Result of edge evaluation

Example

The following example shows how the instruction works:

The previous state of the tag at the CLK input is stored in the "R_TRIG_DB" tag. If a change in the signal state from "0" to "1" is detected in the "TagIn_1" and "TagIn_2" operands or in the "TagIn_3" operand, the "TagOut_Q" output has signal state "1" for one cycle.

See also

Overview of the valid data types (Page 1908)

F_TRIG:Detect negative signal edge

Description

With the "Detect negative signal edge" instruction, you can detect a state change from "1" to "0" at the CLK input. The instruction compares the current value at the CLK input with the state of the previous query (edge memory bit) that is saved in the specified instance. If the instruction detects a state change at the CLK input from "1" to "0", a negative signal edge is generated at the Q output, i.e., the output has the value TRUE or "1" for exactly one cycle.

In all other cases, the signal state at the output of the instruction is "0".

When you insert the instruction in the program, the "Call options" dialog opens automatically. In this dialog you can specify whether the edge memory bit is stored in its own data block (single instance) or as a local tag (multiple instance) in the block interface.

Parameters

The following table shows the parameters of the "Detect negative signal edge" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
CLK	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L, T, C or constant	Incoming signal, the edge of which is to be queried.
Q	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Result of edge evaluation

Example

The following example shows how the instruction works:

The previous state of the tag at the CLK input is stored in the "F_TRIG_DB" tag. If a change in the signal state from "1" to "0" is detected in the "TagIn_1" and "TagIn_2" operands or in the "TagIn_3" operand, the "TagOut_Q" output has signal state "1" for one cycle.

Timer operations

TP: Generate pulse

Description

You can use the instruction "Generate pulse" to set output Q for the duration PT. The instruction is started when the result of logic operation (RLO) at input IN changes from "0" to "1" (positive signal edge). The configured time duration PT begins when the instruction starts. Output Q is set for the time duration PT, regardless of the subsequent course of the input signal (positive edge). Even when a new positive signal edge is detected, the signal state of the Q output is not affected as long as the PT duration is running.

The current time value can be queried at the output ET. The time value starts at T#0s and ends when the value of the time duration PT is reached. If the configured time duration PT is reached and the signal state at input IN is "0", the ET output is reset.

Each call of the "Generate pulse" instruction must be assigned an IEC Timer in which the instruction data is stored.

Note

If the timer is not called in the program because it is skipped, for example, output ET returns a constant value as soon as the timer has expired.

For S7-1200 CPU

An IEC Timer is a structure of the data type IEC_TIMER or TP_TIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TP_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

An IEC Timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TP_TIME or TP_LTIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TP_TIME, TP_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the IEC Timer is stored in its own data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

The instruction data is updated both when the instruction is called and also each time the outputs Q or ET are accessed.

The execution of the "Generate pulse" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

Parameters

The following table shows the parameters of the "Generate pulse" instruction:

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C, P	Start input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	I, Q, M, D, L, P or constant	Duration of the pulse. The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Pulse output
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L	I, Q, M, D, L, P	Current time value

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Generate pulse" instruction:

TON: Generate on-delay

Description

You can use the instruction "Generate on-delay" to delay setting of the Q output by the time configured with the PT time. The instruction is started when the result of logic operation (RLO) at input IN changes from "0" to "1" (positive signal edge). The programmed time PT begins when the instruction starts. When the duration PT expires, output Q has the signal state "1". Output Q remains set as long as the start input is still "1". When the signal state at the start input changes from "1" to "0", the Q output is reset. The timer function is started again when a new positive signal edge is detected at the start input.

The current time value can be queried at the output ET. The time value starts at T#0s and ends when the value of the time duration PT is reached. The ET output is reset as soon as the signal state at the IN input changes to "0".

Each call of the "Generate on-delay" instruction must be assigned an IEC Timer in which the instruction data is stored.

Note

If the timer is not called in the program because it is skipped, for example, output ET returns a constant value as soon as the timer has expired.

For S7-1200 CPU

An IEC Timer is a structure of the data type IEC_TIMER or TON_TIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TON_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

An IEC Timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TON_TIME or TON_LTIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TON_TIME, TON_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the IEC Timer is stored in its own data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, you will find this in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

The instruction data is updated both when the instruction is called and also each time the outputs Q or ET are accessed.

The execution of the "Generate on-delay" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

Parameters

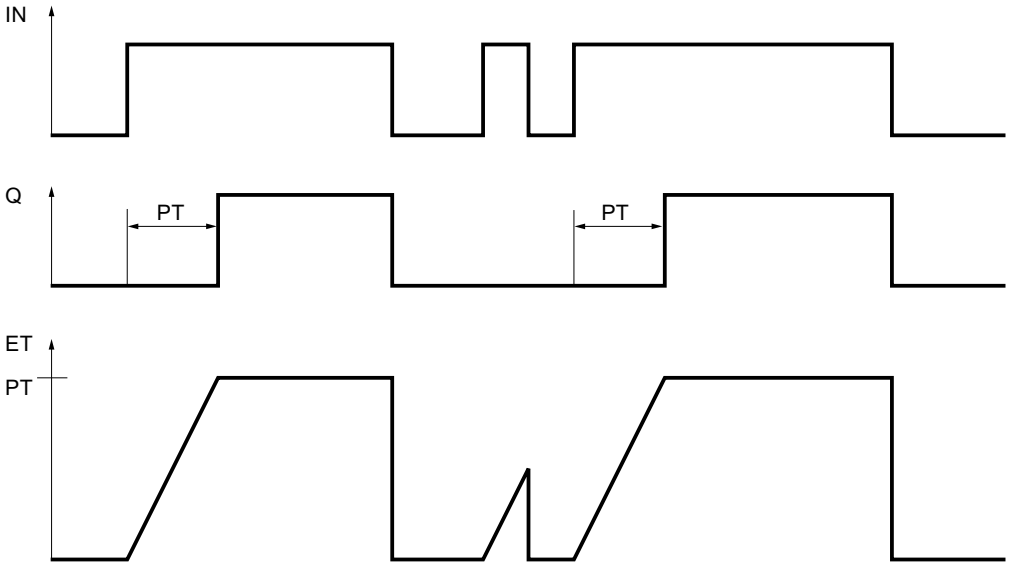
The following table shows the parameters of the "Generate on-delay" instruction:

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C, P	Start input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	I, Q, M, D, L, P or constant	Duration of the on delay. The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Output that is set when the time PT expires.
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L	I, Q, M, D, L, P	Current time value

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Generate on-delay" instruction:



See also

Overview of the valid data types (Page 1908)

TOF: Generate off-delay

Description

You can use the "Generate off-delay" instruction to delay setting of the Q output by the time configured with the PT time. The output Q is set when the result of logic operation (RLO) at input IN changes from "0" to "1" (positive signal edge). When the signal state at input IN changes back to "0" (positive signal edge), the configured time duration PT starts. Output Q remains set as long as the time duration PT is running. When the PT time duration expires, the Q output is reset. If the signal state at input IN changes to "1" before the PT time duration expires, the timer is reset. The signal state at the output Q will continue to be "1".

The current time value can be queried at the output ET. The time value starts at T#0s and ends when the value of the time duration PT is reached. When the time duration PT expires, the ET output remains set to the current value until input IN changes back to "1". If input IN changes to "1" before the time duration PT has expired, the ET output is reset to the value T#0s.

Each call of the "Generate off-delay" instruction must be assigned to an IEC Timer in which the instruction data is stored.

Note

If the timer is not called in the program because it is skipped, for example, output ET returns a constant value as soon as the timer has expired.

For S7-1200 CPU

An IEC Timer is a structure of the data type IEC_TIMER or TOF_TIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TOF_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

An IEC Timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TOF_TIME or TOF_LTIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TOF_TIME, TOF_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the IEC Timer is stored in its own data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, you will find this in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

The instruction data is updated both when the instruction is called and also each time the outputs Q or ET are accessed.

The execution of the "Generate off-delay" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

Parameters

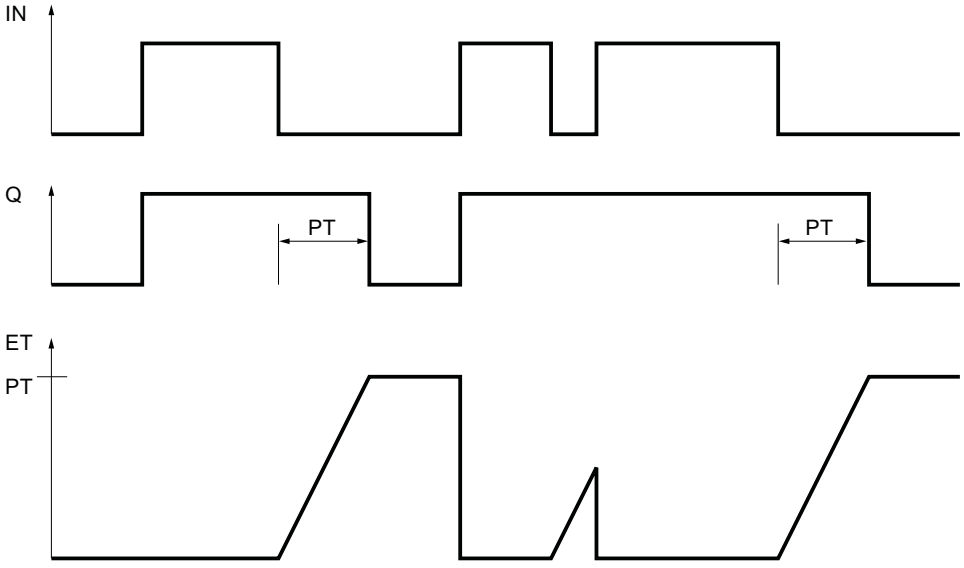
The following table shows the parameters of the "Generate off-delay" instruction:

Parameter	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C, P	Start input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	I, Q, M, D, L, P or constant	Duration of the off delay The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Output that is reset when the timer PT expires.
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L	I, Q, M, D, L, P	Current time value

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Generate off-delay" instruction:



See also

Overview of the valid data types (Page 1908)

TONR: Time accumulator

Description

The instruction "Time accumulator" is used to accumulate time values within a period set by the parameter PT. The instruction is executed and the configured time duration PT is started when the result of logic operation (RLO) at input IN changes from "0" to "1" (positive edge). While the time set at PT is running, the time values are accumulated that are recorded at signal state "1" at input IN. The accumulated time is written to output ET and can be queried there. When the current time value PT is reached, the output Q has the signal state "1". Output Q remains set at "1", even when the signal state at input IN changes to "0".

The R input resets the outputs ET and Q regardless of the signal state at the start input.

Each call of the "Time accumulator" instruction must be assigned to an IEC Timer in which the instruction data is stored.

For S7-1200 CPU

An IEC Timer is a structure of the data type IEC_TIMER or TONR_TIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TONR_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

An IEC Timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TONR_TIME or TONR_LTIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TONR_TIME, TONR_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the IEC Timer is stored in its own data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, you will find this in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

The instruction data is updated both when the instruction is called and also each time the outputs Q or ET are accessed.

The execution of the "Time accumulator" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

Parameters

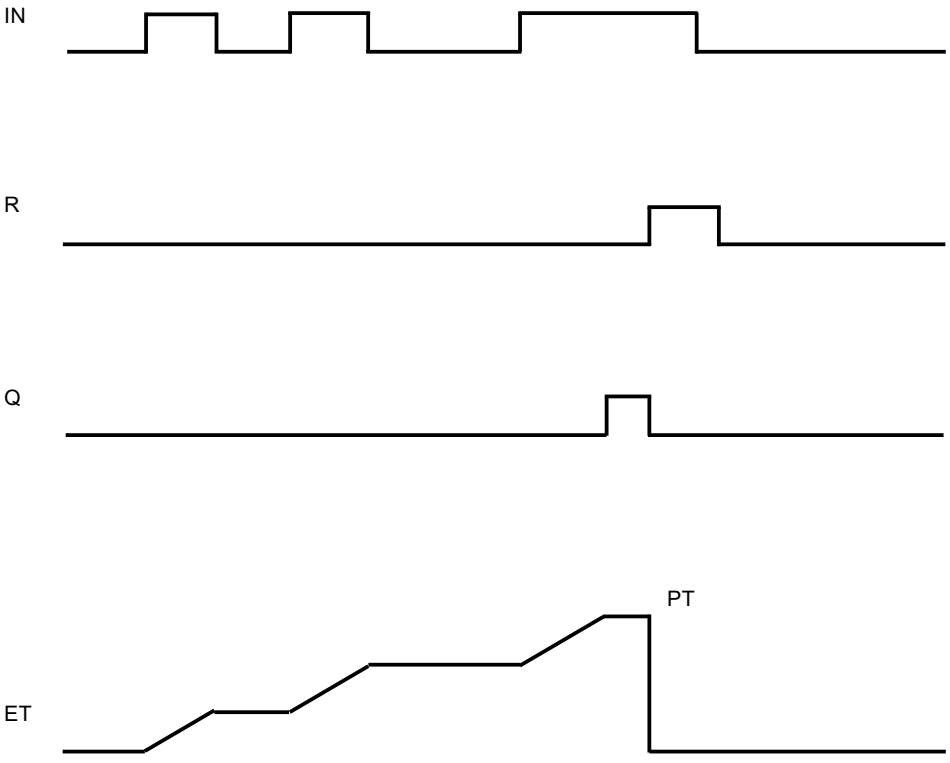
The following table shows the parameters of the "Time accumulator" instruction:

Parameter	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C, P	Start input
R	Input	BOOL	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L, P or constant	Reset input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	I, Q, M, D, L, P or constant	Maximum duration of time recording. The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Output that is set when the time PT expires.
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L	I, Q, M, D, L, P	Current time value

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Time accumulator" instruction:



See also

Overview of the valid data types (Page 1908)

TP: Start pulse timer

Description

Use the instruction "Start pulse timer" to start an IEC Timer with a specified duration as pulse. The IEC Timer is started when the result of logic operation (RLO) changes from "0" to "1" (positive signal edge). The IEC Timer runs for the specified time duration regardless of the subsequent course of the RLO. The expiry of the IEC Timer is also not affected by the detection of a new rising edge. As long as the IEC Timer is running, the querying of the timer status for "1" returns the signal state "1". When the IEC Timer has expired, the timer status returns the signal state "0".

Note

The start and the query of the IEC Timer may be on different expiry levels as each query of the outputs Q or ET updates the IEC_TIMER structure.

For S7-1200 CPU

The instruction "Start pulse timer" stores its data in a structure of the data type IEC_TIMER or TP_TIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TP_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

The instruction "Start pulse timer" stores its data in a structure of the data type IEC_TIMER, IEC_LTIMER, TP_TIME or TP_LTIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TP_TIME, TP_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

The instruction data is updated both when the instruction is called and also each time the specified timer is accessed.

The current timer status is saved in the structure components Q of the IEC Timer. You can query the timer status with the help of a binary logic operation. The query for Q or ET (e. g. "MyTimer".Q or "MyTimer".ET) updates the IEC_TIMER structure.

The execution of the instruction "Start pulse timer" assumes a preceding logic operation. It can be placed only at the end of the network.

Parameters

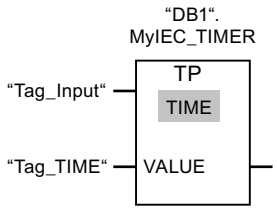
The following table shows the parameters of the instruction "Start pulse timer":

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
VALUE	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	Duration with which the IEC Timer runs.
<IEC Timer>	InOut	IEC_TIMER, TP_TIME	IEC_TIMER, IEC_LTIMER, TP_TIME, TP_LTIME	D, L	IEC Timer which is started.

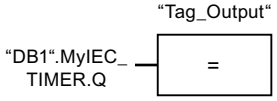
For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The instruction "Start pulse timer" is executed when the signal state of the operand "Tag_Input" changes from "0" to "1". The timer "DB1".MyIEC_TIMER is started for the time stored in the operand "TagTime".



As long as the timer "DB1".MyIEC_TIMER is running, the timer status ("DB1".MyIEC_TIMER.Q) has signal state "1" and the operand "Tag_Output" is set. When the IEC Timer has expired, the signal state of the time status changes back to "0" and the "Tag_Output" operand is reset.

See also

Overview of the valid data types (Page 1908)

TON: Start on-delay timer

Description

Use the "Start on-delay timer" instruction to start an IEC Timer with a specified duration as on-delay. The IEC Timer is started when the result of logic operation (RLO) changes from "0" to "1" (positive signal edge). The IEC Timer runs for the specified time duration. The output returns the signal state "1" if the RLO at the input of the instruction has the signal state "1". If the RLO changes to "0" before the end of the timer, the running IEC Timer is reset. The query of the timer status for "1" returns the signal state "0". The IEC Timer restarts when the next rising signal edge is detected at the input of the instruction.

Note

The start and the query of the IEC Timer may be on different expiry levels as each query of the outputs Q or ET updates the IEC_TIMER structure.

For S7-1200 CPU

The instruction "Start on-delay timer" stores its data in a structure of the data type IEC_TIMER or TON_TIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TON_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

The "Start on-delay timer" instruction stores its data in a structure of the data type IEC_TIMER, IEC_LTIMER, TON_TIME or TON_LTIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TON_TIME, TON_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

The instruction data is updated both when the instruction is called and also each time the specified timer is accessed.

The current timer status is saved in the structure components ET of the IEC Timer. You can query the timer status with the help of a binary logic operation. The query for Q or ET (e. g. "MyTimer".Q or "MyTimer".ET) updates the IEC_TIMER structure.

The execution of the "Start on-delay timer" instruction assumes a preceding logic operation. It can be placed only at the end of the network.

Parameters

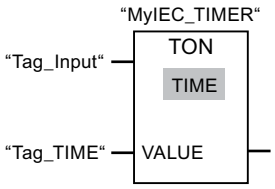
The following table shows the parameters of the instruction "Start on-delay timer":

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
VALUE	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	Duration with which the IEC Timer runs.
<IEC Timer>	InOut	IEC_TIMER, TON_TIME	IEC_TIMER, IEC_LTIMER, TON_TIME, TON_LTIME	D, L	IEC Timer which is started.

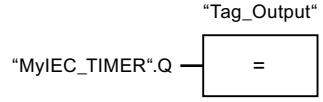
For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "Start on-delay timer" instruction is executed when the signal state of the operand "Tag_Input" changes from "0" to "1". The "MyIEC_TIMER" timer is started for the time stored in the "Tag_TIME" operand.



If the timer "MyIEC_TIMER" has expired and the operand "Tag_Input" has the signal state "1", querying the timer status ("MyIEC_TIMER".Q) returns signal state "1" and the "Tag_Output" operand is set. When the signal state of the operand "Tag_Input" changes to "0", the querying of the timer status returns the signal state "0" and the operand "Tag_Output" is reset.

See also

Overview of the valid data types (Page 1908)

TOF: Start off-delay timer

Description

Use the "Start off-delay timer" instruction to start an IEC Timer with a specified duration as off-delay. The query of the timer status for "1" returns the signal state "0" if the result of the logic operation (RLO) at the input of the instruction has the signal state "1". When the RLO changes from "1" to "0" (negative signal edge), the IEC Timer starts with the specified time duration. The timer status remains at signal state "1" as long as the IEC Timer is running. When the timer has run out and the RLO at the input of the instruction has the signal state "0", the timer status is set to the signal state "0". If the RLO changes to "1" before the end of the timer, the running IEC Timer is reset and the timer status remain at the signal state "1".

Note

The start and the query of the IEC Timer may be on different expiry levels as each query of the outputs Q or ET updates the IEC_TIMER structure.

For S7-1200 CPU

The instruction "Start off-delay timer" stores its data in a structure of the data type IEC_TIMER or TOF_TIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TOF_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

The "Start off-delay timer" instruction stores its data in a structure of the data type IEC_TIMER, IEC_LTIMER, TOF_TIME or TOF_LTIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TOF_TIME, TOF_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

The instruction data is updated both when the instruction is called and also each time the specified timer is accessed.

The current timer status is saved in the structure components ET of the IEC Timer. You can query the timer status with the help of a binary logic operation. The query for Q or ET (e. g. "MyTimer".Q or "MyTimer".ET) updates the IEC_TIMER structure.

The execution of the "Start off-delay timer" instruction assumes a preceding logic operation. It can be placed only at the end of the network.

Parameters

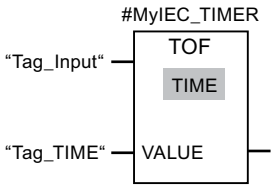
The following table shows the parameters of the instruction "Start off-delay timer":

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
VALUE	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	Duration with which the IEC Timer runs.
<IEC Timer>	InOut	IEC_TIMER, TOF_TIME	IEC_TIMER, IEC_LTI-MER, TOF_TIME, TOF_LTIME	D, L	IEC Timer which is started.

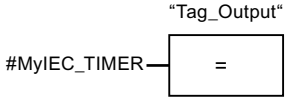
For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "Start off-delay timer" instruction is executed when the signal state of the operand "Tag_Input" changes from "1" to "0". The #MyIEC_TIMER timer is started for the time stored in the operand "Tag_TIME".



As long as timer #MyIEC_TIMER is running, the query of the time status (#MyIEC_TIMER.Q) returns the signal state "1" and operand "Tag_Output" is set. If the timer has expired and the operand "Tag_Input" has the signal state "0", the query of the timer status returns the signal state "0". If the signal state of the operand "Tag_Input" changes to "1" before timer #MyIEC_TIMER expires, the timer is reset. When the signal state of the operand "Tag_Input" is "1", the query of the timer status returns the signal state "1".

See also

Overview of the valid data types (Page 1908)

TONR: Time accumulator

Description

You can use the "Time accumulator" instruction to record how long the signal is at the input of instruction "1". The instruction is started when the result of logic operation (RLO) changes from "0" to "1" (positive signal edge). The time is recorded as long at the RLO is "1". If the RLO changes to "0", the instruction is halted. If the RLO changes back to "1", the time recording is continued. The query of the timer status for "1" returns the signal state "1" if the recorded time exceeds the value of the specified time duration and the RLO at the input of coil is "1".

The timer status and the currently expired timer can be reset to "0" using the "Reset timer" instruction.

Note

The start and the query of the IEC Timer may be on different expiry levels as each query of the outputs Q or ET updates the IEC_TIMER structure.

For S7-1200 CPU

The "Time accumulator" instruction stores its data in a structure of the data type IEC_TIMER or TONR_TIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TONR_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

The "Time accumulator" instruction stores its data in a structure of the data type IEC_TIMER, IEC_LTIMER, TONR_TIME or TONR_LTIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TONR_TIME, TONR_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

The instruction data is updated both when the instruction is called and also each time the specified timer is accessed.

The current timer status is saved in the structure components ET of the IEC Timer. You can query the timer status with the help of a binary logic operation. The query for Q or ET (e. g. "MyTimer".Q or "MyTimer".ET) updates the IEC_TIMER structure.

The execution of the "Time accumulator" instruction requires a preceding logic operation. It can be placed only at the end of the network.

Parameters

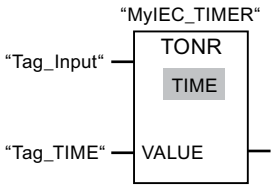
The following table shows the parameters of the "Time accumulator" instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
VALUE	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	Duration with which the IEC Timer runs.
<IEC Timer>	InOut	IEC_TIMER, TONR_TIME	IEC_TIMER, IEC_LTIMER, TONR_TIME, TONR_LTIME	D, L	IEC Timer which is started.

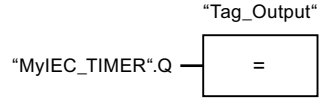
For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "Time accumulator" instruction is executed if there is a positive signal edge in the RLO. The time is recorded as long as the operand "Tag_Input" has the signal state "1".



If the recorded time exceeds the value of the operand "Tag_TIME", then the query of the timer status ("MyIEC_TIMER".Q) will return the signal state "1" and the operand "Tag_Output" will be set.

Overview of the valid data types (Page 1908)

RT: Reset timer (Page 2511)

RT: Reset timer

Description

You can use the "Reset timer" instruction to reset an IEC Timer to "0". You specify the IEC Timer to be reset by entering the name of the data block that contains the structure of the IEC Timer in the placeholder above the instruction.

The instruction is only executed if the result of logic operation (RLO) at the box input is "1". When the instruction is executed the structure components of the IEC Timer are reset to "0" in the specified data block. If the RLO at box input is "0", the instruction is not executed.

The instruction does not influence the RLO. The RLO at the box input is transferred directly to the box output.

You must assign a IEC Timer declared in the program to the "Reset timer" instruction.

The instruction data is updated only when the instruction is called and not each time the assigned IEC Timer is accessed. The query of the data is only identical from the call of the instruction to the next call of the instruction.

Parameters

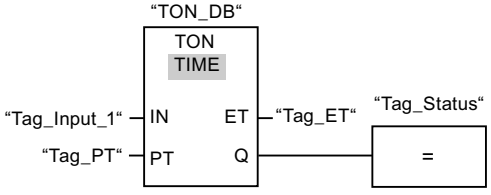
The following table shows the parameters of the instruction "Reset timer":

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<IEC Timer>	InOut	IEC_TIMER, TP_TIME, TON_TIME, TOF_TIME, TONR_TIME	IEC_TIMER, IEC_LTIMER, TP_TIME, TP_LTIME, TON_TIME, TON_LTIME, TOF_TIME, TOF_LTIME, TONR_TIME, TONR_LTIME	D, L	IEC Timer, which is reset.

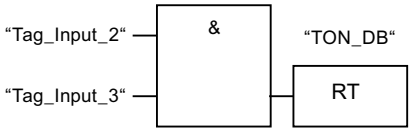
For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "Generate on-delay" instruction executes when the signal state of the "Tag_Input_1" operand changes from "0" to "1". The IEC Timer stored in the instance data block "TON_DB" is started with the time duration that is specified by the operand "Tag_PT".



If the operands "Tag_Input_2" and "Tag_Input_3" have the signal state "1", the "Reset timer" instruction is executed and the IEC Timer stored in the data block "TON_DB" is reset.

Overview of the valid data types (Page 1908)

PT: Load time duration

Description

Use the "Load time duration" instruction to set the time duration of an IEC Timer. The instruction is executed in every cycle when the result of logic operation (RLO) at the input of the instruction has the signal state "1". The instruction writes the specified time duration to the structure of the specified IEC Timer.

Note

If the specified IEC Timer is running during the execution, the instruction overwrites the current time duration of the specified IEC Timer. As a result, the timer status of the IEC Timer can change.

You must assign a IEC Timer declared in the program to the "Load time duration" instruction.

The instruction data is updated when the instruction is called and each time the assigned IEC Timer is accessed. The query for Q or ET (e. g. "MyTimer".Q or "MyTimer".ET) updates the IEC_TIMER structure.

Parameters

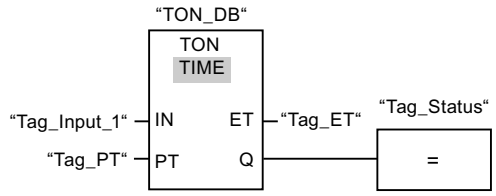
The following table shows the parameters of the instruction "Load time duration":

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	Time duration
<IEC Timer>	InOut	IEC_TIMER, TP_TIME, TON_TIME, TOF_TIME, TONR_TIME	IEC_TIMER, IEC_LTIMER, TP_TIME, TP_LTIME, TON_TIME, TON_LTIME, TOF_TIME, TOF_LTIME, TONR_TIME, TONR_LTIME	D, L	IEC Timer, the duration of which is set.

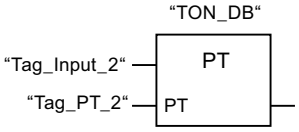
For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "Generate on-delay" instruction executes when the signal state of the "Tag_Input_1" operand changes from "0" to "1". The IEC Timer stored in the instance data block "TON_DB" is started with the time duration that is specified by the operand "Tag_PT".



The "Load time duration" instruction is executed when the operand "Tag_Input_2" has the signal state "1". The instruction writes the time duration "Tag_PT_2" in the instance data block "TON_DB" and at the same time overwrites the value of the operand "Tag_PT" within the data block. As a result, the signal state of the timer status can change at the next query or upon access to "MyTimer".Q or "MyTimer".ET.

Note

The "Tag_Input_2" is executed as pulse flag in order that the time duration is loaded only throughout one program cycle.

Legacy

S_PULSE: Assign pulse timer parameters and start

Description

The "Assign pulse timer parameters and start" instruction starts a programmed timer when a transition from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at input S. The timer expires with the programmed duration (TV) as long as the signal state at input S is "1". If the signal state at input S changes to "0" before the programmed duration expires, the timer is stopped. In this case, the signal state at output Q is "0".

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down

to zero. The time base determines the time period of the time value. The current time value is output binary-coded at output BI and BCD-coded at output BCD.

If the timer is running and the signal state at input R changes to "1", the current time value and the time base are also set to zero. If the timer is not running, the signal state "1" at the R input has no effect.

The "Assign pulse timer parameters and start" instruction needs a preceding logic operation for the edge evaluation and can be placed within or at the end of the network.

The instruction data is updated with each access. It can therefore happen that the query of the data at the start of the cycle returns different values than at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameters

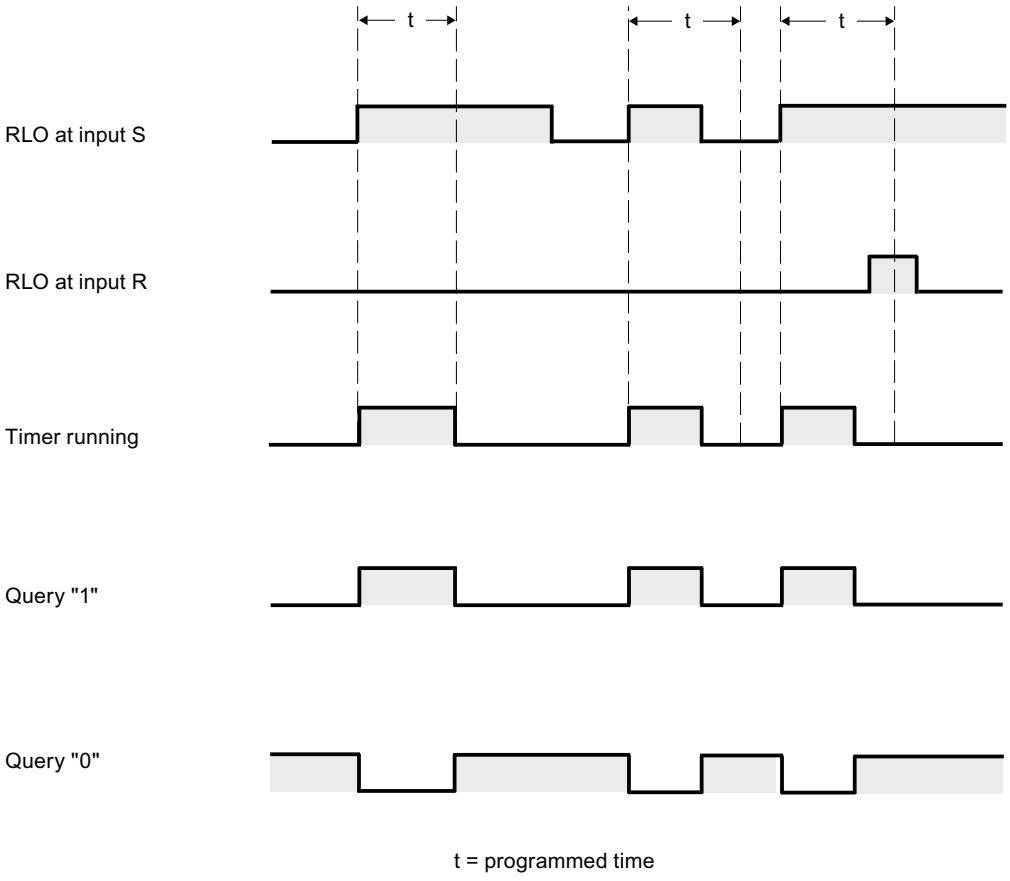
The following table shows the parameters of the "Assign pulse timer parameters and start" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Timer>	InOut/Input	TIMER	T	Time of the instruction The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, T, C, D, L, P	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Time duration
R	Input	BOOL	I, Q, M, T, C, D, L, P or constant	Reset input
BI	Output	WORD	I, Q, M, D, L, P	Current time value (binary-coded)
BCD	Output	WORD	I, Q, M, D, L, P	Current time value (BCD format)
Q	Output	BOOL	I, Q, M, D, L, P	Status of the timer

For additional information on valid data types, refer to "See also".

Pulse timing diagram

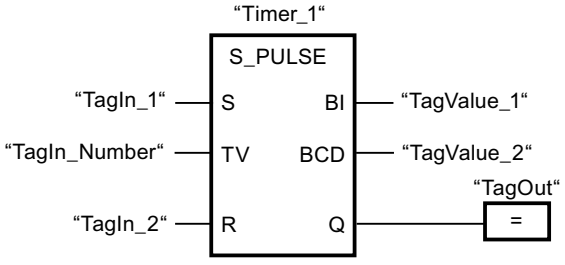
The following figure shows the pulse timing diagram of the "Assign pulse timer parameters and start" instruction:



t = programmed time

Example

The following example shows how the instruction works:



"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "0" to "1". The timer runs for the time value of the "TagIn_Number" operand as long as the "TagIn_1" operand has the signal state "1". If the signal state of the operand "TagIn_1" changes from "1" to "0" before the timer expires, the timer "Timer_1" is stopped. The "TagOut" operand is reset to signal state "0".

The "TagOut" operand has the signal state "1" as long as the timer is running and the "TagIn_1" operand has the signal state "1". When the time has expired or is reset, the "TagOut" operand is reset to "0".

Overview of the valid data types (Page 1908)

S_PEXT: Assign extended pulse timer parameters and start

Description

The "Assign extended pulse timer parameters and start" instruction starts a programmed timer when a transition from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at input S. The timer expires with the programmed duration (TV), even if the signal state at input S changes to "0". As long as the timer is running, output Q has the signal state "1". When the timer has expired, output Q is reset to "0". If the signal state at input S changes from "0" to "1" while the timer is running, the timer is restarted with the duration programmed at input TV.

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down to zero. The time base determines the time period of the time value. The current time value is output binary-coded at output BI and BCD-coded at output BCD.

If the timer is running and the signal state at input R changes to "1", the current time value and the time base are also set to zero. If the timer is not running, the signal state "1" at the R input has no effect.

The "Assign extended pulse timer parameters and start" instruction needs a preceding logic operation for the edge evaluation and can be placed within or at the end of the network.

The instruction data is updated with each access. It can therefore happen that the query of the data at the start of the cycle returns different values than at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameters

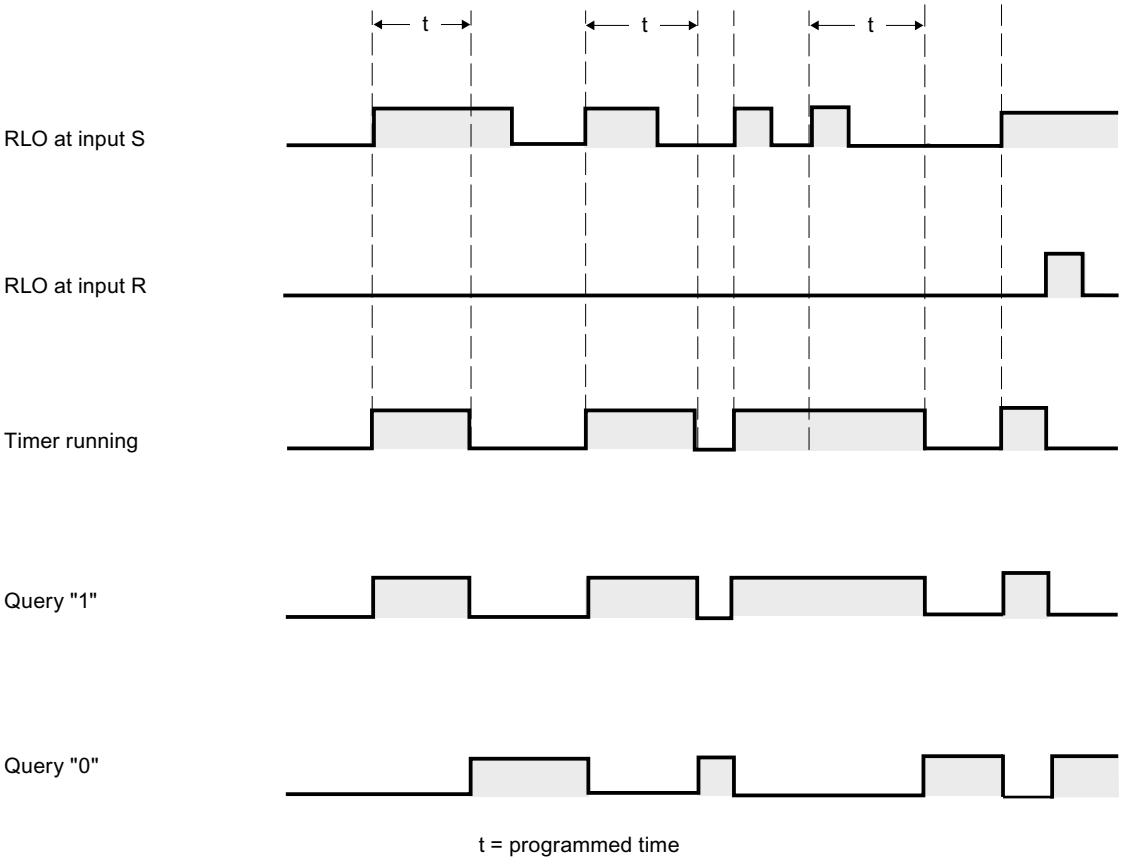
The following table shows the parameters of the "Assign extended pulse timer parameters and start" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Timer>	InOut/Input	TIMER	T	Time of the instruction The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, T, C, D, L, P	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Time duration
R	Input	BOOL	I, Q, M, T, C, D, L, P or constant	Reset input
BI	Output	WORD	I, Q, M, D, L, P	Current time value (binary-coded)
BCD	Output	WORD	I, Q, M, D, L, P	Current time value (BCD format)
Q	Output	BOOL	I, Q, M, D, L, P	Status of the timer

For additional information on valid data types, refer to "See also".

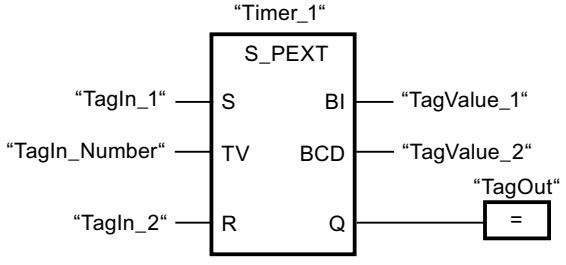
Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign extended pulse timer parameters and start" instruction:



Example

The following example shows how the instruction works:



"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "0" to "1". The timer runs for the time value of the "TagIn_Number" operand without being affected by a negative edge at the S input. If the signal state at the "TagIn_1" operand changes from "0" to "1" before the timer expires, the timer is restarted.

The "TagOut" operand has the signal state "1" as long as the timer is running. When the time has expired or is reset, the "TagOut" operand is reset to "0".

S_ODT: Assign on-delay timer parameters and start

Description

The "Assign on-delay timer parameters and start" instruction starts a programmed timer when a transition from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at input S. The timer expires with the programmed duration (TV) as long as the signal state at input S is "1". If the timer expires correctly and input S still has signal state "1", output Q returns signal state "1". If the signal state at input S changes from "1" to "0" while the timer is running, the timer is stopped. In this case, output Q is reset to signal state "0".

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down to zero. The time base determines the time period of the time value. The current time value is output binary-coded at output BI and BCD-coded at output BCD.

If the time is running and the signal state at input R changes from "0" to "1", the current time value and the time base are also set to zero. In this case, the signal state at output Q is "0". The timer is reset if the signal state is "1" at the R input even if the timer is not running and the RLO at input S is "1".

The "Assign on-delay timer parameters and start" instruction needs a preceding logic operation for the edge evaluation and can be placed within or at the end of the network.

The instruction data is updated with each access. It can therefore happen that the query of the data at the start of the cycle returns different values than at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameters

The following table shows the parameters of the "Assign on-delay timer parameters and start" instruction:

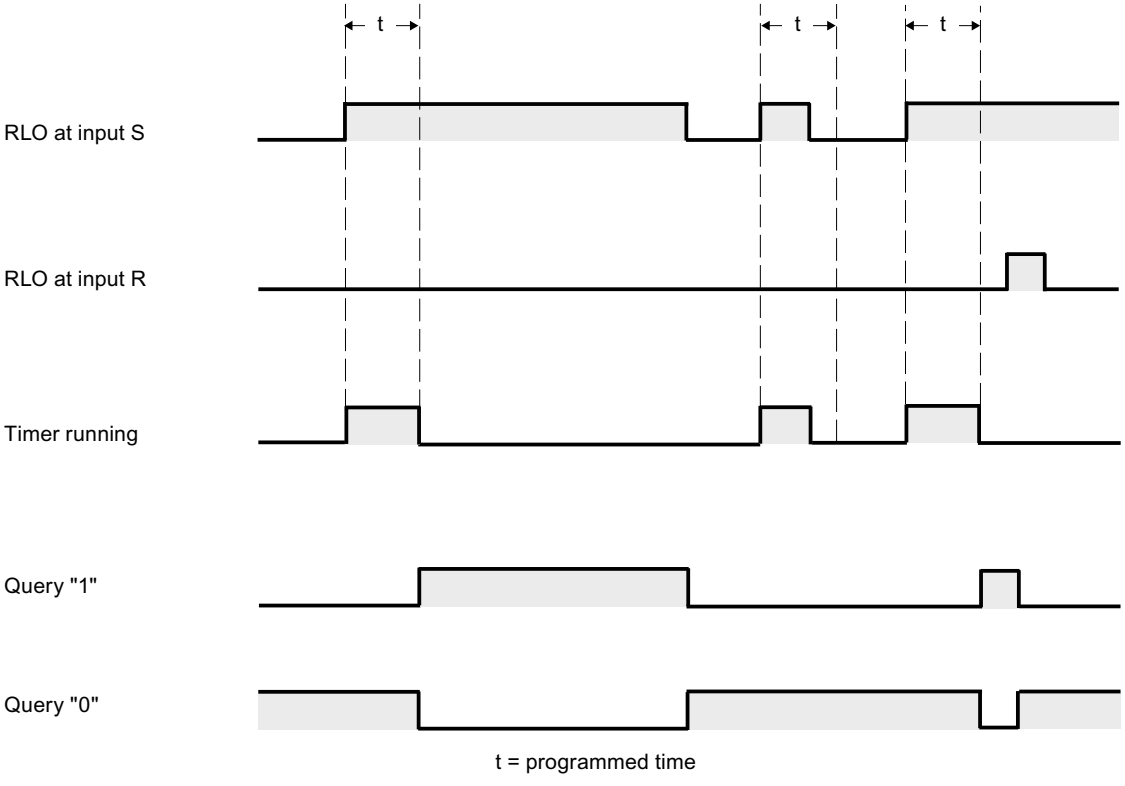
Parameters	Declaration	Data type	Memory area	Description
<Timer>	InOut/Input	TIMER	T	Time of the instruction The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, T, C, D, L, P	Start input

Parameters	Declaration	Data type	Memory area	Description
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Time duration
R	Input	BOOL	I, Q, M, T, C, D, L, P or constant	Reset input
BI	Output	WORD	I, Q, M, D, L, P	Current time value (binary-coded)
BCD	Output	WORD	I, Q, M, D, L, P	Current time value (BCD format)
Q	Output	BOOL	I, Q, M, D, L, P	Status of the timer

For additional information on valid data types, refer to "See also".

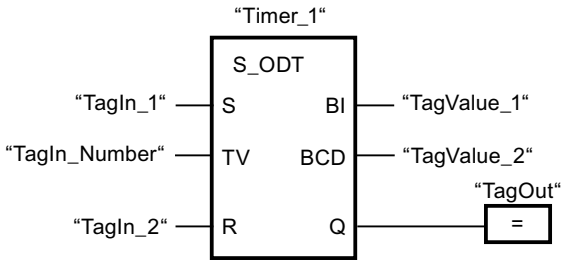
Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign on-delay timer parameters and start" instruction:



Example

The following example shows how the instruction works:



"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "0" to "1". The timer expires with the value of operand "TagIn_Number". If the timer expires and the signal state of the operand is "1", the "TagOut" operand is set to "1". If the signal state at the "TagIn_1" operand changes from "1" to "0" before the timer expires, the timer is stopped. The "TagOut" operand has the signal state "0".

S_ODTS: Assign retentive on-delay timer parameters and start

Description

The "Assign retentive on-delay timer parameters and start" instruction starts a programmed timer when a transition from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at input S. The timer expires with the programmed duration (TV), even if the signal state at input S changes to "0". If the timer expires, the "Q" output returns signal state "1" regardless of the signal state at input "S". If the signal state at input S changes from "0" to "1" while the timer is running, the timer is restarted with the duration programmed at input (TV).

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down to zero. The time base determines the time period of the time value. The current time value is output binary-coded at output BI and BCD-coded at output BCD.

Signal state "1" at input R resets the current time value and time base to "0" regardless of the signal state at start input S. In this case, the signal state at output Q is "0".

The "Assign retentive on-delay timer parameters and start" instruction needs a preceding logic operation for the edge evaluation and can be placed within or at the end of the network.

The instruction data is updated with each access. It can therefore happen that the query of the data at the start of the cycle returns different values than at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameters

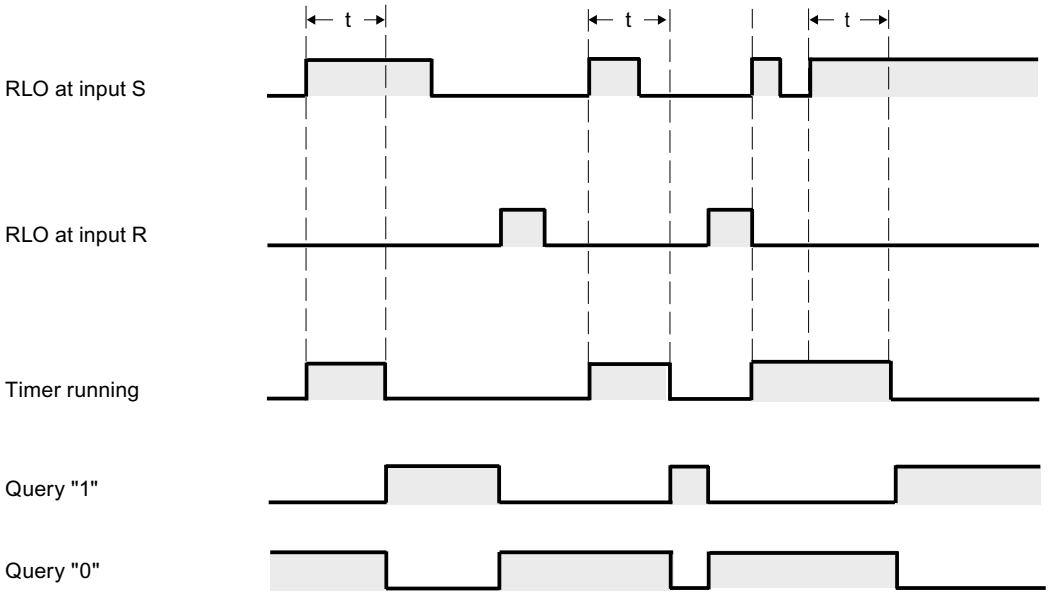
The following table shows the parameters of the "Assign retentive on-delay timer parameters and start" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Timer>	InOut/Input	TIMER	T	Time of the instruction The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, T, C, D, L, P	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Time duration
R	Input	BOOL	I, Q, M, T, C, D, L, P or constant	Reset input
BI	Output	WORD	I, Q, M, D, L, P	Current time value (binary-coded)
BCD	Output	WORD	I, Q, M, D, L, P	Current time value (BCD format)
Q	Output	BOOL	I, Q, M, D, L, P	Status of the timer

For additional information on valid data types, refer to "See also".

Pulse timing diagram

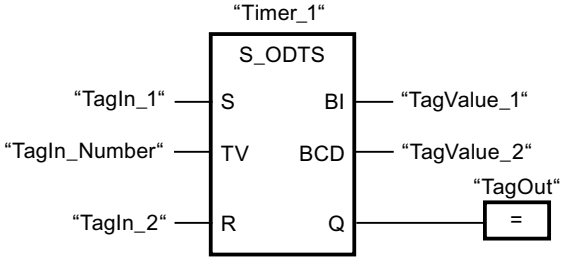
The following figure shows the pulse timing diagram of the "Assign retentive on-delay timer parameters and start" instruction:



t = programmed time

Example

The following example shows how the instruction works:



"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "0" to "1". The timer expires with the time value of the "TagIn_Number" operand, even when the signal state of the "TagIn_1" operand changes to "0". When the time expires, the "TagOut" operand is reset to "1". If the signal state at the "TagIn_1" operand changes from "0" to "1" while the timer is running, the timer is restarted.

Overview of the valid data types (Page 1908)

S_OFFDT: Assign off-delay timer parameters and start

Description

The "Assign off-delay timer parameters and start" instruction starts a programmed timer when a transition from "1" to "0" (negative signal edge) is detected in the result of logic operation (RLO) at input S. The timer expires with the programmed duration (TV). As long as the timer is running or input S returns signal state "1", output Q has signal state "1". If the timer expires and the signal state is "0", output Q is reset to signal state "0". If the signal state at input S changes from "0" to "1" while the timer is running, the timer is stopped. The timer is only restarted after a falling signal edge is detected at input S.

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down to zero. The time base determines the time period of the time value. The current time value is output binary-coded at output BI and BCD-coded at output BCD.

Signal state "1" at input R resets the current time value and time base to "0". In this case, the signal state at output Q is "0".

The "Assign off-delay timer parameters and start" instruction needs a preceding logic operation for the edge evaluation and can be placed within or at the end of the network.

The instruction data is updated with each access. It can therefore happen that the query of the data at the start of the cycle returns different values than at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameters

The following table shows the parameters of the "Assign off-delay timer parameters and start" instruction:

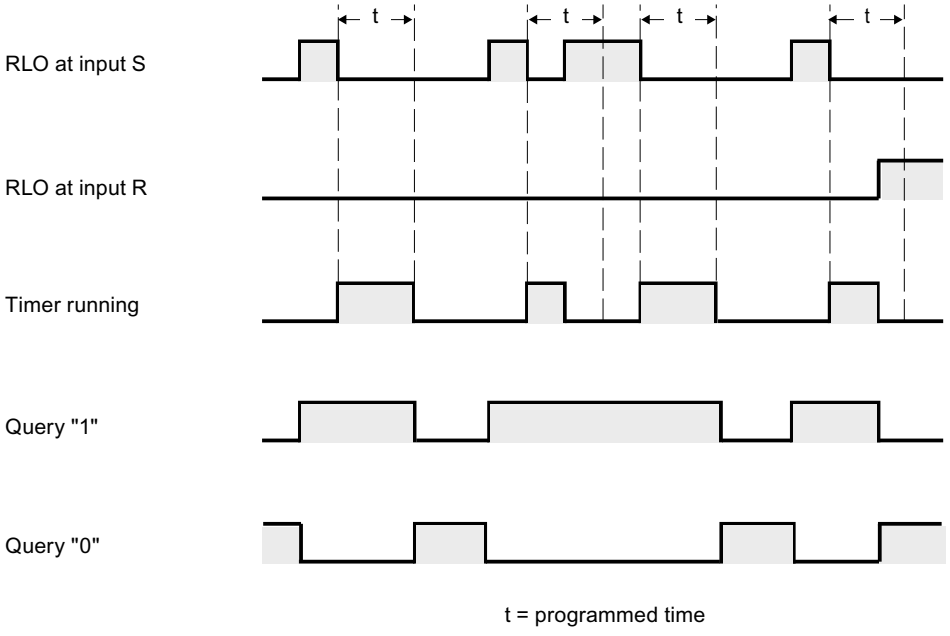
Parameters	Declaration	Data type	Memory area	Description
<Timer>	InOut/Input	TIMER	T	Time of the instruction The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, T, C, D, L, P	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Time duration
R	Input	BOOL	I, Q, M, T, C, D, L, P or constant	Reset input

Parameters	Declaration	Data type	Memory area	Description
BI	Output	WORD	I, Q, M, D, L, P	Current time value (binary-coded)
BCD	Output	WORD	I, Q, M, D, L, P	Current time value (BCD format)
Q	Output	BOOL	I, Q, M, D, L, P	Status of the timer

For additional information on valid data types, refer to "See also".

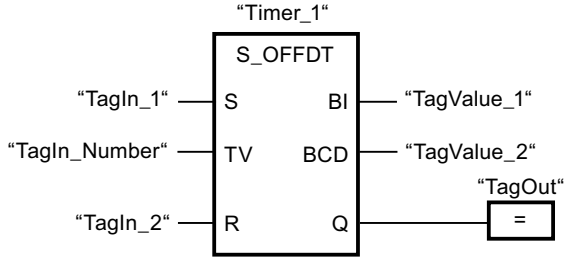
Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign off-delay timer parameters and start" instruction:



Example

The following example shows how the instruction works:



"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "1" to "0". The timer expires with the value of operand "TagIn_Number". The "TagOut" operand is set to "1"

if the timer is running or the "TagIn_1" operand has the signal state "0". If the signal state at the "TagIn_1" operand changes from "0" to "1" while the timer is running, the timer is reset.

SP: Start pulse timer

Description

The instruction "Start pulse timer" starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at the start input. The timer runs with the specified duration as long as the RLO has the signal state "1". As long as the timer is running, the query of timer status "1" returns the signal state "1". If there is a change from "1" to "0" in the RLO before the time value has elapsed, the timer stops. In this case, the query for timer status for "1" returns the signal state "0".

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down to zero. The time base determines the time period of the time value.

The "Start pulse timer" instruction needs a preceding logic operation for the edge evaluation and can only be placed on the right edge of the network.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameters

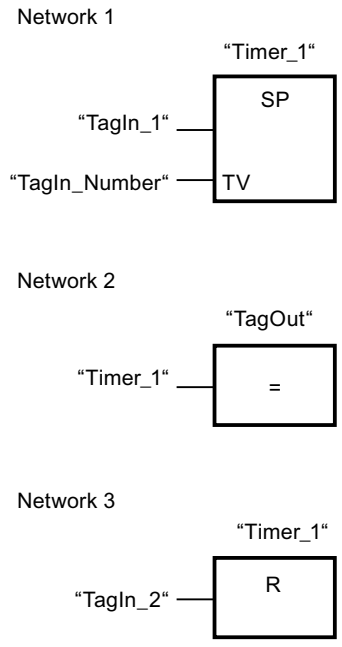
The following table shows the parameters of the instruction "Start pulse timer":

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	BOOL	I, Q, M, T, C, D, L, P	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Time duration
<Timer>	InOut/Input	TIMER	T	Timer which is started. The number of timers depends on the CPU.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "0" to "1". The timer expires with the time value of the "TagIn_Number" operand as long as the signal state of the "TagIn_1" operand is "1". If the signal state at the "TagIn_1" operand changes from "1" to "0" before the timer expires, the timer is stopped. As long as the timer is running, the "TagOut" operand returns signal state "1". If the signal state of the "TagIn_1" operand changes from "0" to "1", the timer is reset, i.e. the timer is stopped and the current time value is set to "0".

SE: Start extended pulse timer

Description

The "Start extended pulse timer" instruction starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at the start input. The timer runs for the specified time period even when the RLO changes to signal state "0". As long as the timer is running, the query of timer status "1" returns the signal state "1". If the RLO changes from "0" to "1" while the timer is running, the timer is restarted with the programmed time period. When the timer expires, the query for timer status for "1" returns the signal state "0".

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down to zero. The time base determines the time period of the time value.

The "Start extended pulse timer" instruction needs a preceding logic operation for the edge evaluation and can only be placed on the right edge of the network.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameters

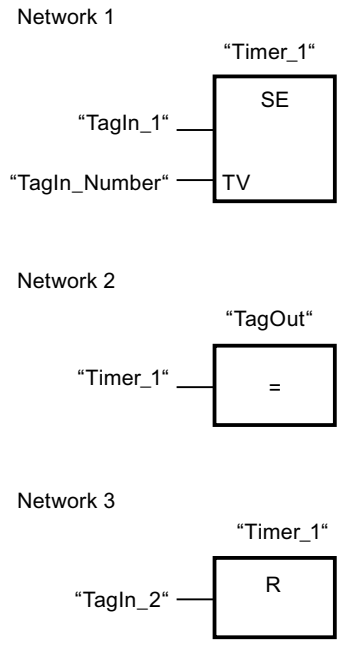
The following table shows the parameters of the instruction "Start extended pulse timer":

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	BOOL	I, Q, M, T, C, D, L, P	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Time duration
<Timer>	InOut/Input	TIMER	T	Timer which is started. The number of timers depends on the CPU.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "0" to "1". The timer expires with the time value of the "TagIn_Number" operand without being affected by a negative edge at the RLO. As long as the timer is running, the "TagOut" operand returns signal state "1". If the signal state at the "TagIn_1" operand changes from "0" to "1" before the timer expires, the timer is restarted.

SD: Start on-delay timer

Description

The "Start on-delay timer" instruction starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at the start input. The timer runs for the specified period of time as long as the RLO is "1". If the timer expires and the RLO has the signal state "1", the query timer status "1" returns the signal state "1". If the RLO changes from "1" to "0" while the timer is running, the timer is stopped. In this case, querying the timer status for "1" returns the signal state "0".

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down to zero. The time base determines the time period of the time value.

The "Start on-delay timer" instruction needs a preceding logic operation for the edge evaluation and can only be placed on the right edge of the network.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameters

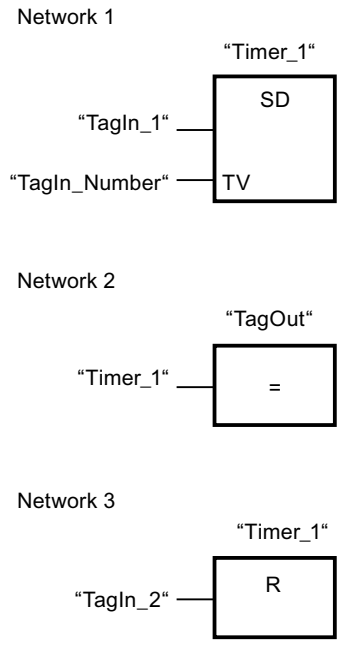
The following table shows the parameters of the instruction "Start on-delay timer":

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	BOOL	I, Q, M, T, C, D, L, P	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Time duration
<Timer>	InOut/Input	TIMER	T	Timer which is started. The number of timers depends on the CPU.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "0" to "1". The timer expires with the value of operand "TagIn_Number". If the timer expires and the RLO has the signal state "1", the "TagOut" operand is set to "1". If the signal state at the "TagIn_1" operand changes from "1" to "0" before the timer expires, the timer is stopped. If the signal state of the "TagIn_2" operand changes to "1", "Timer_1" is reset, i.e. the timer is stopped and the current time value is set to "0".

SS: Start retentive on-delay timer

Description

The "Start retentive on-delay timer" instruction starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at the start input. The timer runs for the specified time period even when the RLO changes to signal state "0". When the timer expires, the query for timer status for "1" returns the signal state "1". When the timer expires, the timer can only be restarted if it is explicitly reset.

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down to zero. The time base determines the time period of the time value.

The "Start retentive on-delay timer" instruction needs a preceding logic operation for the edge evaluation and can only be placed on the right edge of the network.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameters

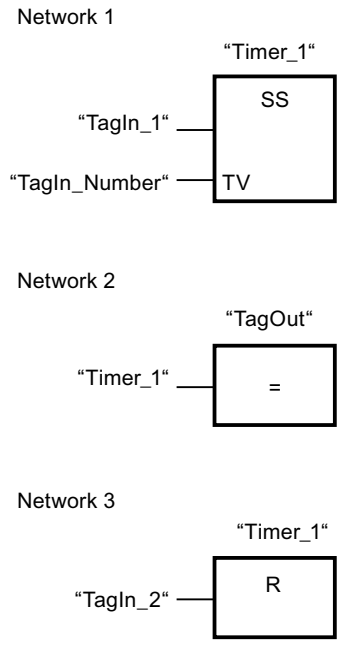
The following table shows the parameters of the instruction "Start retentive on-delay timer":

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	BOOL	I, Q, M, T, C, D, L, P	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Time duration
<Timer>	InOut/Input	TIMER	T	Timer which is started. The number of timers depends on the CPU.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "0" to "1". The timer expires with the value of operand "TagIn_Number". When the time expires, the "TagOut" operand is reset to "1". If the signal state at the "TagIn_1" operand changes from "0" to "1" while the timer is running, the timer is restarted. If the signal state of the "TagIn_2" operand changes to "1", "Timer_1" is reset, i.e. the timer is stopped and the current time value is set to "0".

SF: Start off-delay timer

Description

The "Start off-delay timer" instruction starts a programmed timer when a change from "1" to "0" (negative signal edge) is detected in the result of logic operation (RLO) at the start input. The timer runs for the specified time period. As long as the timer is running, the query of timer status "1" returns the signal state "1". If the RLO changes from "0" to "1" while the timer is running, the timer is reset. The timer is always restarted when the RLO changes from "1" to "0".

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down to zero. The time base determines the time period of the time value.

The "Start off-delay timer" instruction needs a preceding logic operation for the edge evaluation and can only be placed on the right edge of the network.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameters

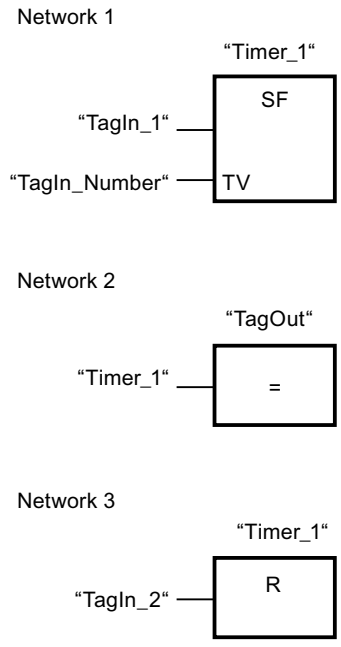
The following table shows the parameters of the instruction "Start off-delay timer":

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	BOOL	I, Q, M, T, C, D, L, P	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Time duration
<Timer>	InOut/Input	TIMER	T	Timer which is started. The number of timers depends on the CPU.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "1" to "0". The timer expires with the value of operand "TagIn_Number". As long as the timer is running, the "TagOut" operand is set to "1". If the signal state at the "TagIn_1" operand changes from "1" to "0" while the timer is running, the timer is restarted. If the signal state of the "TagIn_2" operand changes to "1", "Timer_1" is reset, i.e. the timer is stopped and the current time value is set to "0".

Counter operations

CTU: Count up

Description

You can use the "Count up" instruction to increment the value at output CV. When the signal state at the CU input changes from "0" to "1" (positive signal edge), the instruction is executed and the current counter value at the CV output is incremented by one. The counter value is incremented each time a positive signal edge is detected, until it reaches the high limit for the data type specified at the output CV. When the high limit is reached, the signal state at the CU input no longer has an effect on the instruction.

You can query the counter status in the Q output. The signal state at the Q output is determined by the PV parameter. If the current counter value is greater than or equal to the value of the

PV parameter, the Q output is set to signal state "1". In all other cases, the Q output has signal state "0". You can also specify a constant for the PV parameter.

The value at the CV output is reset to "0" and saved to an edge memory bit when the signal state at input R changes to "1". As long as the R input has signal state "1", the signal state at the CU input has no effect on the instruction.

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Each call of the "Count up" instruction must be assigned an IEC counter in which the instruction data is stored. An IEC counter is a structure with one of the following data types:

For S7-1200 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER	• CTU_SINT / CTU_USINT • CTU_INT / CTU_UINT • CTU_DINT / CTU_UDINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER

For S7-1500 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER	• CTU_SINT / CTU_USINT • CTU_INT / CTU_UINT • CTU_DINT / CTU_UDINT • CTU_LINT / CTU_ULINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER

You can declare an IEC counter as follows:

- Declaration of a data block of system data type IEC_<Counter> (for example, "MyIEC_COUNTER")
- Declaration as a local tag of the type CTU_<Data type> or IEC_<Counter> in the "Static" section of a block (for example #MyIEC_COUNTER)

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the IEC counter is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, you will

find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

When you set up the IEC counter in a separate data block (single instance), the instance data block is created by default with "optimized block access" and the individual tags are defined as retentive. For additional information on setting retentivity in an instance data block, refer to "See also".

When you set up the IEC counter as local tag (multi-instance) in a function block with "optimized block access", it is defined as retentive in the block interface.

The execution of the "Count up" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

Parameters

The following table shows the parameters of the instruction "Count up":

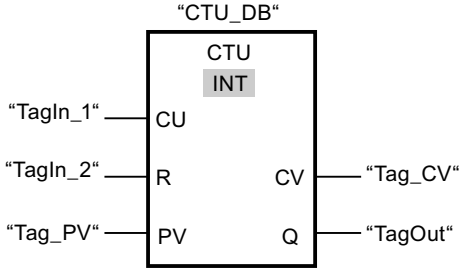
Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
CU	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Count input
R	Input	BOOL	I, Q, M, D, L, P, or constant	I, Q, M, T, C, D, L, P or constant	Reset input
PV	Input	Integers	I, Q, M, D, L, P, or constant	I, Q, M, D, L, P, or constant	Value at which the output Q is set.
Q	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Counter status
CV	Output	Integers, CHAR, WCHAR, DATE	I, Q, M, D, L, P	I, Q, M, D, L, P	Current counter value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:



When the signal state of the "TagIn_1" operand changes from "0" to "1", the "Count up" instruction is executed and the current counter value of the "Tag_CV" operand is incremented

by one. With each additional positive signal edge, the counter value is incremented until the high limit of the specified data type (INT = 32767) is reached.

The value of the PV parameter is adopted as the limit for determining the "TagOut" output. The "TagOut" output has signal state "1" as long as the current counter value is greater than or equal to the value of the "Tag_PV" operand. In all other cases, the "TagOut" output returns the signal state "0".

See also

Overview of the valid data types (Page 1908)

CTD: Count down

Description

You can use the "Count down" instruction to decrement the value at output CV. When the signal state at the CD input changes from "0" to "1" (positive signal edge), the instruction is executed and the current counter value at the CV output is decremented by one. Each time a positive signal edge is detected, the counter value is decremented until it reaches the low limit of the specified data type. When the low limit is reached, the signal state at the CD input no longer has an effect on the instruction.

You can query the counter status in the Q output. If the current counter value is less than or equal to "0", the Q output is set to signal state "1". In all other cases, the Q output has signal state "0". You can also specify a constant for the PV parameter.

The value at the CV output is set to the value of the PV parameter and saved to a edge memory bit when the signal state at the LD input changes from "0" to "1". As long as the LD input has signal state "1", the signal state at the CD input has no effect on the instruction.

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Each call of the "Count down" instruction must be assigned an IEC counter in which the instruction data is stored. An IEC counter is a structure with one of the following data types:

For S7-1200 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER	• CTD_SINT / CTD_USINT • CTD_INT / CTD_UINT • CTD_DINT / CTD_UDINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER

For S7-1500 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER	• CTD_SINT / CTD_USINT • CTD_INT / CTD_UINT • CTD_DINT / CTD_UDINT • CTD_LINT / CTD_ULINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER

You can declare an IEC counter as follows:

- Declaration of a data block of system data type IEC_<Counter> (for example, "MyIEC_COUNTER")
- Declaration as a local tag of the type CTD_<Data type> or IEC_<Counter> in the "Static" section of a block (for example #MyIEC_COUNTER)

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the IEC counter is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

When you set up the IEC counter in a separate data block (single instance), the instance data block is created by default with "optimized block access" and the individual tags are defined as retentive. For additional information on setting retentivity in an instance data block, refer to "See also".

When you set up the IEC counter as local tag (multi-instance) in a function block with "optimized block access", it is defined as retentive in the block interface.

The execution of the "Count down" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

Parameters

The following table shows the parameters of the "Count down" instruction:

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
CD	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Count input
LD	Input	BOOL	I, Q, M, D, L, P, or constant	I, Q, M, T, C, D, L, P or constant	Load input
PV	Input	Integers	I, Q, M, D, L, P, or constant	I, Q, M, D, L, P, or constant	Value to which the CV output is set with LD = 1.

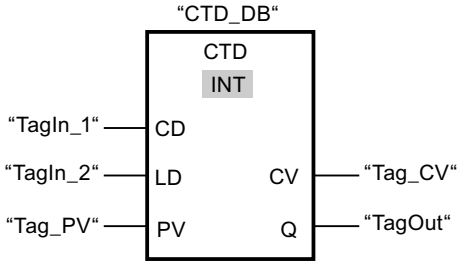
Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
Q	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Counter status
CV	Output	Integers, CHAR, WCHAR, DATE	I, Q, M, D, L, P	I, Q, M, D, L, P	Current counter value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:



When the signal state of the "TagIn_1" operand changes from "0" to "1", the instruction is executed and the value at the "Tag_CV" output is decremented by one. With each additional positive signal edge, the counter value is decremented until the low limit of the specified data type (INT = -32768) is reached.

The value of the PV parameter is adopted as the limit for determining the "TagOut" output. The "TagOut" output has signal state "1" as long as the current counter value is less than or equal to "0". In all other cases, the "TagOut" output returns the signal state "0".

Overview of the valid data types (Page 1908)

CTUD: Count up and down

Description

You can use the "Count up and down" instruction to increment and decrement the counter value at the CV output. If the signal state at the CU input changes from "0" to "1" (positive signal edge), the current counter value is incremented by one and stored at the CV output. If the signal state at the CD input changes from "0" to "1" (positive signal edge), the current counter value at the CV output is decremented by one. If there is a positive signal edge at the CU and CD inputs in one program cycle, the current counter value at the CV output remains unchanged.

The counter value can be incremented until it reaches the high limit of the data type specified at the CV output. When the high limit is reached, the counter value is no longer incremented

on a positive signal edge. The counter value is no longer decremented once the low limit of the specified data type has been reached.

When the signal state at the LD input changes to "1", the counter value at the CV output is set to the value of the PV parameter and stored in a edge memory bit. As long as the LD input has signal state "1", the signal state at the CU and CD inputs has no effect on the instruction.

The counter value is set to "0" and stored in an edge memory bit when the signal state at input R changes to "1". As long as the R input has signal state "1", a change in the signal state of the CU, CD and LD inputs has no effect on the "Count up and down" instruction.

You can query the status of the up counter at the QU output. If the current counter value is greater than or equal to the value of the PV parameter, the QU output is set to signal state "1". In all other cases, the QU output has signal state "0". You can also specify a constant for the PV parameter.

You can query the status of the down counter at the QD output. If the current counter value is less than or equal to zero, the QD output is set to signal state "1". In all other cases, the QD output has signal state "0".

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Each call of the "Count up and down" instruction must be assigned an IEC counter in which the instruction data is stored. An IEC counter is a structure with one of the following data types:

For S7-1200 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER	• CTUD_SINT / CTUD_USINT • CTUD_INT / CTUD_UINT • CTUD_DINT / CTUD_UDINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER

For S7-1500 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER	• CTUD_SINT / CTUD_USINT • CTUD_INT / CTUD_UINT • CTUD_DINT / CTUD_UDINT • CTUD_LINT / CTUD_ULINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER

You can declare an IEC counter as follows:

- Declaration of a data block of system data type IEC_<Counter> (for example, "MyIEC_COUNTER")
- Declaration as a local tag of the type CTUD_<Data type> or IEC_<Counter> in the "Static" section of a block (for example #MyIEC_COUNTER)

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the IEC counter is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

When you set up the IEC counter in a separate data block (single instance), the instance data block is created by default with "optimized block access" and the individual tags are defined as retentive. For additional information on setting retentivity in an instance data block, refer to "See also".

When you set up the IEC counter as local tag (multi-instance) in a function block with "optimized block access", it is defined as retentive in the block interface.

The execution of the "Count up and down" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

Parameters

The following table shows the parameters of the instruction "Count up and down":

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
CU	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Count up input
CD	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Count down input
R	Input	BOOL	I, Q, M, D, L, P, or constant	I, Q, M, T, C, D, L, P or constant	Reset input

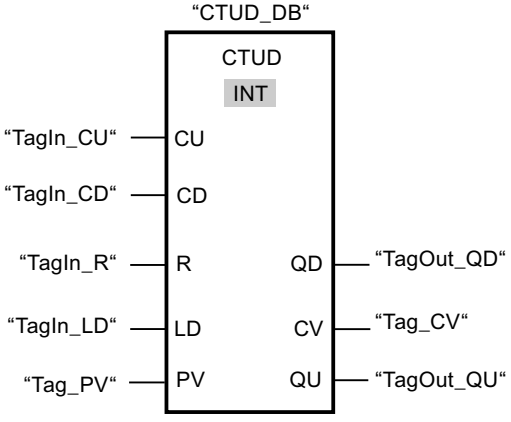
Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
LD	Input	BOOL	I, Q, M, D, L, P, or constant	I, Q, M, T, C, D, L, P or constant	Load input
PV	Input	Integers	I, Q, M, D, L, P, or constant	I, Q, M, D, L, P, or constant	Value at which the output QU is set. / Value to which the CV output is set with LD = 1.
QU	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Up-counter status
QD	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Down-counter status
CV	Output	Integers, CHAR, WCHAR, DATE	I, Q, M, D, L, P	I, Q, M, D, L, P	Current counter value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:



If the signal state at the "TagIn_CU" or "TagIn_CD" input changes from "0" to "1" (positive signal edge), the "Count up and down" instruction is executed. When there is a positive signal edge at the "TagIn_CU" input, the current counter value is incremented by one and stored at the "Tag_CV" output. When there is a positive signal edge at the "TagIn_CD" input, the counter value is decremented by one and stored at the "Tag_CV" output. When there is a positive edge at the CU input, the counter value is incremented until it reaches the high limit (INT = 32767). If input CD has a positive signal edge, the counter value is decremented until it reaches the low limit (INT = -32768).

The "TagOut_GU" output has signal state "1" as long as the current counter value is greater than or equal to the value at the "Tag_PV" input. In all other cases, the "TagOut_QU" output returns the signal state "0".

The "TagOut_QD" output has signal state "1" as long as the current counter value is less than or equal to "0". In all other cases, the "TagOut_QD" output has signal state "0".

Legacy

S_CU: Assign parameters and count up

Description

You can use the "Assign parameters and count up" instruction to increment the value of a counter. If the signal state at the CU input changes from "0" to "1" (positive signal edge), the current counter value is incremented by one. The current counter value is output as a hexadecimal value at output CV and BCD-coded at output CV_BCD. The count is incremented until the limit of "999" is reached. When the limit is reached, the counter value is no longer incremented on a positive signal edge.

When the signal state at input S changes from "0" to "1", the counter value is set to the value of the PV parameter. If the counter is set and if RLO at input CU is "1", the counter will count accordingly in the next scan cycle, even when no change has been detected in the signal edge.

The counter value is set to zero when the signal state at the R input changes to "1". As long as the R input has the signal state "1", processing of the signal state of the CU and S inputs has no effect on the counter value.

The signal state at output Q is "1" if the counter value is greater than zero. If the counter value is equal to zero, output Q has the signal state "0".

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

The "Assign parameters and count up" instruction needs a preceding logic operation for the edge evaluation and can be placed within or at the end of the network.

Parameters

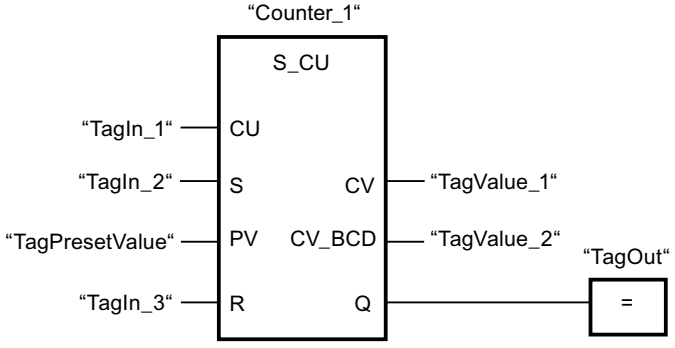
The following table shows the parameters of the "Assign parameters and count up" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Counter>	InOut/Input	COUNTER	C	Counter of the instruction The number of counters depends on the CPU.
CU	Input	BOOL	I, Q, M, D, L, T, C	Count up input
S	Input	BOOL	I, Q, M, D, L, T, C or constant	Input for presetting counter
PV	Input	WORD	I, Q, M, D, L or constant	Preset counter value (C#0 to C#999)
R	Input	BOOL	I, Q, M, D, L, T, C or constant	Reset input
CV	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (hexadecimal)
CV_BCD	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the counter

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



When the signal state at the "TagIn_1" input changes from "0" to "1" (positive signal edge) and the current counter value is less than "999", the counter value is incremented by one. When the signal state at the "TagIn_2" input changes from "0" to "1", the counter value is set to the value of the "TagPresetValue" operand. The counter value is reset to "0" when the "TagIn_3" operand has signal state "1".

The current counter value is hexadecimal in the "TagValue_1" operand and BCD-coded in the "TagValue_2" operand.

The "TagOut" output has the signal state "1" as long as the current counter value is not equal to "0".

See also

Overview of the valid data types (Page 1908)

S_CD: Assign parameters and count down

Description

You can use the "Assign parameters and count down" instruction to decrement the value of a counter. If the signal state at the CD input changes from "0" to "1" (positive signal edge), the counter value is decremented by one. The current counter value is output as a hexadecimal value at output CV and BCD-coded at output CV_BCD. The count is decremented until the low limit of "0" is reached. When the low limit is reached, the counter value is no longer decremented on a positive signal edge.

When the signal state at input S changes from "0" to "1", the counter value is set to the value of the PV parameter. If the counter is set and if RLO at input CD is "1", the counter will count accordingly in the next scan cycle, even when no change has been detected in the signal edge.

The counter value is set to zero when the signal state at the R input changes to "1". As long as the R input has the signal state "1", processing of the signal state of the CD and S inputs has no effect on the counter value.

The signal state at output Q is "1" if the counter value is greater than zero. If the counter value is equal to zero, output Q has the signal state "0".

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

The "Assign parameters and count down" instruction needs a preceding logic operation for the edge evaluation and can be placed within or at the end of the network.

Parameters

The following table shows the parameters of the "Assign parameters and count down" instruction:

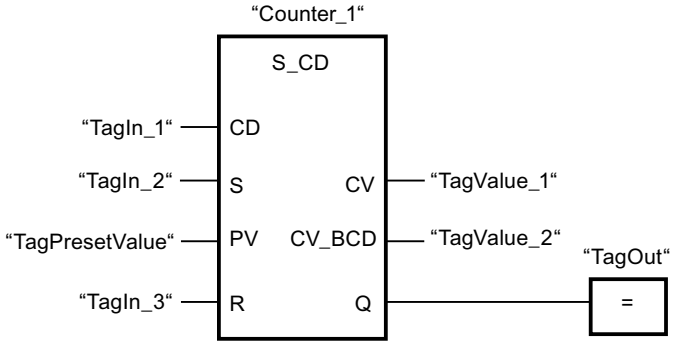
Parameters	Declaration	Data type	Memory area	Description
<Counter>	InOut/Input	COUNTER	C	Counter of the instruction The number of counters depends on the CPU.
CD	Input	BOOL	I, Q, M, D, L or constant	Count down input

Parameters	Declaration	Data type	Memory area	Description
S	Input	BOOL	I, Q, M, D, L, T, C or constant	Input for presetting counter
PV	Input	WORD	I, Q, M, D, L or constant	Preset counter value (C#0 to C#999)
R	Input	BOOL	I, Q, M, D, L, T, C or constant	Reset input
CV	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (hexadecimal)
CV_BCD	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the counter

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



When the signal state at the "TagIn_1" input changes from "0" to "1" (positive signal edge) and the current counter value is greater than "0", the counter value is decremented by one. When the signal state at the "TagIn_2" input changes from "0" to "1", the counter value is set to the value of the "TagPresetValue" operand. The counter value is reset to "0" when the "TagIn_3" operand has signal state "1".

The current counter value is hexadecimal in the "TagValue_1" operand and BCD-coded in the "TagValue_2" operand.

The "TagOut" output has the signal state "1" as long as the current counter value is not equal to "0".

Overview of the valid data types (Page 1908)

S_CUD: Assign parameters and count up / down

Description

You can use the "Assign parameters and count up / down" instruction to increment or decrement the value of a counter. If the signal state at the CU input changes from "0" to "1" (positive signal edge), the current counter value is incremented by one. If the signal state at the CD input changes from "0" to "1" (positive signal edge), the counter value is decremented by one. The current counter value is output as a hexadecimal value at output CV and BCD-coded at output CV_BCD. If there is a positive signal edge at the CU and CD inputs in one program cycle, the counter value remains unchanged.

The counter value is incremented until the high limit of "999" is reached. When the high limit value is reached, the counter value is no longer incremented on a positive signal edge. When the low limit of "0" is reached, the counter value is no longer decremented.

When the signal state at input S changes from "0" to "1", the counter value is set to the value of the PV parameter. If the counter is set and if RLO is "1" at the inputs CU and CD, the counter counts accordingly in the next scan cycle, even if no change in the signal edge is detected.

The counter value is set to zero when the signal state at the R input changes to "1". As long as the R input has the signal state "1", processing of the signal state of the CU, CD and S inputs has no effect on the counter value.

The signal state at output Q is "1" if the counter value is greater than zero. If the counter value is equal to zero, output Q has the signal state "0".

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

The "Assign parameters and count up / down" instruction needs a preceding logic operation for the edge evaluation and can be placed within or at the end of the network.

Parameters

The following table shows the parameters of the "Assign parameters and count up / down" instruction:

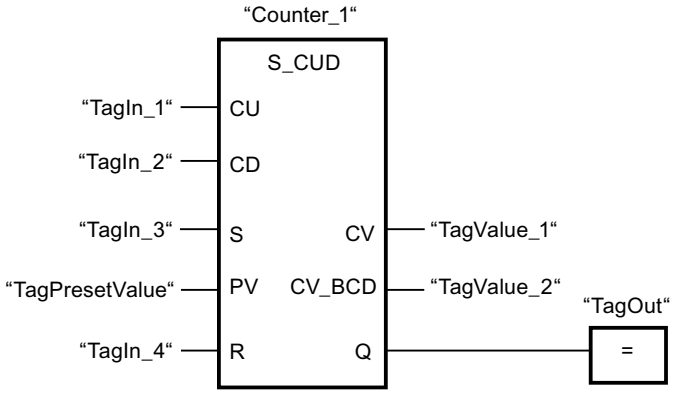
Parameters	Declaration	Data type	Memory area	Description
<Counter>	InOut/Input	COUNTER	C	Counter of the instruction The number of counters depends on the CPU.
CU	Input	BOOL	I, Q, M, D, L, T, C	Count up input
CD	Input	BOOL	I, Q, M, D, L, T, C or constant	Count down input
S	Input	BOOL	I, Q, M, D, L, T, C or constant	Input for presetting counter
PV	Input	WORD	I, Q, M, D, L or constant	Preset counter value (C#0 to C#999)

Parameters	Declaration	Data type	Memory area	Description
R	Input	BOOL	I, Q, M, D, L, T, C or constant	Reset input
CV	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (hexadecimal)
CV_BCD	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the counter

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If the signal state at the "TagIn_1" or "TagIn_2" input changes from "0" to "1" (positive signal edge), the "Assign parameters and count up / down" instruction is executed. When there is a positive signal edge at the "TagIn_1" input and the current counter value is less than "999", the counter value is incremented by one. When there is a positive signal edge at the "TagIn_2" input and the current counter value is greater than "0", the counter value is decremented by one.

When the signal state at the "TagIn_3" input changes from "0" to "1", the counter value is set to the value of the "TagPresetValue" operand. The counter value is reset to "0" when the "TagIn_4" operand has signal state "1".

The current counter value is hexadecimal in the "TagValue_1" operand and BCD-coded in the "TagValue_2" operand.

The "TagOut" output has the signal state "1" as long as the current counter value is not equal to "0".

Overview of the valid data types (Page 1908)

SC: Set counter value

Description

You can use the "Set counter value" instruction to set the value of a counter. The instruction is executed when the result of logic operation (RLO) at the start input of the instruction changes from "0" to "1". When the instruction is executed, the counter is set to the specified counter value.

The "Set counter value" instruction needs a preceding logic operation for the edge evaluation and can only be placed on the right edge of the network.

Parameters

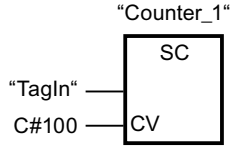
The following table lists the parameters of the "Set counter value" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	BOOL	I, Q, M, T, C, D, L	Start input
CV	Input	WORD	I, Q, M, D, L or constant	Value with which the counter is preset in the BCD format. (C#0 to C#999)
<Counter>	InOut/Input	COUNTER	C	Counter that is preset.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



the counter "Counter_1" starts with the value "100" when the signal state of the "TagIn" operand changes from "0" to "1".

Overview of the valid data types (Page 1908)

CU: Count up

Description

You use the "Count up" instruction to increment the value of the specified counter by the count of one on a rising edge at the start input. The count is incremented until the limit of "999" is reached. When the limit is reached, the counter value is no longer incremented on a positive signal edge.

The "Count up" instruction needs a preceding logic operation for the edge evaluation and can only be placed on the right edge of the network.

Parameters

The following table shows the parameters of the "Count up" instruction:

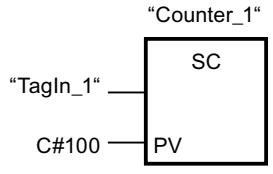
Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	BOOL	I, Q, M, T, C, D, L	Start input
<Counter>	InOut/Input	COUNTER	C	Counter whose value is incremented.

For additional information on valid data types, refer to "See also".

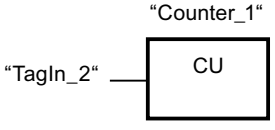
Example

The following example shows how the instruction works:

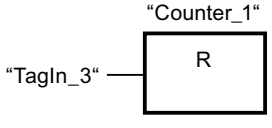
Network 1



Network 2



Network 3



When the signal state of the operand "TagIn_1" changes from "0" to "1" (positive signal edge), the counter "Counter_1" is preset with the value "100".

The value of "Counter_1" is incremented by the count of one when the signal state of the "TagIn_2" operand changes from "0" to "1".

If the "TagIn_3" operand returns signal state "1", the value of "Counter_1" is reset to "0".

Overview of the valid data types (Page 1908)

CD: Count down

Description

You use the "Count down" instruction to decrement the value of the specified counter by the count of one on a rising edge at the start input. The count is decremented until the limit of "0" is reached. When the limit is reached, the counter value is no longer changed on a positive signal edge.

The "Count down" instruction needs a preceding logic operation for the edge evaluation and can only be placed on the right edge of the network.

Parameters

The following table shows the parameters of the "Count down" instruction:

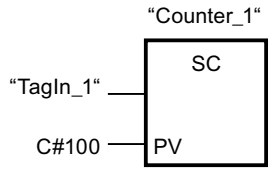
Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	BOOL	I, Q, M, T, C, D, L	Start input
<Counter>	InOut/Input	COUNTER	C	Counter whose value is decremented.

For additional information on valid data types, refer to "See also".

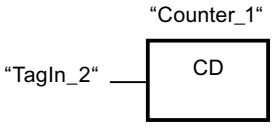
Example

The following example shows how the instruction works:

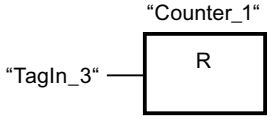
Network 1



Network 2



Network 3



When the signal state of the operand "TagIn_1" changes from "0" to "1" (positive signal edge), the counter "Counter_1" is preset with the value "100".

The value of "Counter_1" is incremented by the count of one when the signal state of the "TagIn_2" operand changes from "0" to "1".

If the "TagIn_3" operand returns signal state "1", the value of "Counter_1" is reset to "0".

Comparator operations

CMP ==: Equal

Description

You can use the "Equal" instruction to query whether the value at input IN1 is equal to the value at input IN2.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0".

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison.

The following table lists examples of string comparisons:

IN1	IN2	RLO of the instruction
'AA'	'AA'	1
'Hello World'	'HelloWorld'	0
'AA'	'aa'	0

The "Equal" instruction also compares individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

If IEC check is enabled, the operands to be compared must be of the same data type. If IEC check is not enabled, the width (length) of the operands must be the same. If the floating-point numbers are being compared, the operands to be compared must be of the same data type regardless of the IEC check setting.

Note

Comparison of floating-point numbers

If you want to compare the data types REAL or LREAL, instead of the instruction "CMP ==: Equal", use the instruction "IN_RANGE: Value within range".

Note

Comparison of the data type PORT

To be able to compare the operands of the PORT data type with the "Equal" instruction, you need to select the WORD data type from the drop-down list of the instructions box.

Parameters

The following table lists the parameters of the "Equal" instruction:

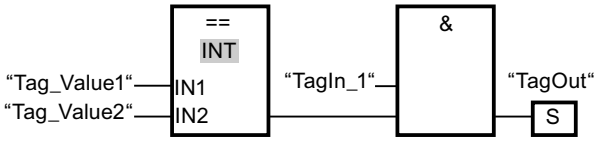
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	Bit strings, integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Bit strings, integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	First comparison value
IN2	Input	Bit strings, integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Bit strings, integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	Second value to compare

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also":

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" = "Tag_Value2".

See also

Overview of the valid data types (Page 1908)

CMP <>: Not equal

Description

You can use the "Not equal" instruction to query whether the value at input IN1 is not equal to the value at input IN2.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0".

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison.

The following table lists examples of string comparisons:

IN1	IN2	RLO of the instruction
'AA'	'aa'	1
'Hello World'	'HelloWorld'	1
'AA'	'AA'	0

The "Not equal" instruction also compares individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

If IEC check is enabled, the operands to be compared must be of the same data type. If IEC check is not enabled, the width (length) of the operands must be the same. If the floating-point

numbers are being compared, the operands to be compared must be of the same data type regardless of the IEC check setting.

Note

Comparison of the data type PORT

To be able to compare the operands of the PORT data type with the "Not equal" instruction, you need to select the WORD data type from the drop-down list of the instructions box.

Parameters

The following table lists the parameters of the "Not equal" instruction:

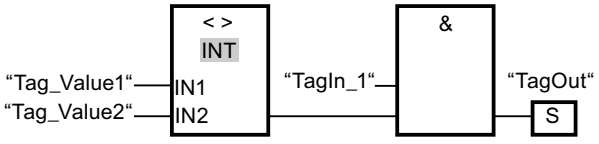
Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	Bit strings, integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Bit strings, integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	First comparison value
IN2	Input	Bit strings, integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Bit strings, integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	Second value to compare

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" <> "Tag_Value2".

Overview of the valid data types (Page 1908)

CMP >=: Greater or equal

Description

You can use the "Greater or equal" instruction to query whether the value at input IN1 is greater or equal to the value at input IN2. Both values to be compared must be of the same data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0".

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison. If the left part of the longer string is identical to the shorter string, the longer string is considered greater.

The following table lists examples of string comparisons:

IN1	IN2	RLO of the instruction
'BB'	'AA'	1
'AAA'	'AA'	1
'Hello World'	'Hello World'	1
'Hello World'	'HelloWorld'	0
'AA'	'aa'	0
'AAA'	'a'	0

The "Greater or equal" instruction also compares individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

In comparing timer values, the RLO of the instruction is "1" if the timer at input IN1 is greater (more recent) than or equal to the timer at input IN2.

Parameters

The following table lists the parameters of the "Greater or equal" instruction:

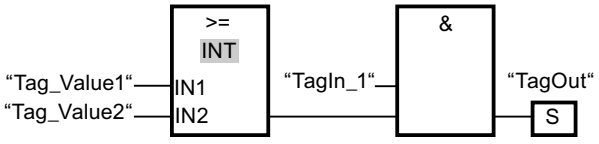
Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	Integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	First comparison value
IN2	Input	Integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	Second value to compare

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" >= "Tag_Value2".

Example of detecting the fill level of a storage area (Page 3874)

CMP <=: Less or equal

Description

You can use the "Less or equal" instruction to query whether the value at input IN1 is less or equal to the value at input IN2. Both values to be compared must be of the same data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0".

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison. If the left part of the longer string is identical to the shorter string, the shorter string is considered smaller.

The following table lists examples of string comparisons:

IN1	IN2	RLO of the instruction
'AA'	'aa'	1
'AAA'	'a'	1
'Hello World'	'Hello World'	1
'HelloWorld'	'Hello World'	0
'BB'	'AA'	0
'AAA'	'AA'	0

The "Less or equal" instruction also compares individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

In comparing timer values, the RLO of the instruction is "1" if the timer at input IN1 is smaller (less recent) than or equal to the timer at input IN2.

Parameters

The following table lists the parameters of the "Less or equal" instruction:

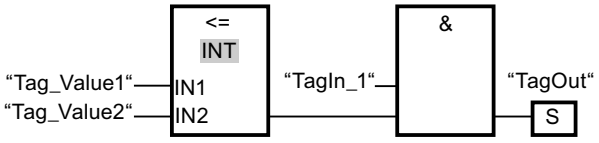
Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	Integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	First comparison value
IN2	Input	Integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	Second value to compare

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" <= "Tag_Value2".

CMP >: Greater than

Description

You can use the "Greater than" instruction to query whether the value at input IN1 is greater than the value at input IN2. Both values to be compared must be of the same data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0".

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison. If the left part of the longer string is identical to the shorter string, the longer string is considered greater.

The following table lists examples of string comparisons:

IN1	IN2	RLO of the instruction
'BB'	'AA'	1
'AAA'	'AA'	1
'AA'	'aa'	0
'AAA'	'a'	0

The "Greater than" instruction also compares individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

In comparing timer values, the RLO of the instruction is "1" if the timer at input IN1 is greater (more recent) than the timer at input IN2.

Parameters

The following table lists the parameters of the "Greater than" instruction:

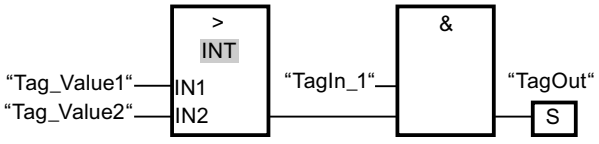
Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	Integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	First comparison value
IN2	Input	Integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	Second value to compare

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" > "Tag_Value2".

Overview of the valid data types (Page 1908)

CMP <: Less than

Description

You can use the "Less than" instruction to query whether the value at input IN1 is less than the value at input IN2. Both values to be compared must be of the same data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0".

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison. If the left part of the longer string is identical to the shorter string, the shorter string is considered smaller.

The following table lists examples of string comparisons:

<Operand1>	<Operand2>	RLO of the instruction
'AA'	'aa'	1
'AAA'	'a'	1
'BB'	'AA'	0
'AAA'	'AA'	0

The "Less than" instruction also compares individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

In comparing timer values, the RLO of the instruction is "1" if the timer at input IN1 is less (less recent) than the timer at input IN2 .

Parameters

The following table lists the parameters of the "Less than" instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	Integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	First comparison value
IN2	Input	Integers, floating-point numbers, character strings, TIME, DATE, TOD, DTL	Integers, floating-point numbers, character strings, TIME, LTIME, DATE, TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	Second value to compare

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:
