
The "TagOut" output is set when the following conditions are fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" < "Tag_Value2".

IN_RANGE: Value within range

Description

You can use the "Value within range" instruction to query whether of the value at input VAL is within a specific value range.

You specify the limits of the value range with the MIN and MAX inputs. The "Value within range" instruction compares the value at input VAL with the values of the inputs MIN and MAX and sends the result to the box output. If the value at input VAL satisfies the comparison MIN <= VAL or VAL <=MAX, the box output has the signal state "1". If the comparison is not fulfilled, the signal state is "0" at the box output.

The comparison function can only execute if the values to be compared are of the same data type.

Parameters

The following table shows the parameters of the "Value within range" instruction:

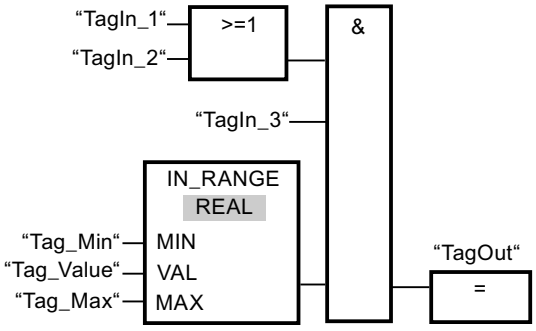
Parameters	Declaration	Data type	Memory area	Description
MIN	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Low limit of the value range
VAL	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Comparison value
MAX	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	High limit of the value range
Box output	Output	BOOL	I, Q, M, D, L	Result of the comparison

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also":

Example

The following example shows how the instruction works:



Output "TagOut" is set when the following conditions are fulfilled:

- The operands "TagIn_1" or "TagIn_2" have signal state "1".
- The operand "TagIn_3" has the signal state "1".
- The value of the operand "Tag_Value" is within the value range that is specified by the current values of the operands "Tag_Min" and "Tag_Max" (MIN <= VAL or VAL <= MAX).

See also

Overview of the valid data types (Page 1908)

OUT_RANGE: Value outside range

Description

You can use the "Value outside range" instruction to query whether of the value at input VAL is outside a specific value range.

You specify the limits of the value range with the MIN and MAX inputs. The "Value outside range" instruction compares the value at input VAL with the values of the inputs MIN and MAX and sends the result to the box output. If the value at input VAL satisfies the comparison MIN > VAL or VAL >MAX, the box output has the signal state "1". The box output has the signal state "1" if a specified operand of data type REAL has an invalid value.

The box output returns the signal state "0", if the value at input VAL does not satisfy the MIN > VAL or VAL > MAX condition.

The comparison function can only execute if the values to be compared are of the same data type.

Parameters

The following table shows the parameters of the "Value outside range" instruction:

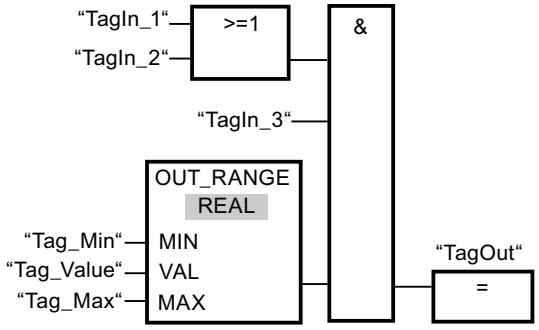
Parameters	Declaration	Data type	Memory area	Description
MIN	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Low limit of the value range
VAL	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Comparison value
MAX	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	High limit of the value range
Box output	Output	BOOL	I, Q, M, D, L	Result of the comparison

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



Output "TagOut" is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The operand "TagIn_3" has the signal state "1".
- The value of the operand "Tag_Value" is outside the value range that is specified by the values of the operands "Tag_Min" and "Tag_Max" (MIN > VAL or VAL > MAX).

Overview of the valid data types (Page 1908)

OK: Check validity

Description

You can use the "Check validity" instruction to check if the value of an operand (<Operand>) is a valid floating-point number. The check is performed in every program cycle. If the operand value at the time of the query is a valid floating-point number, the output box will return the signal state"1". In all other cases, the signal state at the output of the "Check validity" instruction is "0".

You can use the "Check validity" instruction together with the EN mechanism. If you connect the instruction box to an EN enable input, the enable input is set only when the result of the validity query of the value is positive. You can use this function to ensure that an instruction is enabled only when the value of the specified operand is a valid floating-point number.

Parameters

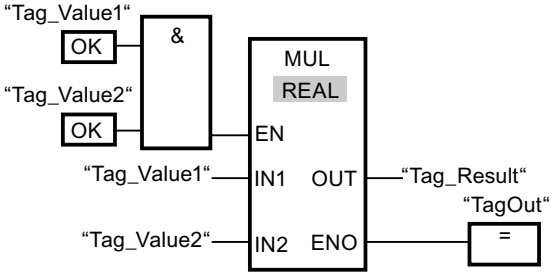
The following example shows how the "Check validity" instruction works:

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	Floating-point numbers	I, Q, M, D, L	Value to be checked.

For additional information on valid data types, refer to "See also":

Example

The following example shows how the instruction works:



When the values of the operands "Tag_Value1" and "Tag_Value2" show valid floating-point numbers, the "Multiply" (MUL) instruction is activated and the ENO output is set. During the execution of the "Multiply" (MUL) instruction, the value of the operand "Tag_Value1" is multiplied by the value of operand "Tag_Value2". The product of the multiplication is then stored in the operand "Tag_Result". If no errors occur during the execution of the instruction, the outputs ENO and "TagOut" are set to signal state "1".

See also

Overview of the valid data types (Page 1908)

NOT_OK: Check invalidity

Description

You can use the "Check invalidity" instruction to check if the value of an operand (<Operand>) is an invalid floating-point number. The check is performed in every program cycle. If the operand value at the time of the query is a valid floating-point number, then the output box will return the signal state "1". In all other cases, the signal state on the output box is "0".

Parameters

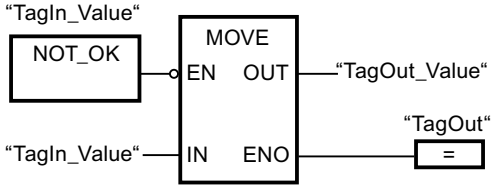
The following table shows the parameters of the instruction "Check invalidity":

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	Floating-point numbers	I, Q, M, D, L	Value to be checked.

For additional information on valid data types, refer to "See also":

Example

The following example shows how the instruction works:



When the value of operand "TagIn_Value" is an invalid floating-point number, the instruction "Move value" (MOVE) is not executed. The "TagOut" output is reset to signal state "0".

VARIANT

EQ_Type: Compare data type for EQUAL with the data type of a tag

Description

You can use the "Compare data type for EQUAL with the data type of a tag" instruction to query the data type of a tag to which a VARIANT points. You are comparing the data type of the tag at IN1 parameter, which you declared in the block interface, with the data type of a tag at IN2 parameter for "Equal to".

The tag at the IN1 parameter must be VARIANT data type. The tag at the IN2 parameter may be an elementary data type or a PLC data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0".

Parameters

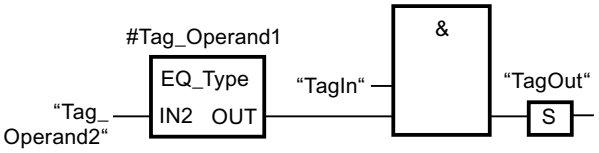
The following table lists the parameters of the "Compare data type for EQUAL with the data type of a tag" instruction:

Parameters	Declaration	Data type	Memory area	Description
IN1	Input	VARIANT	I, Q, M, L	First operand
IN2	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY, PLC data types	I, Q, M, D, L, P	Second operand

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operand "TagIn" has the signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the #Tag_Operand1 operand is equal to "Tag_Operand2".

See also

Overview of the valid data types (Page 1908)

NE_Type: Compare data type for UNEQUAL with the data type of a tag

Description

You can use the "Compare data type for UNEQUAL with the data type of a tag" instruction to query which data type a tag to which a VARIANT points does not have. You are comparing the data type of the tag at IN1 parameter, which you declared in the block interface, with the data type of a tag at IN2 parameter for "Not equal to".

The tag at the IN1 parameter must be VARIANT data type. The tag at the IN2 parameter may be an elementary data type or a PLC data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0".

Parameters

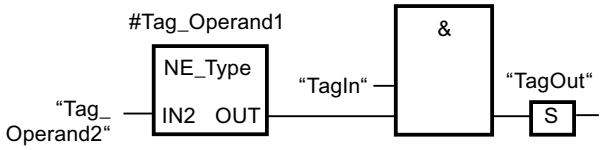
The following table lists the parameters of the "Compare data type for UNEQUAL with the data type of a tag" instruction:

Parameters	Declaration	Data type	Memory area	Description
IN1	Input	VARIANT	I, Q, M, L	First operand
IN2	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY, PLC data types	I, Q, M, D, L, P	Second operand

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operand "TagIn" has the signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the #Tag_Operand1 operand is not equal to "Tag_Operand2".

See also

Overview of the valid data types (Page 1908)

EQ_ElemType: Compare data type of an ARRAY element for EQUAL with the data type of a tag

Description

You can use the "Compare data type of an ARRAY element for EQUAL with the data type of a tag" instruction to query the data type of a tag to which a VARIANT points. You are comparing the data type of the tag at IN1 parameter, which you declared in the block interface, with the data type of a tag at IN2 parameter for "Equal to".

The tag at the IN1 parameter must be VARIANT data type. The tag at the IN2 parameter may be an elementary data type or a PLC data type.

If the data type of the VARIANT tag is an ARRAY, the data type of the ARRAY elements is compared.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0".

Parameters

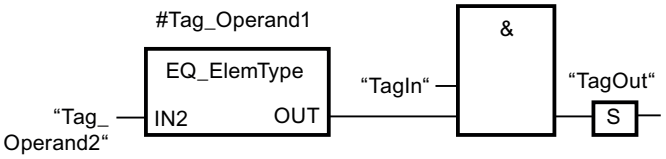
The following table lists the parameters of the "Compare data type of an ARRAY for EQUAL with the data type of a tag" instruction:

Parameters	Declaration	Data type	Memory area	Description
IN1	Input	VARIANT	I, Q, M, L	First operand
IN2	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY, PLC data types	I, Q, M, D, L	Second operand

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operand "TagIn" has the signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the #Tag_Operand1 operand is equal to "Tag_Operand2".

See also

Overview of the valid data types (Page 1908)

NE_ElemType: Compare data type of an ARRAY element for UNEQUAL with the data type of a tag

Description

You can use the "Compare data type of an ARRAY element for UNEQUAL with the data type of a tag" instruction to query which data type a tag does not have to which a VARIANT points. You are comparing the data type of the tag at IN1 parameter, which you declared in the block interface, with the data type of a tag at IN2 parameter for "Not equal to".

The tag at the IN1 parameter must be VARIANT data type. The tag at the IN2 parameter may be an elementary data type or a PLC data type.

If the data type of the VARIANT tag is an ARRAY, the data type of the ARRAY elements is compared.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0".

Parameters

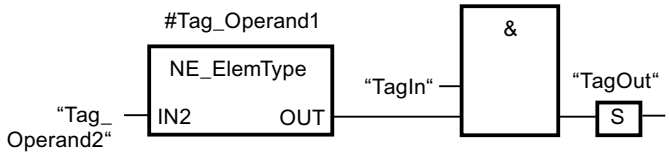
The following table lists the parameters of the "Compare data type of an ARRAY for UNEQUAL with the data type of a tag" instruction:

Parameters	Declaration	Data type	Memory area	Description
IN1	Input	VARIANT	I, Q, M, L	First operand
IN2	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY, PLC data types	I, Q, M, D, L	Second operand

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operand "TagIn" has the signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the #Tag_Operand1 operand is not equal to "Tag_Operand2".

See also

Overview of the valid data types (Page 1908)

IS_NULL: Check for EQUALS NULL pointer

Description

You can use the instruction "Check for EQUALS NULL pointer" to query whether the VARIANT points to a NULL pointer and therefore does not point to an object.

<Operand> must have the VARIANT data type.

Note

VARIANT tag points to an ANY pointer

If the VARIANT tag points to an ANY pointer, the instruction always returns the result RLO = "0" even if the ANY pointer is NULL.

Parameters

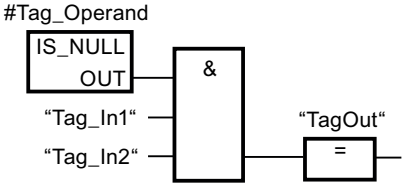
The following table shows the parameters of the "Check for EQUALS NULL pointer" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	VARIANT	I, Q, M, L	Operand that is compared for EQUALS NULL

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operands "Tag_In1" and "Tag_In2" have signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the #Tag_Operand operand does not point to an object.

See also

Overview of the valid data types (Page 1908)

NOT_NULL: Check for UNEQUALS NULL pointer

Description

You can use the instruction "Check for UNEQUALS NULL pointer" to query whether the VARIANT does not point to a NULL pointer and therefore points to an object.

<Operand> must have the VARIANT data type.

Note

VARIANT tag points to an ANY pointer

If the VARIANT tag points to an ANY pointer, the instruction always returns the result RLO = "1" even if the ANY pointer is NULL.

Parameters

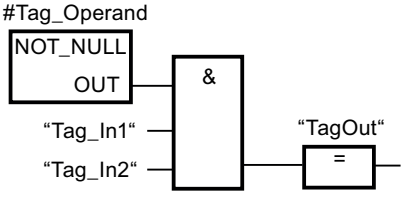
The following table shows the parameters of the "Check for UNEQUALS NULL pointer" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	VARIANT	I, Q, M, L	Operand that is compared for UNEQUALS NULL

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operands "Tag_In1" and "Tag_In2" have signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the #Tag_Operand operand points to an object.

See also

Overview of the valid data types (Page 1908)

IS_ARRAY: Check for ARRAY

Description

You can use the "Check for ARRAY" instruction to query whether the VARIANT points to a tag of the ARRAY data type.

<Operand> must have the VARIANT data type.

Parameters

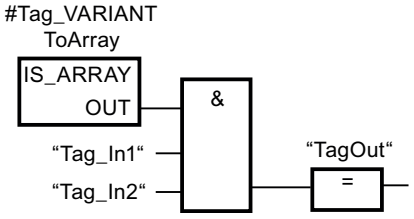
The following table shows the parameters of the "Check for ARRAY" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	VARIANT	I, Q, M, L	Operand that is queried for ARRAY

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The "TagOut" output is set when the following conditions are fulfilled:

- The operands "Tag_In1" and "Tag_In2" have signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the "#Tag_VARIANTToArray" operand is of the ARRAY data type.

Overview of the valid data types (Page 1908)

Math functions

CALCULATE: Calculate

Description

The "Calculate" instruction is used to define and execute an expression for the calculation of mathematical operations or complex logic operations depending on the selected data type.

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box. Depending on the selected data type, you can combine the functionality of specific instructions to execute a complex calculation. The expression to be calculated is specified via a dialog you can open via the "Calculator" icon at the top of the instruction box. The expression can contain the names of the input parameters and the syntax of the instructions. It is not permitted to specify operand names or operand addresses.

In its initial state, the instruction box contains at least 2 inputs (IN1 and IN2). The number of inputs can be extended. The inserted inputs are numbered in ascending order in the box.

The values of the inputs are use to execute the specified expression. Not all defined inputs have to be used in the expression. The result of the instruction is transferred to the box output OUT.

Note

If one of the mathematical operations fails in the expression, then no result is transferred to the OUT output and the ENO enable output has the signal state "1".

If, in the expression, you use inputs that are not available in the box, these inputs are automatically inserted. Provided that there are no gaps in the numbering of the inputs that are to be newly defined in the expression. You cannot, for example, use the input IN4 in the expression if the input IN3 is not defined.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The result or an interim result of the "Calculate" instruction is outside the range permitted for the data type specified at output OUT.
- A floating-point number has an invalid value.
- An error occurred during the execution of one of the instructions specified in the expression.

The following table shows the instructions that, depending on the selected data type, can be combined and executed in the expression of the "Calculate" instruction:

Data type	Instruction	Syntax	Example
Bit strings	AND: AND logic operation	AND	IN1 AND IN2 OR IN3
	OR: OR logic operation	OR	
	XOR: EXCLUSIVE OR logic operation	XOR	
	INV: Create ones complement	NOT	
	SWAP: Swap [1)]	SWAP	
Integers	ADD: Add	+	(IN1 + IN2) * IN3; (ABS(IN2)) * (ABS(IN1))
	SUB: Subtract	-	
	MUL: Multiply	*	
	DIV: Divide	/	
	MOD: Return remainder of division	MOD	
	INV: Create ones complement	NOT	
	NEG: Create twos complement	-(in1)	
	ABS: Form absolute value	ABS( )	

Data type	Instruction	Syntax	Example
Floating-point numbers	ADD: Add	+	((SIN(IN2) * SIN(IN2) + (SIN(IN3) * SIN(IN3)) / IN3)); (SQR(SIN(IN2)) + (SQR(COS(IN3)) / IN2))
	SUB: Subtract	-	
	MUL: Multiply	*	
	DIV: Divide	/	
	EXPT: Exponentiate	**	
	ABS: Form absolute value	ABS( )	
	SQR: Form square	SQR( )	
	SQRT: Form square root	SQRT( )	
	LN: Form natural logarithm	LN( )	
	EXP: Form exponential value	EXP( )	
	FRAC: Return fraction	FRAC( )	
	SIN: Form sine value	SIN( )	
	COS: Form cosine value	COS( )	
	TAN: Form tangent value	TAN( )	
	ASIN: Form arcsine value	ASIN( )	
	ACOS: Form arccosine value	ACOS( )	
	ATAN: Form arctangent value	ATAN( )	
	NEG: Create twos complement	-(in1)	
	TRUNC: Truncate numerical value	TRUNC( )	
	ROUND: Round numerical value	ROUND( )	
	CEIL: Generate next higher integer from floating-point number	CEIL( )	
	FLOOR: Generate next lower integer from floating-point number	FLOOR( )	

[1] Not possible for data type BYTE.

Parameters

The following table shows the parameters of the instruction "Calculate":

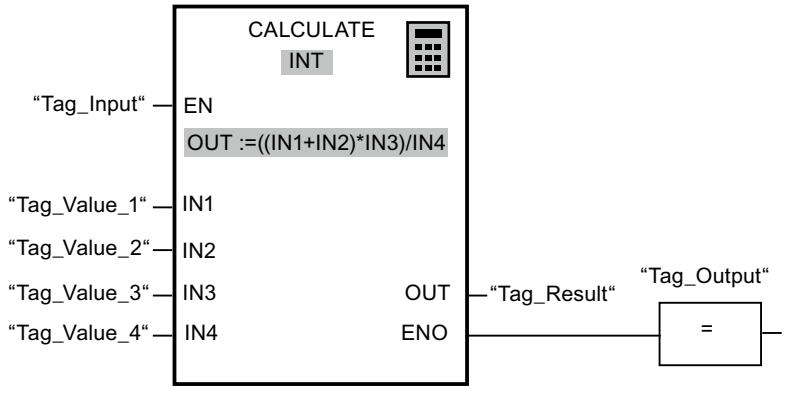
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Bit strings, integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	First available input
IN2	Input	Bit strings, integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Second available input

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
INn	Input	Bit strings, integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Additionally inserted inputs
OUT	Output	Bit strings, integers, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Output to which the end result is to be transferred.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN1	Tag_Value_1	4
IN2	Tag_Value_2	4
IN3	Tag_Value_3	3
IN4	Tag_Value_4	2
OUT	Tag_Result	12

If the "Tag_Input" has the signal state "1", the instruction is executed. The value of operand "Tag_Value_1" is added to the value of operand "Tag_Value_2". The sum is multiplied with the value of the operand "Tag_Value_3". The product is divided by the value of the operand "Tag_Value_4". The quotient is transferred as end result to the operand "Tag_Result" at the OUT output of the instruction. If no errors occur during the execution of the individual instructions, output ENO and the operand "Tag_Output" are set to "1".

See also

Overview of the valid data types (Page 1908)

Example of calculating an equation (Page 3877)

ADD: Add

Description

You can use the "Add" instruction to add the value at input IN1 to the value at input IN2 and query the sum at output OUT (OUT := IN1+IN2).

In its initial state the instruction box contains at least 2 inputs (IN1 and IN2). The number of inputs can be extended. The inserted inputs are numbered in ascending order in the box. During the execution of the instruction, the values of all available input parameters are added. The sum is stored at output OUT.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The result of the instruction is outside the range permitted for the data type specified at output OUT.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the instruction "Add":

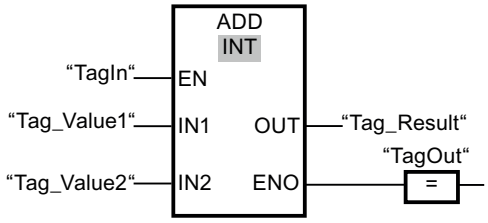
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	First number to be added
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Second number to be added
INn	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Optional input values, which are added.
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Sum

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also":

Example

The following example shows how the instruction works:



If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value1" is added to the value of operand "Tag_Value2". The result of the addition is stored in the operand "Tag_Result". If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

SUB: Subtract

Description

You can use the "Subtract" instruction to subtract the value at input IN2 from the value at input IN1 and query the difference at output OUT (OUT := IN1-IN2).

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The result of the instruction is outside the range permitted for the data type specified at output OUT.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the instruction "Subtract":

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Minuend

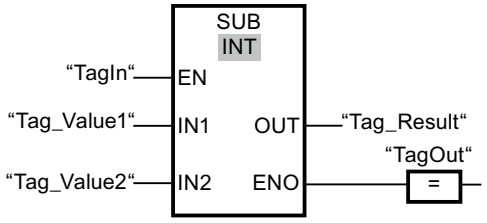
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Subtrahend
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Difference

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value2" is subtracted from the value of operand "Tag_Value1". The result of the subtraction is stored in the operand "Tag_Result". If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

MUL: Multiply

Description

You can use the "Multiply" instruction to multiply the value at input IN1 with the value at input IN2 and query the total at output OUT (OUT := IN1*IN2).

In its initial state the instruction box contains at least 2 inputs (IN1 and IN2). The number of inputs can be extended. The inserted inputs are numbered in ascending order in the box. When the instruction is executed, the values of all available input parameters are multiplied. The product is stored at the OUT output.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The result is outside the range permitted for the data type specified at output OUT.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the instruction "Multiply":

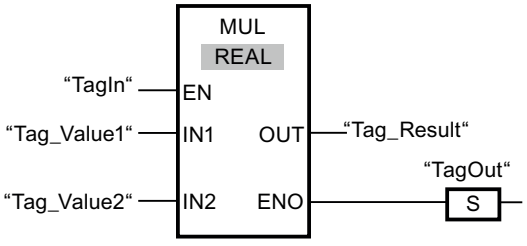
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	First value for multiplication
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Second value for multiplication
INn	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Optional input values, which are multiplied.
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Product

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value1" is multiplied with the value of operand "Tag_Value2". The result of the multiplication is stored in the operand "Tag_Result". If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

DIV: Divide

Description

You can use the "Divide" instruction to divide the value at input IN1 by the value at input IN2 and query the quotient at output OUT (OUT := IN1/IN2).

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The result of the instruction is outside the range permitted for the data type specified at output OUT.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the instruction "Divide":

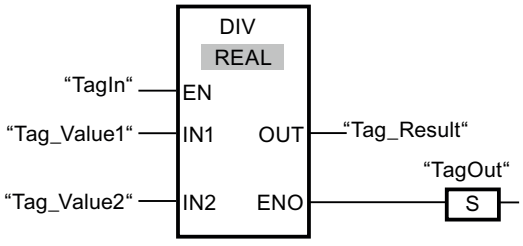
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Dividend
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Divisor
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Quotient value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value1" is divided by the value of operand "Tag_Value2". The result of the division is stored in the operand "Tag_Result". If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

Overview of the valid data types (Page 1908)

MOD: Return remainder of division

Description

You can use the "Return remainder of division" instruction to divide the value at input IN1 by the value at input IN2 and query the remainder of division at output OUT.

Parameters

The following table shows the parameters of the "Return remainder of division" instruction:

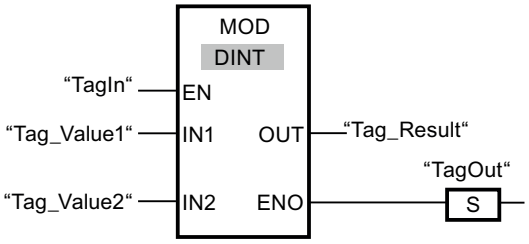
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Integers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Dividend
IN2	Input	Integers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Divisor
OUT	Output	Integers	I, Q, M, D, L, P	I, Q, M, D, L, P	Remainder of division

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value1" is divided by the value of operand "Tag_Value2". The remainder of division is stored in operand "Tag_Result". If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

NEG: Create twos complement

Description

You can use the "Create twos complement" instruction to change the sign of the value at input IN and query the result at output OUT. If there is a positive value at input IN, for example, the negative equivalent of this value is sent to output OUT.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The result of the instruction is outside the range permitted for the data type specified at output OUT.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Create twos complement" instruction:

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output

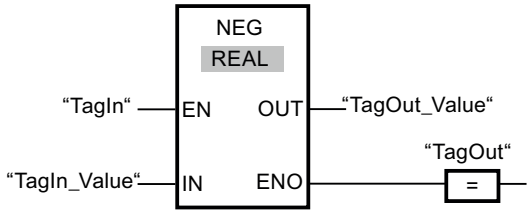
Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN	Input	SINT, INT, DINT, floating-point numbers	SINT, INT, DINT, LINT, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value
OUT	Output	SINT, INT, DINT, floating-point numbers	SINT, INT, DINT, LINT, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Twos complement of the input value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If the "TagIn" operand has signal state "1", the instruction is executed. The sign of the value at input "TagIn_Value" is changed and the result is stored at output "TagOut_Value". If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

INC: Increment

Description

You can use the "Increment" instruction to change the value of the operand at parameter IN/OUT to the next higher value and query the result.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Increment" instruction:

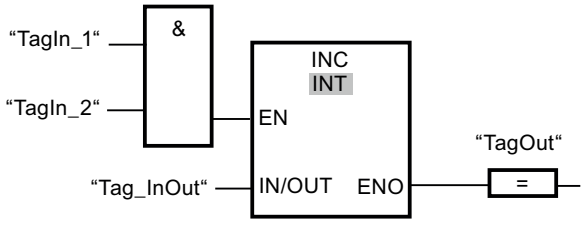
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN/OUT	InOut	Integers	I, Q, M, D, L	I, Q, M, D, L	Value to be incremented.

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If the operands TagIn_1 and TagIn_2 have the signal state "1", the value of the operand "Tag_InOut" is incremented by one and the output "TagOut" is set.

See also

Overview of the valid data types (Page 1908)

DEC: Decrement

Description

You can use the "Decrement" instruction to change the value of the operand at parameter IN/OUT to the next lower value and query the result.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the instruction "Decrement":

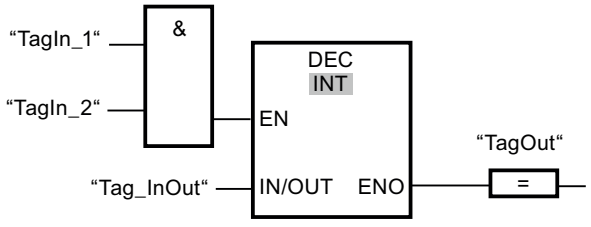
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN/OUT	InOut	Integers	I, Q, M, D, L	I, Q, M, D, L	Value to be decremented.

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If the operands "TagIn_1" and "TagIn_2" have the signal state "1", the value of the operand "Tag_InOut" is decremented by one and the output "TagOut" is set.

See also

Overview of the valid data types (Page 1908)

ABS: Form absolute value

Description

You can use the "Form absolute value" instruction to calculate the absolute value of the value specified at input IN. The result of the instruction is output at the OUT output and can be queried there.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the instruction "Form absolute value":

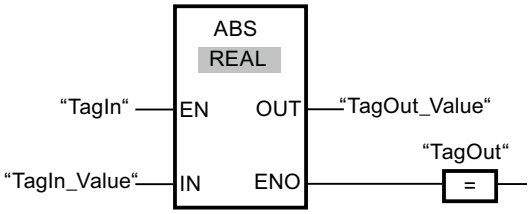
Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	SINT, INT, DINT, floating-point numbers	SINT, INT, DINT, LINT, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value
OUT	Output	SINT, INT, DINT, floating-point numbers	SINT, INT, DINT, LINT, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Absolute value of the input value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	TagIn_Value	-6.234
OUT	TagOut_Value	6.234

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction calculates the absolute value of the value at input "TagIn_Value" and sends the result to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

MIN: Get minimum

Description

The "Get minimum" instruction compares the values at the available inputs and writes the lowest value to the OUT output. The number of inputs can be expanded at the instruction box by additional inputs. The inputs are numbered in ascending order in the box.

In its initial state the instruction contains at least two inputs (IN1 and IN2) and no more than 100 inputs.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The implicit conversion of the data types fails during execution of the instruction.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Get minimum" instruction:

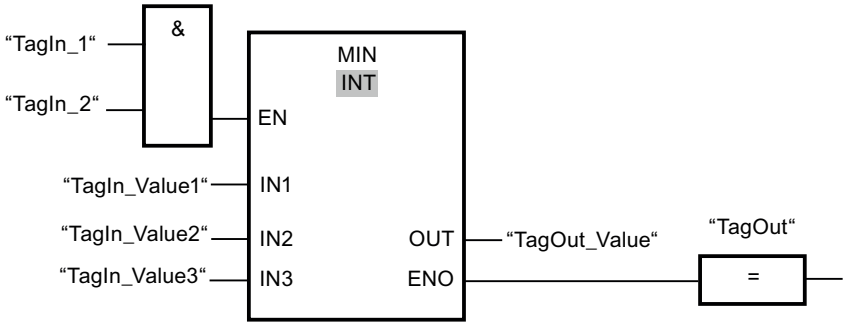
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	First input value
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Second input value
INn	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Additionally inserted inputs whose values are to be compared
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Result
If the IEC check is not enabled, you can also use tags of the data type TIME, LTIME, TOD, LTOD, DATE and LDT by selecting a bit string of the same length as the data type. (e.g. instead of TIME => DINT, UDINT or DWORD = 32 bits)					

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN1	TagIn_Value1	12222
IN2	TagIn_Value2	14444
IN3	TagIn_Value3	13333
OUT	TagOut_Value	12222

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. The instruction compares the values of the specified operands and copies the lowest value ("TagIn_Value1") to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

MAX: Get maximum

Description

The "Get maximum" instruction compares the values at the available inputs and writes the highest value to the OUT output. The number of inputs can be expanded at the instruction box by additional inputs. The inputs are numbered in ascending order in the box.

In its initial state the instruction contains at least two inputs (IN1 and IN2) and no more than 100 inputs.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The implicit conversion of the data types fails during execution of the instruction.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Get maximum" instruction:

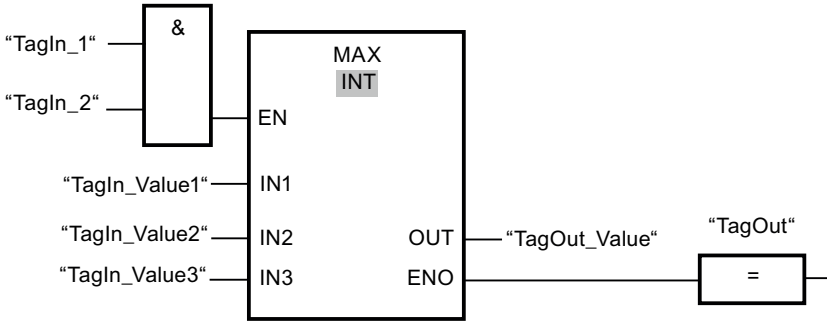
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	First input value
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Second input value
INn	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Additionally inserted inputs whose values are to be compared.
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Result
If the IEC check is not enabled, you can also use tags of the data type TIME, LTIME, TOD, LTOD, DATE and LDT by selecting a bit string of the same length as the data type. (e.g. instead of TIME => DINT, UDINT or DWORD = 32 bits)					

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN1	TagIn_Value1	12222
IN2	TagIn_Value2	14444
IN3	TagIn_Value3	13333
OUT	TagOut_Value	14444

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. The instruction compares the values of the specified operands and copies the highest value ("TagIn_Value2") to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

LIMIT: Set limit value

Description

You can use the "Set limit value" instruction to limit the value at input IN to the values at the inputs MN and MX. If the value at the IN input meets the MN condition <= IN <= MX, it is copied to the OUT output. If the condition is not fulfilled and the input value IN is below the low limit MN, output OUT is set to the value of the input MN. If the high limit MX is exceeded, output OUT is set to the value of the input MX.

If the value at input MN is greater than that at input MX, the result is undefined and the enable output ENO is "0".

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The specified tags are not of the same data type.
- An operand has an invalid value.
- The value at the MN input is greater than the value at the MX input.

Parameters

The following table shows the parameters of the "Set limit value" instruction:

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
MN	Input	Integers, floating-point numbers, TIME, TOD, DATE	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Low limit

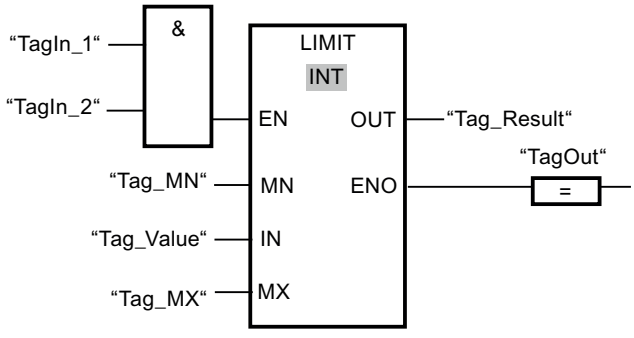
Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN	Input	Integers, floating-point numbers, TIME, TOD, DATE	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value
MX	Input	Integers, floating-point numbers, TIME, TOD, DATE	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	High limit
OUT	Output	Integers, floating-point numbers, TIME, TOD, DATE	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	I, Q, M, D, L, P	Result
The data types TOD, LTOD, DATE, and LDT can only be used if the IEC test is not enabled.						

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
MN	Tag_MN	12000
IN	Tag_Value	8000
MX	Tag_MX	16000
OUT	Tag_Result	12000

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. The value of operand "Tag_Value" is compared with the values of operands "Tag_MN" and "Tag_MX". Since the value of the operand "Tag_Value" is less than the low limit, the value of the operand "Tag_MN" is copied to the "Tag_Result" output. If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

SQR: Form square

Description

The instruction "Form square" is used to square the value of a floating-point number at input IN and to write the result to output OUT.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.

Parameters

The following table shows the parameters of the instruction "Form square":

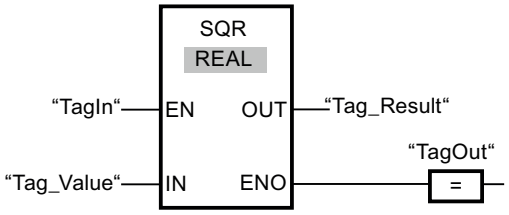
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Square of the input value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	Tag_Value	5.0
OUT	Tag_Result	25.0

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction squares the value of the operand "Tag_Value" and sends the result to output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

SQRT: Form square root

Description

The instruction "Form square root" is used form the square root from the value of the floating-point number at input IN and to write the result to output OUT. The instruction has a positive result if the input value is greater than zero. If input values are less than zero, output OUT returns an invalid floating-point number. If the value at input IN is "0", the result is also "0".

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.
- The value at input IN is negative.

Parameters

The following table shows the parameters of the instruction "Form square root":

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output

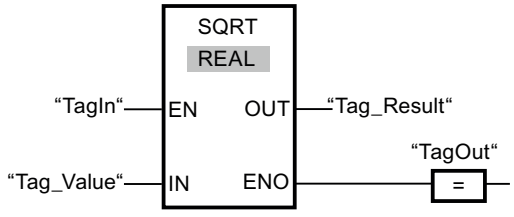
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value
OUT	Output	Floating-point numbers	I, Q, M, D, L	I, Q, M, D, L	Square root of the input value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	Tag_Value	25.0
OUT	Tag_Result	5.0

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction calculates the square root of the operand "Tag_Value" and sends the result to output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

LN: Form natural logarithm

Description

You can use the "Form natural logarithm" instruction to calculate the natural logarithm to base e (e = 2.718282) of the value at input IN. The result is sent to output OUT and can be queried there. The instruction has a positive result if the input value is greater than zero. If input values are less than zero, output OUT returns an invalid floating-point number.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.
- The value at input IN is negative.

Parameters

The following table shows the parameters of the instruction "Form natural logarithm":

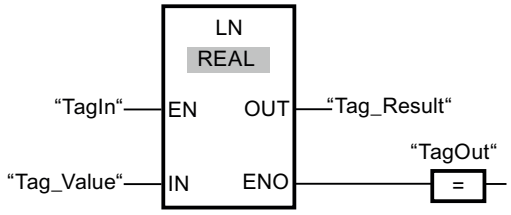
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Natural logarithm of the input value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If the "TagIn" operand has signal state "1", the instruction is executed. The instruction forms the natural logarithm of the value at input "Tag_Value" and sends the result to output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

EXP: Form exponential value

Description

You can use the "Form exponential value" instruction to calculate the exponent from the base e (e = 2.718282) and the value specified at input IN. The result is provided at output OUT and can be queried there (OUT = e^{IN}).

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.

Parameters

The following table shows the parameters of the instruction "Form exponential value":

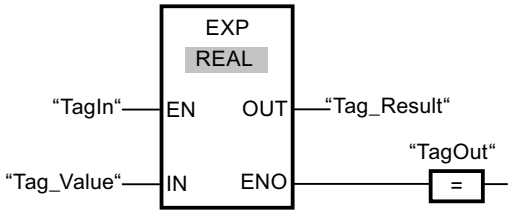
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Exponential value of input value IN

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If the "TagIn" operand has signal state "1", the instruction is executed. The instruction forms the exponent from base e and the value of the operand "Tag_Value" and sends the result to output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

SIN: Form sine value

Description

You can use the "Form sine value" instruction to calculate the sine of an angle. The size of the angle is specified in the radian measure at input IN. The result of the instruction is output at the OUT output and can be queried there.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.

Parameters

The following table shows the parameters of the instruction "Form sine value":

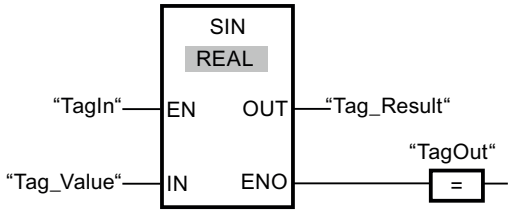
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Size of the angle in radians
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Sine of the specified angle

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	Tag_Value	+1.570796 (π/2)
OUT	Tag_Result	1.0

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction calculates the sine of the angle specified at input "Tag_Value" and sends the result to output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

COS: Form cosine value

Description

You can use the "Form cosine value" instruction to calculate the cosine of an angle. The size of the angle is specified in the radian measure at input IN. The result of the instruction is output at the OUT output and can be queried there.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.

Parameters

The following table shows the parameters of the instruction "Form cosine value":

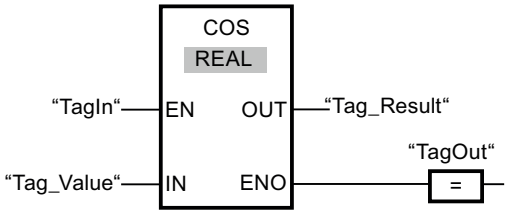
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Size of the angle in radians
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Cosine of the specified angle

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	Tag_Value	+1.570796 (π/2)
OUT	Tag_Result	0

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction calculates the cosine of the angle specified at input "Tag_Value" and sends the result to output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

TAN: Form tangent value

Description

You can use the "Form tangent value" instruction to calculate the tangent of an angle. The size of the angle is specified in the radian measure at input IN. The result of the instruction is provided at output OUT and can be queried there.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.

Parameters

The following table shows the parameters of the instruction "Form tangent value":

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output

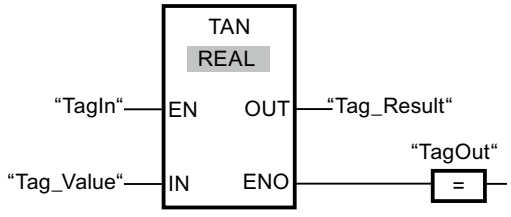
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Size of angle in the radian measure
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Tangent of the specified angle

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Value	+3.141593 (π)
OUT	Tag_Result	0

If the operand "TagIn" has the signal state "1", the "Form tangent value" instruction is executed. The instruction calculates the tangent of the angle specified at input "Tag_Value" and stores the result at output "Tag_Result". If no errors occur during the execution of the instruction, the output "TagOut" is set.

See also

Overview of the valid data types (Page 1908)

ASIN: Form arcsine value

Description

You can use the "Form arcsine value" instruction to calculate the size of the angle from the sine value specified at input IN, which corresponds to this value. Only valid floating-point numbers within the range -1 to +1 can be specified at input IN. The calculated angle size is output in radians at the OUT output and can range in value from -π/2 to +π/2.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.
- The value at input IN is outside the permitted range (-1 to +1).

Parameters

The following table shows the parameters of the instruction "Form arcsine value":

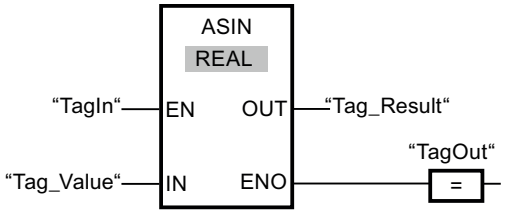
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Sine value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Size of the angle in radians

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	Tag_Value	1.0
OUT	Tag_Result	+1.570796 (π/2)

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction calculates the size of the angle corresponding to the sine value at input "Tag_Value". The result of the instruction is stored at output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

ACOS: Form arccosine value

Description

You can use the "Form arccosine value" instruction to calculate the size of the angle from the cosine value specified at input IN, which corresponds to this value. Only valid floating-point numbers within the range -1 to +1 can be specified at input IN. The calculated angle size is output in radians at output OUT and can range in value from 0 to +π.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.
- The value at input IN is outside the permitted range (-1 to +1).

Parameters

The following table shows the parameters of the instruction "Form arccosine value":

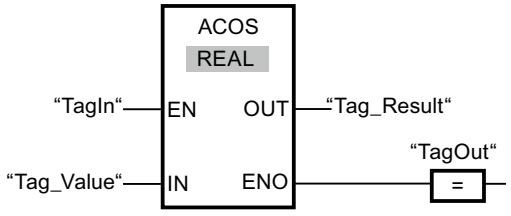
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Cosine value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Size of the angle in radians

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	Tag_Value	0
OUT	Tag_Result	+1.570796 (π/2)

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction calculates the size of the angle corresponding to the cosine value at input "Tag_Value". The result of the instruction is stored at output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

ATAN: Form arctangent value

Description

You can use the "Form arctangent value" instruction to calculate the size of the angle from the tangent value specified at input IN, which corresponds to this value. It is only permitted to specify valid floating-point numbers (or -NaN/+NaN) at input IN. The calculated angle size is output in radians at the OUT output and can range in value from -π/2 to +π/2.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.

Parameters

The following table shows the parameters of the instruction "Form arctangent value":

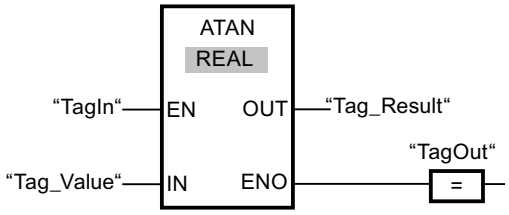
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Tangent value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Size of the angle in radians

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	Tag_Value	1.0
OUT	Tag_Result	+0.785398 (π/4)

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction calculates the size of the angle corresponding to the tangent value at input "Tag_Value". The result of the instruction is stored at output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

Overview of the valid data types (Page 1908)

Invalid floating-point numbers (Page 1927)

FRAC: Return fraction

Description

You can use the "Return fraction" instruction to determine the decimal places of the value at the IN input. The result of the query is stored at output OUT and can be queried there. If the input IN has e.g. the value 123.4567, the output OUT has the value 0.4567.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- Errors occur during the execution of the instruction, for example there is no valid floating-point number at the input.

Parameters

The following table shows the parameters of the "Return fraction" instruction:

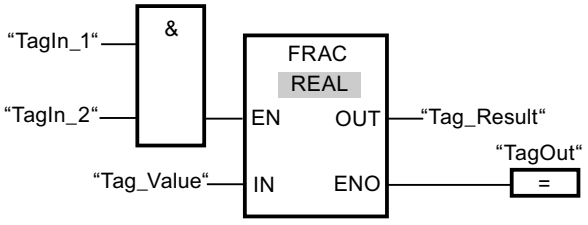
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value, whose decimal places are to be determined.
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Decimal places of the input value at input IN

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	Tag_Value	2.555
OUT	Tag_Result	0.555

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is started. The decimal places from the value at the operand "Tag_Value" are copied to the operand "Tag_Result". If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

EXPT: Exponentiate

Description

You can use the "Exponentiate" instruction to raise the value at the input IN1 by a power specified with the value at input IN2. The result of the instruction is stored at output OUT and can be queried there (OUT = $IN1^{IN2}$).

The value at input IN1 must be a valid floating-point number. Integers are also allowed for setting the input IN2.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- Errors occur during the instruction processing, for example, if there is an overflow.

Parameters

The following table shows the parameters of the instruction "Exponentiate":

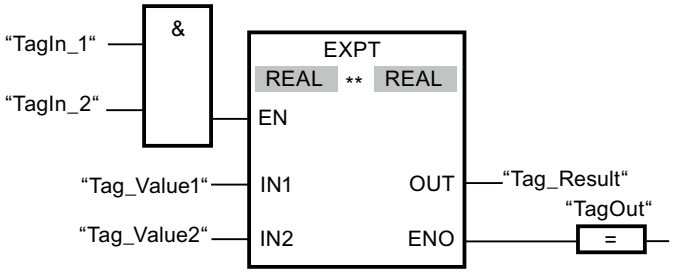
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Base value
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Value with which the base value is exponentiated
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Result

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If the operands "TagIn_1" and "TagIn_2" have signal state "1", the "Exponentiate" instruction is executed. The value of operand "Tag_Value1" is raised by the power of the value of the operand "Tag_Value2". The result is stored at output "Tag_Result". If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

Overview of the valid data types (Page 1908)

Move operations

MOVE: Move value

Description

You use the "Move value" instruction to transfer the content of the operand at the IN input to the operand at the OUT1 output. The transfer is always made in the direction of the higher address.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The data type at the IN parameter does not correspond to the specified data type at the OUT1 parameter.

The following table lists the possible transfers for the S7-1200 CPU series:

Source (IN)	Destination (OUT1)	
	With IEC check	Without IEC check
BYTE	BYTE, WORD, DWORD	BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT, TIME, DATE ,TOD, CHAR
WORD	WORD, DWORD	BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT, TIME, DATE, TOD, CHAR
DWORD	DWORD	BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT, REAL, TIME, DATE, TOD, CHAR

IEC_UL-COUNTER	IEC_ULCOUNTER	IEC_ULCOUNTER

[1)] You can also use the "Move value" instruction to transfer individual characters of a string to operands of the CHAR or WCHAR data type. The number of the character to be transferred is specified in square brackets next to the operand name. "MyString[2]", for example, transfers the second character of the "MyString" string. The transfer of the operand of the data type CHAR or WCHAR to the individual character of a string is also possible. You can also replace a specific character of a string with the character of another string.

[2)] Transferring entire arrays (ARRAY) is possible only when the array components of the operands at input IN and at output OUT1 are of the same data type.

If the bit length of the data type at input IN exceeds the bit length of the data type at output OUT1, the higher-order bits of the source value are lost. If the bit length of the data type at input IN is less than the bit length of the data type at output OUT1, the higher-order bits of the destination value will be overwritten with zeros.

In its initial state, the instruction box contains 1 output (OUT1). The number of outputs can be extended. The added outputs are numbered in ascending order on the box. During the execution of the instruction, the content of the operand at the input IN is transferred to all available outputs. The instruction box cannot be extended if structured data types (DTL, STRUCT, ARRAY) or characters of a string are transferred.

You can also use the "Move block" (MOVE_BLK) and "Move block uninterruptible" (UMOVE_BLK) instructions to move operands of the ARRAY data type. Operand of the data type STRING or WSTRING can be copied with the instruction "Move character string" (S_MOVE).

Parameters

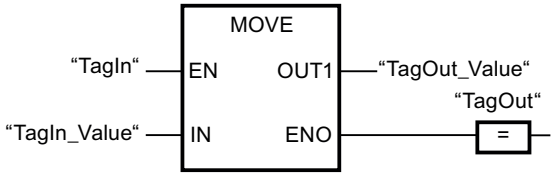
The following table shows the parameters of the "Move value" instruction:

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers, floating-point numbers, timers, date and time, CHAR, WCHAR, STRUCT, ARRAY, IEC data types, PLC data type (UDT)	Bit strings, integers, floating-point numbers, timers, date and time, CHAR; WCHAR, STRUCT, ARRAY, TIMER, COUNTER, IEC data type, PLC data type (UDT)	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Element used to overwrite the destination address.
OUT1	Output	Bit strings, integers, floating-point numbers, timers, date and time, CHAR, WCHAR, STRUCT, ARRAY, IEC data types, PLC data type (UDT)	Bit strings, integers, floating-point numbers, timers, date and time, CHAR; WCHAR, STRUCT, ARRAY, TIMER, COUNTER, IEC data type, PLC data type (UDT)	I, Q, M, D, L	I, Q, M, D, L	Destination address

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	TagIn_Value	0011 1111 1010 1111
OUT1	TagOut_Value	0011 1111 1010 1111

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction copies the content of the "TagIn_Value" operand to the "TagOut_Value" operand. If the instruction is executed without errors, the ENO and "TagOut" enable outputs are set to signal state "1".

Overview of the valid data types (Page 1908)

MOVE_BLK: Move block (Page 2621)

UMOVE_BLK: Move block uninterruptible (Page 2627)

S_MOVE: Move character string (Page 3001)

Deserialize: Deserialize

Description

You can use the "Deserialize" instruction to convert the sequential representation of a PLC data type (UDT) back to a PLC data type and to fill its entire contents.

The memory area in which the sequential representation of a PLC data type is located must have the ARRAY of BYTE data type and be declared with standard access. The capacity of the standard memory area is 64 KB. Make sure that there is enough memory space prior to the conversion.

The instruction enables you to convert multiple sequential representations of converted PLC data types back to their original state step-by-step.

If you only want to convert back a single sequential representation of a PLC data type (UDT), you can also use the instruction "TRCV: Receive data via communication connection".

Note

Applies to CPUs of the S7-1500 series

For a block with the block property "Optimized block access", the bit has a length of 1 byte.

Parameters

The following table lists the parameters of the "Deserialize" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output

Parameters	Declaration	Data type	Memory area	Description
SRC_ARRAY	Input	VARIANT	I, Q, M, L	Global data block in which the generated data stream is stored
DEST_VARIABLE	InOut	VARIANT	I, Q, M, L	Tag in which the returned converted PLC data type (UDT) is stored
POS	InOut	DINT	I, Q, M, D, L	Number of bytes that the converted PLC data types use. The POS parameter is calculated zero-based.
RET_VAL	Output	INT	I, Q, M, D, L	Error information

For additional information on valid data types, refer to "See also".

Parameter RET_VAL

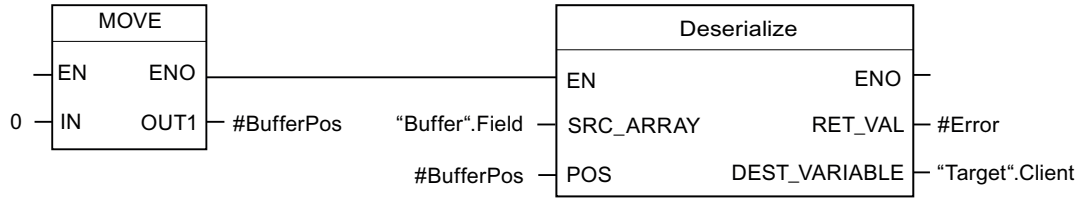
The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B0	The memory areas for the SRC_ARRAY and DEST_VARIABLE parameters overlap.
8136	The data block at the DEST_VARIABLE parameter is not a block with standard access.
8150	The VARIANT data type at the SRC_ARRAY parameter contains no value.
8151	Code generation error at the SRC_ARRAY parameter
8153	There is not enough free memory available at the SRC_ARRAY parameter.
8250	The VARIANT data type at the DEST_VARIABLE parameter contains no value.
8251	Code generation error at the DEST_VARIABLE parameter
8254	Invalid data type at the DEST_VARIABLE parameter
8382	The value at parameter POS is outside the limits of the array.
*The error codes can be displayed as integer or hexadecimal values in the program editor. You will find information on changing display formats in "See also".	

Example

The following example shows how the instruction works:

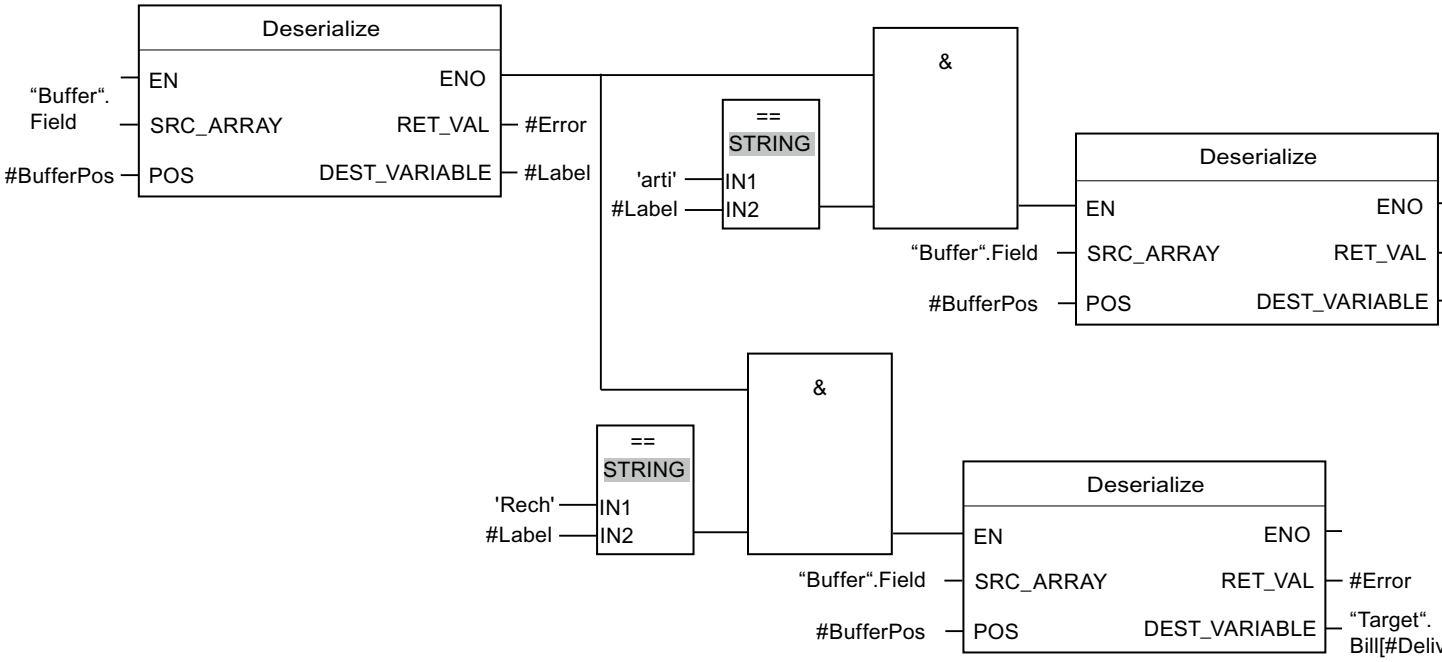
Network 1:



The "Move value" instruction moves the value "0" to the "#BufferPos" operand. The "Deserialize" instruction deserializes the sequential representation of the customer data from

the "Buffer" data block and writes it to the "Target" data block. The number of bytes used by the converted customer data is stored in the "#BufferPos" operand.

Network 2:



The "Deserialize" instruction deserializes the sequential representation of the separator sheet, which was saved with the sequential representation after the customer data, from the "Buffer" data block and writes the characters to the "#Label" operand. The characters are compared using comparison instructions "arti" and "Bill". If the comparison for "arti" = TRUE, these are article data that have been deserialized and written to the "Target" data block. If the comparison for "Bill" = TRUE, these are billing data that have been deserialized and written to the "Target" data block.

The following table shows the declaration of the operands:

Operand	Data type	Declaration
DeliverPos	INT	In the "Input" section of the block interface
BufferPos	DINT	In the "Temp" section of the block interface
Error	INT	In the "Temp" section of the block interface
Label	STRING[4]	In the "Temp" section of the block interface

The following table lists the declarations of the PLC data types:

Name of the PLC data types	Name	Data type
Article	Number	DINT
	Declaration	STRING
	Colli	INT

Name of the PLC data types	Name	Data type
Client	Title	INT
	First name	STRING[10]
	Surname	STRING[10]

The following table shows the declaration of the data blocks:

Name of the data blocks	Name	Data type
Target	Client	"Client" (PLC data type)
	Article	Array[0..10] of "Article" (PLC data type)
	Bill	Array[0..10] of INT
Buffer	Field	Array[0..294] of BYTE

Overview of the valid data types (Page 1908)

PLC data types (Page 1954)

Serialize: Serialize

Description

You can use the "Serialize" instruction to convert several PLC data types (UDT) to a sequential representation without losing parts of their structure.

You can use the instruction to cache multiple structured data from your program in a buffer, which is preferably in a global data block, and send it to another CPU. The memory area in which the converted PLC data types are stored must have the ARRAY of BYTE data type and be declared with standard access. The capacity of the standard memory area is 64 KB. Make sure that there is enough memory space prior to the conversion.

The operand at the POS parameter contains information about the number of bytes used by the converted PLC data types.

If you want to send a single PLC data type (UDT), you can directly call the instruction "TSEND: Send data via communication connection".

Note

Applies to CPUs of the S7-1500 series

For a block with the block property "Optimized block access", the bit has a length of 1 byte.

Parameters

The following table lists the parameters of the instruction "Serialize":

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
SRC_VARIABLE	Input	VARIANT	I, Q, M, L	PLC data type (UDT) that is converted to sequential representation.
DEST_ARRAY	InOut	VARIANT	I, Q, M, L	Data block in which the generated data stream is stored.
POS	InOut	DINT	I, Q, M, D, L	Number of bytes that the converted PLC data types use. The POS parameter is calculated zero-based.
RET_VAL	Output	INT	I, Q, M, D, L	Error information

For additional information on valid data types, refer to "See also".

Parameter RET_VAL

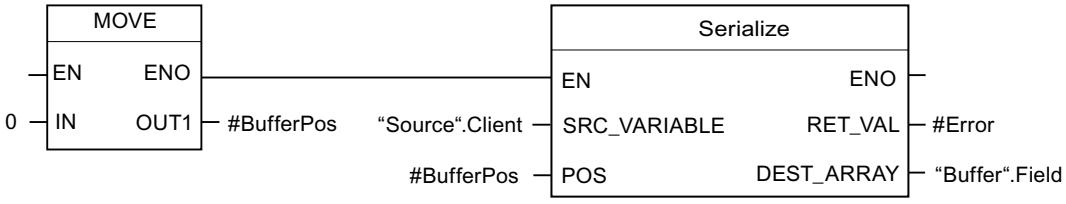
The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B0	The memory areas for the SRC_VARIABLE and DEST_ARRAY parameters overlap.
8150	The VARIANT data type at the SRC_VARIABLE parameter contains no value.
8152	Code generation error at the SRC_VARIABLE parameter
8236	The data block at the DEST_ARRAY parameter is not a block with standard access.
8250	The VARIANT data type at the DEST_ARRAY parameter contains no value.
8252	Code generation error at the DEST_ARRAY parameter
8253	There is not enough free memory available at the DEST_ARRAY parameter.
8254	Invalid data type at the DEST_ARRAY parameter
8382	The value at parameter POS is outside the limits of the array.
*The error codes can be displayed as integer or hexadecimal values in the program editor. You will find information on changing display formats in "See also".	

Example

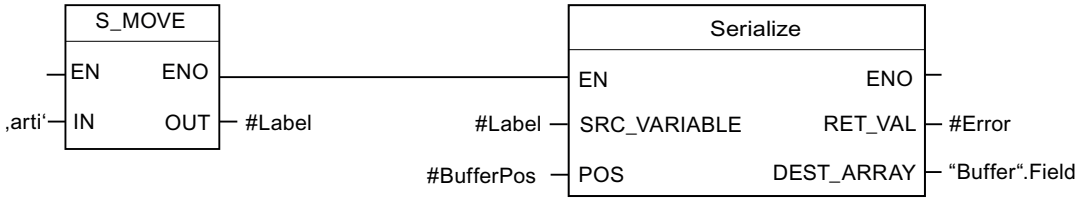
The following example shows how the instruction works:

Network 1:



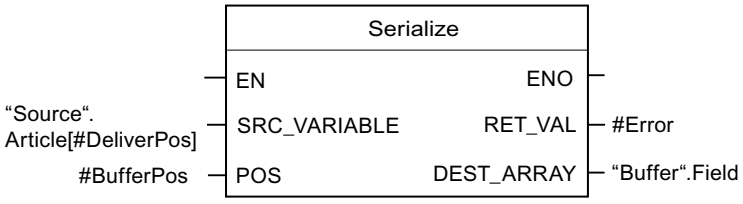
The "Move value" instruction moves the value "0" to the "#BufferPos" operand. The "Serialize" instruction serializes the customer data from the "Source" data block and writes it in sequential representation to the "Buffer" data block. The number of bytes used by the sequential representation is stored in the "#BufferPos" operand.

Network 2:



A kind of separator sheet is inserted now to make it easier to deserialize the sequential representation later. The "Move string" instruction moves the "arti" characters to the "#Label" operand. The "Serialize" instruction writes these characters after the customer data to the "Buffer" data block. The number of bytes that the characters need is added to the number already stored in the "#BufferPos" operand.

Network 3:



The "Serialize" instruction serializes the data of a specific article, which is calculated in runtime, from the "Source" data block and writes it in sequential representation to the "Buffer" data block after the "arti" characters.

The following table shows the declaration of the operands:

Operand	Data type	Declaration
DeliverPos	INT	In the "Input" section of the block interface
BufferPos	DINT	In the "Temp" section of the block interface
Error	INT	In the "Temp" section of the block interface
Label	STRING[4]	In the "Temp" section of the block interface

The following table lists the declarations of the PLC data types:

Name of the PLC data types	Name	Data type
Article	Number	DINT
	Declaration	STRING
	Colli	INT
Client	Title	INT
	First name	STRING[10]
	Surname	STRING[10]

The following table shows the declaration of the data blocks:

Name of the data blocks	Name	Data type
Source	Client	"Client" (PLC data type)
	Article	Array[0..10] of "Article" (PLC data type)
Buffer	Field	Array[0..294] of BYTE

PLC data types (Page 1954)

MOVE_BLK: Move block

Description

You can use the "Move block" instruction to move the content of a memory area (source area) to another memory area (destination area). The number of elements to be moved to the destination area is specified with the COUNT parameter. The width of the elements to be moved is defined by the width of the element at input IN.

The instruction can only be executed if the source area and the destination area have the same data type.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- More data is moved than is made available at input IN or output OUT.

When a ARRAY of BOOL is copied, the enable output ENO for an overflow is set to "1" until the byte limit of the ARRAY structure is exceeded. If the byte limit of the ARRAY structure is exceeded by the value at the COUNT input, the ENO enable output is reset to "0".

Parameters

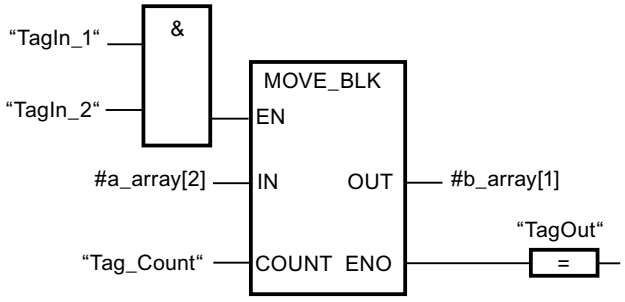
The following table lists the parameters of the "Move block" instruction:

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN [1]	Input	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	D, L	The first element of the source area that is being copied
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Number of elements to be copied from the source area to the destination area
OUT [1]	Output	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	D, L	The first element of the destination area to which the contents of the source area are being copied
[1] The specified data types can only be used as elements of an ARRAY structure.						

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	a_array[2]	The data type of the a_array operand is ARRAY [0..5] of INT. It consists of six elements of data type INT.
COUNT	Tag_Count	3
OUT	b_array[1]	The data type of the b_array operand is ARRAY [0..6] of INT. It consists of seven elements of data type INT.

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. Starting from the third element, the instruction selects three INT elements from the #a_array tag and copies their contents to the #b_array output tag, beginning with the second element. If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

Overview of the valid data types (Page 1908)

MOVE_BLK_VARIANT: Move block

Description

You can use the "Move block" instruction to move the content of a memory area (source area) to another memory area (destination area). You can copy a complete ARRAY or elements of an ARRAY to another ARRAY of the same data type. The size (number of elements) of source and destination ARRAY may be different. You can copy multiple or single elements within an ARRAY.

When you use the instruction at the time to the block is created, the ARRAY does not yet have to be known, as the source and the designation are transferred per VARIANT.

Counting at the parameters SRC_INDEX and DEST_INDEX always begins with the low limit "0", regardless of the later declaration of the ARRAY.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- More data is copied than is made available.

Note

VARIANT in connection with BOOL data type

If you want to interconnect a parameter of data type VARIANT (source or destination area) with a tag of data type BOOL or an ARRAY of BOOL, you have the following options:

1. You can address it symbolically
   Example: Parameter SRC: "Data_block".myArray
2. You can address it with help of ANY pointer. However, you must note that the specified length of the area must be dividable by 8, or the instruction will otherwise not be executed.
   Example: Parameter SRC: P#DB123.DBX456.0 BOOL 1000

Parameters

The following table lists the parameters of the "Move block" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
SRC	Input	VARIANT (which points to an ARRAY or an individual ARRAY element), ARRAY of <Data_type>	I, Q, M, L	Source block from which to copy
COUNT	Input	UDINT	I, Q, M, D, L or constant	Number of elements which are copied Assign the value "1" to the parameter COUNT, if no ARRAY is specified at parameter SRC or at Parameter DEST.

Parameters	Declaration	Data type	Memory area	Description
SRC_INDEX	Input	DINT	I, Q, M, D, L or constant	• The SRC_INDEX parameter is calculated zero-based. If an ARRAY is specified at parameter SRC, the integer at parameter SRC_INDEX specifies the first element within the source area from which it is to be copied. Independent of the declared ARRAY limits. • If no ARRAY is specified at parameter SRC or only one single element of an ARRAY is specified, then assign the value "0" at parameter SRC_INDEX.
DEST_INDEX	Input	DINT	I, Q, M, D, L or constant	• The DEST_INDEX parameter is calculated zero-based. If an ARRAY is specified at parameter DEST, the integer at parameter DEST_INDEX specifies the first element within the destination area to it is to be copied. Independent of the declared ARRAY limits. • If no ARRAY is specified at parameter DEST, then assign the value "0" at parameter DEST_INDEX.
DEST	Output [1)]	VARIANT	I, Q, M, L	Destination area into which the contents of the source block are copied.
RET_VAL	Output	INT	I, Q, M, D, L	Error information: If an error occurs during execution of the instruction, an error code is output in the RET_VAL parameter.
1) The DEST parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

For additional information on valid data types, refer to "See also".

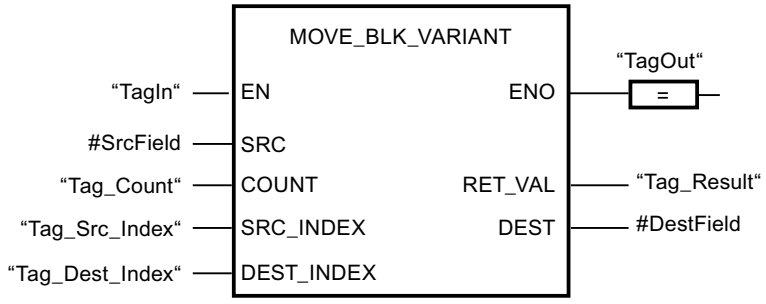
Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	Data types do not correspond
8151	Access to the SRC parameter is not possible.
8152	The operand at the SRC parameter is not typed.
8153	Code generation error at the SRC parameter
8154	The operand at the SRC parameter has the data type BOOL.
8281	The COUNT parameter has an invalid value
8382	The value at the SRC_INDEX parameter is outside the limits of the VARIANT.
8383	The value at parameter SRC_INDEX is outside the high limit of the ARRAY.
8482	The value at the DEST_INDEX parameter is outside the limits of the VARIANT.
8483	The value at parameter DEST_INDEX is outside the high limit of the ARRAY.
8534	The DEST parameter is write protected
8551	Access to the DEST parameter is not possible.
8552	The operand at the DEST parameter is not typed.
8553	Code generation error at the DEST parameter
8554	The operand at the DEST parameter has the data type BOOL.
*The error codes can be displayed as integer or hexadecimal values in the program editor. You will find information on changing display formats in "See also".	

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Declaration in the block interface	Operand	Value
SRC	Input	#SrcField	The local operand #SrcField uses a PLC data type that was still unknown at the time when the block was programmed. (ARRAY[0..10] of "MOVE_UDT"
COUNT	Input	Tag_Count	2
SRC_INDEX	Input	Tag_Src_Index	3
DEST_INDEX	Input	Tag_Dest_Index	3
DEST	InOut	#DestField	The local operand #DestField uses a PLC data type that was still unknown at the time when the block was programmed. (ARRAY[10..20] of "MOVE_UDT"

If the "TagIn" operand has signal state "1", the instruction is executed. Two elements are copied from the source area, beginning from the fourth element of the ARRAY of UDT, to the destination area. The copies are inserted in the ARRAY of UDT starting from the fourth element. If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

UMOVE_BLK: Move block uninterruptible

Description

You can use the "Move block uninterruptible" instruction to move the content of a memory area (source area) to another memory area (destination area). The number of elements to be moved to the destination area is specified with the COUNT parameter. The width of the elements to be moved is defined by the width of the element at input IN.

The instruction can only be executed if the source area and the destination area have the same data type.

Note

The move operation cannot be interrupted by other operating system activities. This is why the interrupt reaction times of the CPU increase during the execution of the "Move block uninterruptible" instruction.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- More data is moved than is made available at input IN or output OUT.

When a ARRAY of BOOL is copied, the enable output ENO for an overflow is set to "1" until the byte limit of the ARRAY structure is exceeded. If the byte limit of the ARRAY structure is exceeded by the value at the COUNT input, the ENO enable output is reset to "0".

You can use the "Move block uninterruptible" instruction to move a maximum of 16 KB. Note the CPU-specific restrictions for this.

Parameters

The following table shows the parameters of the "Move block uninterruptible" instruction:

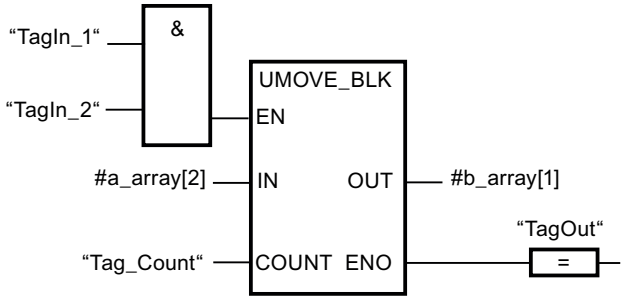
Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN [1)]	Input	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	D, L	The first element of the source area that is being copied
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Number of elements to be copied from the source area to the destination area

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
OUT [1]	Output	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	D, L	The first element of the destination area to which the contents of the source area are being copied
[1] The specified data types can only be used as elements of an array structure.						

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	a_array[2]	The data type of the a_array operand is ARRAY [0..5] of INT. It consists of six elements of data type INT.
COUNT	Tag_Count	3
OUT	b_array[1]	The data type of the b_array operand is ARRAY [0..6] of INT. It consists of seven elements of data type INT.

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. Starting from the third element, the instruction selects three INT elements from the #a_array tag and copies their contents to the #b_array output tag, beginning with the second element. The move operation cannot be interrupted by other operating system activities. If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

Overview of the valid data types (Page 1908)

FILL_BLK: Fill block

Description

You can use the "Fill block" instruction to fill a memory area (destination area) with the value of the IN input. The destination area is filled beginning with the address specified at the OUT output. The number of repeated move operations is specified with the COUNT parameter. When the instruction is executed, the value at the input IN is selected and moved to the destination area as often as specified by the value of the COUNT parameter.

The instruction can only be executed if the source area and the destination area have the same data type.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- More data is moved than is made available at input IN or output OUT.

When a ARRAY of BOOL is copied, the enable output ENO for an overflow is set to "1" until the byte limit of the ARRAY structure is exceeded. If the byte limit of the ARRAY structure is exceeded by the value at the COUNT input, the ENO enable output is reset to "0".

Parameters

The following table shows the parameters of the "Fill block" instruction:

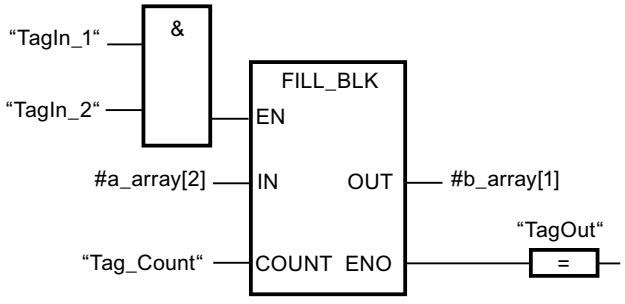
Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN [1)]	Input	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Element used to fill the destination area
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Number of repeated move operations

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
OUT [2]	Output	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	D, L	Address in destination area from which filling starts.
[1] The specified data types can also be used as elements of an Array structure. [2] The specified data types can only be used as elements of an Array structure.						

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	a_array[2]	The data type of the a_array operand is ARRAY [0..5] of INT. It consists of six elements of data type INT.
COUNT	Tag_Count	3
OUT	b_array[1]	The data type of the b_array operand is ARRAY [0..6] of INT. It consists of seven elements of data type INT.

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. The instruction copies the third element (#a_array[2]) of the #a_array tag three times to the #b_array output tag. If no errors occur during the execution of the instruction, the outputs ENO and "TagOut" are set to signal state "1".

See also

Overview of the valid data types (Page 1908)

UFILL_BLK: Fill block uninterruptible

Description

You can use the "Fill block uninterruptible" instruction to fill a memory area (destination area) with the value of the IN input without interruption. The destination area is filled beginning with the address specified at the OUT output. The number of repeated move operations is specified with the COUNT parameter. When the instruction is executed, the value at the input IN is selected and moved to the destination area as often as specified by the value of the COUNT parameter.

The instruction can only be executed if the source area and the destination area have the same data type.

Note

The move operation cannot be interrupted by other operating system activities. This is why the alarm reaction times of the CPU increase during the execution of the "Fill block uninterruptible" instruction.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- More data is moved than is made available at input IN or output OUT.

When a ARRAY of BOOL is copied, the enable output ENO for an overflow is set to "1" until the byte limit of the ARRAY structure is exceeded. If the byte limit of the ARRAY structure is exceeded by the value at the COUNT input, the ENO enable output is reset to "0".

You can use the "Fill block uninterruptible" instruction to move a maximum of 16 KB. Note the CPU-specific restrictions for this.

Parameters

The following table shows the parameters of the "Fill block uninterruptible" instruction:

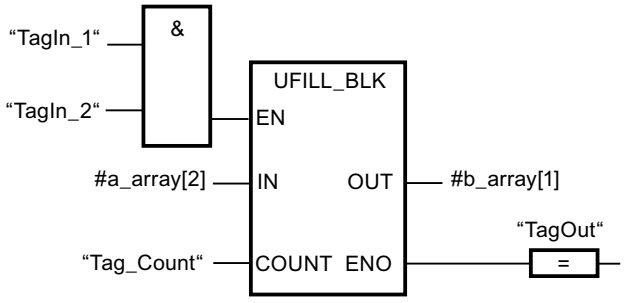
Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN [1)]	Input	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Element used to fill the destination area

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Number of repeated move operations
OUT [2]	Output	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	D, L	Address in destination area from which filling starts.
[1] The specified data types can also be used as elements of an Array structure. [2] The specified data types can only be used as elements of an Array structure.						

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	a_array[2]	The data type of the a_array operand is ARRAY [0..5] of INT. It consists of six elements of data type INT.
COUNT	Tag_Count	3
OUT	b_array[1]	The data type of the b_array operand is ARRAY [0..6] of INT. It consists of seven elements of data type INT.

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. The instruction copies the third element (#a_array[2]) of the #a_array tag three times to the #b_array output tag. The move operation cannot be interrupted by other operating system activities. If

no errors occur during the execution of the instruction, the outputs ENO and "TagOut" are set to signal state "1".

See also

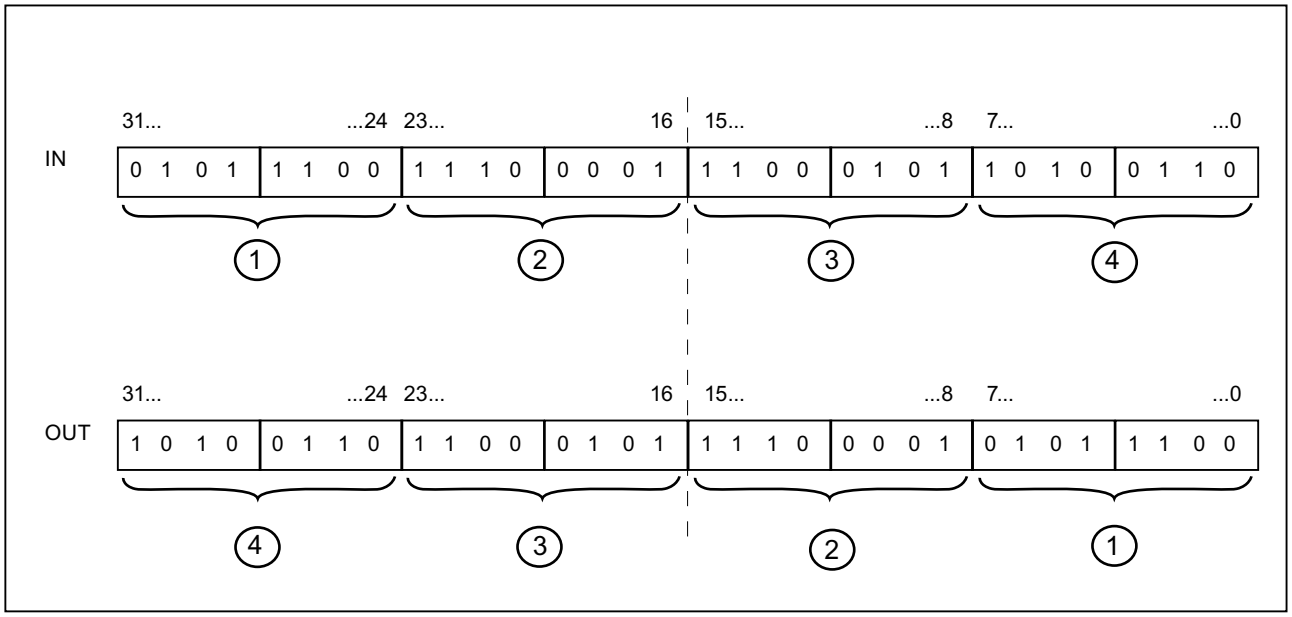
Overview of the valid data types (Page 1908)

SWAP: Swap

Description

You can use the instruction "Swap" to change the order of the bytes within the tag at input IN and query the result at output OUT.

The following figure shows how the bytes of a DWORD data type operand are swapped using the "Swap" instruction:



Parameters

The following table shows the parameters of the "Swap" instruction:

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output

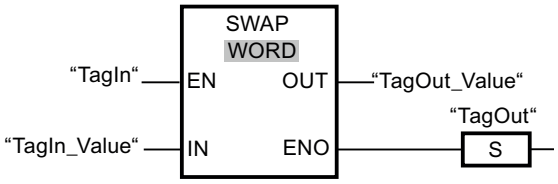
Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN	Input	WORD, DWORD	WORD, DWORD, LWORD	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Operand whose bytes are swapped.
OUT	Output	WORD, DWORD	WORD, DWORD, LWORD	I, Q, M, D, L, P	I, Q, M, D, L, P	Result

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	TagIn_Value	0000 1111 0101 0101
OUT	TagOut_Value	0101 0101 0000 1111

If the "TagIn" operand has signal state "1", the instruction is executed. The arrangement of the bytes is changed and stored in the operand "TagOut_Value".

Overview of the valid data types (Page 1908)

ARRAY DB

ReadFromArrayDB: Read from array data block

Description

The "Read from array data block" instruction is used to read data from an ARRAY data block and write it to a destination area.

An ARRAY data block is a data block that consists of exactly one ARRAY of [Data type]. The elements of the ARRAY can be PLC data type or any other elementary data type. The counting

at the ARRAY always begins with the low limit "0", regardless of the later declaration of the ARRAY.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- If an error occurs during the execution of the instruction.

Parameters

The following table shows the parameters of the "Read from array data block" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
DB	Input	DB_ANY	I, Q, M, D, L	Data block that is read
INDEX	Input	DINT	I, Q, M, D, L, P, or constant	Element that is read
VALUE	Output 1)	VARIANT	I, Q, M, L	Value that is read and output
RET_VAL	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output at the RET_VAL parameter.
1) The VALUE parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

For additional information on valid data types, refer to "See also".

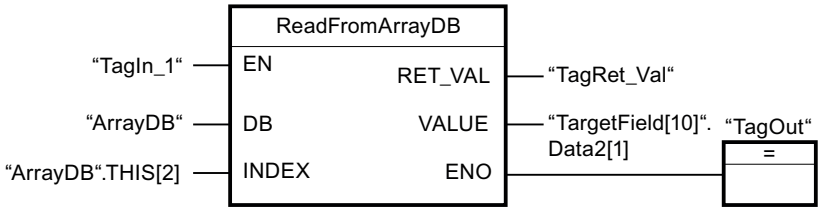
Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
80B5	The copying was interrupted.
8132	The data block does not exist, is too short, write protected, or is located in load memory.
8135	The ARRAY data block contains invalid values.
8154	The data block has the incorrect data type.
8282	The value at parameter INDEX is outside the limits of the ARRAY.
8450	The data type VARIANT at parameter VALUE provides the value "0".
8452	Code generation error
8453	The size of the VALUE parameter does not match the element length in the ARRAY data block.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
DB	ArrayDB	The data type of the "ArrayDB" operand is Array [0 to 10] of INT.
INDEX	ArrayDB.THIS[2]	Third element of the "ArrayDB"
VALUE	TargetField[10].Data2[1]	The data type of the "Target-Field" operand is Array [10 to 20] of "MOVE_UDT".

If the "TagIn1" operand has the signal state "1", the "Read from the array data block" instruction is executed. The third element is read from "ArrayDB" and written to the "TargetField[10].Data2[1]" operand. If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

Overview of the valid data types (Page 1908)

Using ARRAY data blocks (Page 239)

WriteToArrayDB: Write to array data block

Description

The instruction "Write to array data block" is used to write data to an ARRAY data block.

An ARRAY data block is a data block that consists of exactly one ARRAY of [Data type]. The elements of the ARRAY can be PLC data type or any other elementary data type. The counting at the ARRAY always begins with the low limit "0", regardless of the later declaration of the ARRAY.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- If an error occurs during the execution of the instruction.

Parameters

The following table shows the parameters of the "Write to array data block" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
DB	Input	DB_ANY	I, Q, M, D, L	Data block to which data is written
INDEX	Input	DINT	I, Q, M, D, L, P, or constant	Element in the DB to which data is written
VALUE	Input	VARIANT	I, Q, M, L	Value to be written
RET_VAL	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output at the RET_VAL parameter.

For additional information on valid data types, refer to "See also".

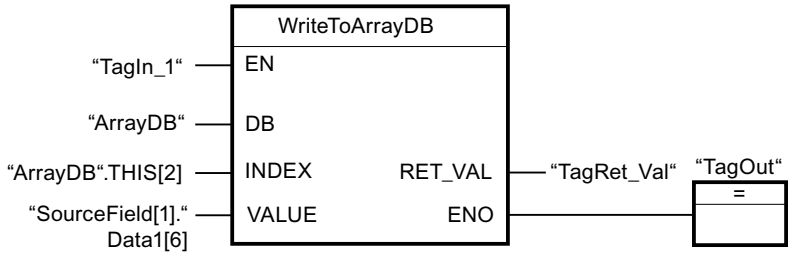
Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
80B5	The copying was interrupted.
8132	The data block does not exist, is too short, or is located in load memory.
8134	The data block is write protected.
8135	The data block is not an ARRAY data block.
8154	The data block has the incorrect data type.
8282	The value at parameter INDEX is outside the limits of the ARRAY.
8350	The data type VARIANT at parameter VALUE provides the value "0".
8352	Code generation error
8353	The size of the VALUE parameter does not match the element length in the ARRAY data block.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
DB	ArrayDB	The data type of the "ArrayDB" operand is Array [0 to 10] of INT.
INDEX	ArrayDB.THIS[2]	Third element of the "ArrayDB"
VALUE	SourceField[1].Data1[6]	The data type of the "Source-Field" operand is Array [0 to 10] of "MOVE_UDT".

If the "TagIn1" operand has the signal state "1", the "Write to ARRAY data block" instruction is executed. From the "SourceField" operand, the "Data1[6]" element from the second element is written to the "ArrayDB". The third element is written to the "ArrayDB". If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

Using ARRAY data blocks (Page 239)

ReadFromArrayDBL: Read from array data block in load memory

Description

The instruction "Read from array data block in load memory" is used to read data from an ARRAY data block in the load memory.

An ARRAY data block is a data block that consists of exactly one ARRAY of [Data type]. The elements of the ARRAY can be PLC data type or any other elementary data type. The counting at the ARRAY always begins with the low limit "0", regardless of the later declaration of the ARRAY.

If the ARRAY data block has been designated with the block attribute "Only store in load memory", it will only be stored in the load memory.

The instruction is executed when a positive signal edge is detected at the REQ parameter. The BUSY parameter then has the signal state "1". The instruction is terminated if a negative signal edge is detected at the BUSY parameter. The DONE parameter has the signal state "1"

for one program cycle and the read value is output at the VALUE parameter within this cycle. With all other program cycles, the value at the VALUE parameter is not changed.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, it is saved to the "Program resources" folder in the "Program blocks > System blocks" path of the project tree. For additional information on this topic, refer to "See also".

Note

The ARRAY data block must be created with the "Optimized" block property.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- If an error occurs during the execution of the instruction.

Parameters

The following table lists the parameters of the "Read from array data block in load memory" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = "1": Begin with the reading of the array DB
DB	Input	DB_ANY	I, Q, M, D, L	Data block that is read
INDEX	Input	DINT	I, Q, M, D, L, P, or constant	Element that is read
VALUE	InOut	VARIANT	I, Q, M, L	Value that is read and output No local constants or tags from the TEMP section must be used.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = "1": The array DB is still being read
DONE	Output	BOOL	I, Q, M, D, L	DONE = "1": The instruction was executed successfully
ERROR	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during the execution of the instruction, an error code is output at the ERROR parameter.

For additional information on valid data types, refer to "See also".

ERROR parameter

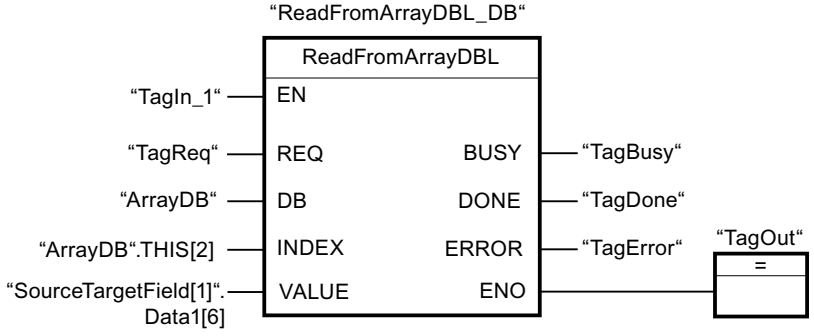
The following table shows the meaning of the values of the ERROR parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
8230	The data block number is incorrect.
8231	The data block does not exist.
8232	The data block is too short, or is not located in load memory.
8235	The data block is not an ARRAY DB.
8254	The data block has the incorrect data type.
8382	The value at parameter INDEX is outside the limits of the ARRAY.
8750	The data type VARIANT at parameter VALUE provides the value "0".
8751	Code generation error
8752	Code generation error
8753	The size of the VALUE parameter does not match the element length in the ARRAY data block.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

You can find descriptions of the error codes triggered by the instructions "READ_DBL: Read from data block in the load memory" and "WRIT_DBL: Write to data block in the load memory" under "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
REQ	TagReq	BOOL
DB	ArrayDB	The data type of the "ArrayDB" operand is Array [0 to 10] of INT.
INDEX	ArrayDB.THIS[2]	Third element of the "ArrayDB"

Parameters	Operand	Value
VALUE	SourceTargetField[1].Data1[6]	The data type of the "SourceTargetField" operand is Array [0 to 10] of "MOVE_UDT".
BUSY	TagBusy	BOOL
DONE	TagDone	BOOL

If the "TagIn1" operand has the signal state "1" and a positive edge is detected at the "TagReq"operand, the "Read from ARRAY data block in load memory" instruction is executed. The third element is read from "ArrayDB" and written to the "SourceTargetField[1].Data1[6]" operand. As soon as a negative signal edge is detected at the "TagBusy" operand, the instruction is terminated and the value at the VALUE parameter is no longer changed. If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set. After the instruction has been processed, the "TagDone" operand the signal state "1".

READ_DBL: Read from data block in the load memory (Page 3351)

Using ARRAY data blocks (Page 239)

WriteToArrayDBL: Write to array data block in load memory

Description

The instruction "Write to array data block in load memory" is used to write data to an ARRAY data block in the load memory.

An ARRAY data block is a data block that consists of exactly one ARRAY of [Data type]. The elements of the ARRAY can be PLC data type or any other elementary data type. The counting at the ARRAY always begins with the low limit "0", regardless of the later declaration of the ARRAY.

If the ARRAY data block has been designated with the block attribute "Only store in load memory", it will only be stored in the load memory.

The instruction is executed when a positive signal edge is detected at the REQ parameter. The BUSY parameter then has the signal state "1". If a negative signal edge is detected at the BUSY parameter, the instruction is terminated and the value at the VALUE parameter is written to the data block. The DONE parameter then has the signal state "1" for one program cycle.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate

data block, it is saved to the "Program resources" folder in the "Program blocks > System blocks" path of the project tree. For additional information on this topic, refer to "See also".

Note

The ARRAY data block must be created with the "Optimized" block property.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- If an error occurs during the execution of the instruction.

Parameters

The following table lists the parameters of the "Write to array data block in load memory" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = "1": Start writing to the array DB
DB	Input	DB_ANY	I, Q, M, D, L	Data block to which data is written
INDEX	Input	DINT	I, Q, M, D, L, P, or constant	Element in the DB to which data is written
VALUE	Input	VARIANT	I, Q, M, L	Value to be written No local constants or tags from the TEMP section must be used.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = "1": The array DB is still being written
DONE	Output	BOOL	I, Q, M, D, L	DONE = "1": The instruction was executed successfully
ERROR	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during the execution of the instruction, an error code is output at the ERROR parameter.

For additional information on valid data types, refer to "See also".

ERROR parameter

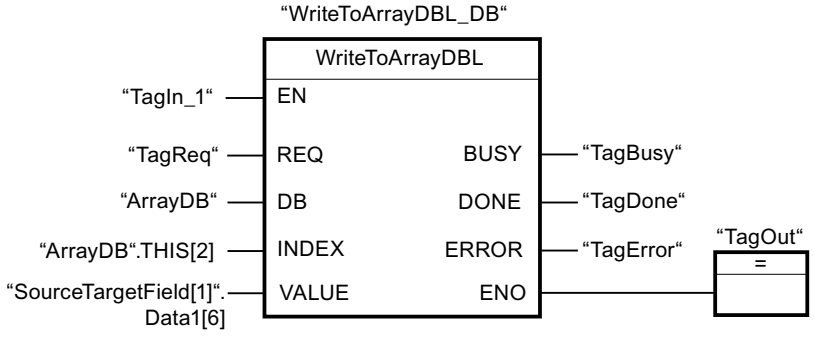
The following table shows the meaning of the values of the ERROR parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
8230	The data block number is incorrect.
8231	The data block does not exist.
8232	The data block is too short, or is not located in load memory.
8234	The data block is write protected.
8235	The data block is not an ARRAY DB.
8254	The data block has the incorrect data type.
8382	The value at parameter INDEX is outside the limits of the ARRAY.
8750	The data type VARIANT at parameter VALUE provides the value "0".
8751	Code generation error
8752	Code generation error
8753	The size of the VALUE parameter does not match the element length in the ARRAY data block.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

You can find descriptions of the error codes triggered by the instructions "READ_DBL: Read from data block in the load memory" and "WRIT_DBL: Write to data block in the load memory" under "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
REQ	TagReq	BOOL
DB	ArrayDB	The data type of the "ArrayDB" operand is Array [0 to 10] of INT.

Parameters	Operand	Value
INDEX	ArrayDB.THIS[2]	Third element of the "ArrayDB"
VALUE	SourceTargetField[1].Data1[6]	The data type of the "SourceTargetField" operand is Array [0 to 10] of "MOVE_UDT".
BUSY	TagBusy	BOOL
DONE	TagDone	BOOL

If the "TagIn1" operand has the signal state "1" and a positive edge is detected at the "TagReq"operand, the "Write to ARRAY data block in load memory" instruction is executed. As soon as a negative signal edge is detected at the "TagBusy" operand, the instruction is terminated and the value at the VALUE parameter is written in the third element in the "ArrayDB". If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set. After the instruction has been processed, the "TagDone" operand the signal state "1".

VARIANT

VariantGet: Read out VARIANT tag value

Description

You can use the "Read out VARIANT tag value" instruction to read the value of the tag to which the VARIANT at the SRC parameter points and write it in the tag at the DST parameter.

The SRC parameter has the VARIANT data type. Any data type except for VARIANT can be specified at the DST parameter.

The data type of the tag at the DST parameter must match the data type to which the VARIANT points.

Note

To copy structures and ARRAYs, you can use the "MOVE_BLK_VARIANT: Move block" instruction. For additional information, refer to "See also".

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The data types do not correspond. (No value is transferred.)

Parameters

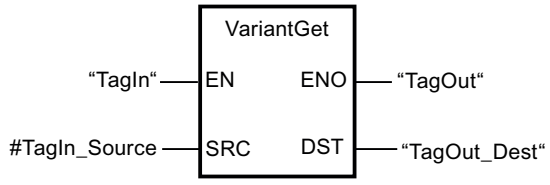
The following table lists the parameters of the instruction "Read out VARIANT tag value":

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
SRC	Input	VARIANT	I, Q, M, L	Tag to be read
DST	Output	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY elements, PLC data types	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If the "TagIn" operand has signal state "1", the instruction is executed. The value of the tag to which the VARIANT at the "#TagIn_Source" operand points, is read and written to the "TagOut_Dest" operand.

See also

Overview of the valid data types (Page 1908)

VARIANT (Page 1951)

MOVE_BLK_VARIANT: Move block (Page 2623)

VariantPut: Write VARIANT tag value

Description

You can use the "Write VARIANT tag value" instruction to write the value of the tag at the SRC parameter to the tag at the DST parameter to which the VARIANT points.

The DST parameter has the VARIANT data type. Any data type except for VARIANT can be specified at the SRC parameter.

The data type of the tag at the SRC parameter must match the data type to which the VARIANT points.

Note

To copy structures and ARRAYs, you can use the "MOVE_BLK_VARIANT: Move block" instruction. For additional information, refer to "See also".

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The data types do not correspond. (No value is transferred.)

Parameters

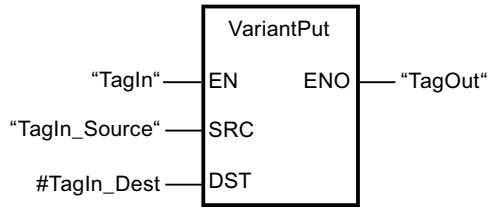
The following table lists the parameters of the instruction "Write VARIANT tag value":

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
SRC	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY elements, PLC data types	I, Q, M, D, L	Tag to be read
DST	Input	VARIANT	I, Q, M, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If the "TagIn" operand has signal state "1", the instruction is executed. The value of the "TagIn_Source" operand is written to the tag to which the VARIANT at the #TagIn_Dest operand points.

See also

Overview of the valid data types (Page 1908)

VARIANT (Page 1951)

MOVE_BLK_VARIANT: Move block (Page 2623)

CountOfElements: Get number of ARRAY elements

Description

You can use the "Get number of ARRAY elements" instruction to query how many ARRAY elements a tag pointing to an VARIANT has.

If it is a one-dimensional ARRAY, the difference between the high and low limit +1 is output as a result. If it is a multi-dimensional ARRAY, the product of all dimensions is output as the result.

The IN parameter must have the VARIANT data type.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The VARIANT tag is not an ARRAY. (The result is "0".)

If the VARIANT points to an ARRAY of BOOL, the fill elements are also included in the count. (For example, 8 is returned for an ARRAY[0..1] of BOOL)

Parameters

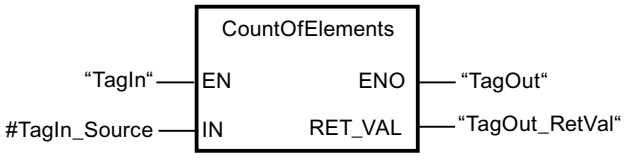
The following table shows the parameters of the "Get number of ARRAY elements" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	VARIANT	I, Q, M, L	Tag to be queried
RET_VAL	Output	UDINT	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



If the "TagIn" operand has the signal state "1", the "Get number of ARRAY elements" instruction is executed. The number of ARRAY elements of the tag to which the VARIANT at the "#TagIn_Source" operand points is read and output at the "TagOut_RetVal" operand.

Legacy

FieldRead: Read field

Description

You can use the "Read field" instruction to read out a specific component from the field specified in the MEMBER parameter and transfer its content to the tag in the VALUE parameter. You use the parameter INDEX to define the index of the field components that are to be read. At the parameter MEMBER you specify the first component of the field to be read.

The data types of the field component at parameter MEMBER, the index and the tags at parameter VALUE must correspond to the data type of the instruction "Read field" because implicit conversion is not possible.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The field component specified at the parameter INDEX is not defined in the field specified at the parameter MEMBER.
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the instruction "Read field":

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output

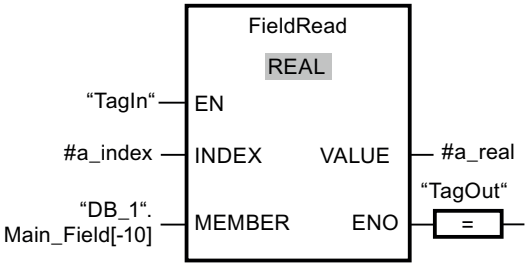
Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
INDEX	Input	DINT	DINT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Index of field components whose content is read out
MEMBER	Input	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR and WCHAR as components of an ARRAY tag	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, LTOD, CHAR and WCHAR as components of an ARRAY tag	D, L	D, L	First component of the field from which will be read
VALUE	Output	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, LTOD CHAR, WCHAR	I, Q, M, D, L, P	I, Q, M, D, L, P	Operand to which the contents of the field component are transferred.

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Tag	Value
INDEX	a_index	4
MEMBER	"DB_1".Main_Field[-10]	First component of the "Main_Field[-10..10] of REAL" field in the data block "DB_1"
VALUE	a_real	Component with index 4 of the "Main_Field[-10..10] of REAL" field

The field component with index 4 is read from the "Main_Field[-10...10] of REAL" field and written to the "a_real" tag. The field component to be read is defined by the value at the parameter INDEX.

See also

Overview of the valid data types (Page 1908)

FieldWrite: Write field

Description

The "Write field" instruction is used to transfer the content of the tag at the VALUE input to a specific component of the field at the MEMBER output. You use the value at the INDEX input to specify the index of the field component that is described. At the MEMBER output, enter the first component of the field which is to be written to.

The data types of the field component at parameter MEMBER, the index and the tags at parameter VALUE must correspond to the data type of the instruction "Read field" because implicit conversion is not possible.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The field component specified at the input INDEX is not defined in the field specified at the output MEMBER.
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the instruction "Write field":

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output

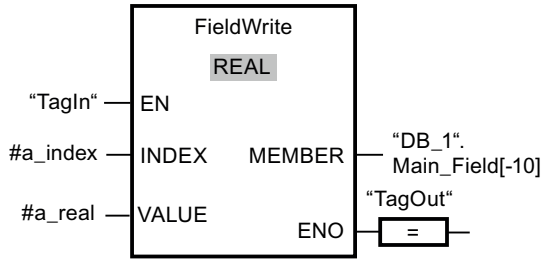
Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
INDEX	Input	DINT	DINT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Index of field component that is written with the content of VALUE
VALUE	Input	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, LTOD CHAR, WCHAR	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Operand whose contents are copied
MEMBER	Output	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR and WCHAR as components of an ARRAY tag	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, LTOD, CHAR and WCHAR as components of an ARRAY tag	D, L	D, L	First component of the field to which the content of VALUE is written.

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
INDEX	a_index	4
VALUE	a_real	10.54
MEMBER	"DB_1".Main_Field[-10]	First component of the "Main_Field[-10..10] of REAL" field in the data block "DB_1"

The value "10.54" of the "a_real" tag is written to the field component with index 4 of the "Main_Field[-10 ... 10] of REAL" field. The index of the field component to which the content of the tag "a_real" is transferred is specified by the value at the input INDEX.

Overview of the valid data types (Page 1908)

BLKMOV: Move block

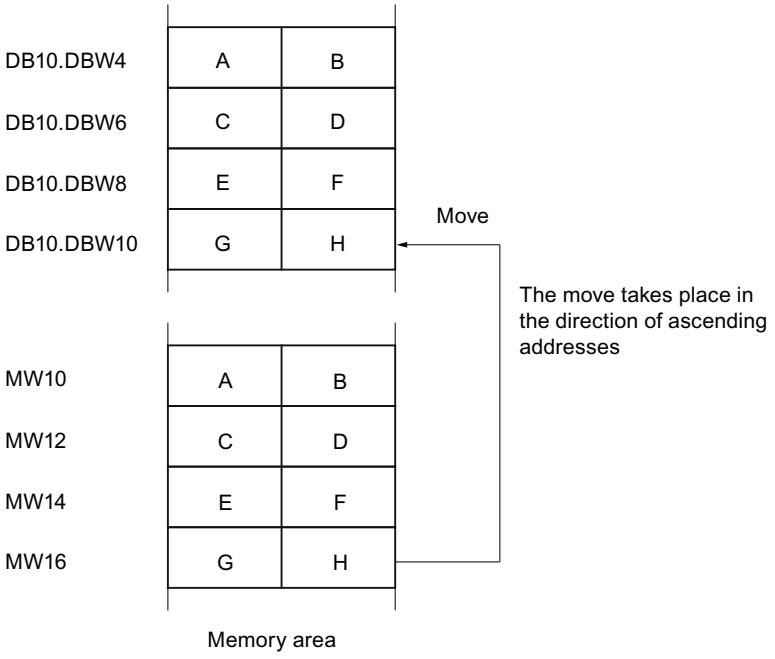
Description

You can use the "Move block" instruction to move the content of a memory area (source area) to another memory area (destination area). The move operation takes place in the direction of ascending addresses. You use VARIANT to define the source and destination areas.

Note

The tags of the instruction can only be used in data blocks in which the "Optimized block access" attribute is not set. If the tag with the retentivity setting "Set in IDB" has been declared, you can also use the tags "with optimized access".

The following figure shows the principle of the move operation:



Consistency of source and destination data

Make sure that the source data remain unchanged during the execution of the "Move block" instruction. Otherwise, consistency of the destination data cannot be guaranteed.

Interruptibility

There is no limit to the nesting depth.

Memory areas

You can use the "Move block" instruction to move the following memory areas:

- Areas of a data block
- Bit memory
- Process image input
- Process image output

General rules for moving

The source and destination areas must not overlap. If the source and destination areas have different lengths, only the length of the smaller area will be moved.

If the source area is smaller than the destination area, the entire source area will be written to the destination area. The remaining bytes of the destination area remain unchanged.

If the destination area is smaller than the source area, the entire destination area will be written. The remaining bytes of the source area are ignored.

If a block of data type BOOL is moved, the tag must be addressed absolutely and the specified length of the area must be divisible by 8, otherwise the instruction cannot be executed.

Rules for moving character strings

You can use the "Move block" instruction to also move source and destination areas of the STRING data type. If only the source area is STRING data type, the characters will be moved that are actually contained in the character string. Information on the actual and maximum length is also written to the destination area. If the source and destination area are both STRING data type, the current length of the character string in the destination area is set to the number of characters actually moved.

If you want to move the information on the maximum and actual length of a character string, specify the areas in bytes in the SRCBLK and DSTBLK parameters.

Parameters

The following table shows the parameters of the "Move block" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
SRCBLK	Input	VARIANT	I, Q, M, L, P	I, Q, M, L, P	Specifies the memory area to be moved (source area).
RET_VAL	Output	INT	I, Q, M, D, L, P	I, Q, M, D, L, P	Error information: If an error occurs during the execution of the instruction, an error code is output at the RET_VAL parameter.
DSTBLK	Output [1)]	VARIANT	I, Q, M, L, P	I, Q, M, L, P	Specifies the memory area to which the block is to be moved (destination area).
1) The DSTBLK parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.					

Parameter RET_VAL

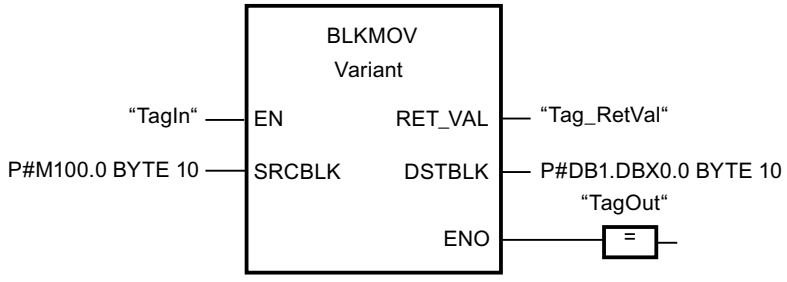
The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
8092	The source or target area is only available in the load memory.

Error code* (W#16#...)	Explanation
8152	The WSTRING, WCHAR and BOOL data types are not supported at the SRCBLK parameter.
8352	The WSTRING, WCHAR and BOOL data types are not supported at the DSTBLK parameter.
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:



If the "TagIn" operand has signal state "1", the instruction is executed. The instruction copies 10 bytes starting from MB100 and writes them to DB1. If an error occurs during the move operation, its error code is output in the "Tag_RetVal" tag.

Overview of the valid data types (Page 1908)

GET_ERR_ID: Get error ID locally (Page 2697)

UBLKMOV: Move block uninterruptible

Description

You can use the "Move block uninterruptible" instruction to move the content of a memory area (source area) to another memory area (destination area). The move operation takes place in the direction of ascending addresses. You use VARIANT to define the source and destination areas.

The move operation cannot be interrupted by other operating system activities. As a result the interrupt reaction time of the CPU can increase during the execution of the "Move block uninterruptible" instruction.

Note

The tags of the instruction can only be used in data blocks in which the "Optimized block access" attribute is not set. If the tag with the retentivity setting "Set in IDB" has been declared, you can also use the tags "with optimized access".

Memory areas

You can use the "Move block uninterruptible" instruction to move the following memory areas:

- Areas of a data block
- Bit memory
- Process image input
- Process image output

General rules for moving

The source and destination area must not overlap during the execution of the "Move block uninterruptible" instruction. If the source area is smaller than the destination area, the entire source area will be written to the destination area. The remaining bytes of the destination area remain unchanged.

If the destination area is smaller than the source area, the entire destination area will be written. The remaining bytes of the source area are ignored.

If a source or destination area defined as a formal parameter is smaller than a destination or source area specified in the SRCBLK or DSTBLK parameter, no data is transferred.

If a block of data type BOOL is moved, the tag must be addressed absolutely and the specified length of the area must be divisible by 8, otherwise the instruction cannot be executed.

You can use the "Move block uninterruptible" instruction to move a maximum of 16 KB. Note the CPU-specific restrictions for this.

Rules for moving character strings

You can use the "Move block uninterruptible" instruction to also move source and destination areas of the STRING data type. If only the source area is STRING data type, the characters will be moved that are actually contained in the character string. Information on the actual and maximum length are not written in the destination area. If the source and destination area are both STRING data type, the current length of the character string in the destination area is set to the number of characters actually moved. If areas of the STRING data type are moved, specify "1" as area length.

Parameters

The following table shows the parameters of the "Move block uninterruptible" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
SRCBLK	Input	VARIANT	I, Q, M, L, P	I, Q, M, L, P	Specifies the memory area to be moved (source area).
RET_VAL	Output	INT	I, Q, M, D, L, P	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output in the RET_VAL parameter.
DSTBLK	Output [1]	VARIANT	I, Q, M, L, P	I, Q, M, L, P	Specifies the memory area to which the block is to be moved (destination area).
1) The DSTBLK parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.					

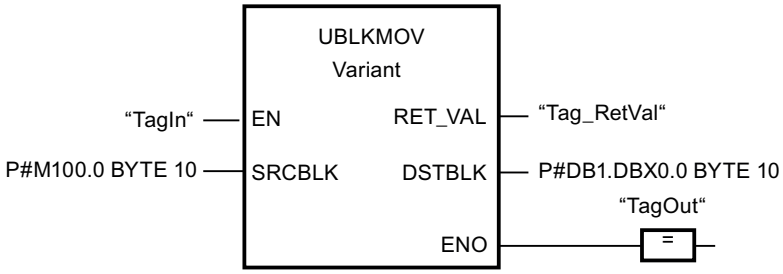
Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code (W#16#...)	Explanation
0000	No error
8091	The source or destination area is located in the load memory only.
8152	The WSTRING, WCHAR and BOOL data types are not supported at the SRCBLK parameter.
8352	The WSTRING, WCHAR and BOOL data types are not supported at the DSTBLK parameter.
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal values in the program editor. You will find information on changing display formats in "See also".	

Example

The following example shows how the instruction works:



If the "TagIn" operand has signal state "1", the instruction is executed. The instruction copies 10 bytes starting from MB100 and writes them to DB1. If an error occurs during the move operation, its error code is output in the "Tag_RetVal" tag.

GET_ERR_ID: Get error ID locally (Page 2697)

FILL: Fill block

Description

You can use the "Fill block" instruction to fill a memory area (destination area) with the content of another memory area (source area). The "Fill block" instruction moves the content of the source area to the destination area until the destination area is completely written. The move operation takes place in the direction of ascending addresses.

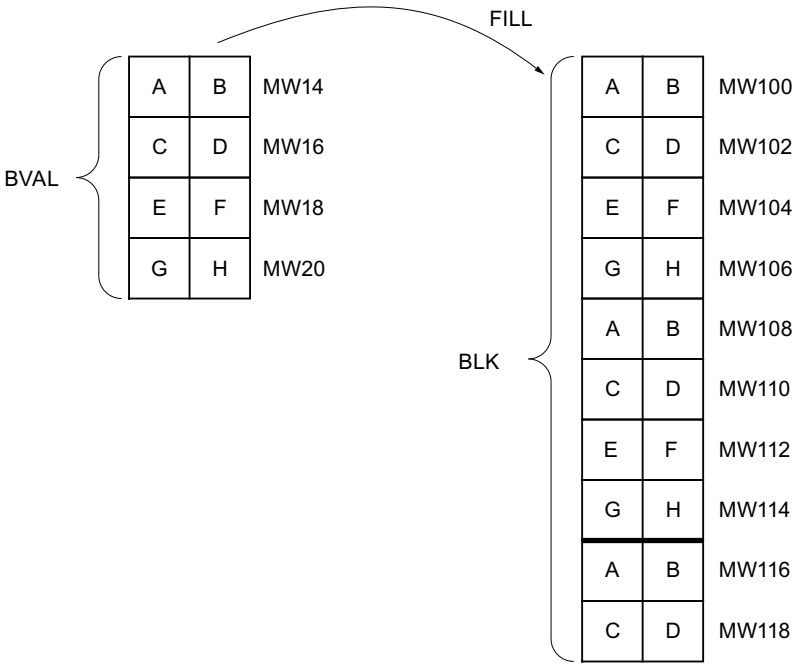
You use VARIANT to define the source and destination areas.

Note

The tags of the instruction can only be used in data blocks in which the "Optimized block access" attribute is not set. If the tag with the retentivity setting "Set in IDB" has been declared, you can also use the tags "with optimized access".

For blocks with the "Optimized block access" attribute, you can use the "FILL_BLK instruction. Fill block" instruction.

The following figure shows the principle of the move operation:



Consistency of source and destination data

Note that while the instruction "Fill block" is being executed, the source data remains unchanged; otherwise the consistency of the destination data cannot be guaranteed.

Memory areas

You can use the "Fill block" instruction to move the following memory areas:

- Areas of a data block
- Bit memory
- Process image input
- Process image output

General rules for moving

The source and destination areas must not overlap. If the destination area to be preset is not an integer multiple of the length of the BVAL input parameter, the destination area is nevertheless written up to the last byte.

If the destination area to be preset is smaller than the source area, the function only copies as much data as can be written to the destination area.

If the destination or source area actually present is smaller than the assigned memory area for the source or destination area (BVAL, BLK parameters), no data is transferred.

If the ANY pointer (source or destination) is of the data type BOOL, it must be addressed absolutely and the length specified must be divisible by 8; otherwise the instruction is not executed.

If the destination area is data type STRING, the instruction writes the entire string including the administration information.

Parameters

The following table shows the parameters of the "Fill block" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
BVAL	Input	VARIANT	I, Q, M, L, P	Specification of the memory area (source area), the content of which is used to fill the destination area at the BLK parameter.
RET_VAL	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output in the RET_VAL parameter.
BLK	Output 1)	VARIANT	I, Q, M, L, P	Specification of the memory area that will be filled with the content of the source area.
1) The BLK parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

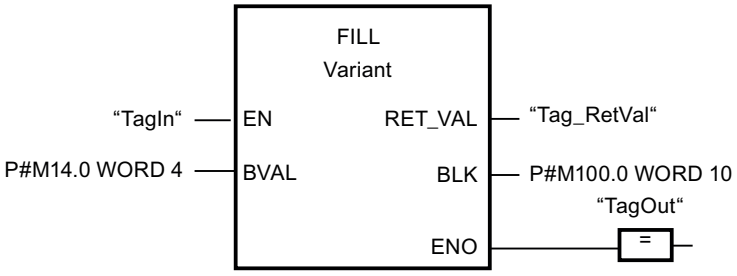
Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
8092	The source or destination area is located in the load memory only.
8152	The WSTRING, WCHAR and BOOL data types are not supported at the BVAL parameter.
8352	The WSTRING, WCHAR and BOOL data types are not supported at the BLK parameter.
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal values in the program editor. You will find information on changing display formats in "See also".	

Example

The following example shows how the instruction works:



If the "TagIn" operand has signal state "1", the instruction is executed. The instruction copies the source area from MW14 to MW20 and fills the destination area from MW100 to MW118 with the content of the 4 words contained in the memory area in the BVAL parameter.

Conversion operations

CONVERT: Convert value

Description

The "Convert value" instruction reads the content of the IN parameter and converts it according to the data types set in the instruction box. The converted value is output at the OUT output.

For information on possible conversions, refer to the "Explicit conversion" section at "See also".

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- Errors, such as an overflow, occur during execution.

Conversion options for bit strings

The bit strings BYTE and WORD cannot be selected in the instruction box. It is, however, possible to specify an operand of the data type DWORD or LWORD for a parameter of the instruction if the length of the input and output operand match. The operand will be interpreted and implicitly converted from the data type of a bit string according to the data type of the input or output parameter. The data type DWORD is for example interpreted as DINT/UDINT and LWORD as LINT/ULINT. These conversion options are available even if the "IEC check" is enabled.

Note

For CPUs of the S7-1500 series: The data types DWORD and LWORD can only be converted from or to data type REAL or LREAL.

Parameters

The following table shows the parameters of the "Convert value" instruction:

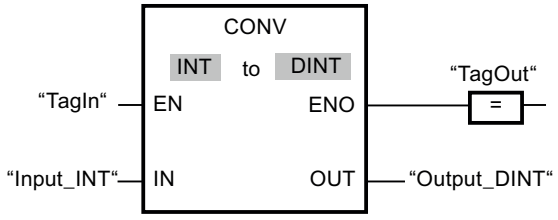
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers, floating-point numbers, CHAR, WCHAR, BCD16, BCD32	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Value to be converted.
OUT	Output	Bit strings, integers, floating-point numbers, CHAR, WCHAR, BCD16, BCD32	I, Q, M, D, L, P	I, Q, M, D, L, P	Result of the conversion

You can select the data types of the instruction from the "???" drop-down lists of the instruction box.

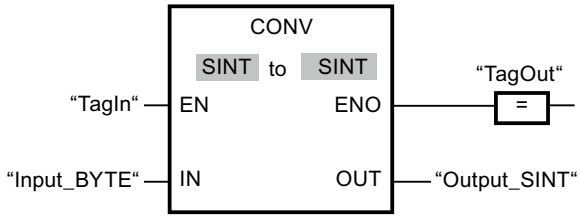
For additional information on valid data types, refer to "See also".

Example

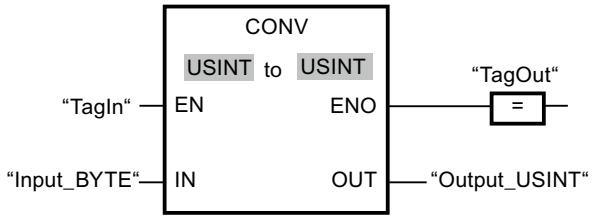
The following example shows conversion of an integer (16 bit) to another integer (32 bit):



The following example shows conversion of a byte (8 bit) to the integer SINT (8 bit):



The following example shows conversion of a byte (8 bit) to the unsigned integer USINT (8 bit):



The conversions are possible, because the length of the two operands is the same.

ROUND: Round numerical value

Description

You can use the "Round numerical value" instruction to round the value at input IN to the nearest integer. The instruction interprets the value at input IN as a floating-point number and converts this to the nearest integer. If the input value is exactly between an even and odd number, then the even number is converted. The result of the instruction is output at the OUT output and can be queried there.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the "Round numerical value" instruction:

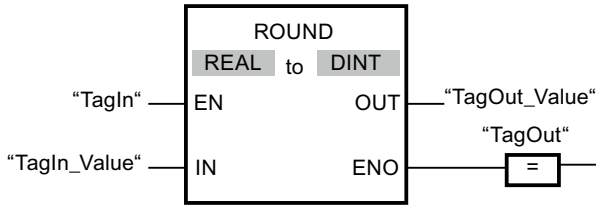
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value to be rounded.
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Result of the rounding

You can select the data types of the instruction from the "???" drop-down lists of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value	
IN	TagIn_Value	1.50000000	-1.50000000
OUT	TagOut_Value	2	-2

If the "TagIn" operand has signal state "1", the instruction is executed. The floating-point number at input "TagIn_Value" is rounded to the nearest even integer and sent to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

Explicit conversion (Page 2113)

CEIL: Generate next higher integer from floating-point number

Description

You can use the "Generate next higher integer from floating-point number" instruction to round the value at input IN to the next higher integer. The instruction interprets the value at input IN as a floating-point number and converts this to the next higher integer. The result of the instruction is output at the OUT output and can be queried there. The output value can be greater than or equal to the input value.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the instruction "Generate next higher integer from floating-point number":

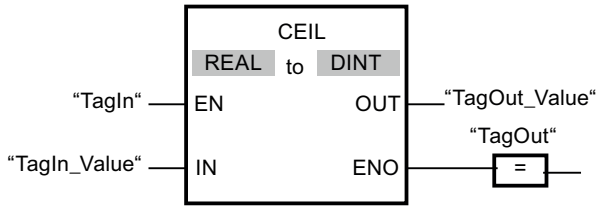
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value as floating-point number
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Result with the next higher integer

You can select the data types of the instruction from the "???" drop-down lists of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value	
IN	TagIn_Value	0.50000000	-0.50000000
OUT	TagOut_Value	1	0

If the "TagIn" operand has signal state "1", the instruction is executed. The floating-point number at input "TagIn_Value" is rounded to the next higher integer and sent to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

Overview of the valid data types (Page 1908)

Explicit conversion (Page 2113)

FLOOR: Generate next lower integer from floating-point number

Description

You can use the "Generate next lower integer from floating-point number" instruction to round the value at input IN to the next lower integer. The instruction interprets the value at input IN as a floating-point number and converts this to the next lower integer. The result of the instruction is provided at output OUT and can be queried there. The output value can be less than or equal to the input value.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the instruction "Generate next lower integer from floating-point number":

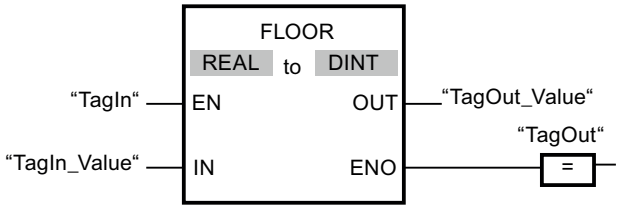
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value as floating-point number
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Result with the next lower integer

You can select the data types of the instruction from the "???" drop-down lists of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value	
IN	TagIn_Value	0.50000000	-0.50000000
OUT	TagOut_Value	0	-1

If the "TagIn" operand has signal state "1", the instruction is executed. The floating-point number at input "TagIn_Value" is rounded to the next lower integer and displayed at output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

Overview of the valid data types (Page 1908)

Explicit conversion (Page 2113)

TRUNC: Truncate numerical value

Description

You can use the "Truncate numerical value" instruction to form an integer from the value at input IN. The value at input IN is interpreted as a floating-point number. The instruction selects only the integer part of the floating-point number and sends this to output OUT without decimal places.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the instruction "Truncate numerical value":

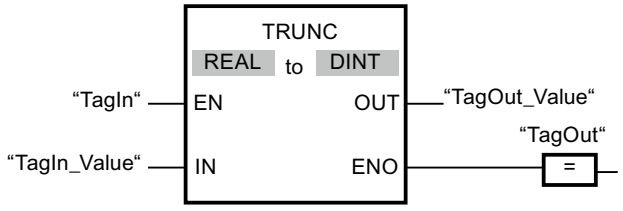
Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L or constant	Input value as floating-point number
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L	Result with integer part of the floating-point number

You can select the data types of the instruction from the "???" drop-down lists of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value	
IN	TagIn_Value	1.50000000	-1.50000000
OUT	TagOut_Value	1	-1

If the "TagIn" operand has signal state "1", the instruction is executed. The integer part of the floating-point number at input "TagIn_Value" is converted to an integer and sent to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

Overview of the valid data types (Page 1908)

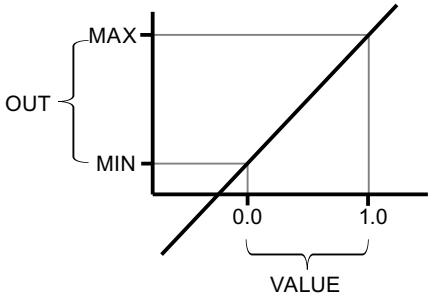
Explicit conversion (Page 2113)

SCALE_X: Scale

Description

You can use the "Scale" instruction to scale the value at the VALUE input by mapping it to a specified value range. When the instruction "Scale" is executed, the floating-point value at input VALUE is scaled to the value range, which is defined by the parameters MIN and MAX. The result of the scaling is an integer, which is stored at output OUT.

The following figure shows an example of how values can be scaled:



The "Scale" instruction works with the following equation:

OUT = [VALUE * (MAX – MIN)] + MIN

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input MIN is greater than or equal to the value at input MAX.
- The value of a specified floating-point number is outside the range of the normalized numbers according to IEEE-754.
- An overflow occurs.
- The value at input VALUE is NaN (Not a number = result of an invalid arithmetic operation).

Note

For more information on the conversion of analog values, refer to the respective manual.

Parameters

The following table shows the parameters of the "Scale" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
MIN	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Low limit of the value range
VALUE	Input	Floating-point numbers	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Value to be scaled. If you enter a constant, you must declare it.
MAX	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	I, Q, M, D, L or constant	High limit of the value range
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L	I, Q, M, D, L	Result of scaling

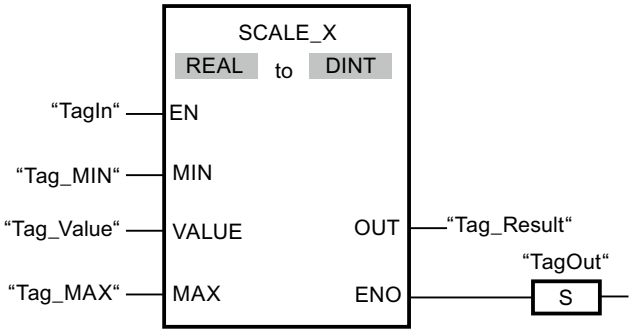
You can select the data types of the instruction from the "???" drop-down lists of the instruction box.

For additional information on valid data types, refer to "See also".

For additional information on declaring constants, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
MIN	Tag_MIN	10
VALUE	Tag_Value	0.5

Parameters	Operand	Value
MAX	Tag_MAX	30
OUT	Tag_Result	20

If the "TagIn" operand has signal state "1", the instruction is executed. The value at input "Tag_Value" is scaled to the range of values defined by the values at inputs "Tag_MIN" and "Tag_MAX". The result is stored at output "Tag_Result". If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

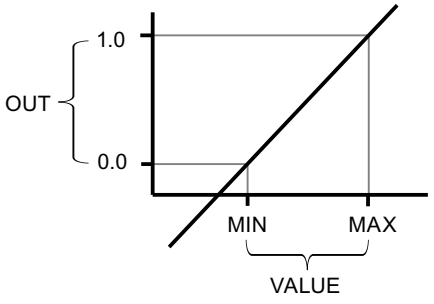
NORM_X: Normalize (Page 2672)

NORM_X: Normalize

Description

You can use the instruction "Normalize" to normalize the value of the tag at the VALUE input by mapping it to a linear scale. You can use the parameters MIN and MAX to define the limits of a value range that is applied to the scale. Depending on the location of the normalized value in this value range, the result at output OUT is calculated and stored as a floating-point number. If the value to be normalized is equal to the value at input MIN, output OUT returns the value "0.0". If the value to be normalized is equal to the value at input MAX, output OUT returns the value "1.0".

The following figure shows an example of how values can be normalized:



The "Normalize" instruction works with the following equation:

OUT = (VALUE – MIN) / (MAX – MIN)

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input MIN is greater than or equal to the value at input MAX.
- The value of a specified floating-point number is outside the range of the normalized numbers according to IEEE-754.
- The value at input VALUE is NaN (result of an invalid arithmetic operation).

Note

For more information on the conversion of analog values, refer to the respective manual.

Parameters

The following table shows the parameters of the instruction "Normalize":

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
MIN [1)]	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Low limit of the value range
VALUE [1)]	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Value to be normalized.
MAX [1)]	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	I, Q, M, D, L or constant	High limit of the value range
OUT	Output	Floating-point numbers	I, Q, M, D, L	I, Q, M, D, L	Result of the normalization
[1)] If you use constants in these three parameters, you only need to declare one of them.					

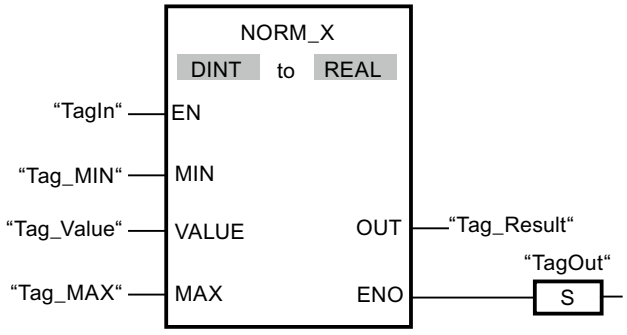
You can select the data types of the instruction from the "???" drop-down lists of the instruction box.

For additional information on valid data types, refer to "See also".

For additional information on declaring constants, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
MIN	Tag_MIN	10
VALUE	Tag_Value	20
MAX	Tag_MAX	30
OUT	Tag_Result	0.5

If the "TagIn" operand has signal state "1", the instruction is executed. The value at input "Tag_Value" is assigned to the range of values defined by the values at inputs "Tag_MIN" and "Tag_MAX". The tag value at input "Tag_Value" is normalized corresponding to the defined value range. The result is stored as a floating-point number at output "Tag_Result". If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

Overview of the valid data types (Page 1908)

SCALE_X: Scale (Page 2670)

Legacy

SCALE: Scale

Description

Use the "Scale" instruction to convert the integer in the IN parameter into a floating-point number, which can be scaled in physical units between a low limit value and a high limit value. You use the LO_LIM and HI_LIM parameters to specify the low limit and high limit of the value range to which the input value is scaled. The result of the instruction is output at the OUT parameter.

The "Scale" instruction works with the following equation:

OUT = [((FLOAT (IN) – K1)/(K2–K1)) * (HI_LIM–LO_LIM)] + LO_LIM

The values of the constants "K1" and "K2" are determined by the signal state of the BIPOLAR parameter. The following signal states are possible in the BIPOLAR parameter:

- Signal state "1": It is assumed that the value at the IN parameter is bipolar and in a value range between -27648 and 27648. In this case, the constant "K1" has the value -27648.0 and the constant "K2" the value +27648.0.
- Signal state "0": It is assumed that the value at the IN parameter is unipolar and in a value range between 0 and 27648. In this case, the constant "K1" has the value 0.0 and the constant "K2" the value +27648.0.

When the value at the IN parameter is greater than the value of the constant "K2", the result of the instruction is set to the value of the high limit (HI_LIM) and an error is output.

When the value at the IN parameter is less than the value of the constant "K1", the result of the instruction is set to the value of the low limit value (LO_LIM) and an error is output.

When the indicated low limit value is greater than the high limit value (LO_LIM > HI_LIM), the result is scaled in reverse proportion to the input value.

Parameters

The following table shows the parameters of the "Scale" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	INT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value to be scaled.
HI_LIM	Input	REAL	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	High limit
LO_LIM	Input	REAL	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Low limit
BIPOLAR	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Indicates if the value at IN parameter is to be interpreted as bipolar or unipolar. The parameter can assume the following values: 1: Bipolar 0: Unipolar
OUT	Output	REAL	I, Q, M, D, L, P	I, Q, M, D, L, P	Result of the instruction
RET_VAL	Output	WORD	I, Q, M, D, L, P	I, Q, M, D, L, P	Error information

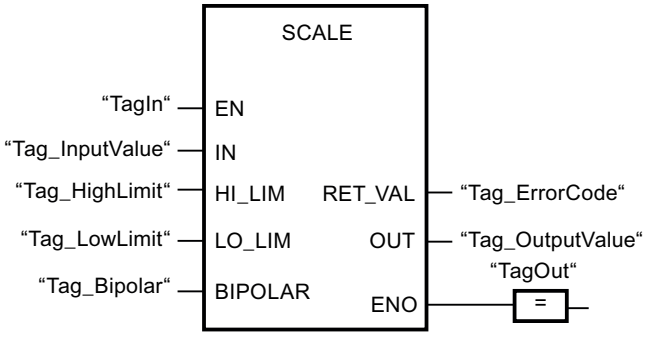
Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
0008	The value of the IN parameter is greater than the value of the "K2" constant or less than the value of the "K1" constant.
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal values in the program editor. You will find information on changing display formats in "See also".	

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	Tag_InputValue	22
HI_LIM	Tag_HighLimit	100.0
LO_LIM	Tag_LowLimit	0.0
BIPOLAR	Tag_Bipolar	1
OUT	Tag_OutputValue	50.03978588
RET_VAL	Tag_ErrorCode	W#16#0000

Overview of the valid data types (Page 1908)

GET_ERR_ID: Get error ID locally (Page 2697)

UNSCALE: Unscale

Description

The "Unscale" instruction unscales the floating-point number at the IN parameter into physical units between a low limit value and a high limit and converts them into integers. You use the LO_LIM and HI_LIM parameters to specify the low limit and high limit of the value range to which the input value is unscaled. The result of the instruction is output at the OUT parameter.

The "Unscale" instruction works with the following equation:

OUT = [((IN–LO_LIM)/(HI_LIM–LO_LIM)) * (K2–K1)] + K1

The values of the constants "K1" and "K2" are determined by the signal state of the BIPOLAR parameter. The following signal states are possible in the BIPOLAR parameter:

- Signal state "1": It is assumed that the value at the IN parameter is bipolar and in a value range between -27648 and 27648. In this case, the constant "K1" has the value -27648.0 and the constant "K2" the value +27648.0.
- Signal state "0": It is assumed that the value at the IN parameter is unipolar and in a value range between 0 and 27648. In this case, the constant "K1" has the value 0.0 and the constant "K2" the value +27648.0.

When the value at the IN parameter is greater than the value of the constant "HI_LIM", the result of the instruction is set to the value of the constant (K2) and an error is output.

When the value at the IN parameter is less than the value of the constant of the low limit (LO_LIM), the result of the instruction is set to the value of the constant (K1) and an error is output.

Parameters

The following table shows the parameters of the "Unscale" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	REAL	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value to be unscaled to an integer value.
HI_LIM	Input	REAL	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	High limit
LO_LIM	Input	REAL	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Low limit

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
BIPOLAR	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Indicates if the value at the IN parameter is to be interpreted as bipolar or unipolar. The parameter can assume the following values: 1: Bipolar 0: Unipolar
OUT	Output	INT	I, Q, M, D, L, P	I, Q, M, D, L, P	Result of the instruction
RET_VAL	Output	WORD	I, Q, M, D, L, P	I, Q, M, D, L, P	Error information

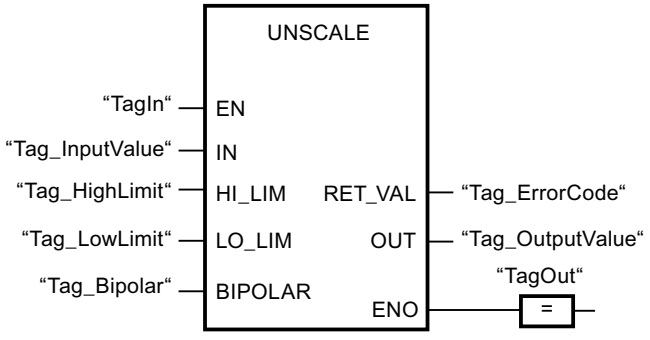
Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
0008	The value of the IN parameter is greater than the value of the high limit (HI_LIM) or less than the value of the low limit (LO_LIM).
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal values in the program editor. You will find information on changing display formats in "See also".	

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_InputValue	50.03978588
HI_LIM	Tag_HighLimit	100.0
LO_LIM	Tag_LowLimit	0.0
BIPOLAR	Tag_Bipolar	1
OUT	Tag_OutputValue	22
RET_VAL	Tag_ErrorCode	W#16#0000

Program control operations

JMP: Jump if RLO = 1

Description

You can use the "Jump if RLO = 1" instruction to interrupt the linear execution of the program and resume it in another network. The target network must be identified by a jump label (LABEL). The jump label description is entered in the placeholder above the instruction box.

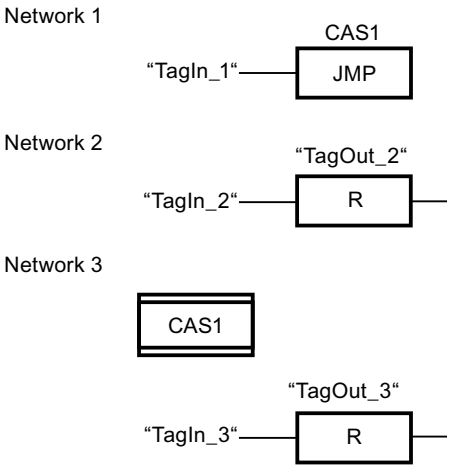
The specified jump label must be in the same block in which the instruction is executed. The name you specify can only occur once in the block. Only one jumping coil can occur in a network.

If the result of logic operation (RLO) at the input of the instruction is "1", the jump to the network identified by the jump label is executed. The jump direction can be towards higher or lower network numbers.

If the condition at the input of the instruction is not fulfilled (RLO = 0), execution of the program continues in the next network.

Example

The following example shows how the instruction works:



If the "TagIn_1" operand has signal state "1", the instruction is executed. The linear execution of the program is interrupted and continues in Network 3, which is identified by the jump label CAS1. If input "TagIn_3" has the signal state "1", output "TagOut_3" is reset.

See also

Overview of the valid data types (Page 1908)

JMPN: Jump if RLO = 0

Description

You can use the instruction "Jump if RLO = 0" to interrupt the linear execution of the program and resume it in another network, when the result of logic operation at the input of the instruction is "0". The target network must be identified by a jump label (LABEL). The jump label description is entered in the placeholder above the instruction box.

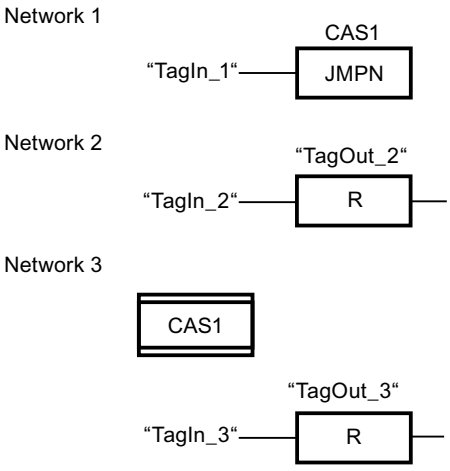
The specified jump label must be in the same block in which the instruction is executed. The name you specify can only occur once in the block. Only one jumping coil can occur in a network.

If the result of logic operation (RLO) at the input of the instruction is "0", the jump to the network identified by the jump label is executed. The jump direction can be towards higher or lower network numbers.

If the result of the logic operation RLO at the input of the instruction is "1", execution of the program continues in the next network.

Example

The following example shows how the instruction works:



If the "TagIn_1" operand has signal state "0", the instruction is executed. The linear execution of the program is interrupted and continues in Network 3, which is identified by the jump label CAS1. If input "TagIn_3" has the signal state "1", output "TagOut_3" is reset.

See also

Overview of the valid data types (Page 1908)

LABEL: Jump label

Description

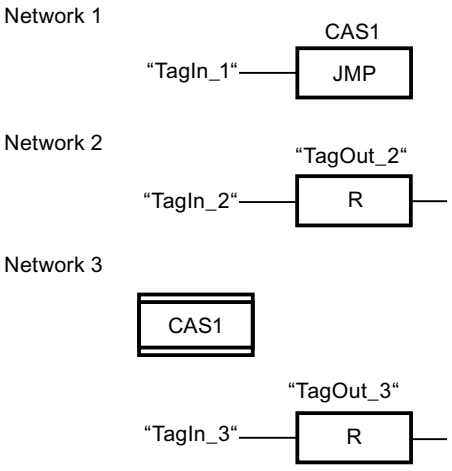
The jump label identifies a destination network in which the execution of the program can be resumed after the execution of a jump instruction.

The jump label and the instruction in which the jump label is specified must be located in the same block. The name of a jump label can only be assigned once in a block. You can declare up to 32 jump labels when you use a CPU S7-1200 and a maximum of 256 jump labels when you use a CPU S7-1500.

Only one jump label can be placed in a network. Each jump label can jump to several locations.

Example

The following example shows how the instruction works:



If the "TagIn_1" operand has signal state "1", the instruction is executed. The linear execution of the program is interrupted and continues in Network 3, which is identified by the jump label CAS1. If input "TagIn_3" has the signal state "1", output "TagOut_3" is reset.

Overview of the valid data types (Page 1908)

JMP_LIST: Define jump list

Description

You can use the "Define jump list" instruction to define several conditional jumps and continue the program execution in a specific network depending on the value of the K parameter.

You define the jumps with jump labels (LABEL), which you specify at the outputs of the instruction box. The number of outputs can be expanded in the instruction box. You can declare up to 32 outputs when you use a CPU S7-1200 and a maximum of 99 outputs when you use a CPU S7-1500.

The numbering of the outputs begins with the value "0" and is continued in ascending order with each new output. Only jump labels can be specified at the outputs of the instruction. It is not permitted to specify instructions or operands.

The value of the K parameter specifies the number of the output and thus the jump label where the program execution is to be resumed. If the value in the K parameter is greater than the number of available outputs, the program execution is resumed in the next network of the block.

The "Define jump list" instruction is only executed if the signal state is "1" at the EN enable input.

Parameters

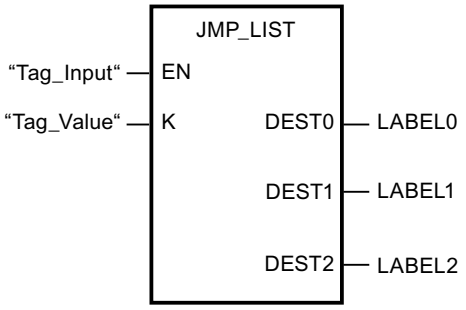
The following table shows the parameters of the "Define jump list" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, L, D	Enable input
K	Input	UINT	I, Q, M, L, D or constant	Specifies the number of the output and thus the jump that is executed.
DEST0	-	-	-	First jump label
DEST1	-	-	-	Second jump label
DESTn	-	-	-	Optional jump labels

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand/jump label	Value
K	Tag_Value	1
DEST0	LABEL0	Jump to the network that is identified with the jump label "LABEL0".
DEST1	LABEL1	Jump to the network that is identified with the jump label "LABEL1".
DEST2	LABEL2	Jump to the network that is identified with the jump label "LABEL2".

If the "Tag_Input" operand has signal state "1", the instruction is executed. The execution of the program is continued according to the value of the operand "Tag_Value" in the network that is identified with the jump label "LABEL1".

Overview of the valid data types (Page 1908)

SWITCH: Jump distributor

Description

You can use the "Jump distributor" instruction to define multiple program jumps to be executed depending on the result of one or more comparison instructions.

At the parameter K, you specify the value to be compared. This value is compared with the values that the individual inputs return. You select the type of comparison for each input. The availability of various comparison instructions depends on the data type of the instruction.

The following table shows the comparison instructions that are available depending on the selected data type:

Data type		Instruction	Syntax
S7-1200	S7-1500		
Bit strings	Bit strings	Equal	==
		Not equal	<>
Integers, floating-point numbers, TIME, DATE, TOD	Integers, floating-point numbers, TIME, LTIME, DATE, TOD, LTOD, LDT	Equal	==
		Not equal	<>
		Greater or equal	>=
		Less or equal	<=
		Greater than	>
		Less than	<

You can select the data type of the instruction from the "???" drop-down list of the instruction box. If you select a comparison instruction and the data type of the instruction is not yet defined, then the "???" drop-down list will only list those data types that are permitted for the selected comparison instruction.

The execution of the instruction begins with the first comparison and is executed until a comparison condition is fulfilled. When a comparison condition is fulfilled the subsequent comparison conditions are not considered. If none of the specified comparison conditions are fulfilled, the jump is executed at output ELSE. If not jump label is defined at output ELSE, the linear execution of the program is not interrupted but instead continued in the next network.

In its initial state the instruction box contains at least 2 outputs (DEST0 and DEST1). The number of outputs can be extended. The numbering of the outputs begins with the value "0" and is continued in ascending order with each new output. Specify jump labels (LABEL) at the outputs of the instruction. It is not permitted to specify instructions or operands at the outputs of the instruction.

An input is automatically inserted to each additional output. The jump programmed at an output is executed when the comparison condition of the corresponding is fulfilled.

Parameters

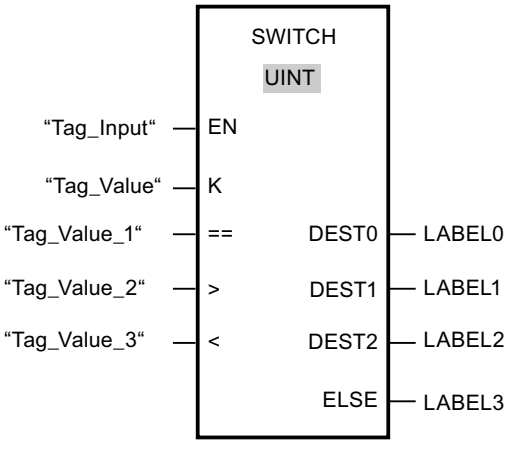
The following table shows the parameters of the instruction "Jump distributor":

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
K	Input	UINT	UINT	I, Q, M, D, L or constant	Specifies the value to be compared.
<Comparison values>	Input	Bit strings, integers, floating-point numbers, TIME, DATE, TOD	Bit strings, integers, floating-point numbers, TIME, LTIME, DATE, TOD, LTOD, LDT	I, Q, M, D, L or constant	Input values with which the value of the parameter K is compared.
DEST0	-	-	-	-	First jump label
DEST1	-	-	-	-	Second jump label
DEST(n)	-	-	-	-	Optional jump labels (n = 2 to 99)
ELSE	-	-	-	-	Program jump which is executed if none of the comparison conditions are fulfilled.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand/jump label	Value
K	Tag_Value	23
==	Tag_Value_1	20
>	Tag_Value_2	21
<	Tag_Value_3	19
DEST0	LABEL0	Jump to jump label "LABEL0", if the value of parameter K is equal to 20.
DEST1	LABEL1	Jump to jump label "LABEL1", if the value of parameter K is greater than 21.
DEST2	LABEL2	Jump to jump label "LABEL2", if the value of parameter K is less than 19.
ELSE	LABEL 3	Jump to jump label "LABEL3", if none of the comparison conditions are fulfilled.

If the operand "Tag_Input" changes to signal state "1", the instruction is executed. The execution of the program is continued in the network that is identified with the jump label "LABEL1".

See also

Overview of the valid data types (Page 1908)

RET: Return

Description

You can use the instruction "Return" to stop the execution of a block. This results in three types, in which the block processing can be completed:

- Without call of the "Return" instruction
  The block is exited after the execution of the last network. The ENO of the call function is set to the signal state "1".
- Call of the "Return" instruction with logic operation (see example)
  If the left connector has the signal state "1", then the block is exited. The ENO of the function call corresponds to the operand.
- Call of the "Return" instruction without logic operation
  The block is exited. The ENO of the function call corresponds to the operand.

Note

Only one jumping coil may be used in a network ("Return", "Jump if RLO = 1", "Jump if RLO = 0").

If the result of logic operation (RLO) at the input of the instruction "Return" is "1", the execution of the program is terminated in the currently called block and continued after the call function in the calling block (for example, in the calling OB). The status (ENO) of the call function is determined by the parameter of the instruction. This can assume the following values:

- RLO
- TRUE/FALSE
- <Operand>

To set the parameter values, double-click the instruction and select the corresponding value in the drop-down list.

The following table shows the status of the call function when the instruction "Return" is programmed in a network within the called block:

RLO	Parameter value	ENO of the call function
1	RLO	1
	TRUE	1
	FALSE	0
	<Operand>	<Operand>
0	RLO	In this case, the execution of the program continues in the next network of the called block.
	TRUE	
	FALSE	
	<Operand>	

If an OB is completed, another block is selected by the priority class system and started or re-executed.

- If the OB program cycle was completed, it is restarted.
- If an OB, which interrupted another block (e.g. an Alarm OB), is completed, then the interrupted block (e.g. OB program cycle) is executed.

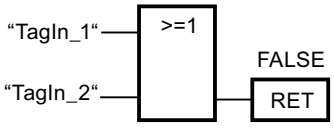
Parameters

The following table shows the parameters of the instruction "Return":

Parameters	Declaration	Data type	Memory area	Description
Status of the calling function when RLO = 1:				
RLO	-	-	-	Is set to the signal state of the RLO.
TRUE	-	-	-	1
FALSE	-	-	-	0
<Operand>	Input	BOOL	I, Q, M, D, L	Signal state of the specified operand

Example

The following example shows how the instruction works:



If one of the operands "TagIn_1" or "TagIn_2" have signal state "1", the instruction is executed. Program execution in the called block is terminated and continues in the calling block. The enable output ENO of the call function is reset to signal state "0".

Runtime control

ENDIS_PW: Limit and enable password legitimation

Description

You use the "Limit and enable password legitimation" instruction to specify whether passwords configured for the CPU are legitimized or not. In this way, you can prevent legitimized connections, even if the correct password is known.

When the instruction is called and the REQ parameter has the signal state "0", the currently set state is displayed at the output parameters. If changes have been made to the input parameters, these are not transferred to the output parameters.

When the instruction is called and the REQ parameter has the signal state "1", the signal state is taken from the input parameters (F_PWD, FULL_PWD, R_PWD, HMI_PWD). FALSE means that legitimation per password is not permitted; TRUE means the password can be used.

Disable or enabling of the passwords can be allowed or prohibited individually. For example, all passwords can be prohibited except the fail-safe password. You can thus limit access options to a small user group. The output parameters (F_PWD_ON, FULL_PWD_ON, R_PWD_ON, HMI_PWD_ON) always show the current status of the password use, regardless of the REQ parameter.

Passwords that are not configured must have the signal state TRUE at the input and return the signal state TRUE at the output. The fail-safe password can only be configured for an F-CPU and must therefore always be interconnected with the signal state TRUE in a standard CPU. If the instruction returns an error, the call has no effect and the previous lock is still in effect.

Disabled passwords can be enabled again under the following conditions:

- The CPU is reset to its factory settings.
- The front panel of the S7-1500 CPU supports a dialog that allows you to navigate to the appropriate menu in which the passwords can be enabled again.

- When you call the "Limit and enable password legitimation" instruction, the input parameter of the desired password has the signal state "1".
- Set the mode selector to STOP. The restriction to password legitimation is re-established as soon as the switch is set back to RUN.
- Plugging an empty memory card (transfer module or program card) into an S7-1200 CPU.
- The transition from POWER OFF to POWER ON disables the protection in the S7-1200 CPU. The "Limit and enable password legitimation" instruction must be called once again in the program (e.g. in the startup OB).

Note

The "Limit and enable password legitimation" instruction blocks access from HMI systems if the HMI password has not been enabled.

Note

Existing legitimized connections retain their access rights and you cannot use the "Limit and enable password legitimation" instruction to restrict them.

Preventing unintentional lockout on an S7-1500 CPU

The settings can be made on the front panel of the CPU and the CPU saves the most recent setting.

To prevent accidental lockout, the protection can be disabled by setting the mode selector to STOP with an S7-1500 CPU. The protection is automatically enabled again by setting mode selector to RUN without having to call the "Limit and enable password legitimation" instruction again or taking additional actions on the front panel.

Preventing unintentional lockout on an S7-1200 CPU

Because the S7-1200 CPU does not have a mode switch, protection is disabled with POWER OFF - POWER ON. This means that it is possible and advisable to prevent accidental lockout with the help of specific program sequences within your program.

To do so, program a time control either by means of a cyclic interrupt OB or a timer in the Main OB (OB 1). This gives you the option of calling the "Limit and enable password legitimation" instruction in the respective OB (e.g., OB 1 or OB 35) relatively quickly after a transition from POWER OFF to POWER ON and the associated disabling of the protection. Call the instruction in the startup OB (OB 100) to keep the time window in which the instruction is inactive and there are no limitations for password legitimation relatively small. This procedure will give you the best possible protection from unauthorized access.

If there has been an accidental lockout, you can skip the call in the startup OB (by querying an input parameter, for example) and you have the set time (for example, 10 seconds up to 1 minute) to establish a connection to the CPU before the lock becomes active once again.

If there is no timer in your program code and a lockout has occurred, insert an empty transfer card or an empty program card into the CPU. The empty transfer card or program card deletes the internal load memory of the CPU. You must then download the user program once again from STEP 7 to the CPU.

Procedure for lost passwords with an S7-1200 CPU

If you have lost the password for a password-protected S7-1200 CPU, delete the password-protected program with an empty transfer card or program card. The empty transfer card or program card deletes the internal load memory of the CPU. You can then load a new user program from STEP 7 Basic in the CPU.

Warning

Inserting an empty transfer card

When you insert a transfer card in a CPU during runtime, the CPU goes to STOP mode. If operating states are unstable, controllers may fail and thus cause the uncontrolled operation of the controlled devices. This leads to an unforeseen operation of the automation system which can cause deadly or serious injuries and/or damage to property.

Once you have pulled the transfer card, the content of the transfer card is available in the internal load memory. Make sure that the card does not include a program at this point.

Warning

Inserting an empty program card

When you insert a program card in a CPU during runtime, the CPU goes to STOP mode. If operating states are unstable, controllers may fail and thus cause the uncontrolled operation of the controlled devices. This leads to an unforeseen operation of the automation system which can cause deadly or serious injuries and/or damage to property.

Make sure that the program card is empty. The internal load memory is copied to the empty program card. Once you have pulled the previously empty program card, the internal load memory is empty.

You must remove the transfer card or program card before you put the CPU into RUN mode.

Effects of password use on the operating modes

The following table shows what effects the password use by means of the "Limit and enable password legitimation" instruction has on the operating modes and the corresponding user actions.

Action	Password protection by means of the instruction
Basic state after • Operating mode switch to STOP • Reset memory manually (PG, switch, change of MC (Motion Control)) • Reset to factory setting	Not activated (no restrictions)
Basic state after POWER ON	• S7-1200 CPU: The lock is disabled and the instruction must be called once again in the program (e.g., in the startup OB). • S7-1500 CPU: Enabled (if a lock was activated before POWER OFF). The option of not allowing passwords is retentive.
Operating mode transition RUN/STARTUP/HOLD -> STOP (by terminating the instruction, an error or communication) or STOP -> STARTUP/RUN/HOLD	Activated Passwords still cannot be used.

Parameters

The following table shows the parameters of the "Limit and enable password legitimation" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
REQ	Input	BOOL	I, Q, M, D, L or constant	When the REQ parameter has the signal state "0", the currently set signal state of the passwords is queried.
F_PWD	Input	BOOL	I, Q, M, D, L or constant	Read/write access including fail-safe • F_PWD = "0": Do not allow password • F_PWD = "1": Allow password
FULL_PWD	Input	BOOL	I, Q, M, D, L or constant	Read/write access • FULL_PWD = "0": Do not allow password • FULL_PWD = "1": Allow password
R_PWD	Input	BOOL	I, Q, M, D, L or constant	Read access • R_PWD = "0": Do not allow password • R_PWD = "1": Allow password

Parameters	Declaration	Data type	Memory area	Description
HMI_PWD	Input	BOOL	I, Q, M, D, L or constant	HMI access • HMI_PWD = "0": Do not allow password • HMI_PWD = "1": Allow password
F_PWD_ON	Output	BOOL	I, Q, M, D, L	Read/write access including fail-safe • F_PWD_ON = "0": Password not allowed • F_PWD_ON = "1": Password allowed
FULL_PWD_ON	Output	BOOL	I, Q, M, D, L	Read/write access status • FULL_PWD_ON = "0": Password not allowed • FULL_PWD_ON = "1": Password allowed
R_PWD_ON	Output	BOOL	I, Q, M, D, L	Read-access status • R_PWD_ON = "0": Password not allowed • R_PWD_ON = "1": Password allowed
HMI_PWD_ON	Output	BOOL	I, Q, M, D, L	HMI-access status • HMI_PWD_ON = "0": Password not allowed • HMI_PWD_ON = "1": Password allowed
RET_VAL	Output	WORD	I, Q, M, D, L	Error information

For additional information on valid data types, refer to "See also".

Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
8090	The "Limit and enable password legitimation" instruction is not supported
80D0	The password for fail-safe is not configured. The signal state must be TRUE for standard CPUs.
80D1	The read/write access is not configured
80D2	The read access is not configured
80D3	The HMI access is not configured
*The error codes can be displayed as integer or hexadecimal values in the program editor. You will find information on changing display formats in "See also".

Overview of the valid data types (Page 1908)

RE_TRIGR: Restart cycle monitoring time

Description

You can use the "Restart cycle monitoring time" instruction to restart the cycle time monitoring of the CPU. The cycle monitoring time then starts again for the time you have set in the CPU configuration.

The instruction "Restart cycle monitoring time" can be called in all blocks regardless of the priority .

If the instruction is called in a block with a higher priority, for example a hardware interrupt, diagnostics interrupt or a cyclic interrupt, the instruction is not executed and the enable output ENO is set to signal state "0".

The "Restart cycle monitoring time" instruction executes completely within a time span (10 times the maximum program cycle), regardless of the number of calls. Once this time has expired, the program cycle can no longer be prolonged.

Parameters

The instruction "Restart cycle monitoring time" has no parameters.

See also

Overview of the valid data types (Page 1908)

STP: Exit program

Description

The instruction "Exit program" instruction is used to set the CPU to STOP mode and therefore to terminate the execution of the program. The effects of changing from RUN to STOP depend on the CPU configuration.

When the (RLO) at the input of the instruction is "1", the CPU changes to STOP mode and the execution of the program is terminated. The signal state at the output of the instruction is not evaluated.

If the RLO at the input of the instruction is "0", then the instruction will not be executed.

Parameters

The instruction "Exit program" has no parameters.

See also

Overview of the valid data types (Page 1908)

GET_ERROR: Get error locally

Description

The "Get error locally" instruction is used to query the occurrence of errors within a block. This is usually to access error. If the system reports an error during the processing of the block, detailed information is stored in the operand at the ERROR output for the first error to occur during the execution of the block since the last execution of the instruction.

Only operands of the "ErrorStruct" system data type can be specified at the ERROR output. The "ErrorStruct" system data type specifies the exact structure in which the information about the error is stored. Using additional instructions, you can evaluate this structure and program an appropriate response. If several errors occur in the block, the error information about the next error to occur in the instruction is output only after the first error that occurred has been remedied.

Note

The ERROR output is only changed if error information is present. To set the output back to "0" after handling an error, you have the following options:

- Declare the tag in the "Temp" section of the block interface.
- Reset the tag to "0" before calling the instruction.
- Query the enable output ENO.

The enable output ENO of the instruction "Get error locally" instruction is set only if the enable input EN returns signal state "1" and error information is present. If one of these conditions is not fulfilled, the remaining program execution is not affected by the "Get error locally" instruction.

You can find an example of how you can implement the instruction in combination with other troubleshooting options under "See also".

Note

The "Get error locally" instruction enables local error handling within a block. If "Get error locally" is inserted in the program code of a block, any predefined system reactions are ignored if errors occur.

Parameters

The following table lists the parameters of the "Get error locally" instruction:

Parameters	Declaration	Data type	Memory area	Description
ERROR	Output	ErrorStruct	D, L	Error information

Data type "ErrorStruct"

The following table lists the structure of the "ErrorStruct" data type:

Structure component		Data type	Description
ERROR_ID		WORD	Error ID
FLAGS		BYTE	Shows if an error occurred during a block call. 16#01: Error during a block call 16#00: No error during a block call
REACTION		BYTE	Default reaction: 0: Ignore (write error), 1: Continue with substitute value "0" (read error), 2: Skip instruction (system error)
CODE_ADDRESS		CREF	Information about the address and type of block
	BLOCK_TYPE	BYTE	Type of block where the error occurred: 1: OB 2: FC 3: FB
	CB_NUMBER	UINT	Number of the code block
	OFFSET	UDINT	Reference to the internal memory
MODE		BYTE	Information about the address of an operand
OPERAND_NUMBER		UINT	Operand number of the machine command
POINTER_NUMBER_LOCATION		UINT	(A) Internal pointer
SLOT_NUMBER_SCOPE		UINT	(B) Storage area in internal memory
DATA_ADDRESS		NREF	Information about the address of an operand
	AREA	BYTE	(C) Memory area: L: 16#40 – 4E, 86, 87, 8E, 8F, C0 – CE I: 16#81 Q: 16#82 M: 16#83 DB: 16#84, 85, 8A, 8B Range violations for a directly editable tag of data type DINT: 16#04

Structure component		Data type	Description
	DB_NUMBER	UINT	(D) Number of the data block
	OFFSET	UDINT	(E) Relative address of the operand

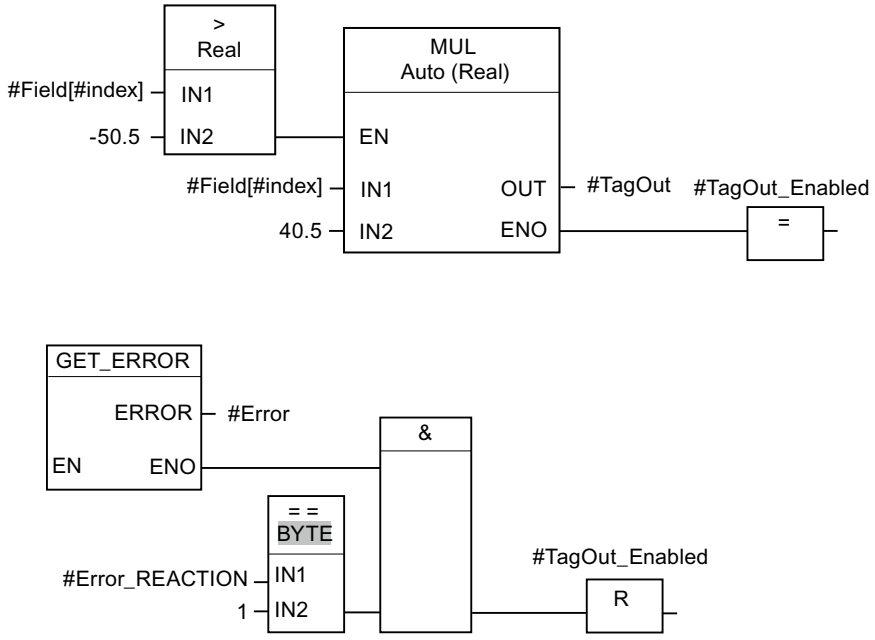
Structure component "ERROR_ID"

The following table lists the values that can be output at the structure component "ERROR_ID":

ID* (hexadecimal)	ID* (decimal)	Description
0	0	No error
2503	9475	Invalid pointer
2520	9504	Invalid STRING
2522	9506	Read error: Operand outside the valid range
2523	9507	Write error: Operand outside the valid range
2524	9508	Read error: Invalid operand
2525	9509	Write error: Invalid operand
2528	9512	Read error: Data alignment
2529	9513	Write error: Data alignment
252C	9516	Invalid pointer
2530	9520	Write error: Data block
2533	9523	Invalid pointer used
2538	9528	Access error: DB does not exist
2539	9529	Access error: Wrong DB used
253A	9530	Global data block does not exist
253C	9532	Faulty information or the function does not exist
253D	9533	System function does not exist
253E	9534	Faulty information or the function block does not exist
253F	9535	System block does not exist
2550	9552	Access error: DB does not exist
2551	9553	Access error: Wrong DB used
2575	9589	Error in the program nesting depth
2576	9590	Error in the local data distribution
2577	9591	The block property "Parameter passing via registers" is not selected.
25A0	9632	Internal error in TP
25A1	9633	Tag is write-protected
25A2	9634	Invalid numerical value of tag
2942	10562	Read error: Input
2943	10563	Write error: Output
*The error codes can be displayed as integer or hexadecimal values in the program editor. You will find information on changing display formats in "See also".		

Example

The following example shows how the instruction works:



An error occurred accessing the #Field[#index] tag. The enable output ENO of the "Multiply" instruction and the #TagOut_Enabled operand have signal state "1" despite the read/access error and the multiplication is performed with the value "0.0". If this error scenario occurs, it is recommended to program the "Get error locally" instruction after the "Multiply" instruction to get the error. The error information supplied by the "Get error locally" instruction is evaluated with the comparison instruction "Equal". If the "#Error.REACTION" structure component has the value "1", this involves a read/access error and the #TagOut_Enabled output is reset.

Querying and fixing errors in the program code (Page 228)

GET_ERR_ID: Get error ID locally

Description

The "Get error ID locally" instruction is used to query the occurrence of errors within a block. This is usually to access error. If the system reports during the block processing errors within the block execution since the last execution of the instruction, the error ID of the first error that occurred in the tag is stored at the ID output.

Only operands of the WORD data type can be specified at the ID output. If several errors occur in the block, the error ID of the next error to occur in the instruction is output only after the first error that occurred has been remedied.

Note

The ID output is only changed if error information is present. To set the output back to "0" after handling an error, you have the following options:

- Declare the tag in the "Temp" section of the block interface.
- Reset the tag to "0" before calling the instruction.
- Query the enable output ENO.

The enable output ENO of the instruction "Get error ID locally" instruction is set only if the enable input EN returns signal state "1" and error information is present. If one of these conditions is not fulfilled, the remaining program execution is not affected by the "Get error ID locally" instruction.

You can find an example of how you can implement the instruction in combination with other troubleshooting options under "See also".

Note

The "Get error ID locally" instruction enables local error handling within a block. If the "Get error ID locally" instruction is inserted in the program code of a block, any predefined system reactions are ignored if errors occur.

Parameters

The following table lists the parameters of the "Get error ID locally" instruction:

Parameters	Declaration	Data type	Memory area	Description
ID	Output	WORD	I, Q, M, D, L	Error ID

Parameter ID

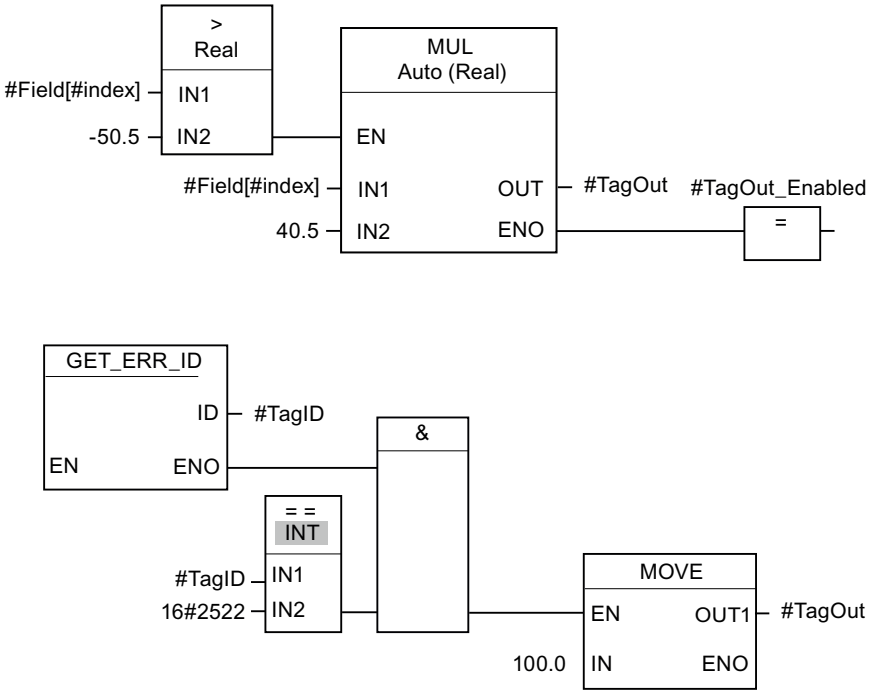
The following table lists the values that can be output at the ID parameter:

ID* (hexadecimal)	ID* (decimal)	Description
0	0	No error
2503	9475	Invalid pointer
2520	9504	Invalid STRING
2522	9506	Read error: Operand outside the valid range
2523	9507	Write error: Operand outside the valid range
2524	9508	Read error: Invalid operand
2525	9509	Write error: Invalid operand
2528	9512	Read error: Data alignment
2529	9513	Write error: Data alignment

ID* (hexadecimal)	ID* (decimal)	Description
252C	9516	Invalid pointer
2530	9520	Write error: Data block
2533	9523	Invalid pointer used
2538	9528	Access error: DB does not exist
2539	9529	Access error: Wrong DB used
253A	9530	Global data block does not exist
253C	9532	Faulty information or the function does not exist
253D	9533	System function does not exist
253E	9534	Faulty information or the function block does not exist
253F	9535	System block does not exist
2550	9552	Access error: DB does not exist
2551	9553	Access error: Wrong DB used
2575	9589	Error in the program nesting depth
2576	9590	Error in the local data distribution
2577	9591	The block property "Parameter passing via registers" is not selected.
25A0	9632	Internal error in TP
25A1	9633	Tag is write-protected
25A2	9634	Invalid numerical value of tag
2942	10562	Read error: Input
2943	10563	Write error: Output
*The error codes can be displayed as integer or hexadecimal values in the program editor. You will find information on changing display formats in "See also".		

Example

The following example shows how the instruction works:



An error occurred accessing the #Field[#index] tag. The enable output ENO of the "Multiply" instruction and the #TagOut_Enabled operand have signal state "1" despite the read/access error and the multiplication is performed with the value "0.0". If this error scenario occurs, it is recommended to program the "Get error ID locally" instruction after the "Multiply" instruction to get the error. The error information supplied by the "Get error ID locally" instruction is evaluated with the comparison instruction "Equal". If the #TagID operand returns the ID 2522, this involves a read/access error and the value "100.0" is written to the #TagOut output.

Querying and fixing errors in the program code (Page 228)

INIT_RD: Initialize all retain data

Description

The "Initialize all retain data" instruction is used to reset the retentive data of all data blocks, bit memories and SIMATIC timers and counters at the same time. The instruction can only be executed within a startup OB because the execution exceeds the program cycle duration.

Parameters

The following table shows the parameters of the "Initialize all retain data" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
REQ	Input	BOOL	I, Q, M, D, L, T, C or constant	If the input "REQ" has the signal state "1", all retentive data are reset.
RET_VAL	Output	INT	I, Q, M, D, L	Error information: If an error occurs during execution of the instruction, an error code is output in the RET_VAL parameter.

For additional information on valid data types, refer to "See also".

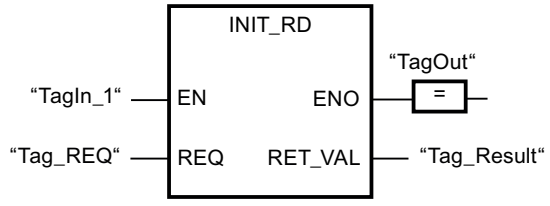
Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B5	The instruction cannot be executed because it was not programmed within a startup OB.
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal values in the program editor. You will find information on changing display formats in "See also".	

Example

The following example shows how the instruction works:



If the operands "TagIn_1" and "Tag_REQ" have signal state "1", the instruction is executed. All retentive data of all data blocks, bit memories and SIMATIC timers and counters are reset. If the instruction is executed without errors, the ENO enable output has the signal state "1".

GET_ERR_ID: Get error ID locally (Page 2697)

WAIT: Configure time delay

Description

The "Configure time delay" instruction pauses the program execution for a specific period of time. You indicate the period of time in microseconds on the WT parameter of the instruction.

You can configure time delays from -32768 up to +32767 microseconds (µs). The smallest possible delay time depends on the respective CPU and corresponds to the execution time of the "Configure time delay" instruction.

The execution of the instruction can be interrupted by higher priority events.

The "Configure time delay" instruction returns no error information.

Parameters

The following table shows the parameters of the "Configure time delay" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
WT	Input	INT	I, Q, M, D, L, P or constant	Time delay in microseconds (µs)

Overview of the valid data types (Page 1908)

RUNTIME: Measure program runtime

Description

The "Measure program runtime" instruction is used to measure the runtime of the entire program, individual blocks or command sequences.

If you want to measure the runtime of your entire program, call the instruction "Measure program runtime" in OB1. Measurement of the runtime is started with the first call and the output RET_VAL returns the runtime of the program after the second call. The measured runtime includes all CPU processes that can occur during the program execution, for example, interruptions caused by higher-level events or communication. The instruction "Measure program runtime" reads an internal counter of the CPU and write the value to the IN-OUT parameter MEM. The instruction calculates the current program runtime according to the internal counter frequency and writes it to output RET_VAL.

If you want to measure the runtime of individual blocks or individual command sequences, you need three separate networks. Call the instruction "Measure program runtime" in an individual network within your program. You set the starting point of the runtime measurement with this first call of the instruction. Then you call the required program block or the command sequence in the next network. In another network, call the "Measure program runtime" instruction a second time and assign the same memory to the IN-OUT parameter MEM as you did during the first call of the instruction. The "Measure program runtime" instruction in the third network reads an internal CPU counter and calculates the current runtime of the program block or the command sequence according to the internal counter frequency and writes it to the output RET_VAL.

The following applies to S7-1200 CPUs with firmware version earlier than V4.1: The "Measure program runtime" instruction uses an internal high-frequency counter to calculate the time. If the counter overflows (this can occur up to once per minute), the instruction returns values <= 0.0. Ignore these runtime values.

Note

The runtime of a command sequence cannot be determined exactly, because the sequence of instructions within a command sequence is changed during optimized compilation of the program.

Parameters

The following table lists the parameters of the "Measure program runtime" instruction:

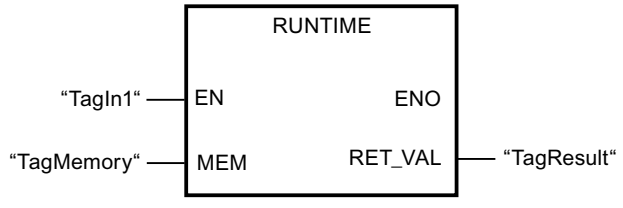
Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
MEM	InOut	LREAL	I, Q, M, D, L	Saves the starting point of the runtime measurement.
RET_VAL	Output	LREAL	I, Q, M, D, L	Returns the measured runtime in seconds

For additional information on valid data types, refer to "See also".

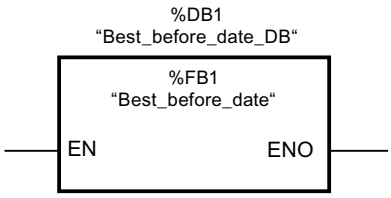
Example

The following example shows how the instruction works based on the runtime calculation of a program block:

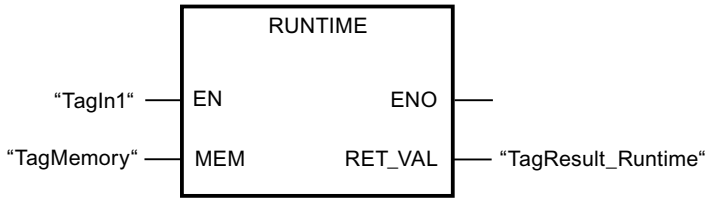
Network 1:



Network 2:



Network 3:



When the "TagIn1" operand in network 1 has the signal state "1", the instruction is executed. The starting point for the runtime measurement is set with the first call of the instruction and buffered as reference for the second call of the instruction in the "TagMemory" operand.

The "Best_before_date" program block FB1 is called in network 2.

When the FB1 program block has been executed and the "TagIn1" operand has the signal state "1", the instruction in network 3 is executed. The second call of the instruction calculates the runtime of the program block and writes the result to the output RET_VAL.

Overview of the valid data types (Page 1908)

Word logic operations

AND: AND logic operation

Description

You can use the instruction "AND logic operation" to link the value at input IN1 to the value at input IN2 bit-by-bit by AND logic and query the result at the output OUT.

When the instruction is executed, bit 0 of the value at input IN1 is linked by AND logic to bit 0 of the value at input IN2. The result is stored in bit 0 of output OUT. The same logic operation is executed for all other bits of the specified values.

In its initial state the instruction box contains at least 2 inputs (IN1 and IN2). The number of inputs can be extended. The inserted inputs are numbered in ascending order in the box. During the execution of the instruction, the values of all available input parameters are linked by AND logic. The result is stored at output "OUT".

The result bit has the signal state "1" only when both of the bits in the logic operation also have signal state "1". If one of the two bits of the logic operation has signal state "0", the corresponding result bit is reset.

Parameters

The following table shows the parameters of the instruction "AND logic operation":

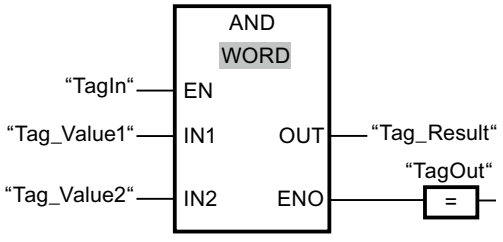
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Bit strings	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	First value for logic operation
IN2	Input	Bit strings	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Second value for logic operation
INn	Input	Bit strings	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Optional input values
OUT	Output	Bit strings	I, Q, M, D, L, P	I, Q, M, D, L, P	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN1	Tag_Value1	0101 0101 0101 0101
IN2	Tag_Value2	0000 0000 0000 1111
OUT	Tag_Result	0000 0000 0000 0101

If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value1" is linked by AND to the value of the operand "Tag_Value2". The result is mapped bit-for-bit and sent to the operand "Tag_Result". The enable output ENO and the output "TagOut" are set to signal state "1".

See also

Overview of the valid data types (Page 1908)

OR: OR logic operation

Description

You can use the instruction "OR logic operation" to link the value at input IN1 to the value at input IN2 bit-by-bit by OR logic and query the result at the output OUT.

When the instruction is executed, bit 0 of the value at input IN1 is linked by OR logic to bit 0 of the value at input IN2. The result is stored in bit 0 of output OUT. The same logic operation is executed for all bits of the specified tags.

In its initial state the instruction box contains at least 2 inputs (IN1 and IN2). The number of inputs can be extended in the instruction box. The inserted inputs are numbered in ascending order in the box. During the execution of the instruction, the values of all available input parameters are linked by OR logic. The result is stored at output "OUT".

The result bit has the signal state "1" when at least one of the two bits in the logic operation has signal state "1". If both of the bits of the logic operation have signal state "0", the corresponding result bit is reset.

Parameters

The following table shows the parameters of the instruction "OR logic operation":

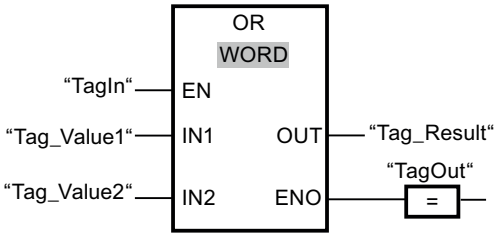
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Bit strings	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	First value for logic operation
IN2	Input	Bit strings	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Second value for logic operation
INn	Input	Bit strings	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Optional input values
OUT	Output	Bit strings	I, Q, M, D, L, P	I, Q, M, D, L, P	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN1	Tag_Value1	0101 0101 0101 0101
IN2	Tag_Value2	0000 0000 0000 1111
OUT	Tag_Result	0101 0101 0101 1111

If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value1" is linked by OR to the value of the operand "Tag_Value2". The result is mapped bit-for-bit and sent to the operand "Tag_Result". The enable output ENO and the output "TagOut" are set to signal state "1".

See also

Overview of the valid data types (Page 1908)

XOR: EXCLUSIVE OR logic operation

Description

You can use the instruction "EXCLUSIVE OR logic operation" to link the value at input IN1 to the value at input IN2 bit-by-bit by EXCLUSIVE OR logic and query the result at the output OUT.

When the instruction is executed, bit 0 of the value at input IN1 is linked by EXCLUSIVE OR logic to bit 0 of the value at input IN2. The result is stored in bit 0 of output OUT. The same logic operation is executed for all other bits of the specified value.

In its initial state the instruction box contains at least 2 inputs (IN1 and IN2). The number of inputs can be extended in the instruction box. The inserted inputs are numbered in ascending order in the box. During the execution of the instruction, the values of all available input parameters are linked by EXCLUSIVE OR logic. The result is stored at output "OUT".

The result bit has the signal state "1" when one of the two bits in the logic operation has signal state "1". If both of the bits of the logic operation have signal state "1" or "0", the corresponding result bit is reset.

Parameters

The following table shows the parameters of the instruction "EXCLUSIVE OR logic operation":

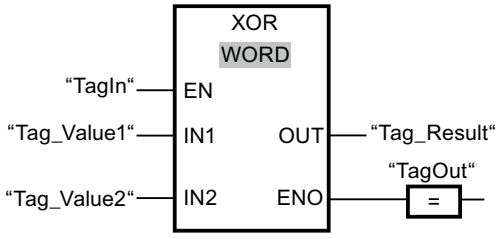
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Bit strings	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	First value for logic operation
IN2	Input	Bit strings	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Second value for logic operation
INn	Input	Bit strings	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Optional input values
OUT	Output	Bit strings	I, Q, M, D, L, P	I, Q, M, D, L, P	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN1	Tag_Value1	0101 0101 0101 0101
IN2	Tag_Value2	0000 0000 0000 1111
OUT	Tag_Result	0101 0101 0101 1010

If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value1" is linked by EXCLUSIVE OR to the value of the operand "Tag_Value2". The result is mapped bit-for-bit and sent to the operand "Tag_Result". The enable output ENO and the output "TagOut" are set to signal state "1".

See also

Overview of the valid data types (Page 1908)

INVERT: Create ones complement

Description

You can use the instruction "Create ones complement" to invert the signal status of the bits at input IN. When the instruction is processed, the value at input IN is linked to EXCLUSIVE OR by a hexadecimal mask (W#16#FFFF for 16-bit numbers or DW#16#FFFF FFFF for 32-bit number). This inverts the signal state of the individual bits that are then stored at output OUT.

Parameters

The following table shows the parameters of the instruction "Create ones complement":

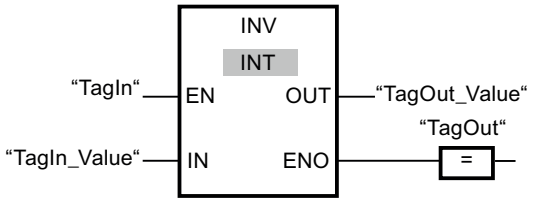
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers	I, Q, M, D, L, P, or constant	I, Q, M, D, L, P, or constant	Input value
OUT	Output	Bit strings, integers	I, Q, M, D, L, P	I, Q, M, D, L, P	Ones complement of the value at input IN

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value	
IN	TagIn_Value	W#16#000F	W#16#7E
OUT	TagOut_Value	W#16#FFF0	W#16#81

If operand "TagIn" has the signal state "1", the "Create ones complement" instruction is executed. The instruction inverts the signal state of the individual bits at input "TagIn_Value" and writes the result to output "TagOut_Value". The enable output ENO and the output "TagOut" are set to signal state "1".

See also

Overview of the valid data types (Page 1908)

DECO: Decode

Description

You can use the "Decode" instruction to set a bit in the output value specified by the input value.

The "Decode" instruction reads the value at the IN input and sets the bit in the output value whose bit position corresponds to the read value. The other bits in the output value are filled with zeroes. If the value at input IN is greater than 31, a modulo 32 instruction is executed.

Parameters

The following table shows the parameters of the "Decode" instruction:

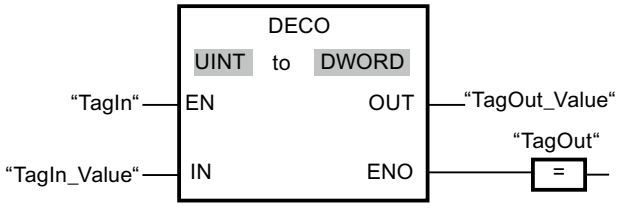
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	UINT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Position of the bit in the output value which is set.
OUT	Output	Bit strings	I, Q, M, D, L, P	I, Q, M, D, L, P	Output value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

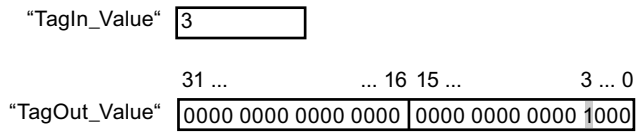
For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following figure shows how the instruction works using concrete operand values:



If the "TagIn" operand has signal state "1", the instruction is executed. The instruction reads bit number "3" from the value of the operand "TagIn_Value" and sets the third bit to the value of the operand "TagOut_Value".

If no errors occur during the execution of the instruction, the output ENO has the signal state "1" and the output "TagOut" is set.

See also

Overview of the valid data types (Page 1908)

ENCO: Encode

Description

The instruction "Encode" is used to read the bit number of the lowest bit in the input value and output it to the output OUT.

The instruction "Encode" selects the least significant bit of the value at the IN input and writes its bit number to the tag in the output OUT.

Parameters

The following table shows the parameters of the instruction "Encode":

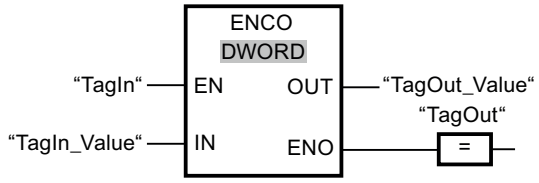
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Bit strings	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value
OUT	Output	INT	I, Q, M, D, L, P	I, Q, M, D, L, P	Output value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

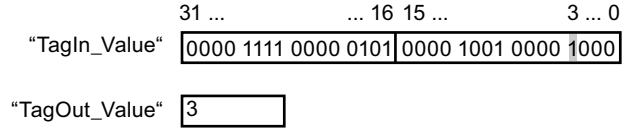
For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following figure shows how the instruction works using concrete operand values:



If the "TagIn" operand has signal state "1", the instruction is executed. The instruction selects bit position "3" as the least significant bit at input "TagIn_Value" and writes the value "3" to the tag at the output "TagOut_Value.

If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

SEL: Select

Description

Depending on the signal state at switch (input G), the "Select" instruction selects one of the inputs IN0 or IN1 and moves its content to the output OUT. When the input G has the signal state "0", the value at the input IN0 is moved. When the input G has the signal state "1", the value at the input IN1 is moved to the output OUT.

The instruction can only be executed if the enable input EN has the signal state "1" and the tags of all parameters are of the same data type.

Parameters

The following table shows the parameters of the "Select" instruction:

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output

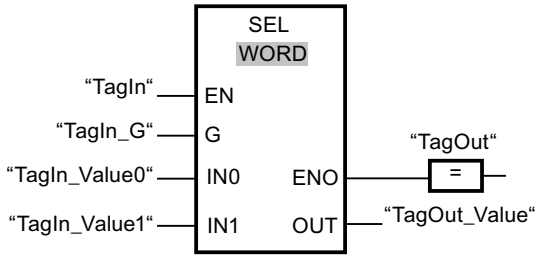
Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
G	Input	BOOL	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L, T, C or constant	Switch
IN0	Input	Bit strings, integers, floating-point numbers, timers, TOD, DATE, CHAR, WCHAR	Bit strings, integers, floating-point numbers, timers, TOD, LTOD, DATE, TDT, CHAR, WCHAR	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	First input value
IN1	Input	Bit strings, integers, floating-point numbers, timers, TOD, DATE, CHAR, WCHAR	Bit strings, integers, floating-point numbers, timers, TOD, LTOD, DATE, TDT, CHAR, WCHAR	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Second input value
OUT	Output	Bit strings, integers, floating-point numbers, timers, TOD, DATE, CHAR, WCHAR	Bit strings, integers, floating-point numbers, timers, TOD, LTOD, DATE, TDT, CHAR, WCHAR	I, Q, M, D, L, P	I, Q, M, D, L, P	Result

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value	
G	TagIn_G	0	1
IN0	TagIn_Value0	W#16#0000	W#16#4C
IN1	TagIn_Value1	W#16#FFFF	W#16#5E
OUT	TagOut_Value	W#16#0000	W#16#5E

If the "TagIn" operand has signal state "1", the instruction is executed. Based on the signal state at the input "TagIn_G", the value at input "TagIn_Value0" or "TagIn_Value1" is selected and copied to output "TagOut_Value". If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 1908)

MUX: Multiplex

Description

You can use the instruction "Multiplex" to copy the content of a selected input to output OUT. In its initial state the instruction box contains at least 2 inputs (IN0 and IN1). The number of selectable inputs of the instruction box can be expanded. You can declare a maximum of 32 inputs.

The inputs are numbered automatically in the box. Numbering starts at IN0 and is incremented continuously with each new input. You use the K parameter to define the input whose content is to be copied to the OUT output. If the value of the parameter K is greater than the number of available inputs, the content of the parameter ELSE is copied to output OUT and enable output ENO is assigned the signal state "0".

The "Multiplex" instruction can only be executed if the tags have the same data type in all inputs and in the OUT output. The K parameter is an exception, since only integers can be specified for it.

The enable output ENO is reset if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The input at the K parameter is located outside the available inputs. This is the reaction regardless of whether the ELSE input will be used or not. The value at the OUT output remains unchanged.
- Errors occurred during execution of the instruction.

Parameters

The following table shows the parameters of the "Multiplex" instruction:

Parameters	Declaring	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
K	Input	Integers	Integers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Specifies the input whose content is to be copied. • If K = 0 => Parameter IN0 • If K = 1 => Parameter IN1, etc.
IN0	Input	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	First input value

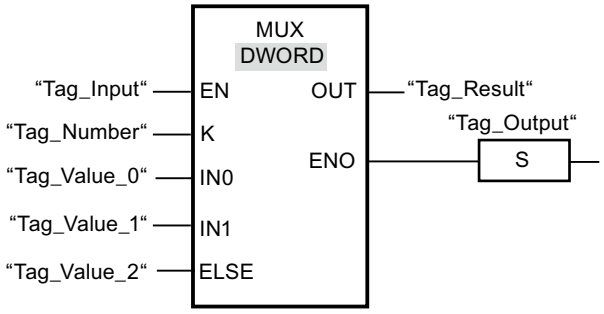
Parameters	Declaring	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN1	Input	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Second input value
INn	Input	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Optional input values
ELSE	Input	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Specifies the value to be copied when K > n
OUT	Output	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	I, Q, M, D, L, P	Output to which the value is to be copied

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
K	Tag_Number	1
IN0	Tag_ValueI_0	DW#16#00000000
IN1	Tag_Value_1	DW#16#003E4A7D
ELSE	Tag_Value_2	DW#16#FFFF0000
OUT	Tag_Result	DW#16#003E4A7D

If the "Tag_Input" operand has signal state "1", the instruction is executed. Depending on the value of the operand "Tag_Number", the value at input "Tag_Value_1" is copied and assigned to the operand at output "Tag_Result". If no errors occur during the execution of the instruction, the outputs ENO and "Tag_Output" are set.

DEMUX: Demultiplex

Description

You can use the instruction "Demultiplex" to copy the content of the input IN to a selected output. In its initial state the instruction box contains at least 2 outputs (OUT0 and OUT1). The number of selectable outputs can be extended in the instruction box. The outputs are numbered automatically in the box. Numbering starts at OUT0 and continues consecutively with each new output. You use the K parameter to define the output to which the content of the IN input is to be copied. The other outputs are not changed. If the value of the parameter K is greater than the number of available outputs, then the content of input IN in the parameter ELSE and the enable output ENO will be assigned to the signal state "0".

The instruction "Demultiplex" can only be executed if the tags at the input IN and at all outputs are of the same data type. The K parameter is an exception, since only integers can be specified for it.

The enable output ENO is reset if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value of the K parameter is greater than the number of available outputs.
- Errors occurred during execution of the instruction.

Parameters

The following table shows the parameters of the instruction "Demultiplex":

Parameter	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
K	Input	Integers	Integers	I, Q, M, D, L, P, or constant	I, Q, M, D, L, P, or constant	Specifies the output to which the input value (IN) is copied. • If K = 0 => Parameter OUT0 • If K = 1 => Parameter OUT1, etc.
IN	Input	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P, or constant	I, Q, M, D, L, P, or constant	Input value
OUT0	Output	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	I, Q, M, D, L, P	First output

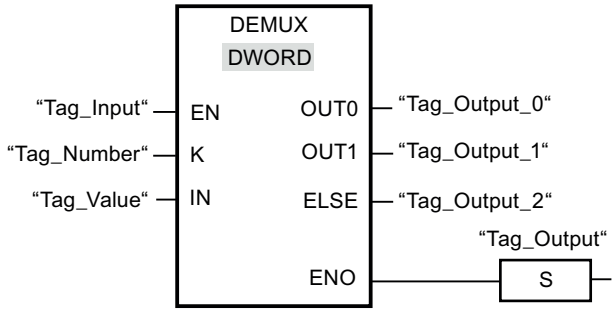
Parameter	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
OUT1	Output	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	I, Q, M, D, L, P	Second output
OUTn	Output	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	I, Q, M, D, L, P	Optional outputs
ELSE	Output	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	I, Q, M, D, L, P	Output to which the input value (IN) at K > n is copied.

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on available data types, refer to "See also".

Example

The following example shows how the instruction works:



The following tables show how the instruction works using specific operand values:

Table 11-26 Input values of the "Demultiplex" instruction before network execution

Parameter	Operand	Values	
K	Tag_Number	1	4
IN	Tag_Value	DW#16#FFFFFFFF	DW#16#003E4A7D

Table 11-27 Output values of the "Demultiplex" instruction after network execution

Parameter	Operand	Values	
OUT0	Tag_Output_0	Unchanged	Unchanged
OUT1	Tag_Output_1	DW#16#FFFFFFFF	Unchanged
ELSE	Tag_Output_2	Unchanged	DW#16#003E4A7D

If the "Tag_Input" input has the signal state"1", the "Demultiplex" instruction is executed. Depending on the value of the operand "Tag_Number", the value at input "IN" is copied to the corresponding output.

Shift and rotate

SHR: Shift right

Description

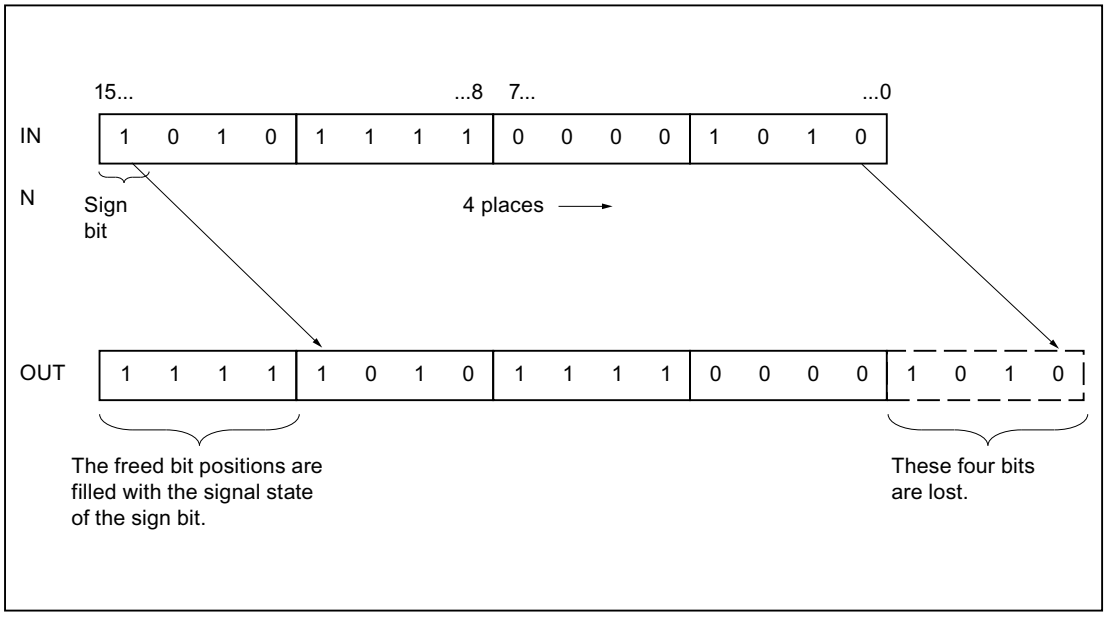
You can use the "Shift right" instruction to shift the content of the operand at the input IN bit-by-bit to the right and query the result at the OUT output. The input N is used to specify the number of bit positions by which the specified value should be moved.

If the value at the input N is "0", the value at input IN is copied unchanged to the operand at output OUT.

If the value at the input N is greater than the number of available bit positions, the operand value at input IN is shifted to the right by the available number of bit positions.

The freed bit positions in the left area of the operand are filled by zeroes when values without signs are shifted. If the specified value has a sign, the free bit positions are filled with the signal state of the sign bit.

The following figure show how the content of an operand of integer data type is shifted four bit positions to the right:



Parameters

The following table shows the parameters of the instruction "Shift right":

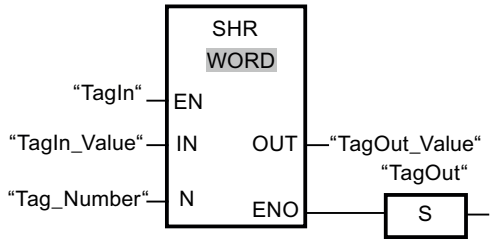
Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Value to be shifted
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Number of bit positions by which the value is shifted
OUT	Output	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	I, Q, M, D, L	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	TagIn_Value	0011 1111 1010 1111
N	Tag_Number	3
OUT	TagOut_Value	0000 0111 1111 0101

If the "TagIn" operand has signal state "1", the instruction is executed. The content of the operand "TagIn_Value" is shifted three bit positions to the right. The result is output at the "TagOut_Value" output. If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

Overview of the valid data types (Page 1908)

SHL: Shift left

Description

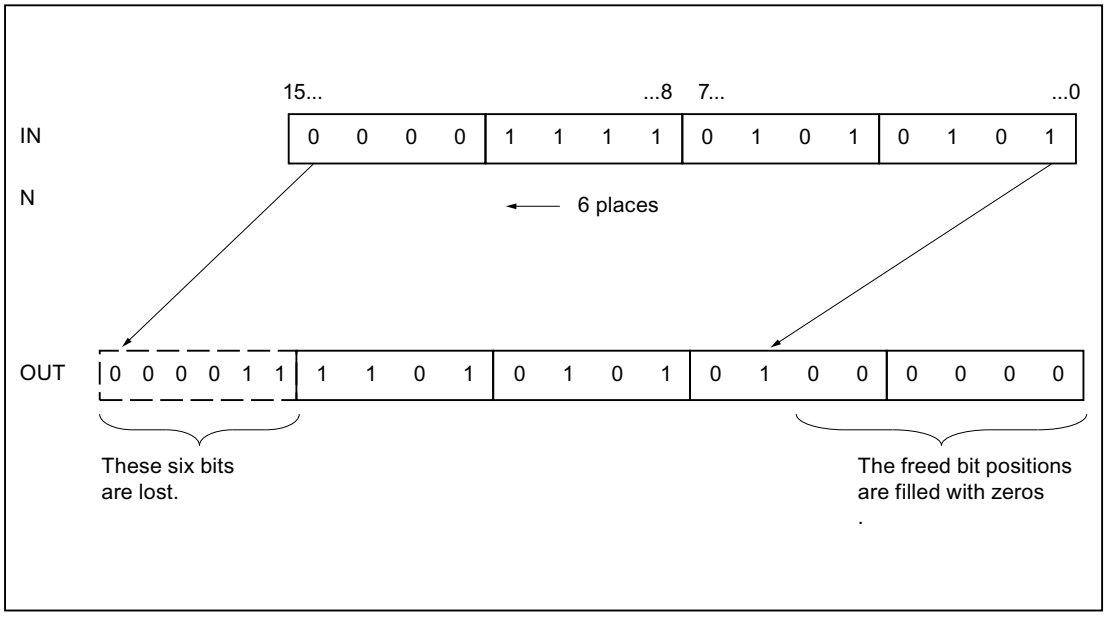
You can use the "Shift left" instruction to shift the content of the operand at the input IN bit-by-bit to the left and query the result at the OUT output. The input N is used to specify the number of bit positions by which the specified value should be moved.

If the value at the input N is "0", the value at input IN is copied unchanged to the operand at output OUT.

If the value at the input N is greater than the number of available bit positions, the operand value at input IN is shifted to the left by the available number of bit positions.

The bit positions in the right part of the operand freed by shifting are filled with zeros.

The following figure shows how the content of an operand of the WORD data type is shifted by six bit positions to the left:



Parameters

The following table shows the parameters of the instruction "Shift left":

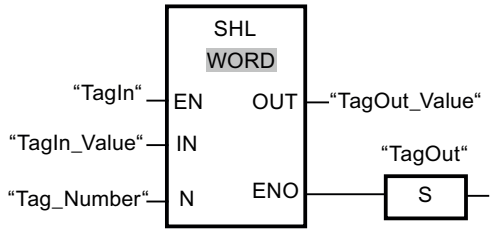
Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Value to be shifted.
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Number of bit positions by which the value is shifted.
OUT	Output	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	I, Q, M, D, L	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	TagIn_Value	0011 1111 1010 1111
N	Tag_Number	4
OUT	TagOut_Value	1111 1010 1111 0000

If the "TagIn" operand has signal state "1", the instruction is executed. The content of the operand "TagIn_Value" is shifted four bit positions to the left. The result is output at the "TagOut_Value" output. If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

Overview of the valid data types (Page 1908)

ROR: Rotate right

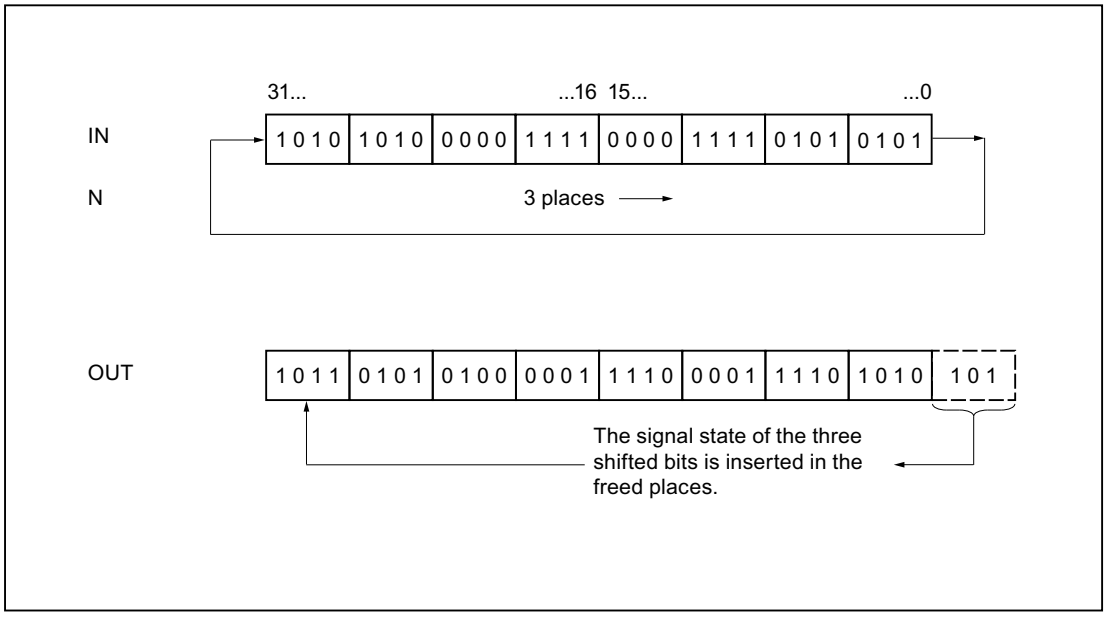
Description

You can use the "Rotate right" instruction to rotate the content of the operand at the input IN bit-by-bit to the right and query the result at the OUT output. The input N is used to specify the number of bit positions by which the specified value should be rotated. The bit positions freed by rotating on the left-hand side are filled true-to-position with the bit positions that are pushed out from the left-hand side.

If the value at the input N is "0", the value at input IN is copied unchanged to the operand at output OUT.

If the value of the N parameter is greater than the number of available bit positions, the operand value at the IN input is nevertheless rotated by the specified number of bit positions.

The following figure shows how the content of an operand of the DWORD data type is rotated three bit positions to the right:



Parameters

The following table shows the parameters of the instruction "Rotate right":

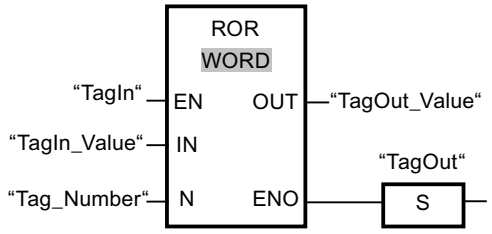
Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Value to be rotated
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Number of bit positions by which the value is rotated
OUT	Output	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	I, Q, M, D, L	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	TagIn_Value	0000 1111 1001 0101
N	Tag_Number	5
OUT	TagOut_Value	1010 1000 0111 1100

If the "TagIn" operand has signal state "1", the instruction is executed. The content of the operand "TagIn_Value" is rotated five bit positions to the right. The result is output at the "TagOut_Value" output. If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

ROL: Rotate left

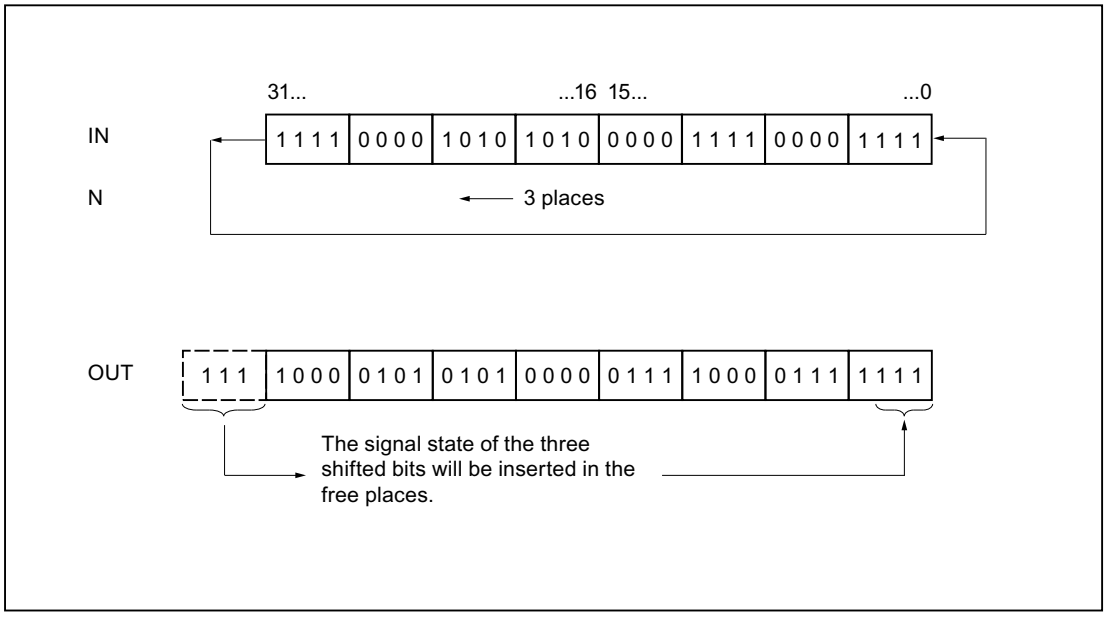
Description

You can use the "Rotate left" instruction to rotate the content of the operand at the input IN bit-by-bit to the left and query the result at the OUT output. The input N is used to specify the number of bit positions by which the specified value should be rotated. The bit positions freed by rotating on the right-hand side are filled true-to-position with the bit positions that are pushed out from the left-hand side.

If the value at the input N is "0", the value at input IN is copied to the operand at output OUT.

If the value of the N parameter is greater than the number of available bit positions, the operand value at the IN input is nevertheless rotated by the specified number of bit positions.

The following figure shows how the content of an operand of the DWORD data type is rotated three bit positions to the left:



Parameters

The following table shows the parameters of the instruction "Rotate left":

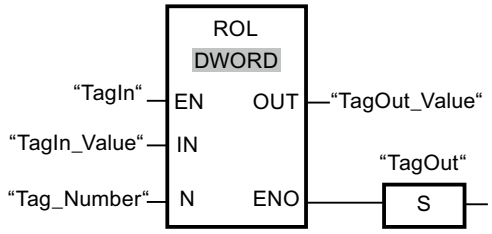
Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Value to be rotated.
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Number of bit positions by which the value is rotated.
OUT	Output	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	I, Q, M, D, L	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:



The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	TagIn_Value	1010 1000 1111 0110
N	Tag_Number	5
OUT	TagOut_Value	0001 1110 1101 0101

If the "TagIn" has the signal state "1", the instruction is executed. The content of the operand "TagIn_Value" is rotated five bit positions to the left. The result is output at the "TagOut_Value" output. If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

Legacy

DRUM: Implement sequencer

Description

You can use the "Implement sequencer" instruction to assign the programmed values of the OUT_VAL parameter of the corresponding step to the programmed output bits (OUT1 to OUT16) and the output word (OUT_WORD). The specific step must thereby satisfy the conditions of the programmed enable mask on the S_MASK parameter while the instruction remains at this step. The instruction advances to the next step if the event for the step is true and the programmed time for the current step elapses, or if the value at the JOG parameter changes from "0" to "1". The instruction is reset if the signal state on the RESET parameter changes to "1". The current step is hereby equated to the preset step (DSP).

The amount of time spent on a step is determined by the product of the preset timebase (DTBP) and the preset counter value (S_PRESET) for each step. At the start of a new step, this calculated value is loaded into the DCC parameter, which contains the time remaining for the current step. If, for example the value at the DTBP parameter is "2" and the preset value for the first step is "100" (100 ms), the DCC parameter has the value "200" (200 ms).

A step can be programmed with a timer value, an event, or both. Steps that have an event bit and the timer value "0" advance to the next step as soon as the signal state of the event bit is "1". Steps that are programmed only with a timer value start the time immediately. Steps that are programmed with an event bit and a timer value greater than "0" start the time when the signal state of the event bit is "1". The event bits are initialized with a signal state of "1".

When the sequencer is on the last programmed step (LST_STEP) and the time for this step has expired, the signal state on the Q parameter is set to "1"; otherwise it is set to "0". When the Q parameter is set, the instruction remains on the step until it is reset.

In the configurable mask (S_MASK), you can select the individual bits in the output word (OUT_WORD) and set or reset the output bits (OUT1 to OUT16) by means of the output values (OUT_VAL). If a bit of the configurable mask has signal state "1", the OUT_VAL value sets or resets the corresponding bit. If the signal state of a bit of the configurable mask is "0", the corresponding bit is left unchanged. All the bits of the configurable mask for all 16 steps are initialized with a signal state of "1".

The output bit at the OUT1 parameter corresponds to the least significant bit of the output word (OUT_WORD). The output bit at the OUT16 parameter corresponds to the most significant bit of the output word (OUT_WORD).

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, it is saved to the "Program resources" folder in the "Program blocks > System blocks" path of the project tree. For additional information on this topic, refer to "See also".

Parameters

The following table shows the parameters of the "Implement sequencer" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
RESET	Input	BOOL	I, Q, M, D, L or constant	The signal state "1" indicates the reset condition.
JOG	Input	BOOL	I, Q, M, D, L or constant	When the signal state changes from "0" to "1", the instruction advances to the next step.
DRUM_EN	Input	BOOL	I, Q, M, D, L or constant	The signal state "1" causes the sequencer to advance based on the event and time criteria.
LST_STEP	Input	BYTE	I, Q, M, D, L or constant	Number of the last programmed step
EVENT(i), 1 ≤ i ≤ 16	Input	BOOL	I, Q, M, D, L or constant	Event bit (i); Initial signal state is "1".
OUT(j), 1 ≤ j ≤ 16	Output	BOOL	I, Q, M, D, L	Output bit (j)

Parameter	Declaration	Data type	Memory area	Description
Q	Output	BOOL	I, Q, M, D, L	The signal state "1" indicates that the time for the last step has elapsed.
OUT_WORD	Output	WORD	I, Q, M, D, L, P	Word address to which the sequencer writes the output values.
ERR_CODE	Output	WORD	I, Q, M, D, L, P	Error information
JOG_HIS	Static	BOOL	I, Q, M, D, L or constant	JOG parameter history bit
EOD	Static	BOOL	I, Q, M, D, L or constant	The signal state "1" indicates that the time for the last step has elapsed.
DSP	Static	BYTE	I, Q, M, D, L, P, or constant	Preset step of the sequencer
DSC	Static	BYTE	I, Q, M, D, L, P, or constant	Current step of the sequencer
DCC	Static	DWORD	I, Q, M, D, L, P, or constant	Current numerical value of the sequencer
DTBP	Static	WORD	I, Q, M, D, L, P, or constant	Preset timebase of the sequencer
PrevTime	Static	TIME	I, Q, M, D, L or constant	Previous system time
S_PRESET	Static	ARRAY[1..16] of WORD	I, Q, M, D, L or constant	Preset count for each step [1 to 16]; where 1 clock pulse = 1 ms.
OUT_VAL	Static	ARRAY[1..16, 0..15] of BOOL	I, Q, M, D, L or constant	Output values for each step [1 to 16, 0 to 15].
S_MASK	Static	ARRAY[1..16, 0..15] of BOOL	I, Q, M, D, L or constant	Configurable mask for each step [1 to 16, 0 to 15]. Initial signal states are "1".

For additional information on valid data types, refer to "See also".

Parameter ERR_CODE

The following table shows the meaning of the values of the ERR_CODE parameter:

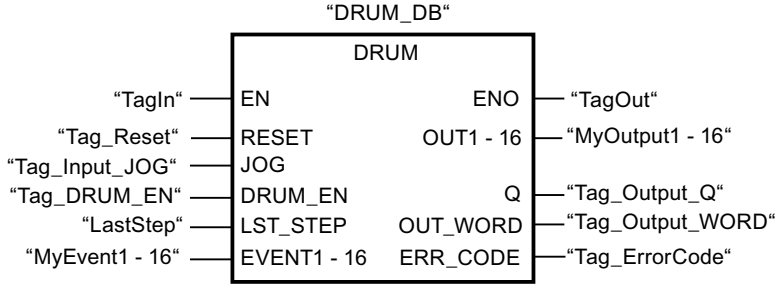
ERR_CODE*	Explanation
W#16#0000	No error
W#16#000B	The value at the LST_STEP parameter is less than 1 or greater than 16.
W#16#000C	The value at the DSC parameter is less than 1 or greater than the value of the LST_STEP parameter.
W#16#000D	The value at the DSP parameter is less than 1 or greater than the value of the LST_STEP parameter.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

In the following example the instruction advances from step 1 to step 2. The output bits (OUT1 to OUT16) and the output word (OUT_WORD) are set according to the mask configured for step 2 and the values of the OUT_VAL parameter.

Note

You can initialize static parameters in the data block.



The following tables show how the instruction works using specific values.

Before processing

In this example, the following values are used for initializing the input parameters:

Parameters	Operand	Address	Value
RESET	Tag_Reset	M0.0	FALSE
JOG	Tag_Input_JOG	M0.1	FALSE
DRUM_EN	Tag_Input_DrumEN	M0.2	TRUE
LST_STEP	Tag_Number_LastStep	MB1	B#16#08
EVENT2	MyTag_Event_2	M20.0	FALSE
EVENT4	MyTag_Event_4	M20.1	FALSE
EVENT6	MyTag_Event_6	M20.2	FALSE
EVENT8	MyTag_Event_8	M20.3	FALSE
EVENT10	MyTag_Event_10	M20.4	FALSE
EVENT12	MyTag_Event_12	M20.5	FALSE
EVENT14	MyTag_Event_14	M20.6	FALSE
EVENT16	MyTag_Event_16	M20.7	FALSE

The following values are saved in the "DRUM_DB" instance data block of the instruction:

Parameter	Address	Value
JOG_HIS	DBX12.0	FALSE
EOD	DBX12.1	FALSE
DSP	DBB13	W#16#0001
DSC	DBB14	W#16#0001
DCC	DBD16	DW#16#0000000A

Parameter	Address	Value
DTBP	DBW20	W#16#0001
S_PRESET[1]	DBW26	W#16#0064
S_PRESET[2]	DBW28	W#16#00C8
OUT_VAL[1,0]	DBX58.0	TRUE
OUT_VAL[1,1]	DBX58.1	TRUE
OUT_VAL[1,2]	DBX58.2	TRUE
OUT_VAL[1,3]	DBX58.3	TRUE
OUT_VAL[1,4]	DBX58.4	TRUE
OUT_VAL[1,5]	DBX58.5	TRUE
OUT_VAL[1,6]	DBX58.6	TRUE
OUT_VAL[1,7]	DBX58.7	TRUE
OUT_VAL[1,8]	DBX59.0	TRUE
OUT_VAL[1,9]	DBX59.1	TRUE
OUT_VAL[1,10]	DBX59.2	TRUE
OUT_VAL[1,11]	DBX59.3	TRUE
OUT_VAL[1,12]	DBX59.4	TRUE
OUT_VAL[1,13]	DBX59.5	TRUE
OUT_VAL[1,14]	DBX59.6	TRUE
OUT_VAL[1,15]	DBX59.7	TRUE
OUT_VAL[2,0]	DBX60.0	FALSE
OUT_VAL[2,1]	DBX60.1	FALSE
OUT_VAL[2,2]	DBX60.2	FALSE
OUT_VAL[2,3]	DBX60.3	FALSE
OUT_VAL[2,4]	DBX60.4	FALSE
OUT_VAL[2,5]	DBX60.5	FALSE
OUT_VAL[2,6]	DBX60.6	FALSE
OUT_VAL[2,7]	DBX60.7	FALSE
OUT_VAL[2,8]	DBX61.0	FALSE
OUT_VAL[2,9]	DBX61.1	FALSE
OUT_VAL[2,10]	DBX61.2	FALSE
OUT_VAL[2,11]	DBX61.3	FALSE
OUT_VAL[2,12]	DBX61.4	FALSE
OUT_VAL[2,13]	DBX61.5	FALSE
OUT_VAL[2,14]	DBX61.6	FALSE
OUT_VAL[2,15]	DBX61.7	FALSE
S_MASK[2,0]	DBX92.0	FALSE
S_MASK[2,1]	DBX92.1	TRUE
S_MASK[2,2]	DBX92.2	TRUE
S_MASK[2,3]	DBX92.3	TRUE
S_MASK[2,4]	DBX92.4	TRUE
S_MASK[2,5]	DBX92.5	FALSE
S_MASK[2,6]	DBX92.6	TRUE
S_MASK[2,7]	DBX92.7	TRUE

Parameter	Address	Value
S_MASK[2,8]	DBX93.0	FALSE
S_MASK[2,9]	DBX93.1	FALSE
S_MASK[2,10]	DBX93.2	TRUE
S_MASK[2,11]	DBX93.3	TRUE
S_MASK[2,12]	DBX93.4	TRUE
S_MASK[2,13]	DBX93.5	TRUE
S_MASK[2,14]	DBX93.6	FALSE
S_MASK[2,15]	DBX93.7	TRUE

The output parameters are set to the following values before the execution of the instruction:

Parameter	Operand	Address	Value
Q	Tag_Output_Q	M6.0	FALSE
OUTWORD	Tag_OutputWord	MW8	W#16#FFFF
OUT1	MyTag_Output_1	M4.0	TRUE
OUT2	MyTag_Output_2	M4.1	TRUE
OUT3	MyTag_Output_3	M4.2	TRUE
OUT4	MyTag_Output_4	M4.3	TRUE
OUT5	MyTag_Output_5	M4.4	TRUE
OUT6	MyTag_Output_6	M4.5	TRUE
OUT7	MyTag_Output_7	M4.6	TRUE
OUT8	MyTag_Output_8	M4.7	TRUE
OUT9	MyTag_Output_9	M5.0	TRUE
OUT10	MyTag_Output_10	M5.1	TRUE
OUT11	MyTag_Output_11	M5.2	TRUE
OUT12	MyTag_Output_12	M5.3	TRUE
OUT13	MyTag_Output_13	M5.4	TRUE
OUT14	MyTag_Output_14	M5.5	TRUE
OUT15	MyTag_Output_15	M5.6	TRUE
OUT16	MyTag_Output_16	M5.7	TRUE

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameter	Operand	Address	Value
OUT1	MyTag_Output_1	M4.0	TRUE
OUT2	MyTag_Output_2	M4.1	FALSE
OUT3	MyTag_Output_3	M4.2	FALSE
OUT4	MyTag_Output_4	M4.3	FALSE
OUT5	MyTag_Output_5	M4.4	FALSE
OUT6	MyTag_Output_6	M4.5	TRUE
OUT7	MyTag_Output_7	M4.6	FALSE

Parameter	Operand	Address	Value
OUT8	MyTag_Output_8	M4.7	FALSE
OUT9	MyTag_Output_9	M5.0	TRUE
OUT10	MyTag_Output_10	M5.1	TRUE
OUT11	MyTag_Output_11	M5.2	FALSE
OUT12	MyTag_Output_12	M5.3	FALSE
OUT13	MyTag_Output_13	M5.4	FALSE
OUT14	MyTag_Output_14	M5.5	FALSE
OUT15	MyTag_Output_15	M5.6	TRUE
OUT16	MyTag_Output_16	M5.7	FALSE
Q	Tag_Output_Q	M6.0	FALSE
OUTWORD	Tag_OutputWord	MW8	W#16#4321
ERR_CODE	Tag_ErrorCode	MW10	W#16#0000

The following values are changed in the instance data block "DRUM_DB" of the instruction after the execution of the instruction:

Parameter	Address	Value
JOG_HIS	DBX12.0	FALSE
EOD	DBX12.1	FALSE
DSC	DBB14	W#16#0002
DCC	DBD16	DW#16#000000C8

Overview of the valid data types (Page 1908)

DCAT: Discrete control-timer alarm

Description

The "Discrete control-timer alarm" instruction is used to accumulate the time from the point at which the CMD parameter issued the command to open or close. The time is accumulated until the preset time (PT) is exceeded or the information is received that the device was opened or closed (O_FB or C_FB) within the specified time. If the preset time is exceeded before the information on the opening or closing of the device is received, the corresponding alarm is activated. If the signal state of the command input changes state before the preset time, the time is restarted.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

The "Discrete control-timer alarm" instruction has the following reactions to the input conditions:

- When the signal state of the CMD parameter changes from "0" to "1", the signal states of the parameters Q, CMD_HIS, ET (only if ET is < PT) OA and CA are influenced as follows:
  - The parameters Q and CMD_HIS are set to "1".
  - The parameters ET, OA and CA are reset to "0".
- When the signal state of the parameter CMD changes from "1" to "0", the parameters Q, ET (only if ET < PT), OA, CA and CMD_HIS are reset to "0".
- When the signal state of the CMD and CMD_HIS parameters is "1" and the parameter O_FB is set to "0", the time difference (ms) since the last execution of the instruction is added to the value at the parameter ET. If the value of the parameter ET exceeds the value of the parameter PT, the signal state at the parameter OA is set to "1". If the value of the ET parameter does not exceed the value of the PT parameter, the signal state at the OA parameter is reset to "0". The value at the parameter CMD_HIS is reset to the value of the parameter CMD.
- If the signal state of the CMD, CMD_HIS and O_FB parameters are set to "1" and the parameter C_FB has the value "0", the signal state of the parameter OA is set to "0". The value of the parameter ET is set to the value of the parameter PT. If the signal state of the O_FB parameter changes to "0", the alarm is set the next time the instruction is executed. The value of the parameter CMD_HIS is set to the value of the parameter CMD.
- If the CMD, CMD_HIS and C_FB parameters return signal state "0", the time difference (ms) since the last execution of the instruction is added to the value of the ET parameter. If the value of the ET parameter exceeds the value of the PT parameter, the signal state of the parameter CA is reset to "1". If the value at the parameter PT is not exceeded, the parameter CA has the signal state "0". The value of the parameter CMD_HIS is set to the value of the parameter CMD.
- If the parameters CMD, CMD_HIS and O_FB have the signal state "0" and the parameter C_FB is set to "1", the parameter CA is set to "0". The value of the parameter ET is set to the value of the parameter PT. If the signal state of the C_FB parameter changes to "0", the alarm is set the next time the instruction is executed. The value of the parameter CMD_HIS is set to the value of the parameter CMD.
- If the parameters O_FB and C_FB simultaneously have the signal state "1", the signal states of both alarm outputs are set to "1".

The "Discrete control-timer alarm" instruction returns no error information.

Parameters

The following table shows the parameters of the "Discrete control-timer alarm" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output

Parameter	Declaration	Data type	Memory area	Description
CMD	Input	BOOL	I, Q, M, D, L or constant	The signal state "0" indicates a "close" command. The signal state "1" indicates the "open" command.
O_FB	Input	BOOL	I, Q, M, D, L or constant	Feedback input when opening
C_FB	Input	BOOL	I, Q, M, D, L or constant	Feedback input when closing
Q	Output	BOOL	I, Q, M, D, L	Shows the status of the parameter CMD
OA	Output	BOOL	I, Q, M, D, L	Alarm output when opening
CA	Output	BOOL	I, Q, M, D, L	Alarm output when closing
ET	Static	DINT	D, L or constant	Currently elapsed time, where one count = 1 ms.
PT	Static	DINT	D, L or constant	Preset timer value, where one count = 1 ms.
PREV_TIME	Static	DWORD	D, L or constant	Previous system time
CMD_HIS	Static	BOOL	D, L or constant	CMD history bit

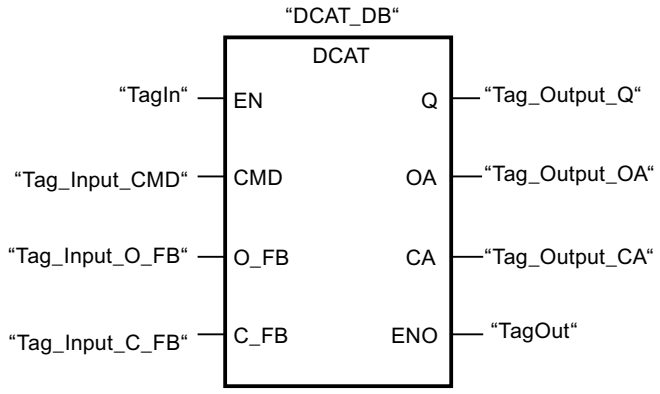
For additional information on valid data types, refer to "See also".

Example

In the following example the parameter CMD changes from "0" to "1". After the execution of the instruction the parameter Q is set to "1" and the two alarm outputs OA and CA have the signal state "0". The parameter CMD_HIS of the instance data block is set to the signal state "1" and the parameter ET is reset to "0".

Note

You can initialize static parameters in the data block.



The following tables show how the instruction works using specific values.

Before processing

In this example, the following values are used for the input and output parameters:

Parameter	Operand	Value
CMD	Tag_Input_CMD	TRUE
O_FB	Tag_Input_O_FB	FALSE
C_FB	Tag_Input_C_FB	FALSE
Q	Tag_Output_Q	FALSE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE

The following values are saved in the instance data block "DCAT_DB" of the instruction:

Parameter	Address	Value
ET	DBD4	L#12
PT	DBD8	L#222
CMD_HIS	DBX16.0	FALSE

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameter	Operand	Value
Q	Tag_Output_Q	TRUE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE

The following values are saved in the instance data block "DCAT_DB" of the instruction:

Parameter	Address	Value
ET	DBD4	L#0
CMD_HIS	DBX16.0	TRUE

Overview of the valid data types (Page 1908)

MCAT: Motor control-timer alarm

Description

You can use the "Motor control-timer alarm" instruction to accumulate the time from the point in time as of which one of the command inputs (open or close) is activated. The time is accumulated until the preset time is exceeded or the relevant feedback input indicates that the device has executed the requested operation within the specified time. If the preset time is exceeded before the feedback is received, the corresponding alarm is triggered.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

The instruction "Motor control-timer alarm" returns no error information.

Execution of the "Motor control-timer alarm" instruction

The following table shows the reactions of the instruction "Motor control-timer alarm" to the various input conditions:

Input parameters								Output parameters								
ET	O_HIS	C_HIS	O_CMD	C_CMD	S_CMD	O_FB	C_FB	OO	CO	OA	CA	ET	O_HIS	C_HIS	Q	Status
X	1	1	X	X	X	X	X	0	0	1	1	PT	0	0	0	Alarm
X	X	X	X	X	X	1	1	0	0	1	1	PT	0	0	0	Alarm
X	X	X	X	X	1	X	X	0	0	0	0	X	0	0	1	Stop
X	X	X	1	1	X	X	X	0	0	0	0	X	0	0	1	Stop
X	0	X	1	0	0	X	X	1	0	0	0	0	1	0	1	Start opening
<PT	1	0	X	0	0	0	X	1	0	0	0	INC	1	0	1	Open
X	1	0	X	0	0	1	0	0	0	0	0	PT	1	0	1	Opened
>=PT	1	0	X	0	0	0	X	0	0	1	0	PT	1	0	0	Opening alarm
X	X	0	0	1	0	X	X	0	1	0	0	0	0	1	1	Start closing
<PT	0	1	0	X	0	X	0	0	1	0	0	INC	0	1	1	Close
X	0	1	0	X	0	0	1	0	0	0	0	PT	0	1	1	Closed
>=PT	0	1	0	X	0	X	0	0	0	0	1	PT	0	1	0	Closing alarm
X	0	0	0	0	0	X	X	0	0	0	0	X	0	0	1	Stopped
Legend:																
INC	Add the time difference (ms) since the last processing of the FB to ET															
PT	PT is set to the same value as ET															

Input parameters	Output parameters
X	Cannot be used
<PT	ET < PT
>=PT	ET >= PT
If the input parameters O_HIS and C_HIS both have the signal state "1", they are immediately set to signal state "0". In this case, the last row of the above-named table (X) is valid. Because it is therefore no longer possible to check whether the input parameters O_HIS and C_HIS have the signal state "1", the output parameters are set as follows in this case: OO = FALSE CO = FALSE OA = FALSE CA = FALSE ET = PT Q = TRUE	

Parameters

The following table shows the parameters of the "Motor control-timer alarm" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
O_CMD	Input	BOOL	I, Q, M, D, L or constant	"Open" command input
C_CMD	Input	BOOL	I, Q, M, D, L or constant	"Close" command input
S_CMD	Input	BOOL	I, Q, M, D, L or constant	"Stop" command input
O_FB	Input	BOOL	I, Q, M, D, L or constant	Feedback input when opening
C_FB	Input	BOOL	I, Q, M, D, L or constant	Feedback input when closing
OO	Output	BOOL	I, Q, M, D, L	"Open" output
CO	Output	BOOL	I, Q, M, D, L	"Close" output
OA	Output	BOOL	I, Q, M, D, L	Alarm output when opening
CA	Output	BOOL	I, Q, M, D, L	Alarm output when closing
Q	Output	BOOL	I, Q, M, D, L	A signal state of "0" indicates an error condition.
ET	Static	DINT	D, L or constant	Currently elapsed time, where one clock pulse = 1 ms
PT	Static	DINT	D, L or constant	Preset time value, where one clock pulse = 1 ms
PREV_TIME	Static	DWORD	D, L or constant	Previous system time
O_HIS	Static	BOOL	D, L or constant	"Open" history bit
C_HIS	Static	BOOL	D, L or constant	"Close" history bit

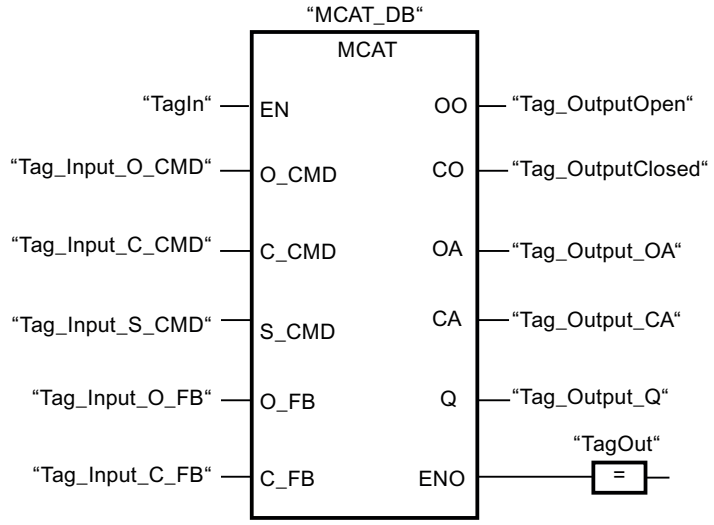
For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

Note

You can initialize static parameters in the data block.



The following tables show how the instruction works based on concrete values:

Before processing

In this example the following values are used for the input and output parameters:

Parameters	Operand	Value
O_CMD	Tag_Input_O_CMD	TRUE
C_CMD	Tag_Input_C_CMD	FALSE
S_CMD	Tag_Input_S_CMD	FALSE
O_FB	Tag_Input_O_FB	FALSE
C_FB	Tag_Input_C_FB	FALSE
OO	Tag_OutputOpen	FALSE
CO	Tag_OutputClosed	FALSE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE
Q	Tag_Output_Q	FALSE

The following values are saved in the "MCAT_DB" instance data block of the instruction:

Parameters	Address	Value
ET	DBD4	L#2
PT	DBD8	L#22
O_HIS	DBX16.0	TRUE
C_HIS	DBX16.1	FALSE

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameters	Operand	Value
OO	Tag_OutputOpen	TRUE
CO	Tag_OutputClosed	FALSE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE
Q	Tag_Output_Q	TRUE

The following values are saved in the "MCAT_DB" instance data block of the instruction:

Parameters	Address	Value
ET	DBD4	L#0
O_HIS	DBX16.0	TRUE
CMD_HIS	DBX16.1	FALSE

Overview of the valid data types (Page 1908)

IMC: Compare input bits with the bits of a mask

Description

The instruction "Compare input bits with the bits of a mask" is used to compare the signal state of up to 16 programmed input bits (IN_BIT0 to IN_BIT15) with the corresponding bits of a mask. Up to 16 steps with masks can be programmed. The value of the IN_BIT0 parameter is compared with the value of the mask CMP_VAL[x,0], with "x" indicating the step number. At the CMP_STEP parameter, specify the step number of the mask that is used for the comparison. All programmed values are compared in the same manner. Unprogrammed input bits or unprogrammed bits of the mask have the default signal state FALSE.

If a match is found in the comparison, the signal state of the OUT parameter is set to "1". Otherwise, the OUT parameter is set to "0".

If the value of the CMP_STEP parameter is greater than 15, the instruction is not executed. An error message is output at the ERR_CODE parameter.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

Parameters

The following table shows the parameters of the "Compare input bits with the bits of a mask" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN_BIT0	Input	BOOL	I, Q, M, D, L or constant	Input bit 0 is compared with bit 0 of the mask.
IN_BIT1	Input	BOOL	I, Q, M, D, L or constant	Input bit 1 is compared with bit 1 of the mask.
IN_BIT2	Input	BOOL	I, Q, M, D, L or constant	Input bit 2 is compared with bit 2 of the mask.
IN_BIT3	Input	BOOL	I, Q, M, D, L or constant	Input bit 3 is compared with bit 3 of the mask.
IN_BIT4	Input	BOOL	I, Q, M, D, L or constant	Input bit 4 is compared with bit 4 of the mask.
IN_BIT5	Input	BOOL	I, Q, M, D, L or constant	Input bit 5 is compared with bit 5 of the mask.
IN_BIT6	Input	BOOL	I, Q, M, D, L or constant	Input bit 6 is compared with bit 6 of the mask.
IN_BIT7	Input	BOOL	I, Q, M, D, L or constant	Input bit 7 is compared with bit 7 of the mask.
IN_BIT8	Input	BOOL	I, Q, M, D, L or constant	Input bit 8 is compared with bit 8 of the mask.
IN_BIT9	Input	BOOL	I, Q, M, D, L or constant	Input bit 9 is compared with bit 9 of the mask.
IN_BIT10	Input	BOOL	I, Q, M, D, L or constant	Input bit 10 is compared with bit 10 of the mask.
IN_BIT11	Input	BOOL	I, Q, M, D, L or constant	Input bit 11 is compared with bit 11 of the mask.
IN_BIT12	Input	BOOL	I, Q, M, D, L or constant	Input bit 12 is compared with bit 12 of the mask.
IN_BIT13	Input	BOOL	I, Q, M, D, L or constant	Input bit 13 is compared with bit 13 of the mask.
IN_BIT14	Input	BOOL	I, Q, M, D, L or constant	Input bit 14 is compared with bit 14 of the mask.
IN_BIT15	Input	BOOL	I, Q, M, D, L or constant	Input bit 15 is compared with bit 15 of the mask.
CMP_STEP	Input	BYTE	I, Q, M, D, L, P or constant	The step number of the mask used for the comparison.
OUT	Output	BOOL	I, Q, M, D, L	The signal state "1" indicates that a match was found. The signal state "0" indicates that no match was found.

Parameter	Declaration	Data type	Memory area	Description
ERR_CODE	Output	WORD	I, Q, M, D, L, P	Error information
CMP_VAL	Static	ARRAY OF WORD	I, Q, M, D, L or constant	Comparison masks [0 to 15, 0 to 15]: The first number of the index is the step number and the second number is the bit number of the mask.

For additional information on valid data types, refer to "See also".

Parameters ERR_CODE

The following table shows the meaning of the values of the ERR_CODE parameter:

Error code* (W#16#...)	Explanation
0000	No error
000A	The value at the CMP_STEP parameter is greater than 15.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".

Overview of the valid data types (Page 1908)

SMC: Compare scan matrix

Description

The instruction "Compare scan matrix" is used to compare the signal state of up to 16 programmed input bits (IN_BIT0 to IN_BIT15) with the corresponding bits of the comparison masks for each step. Processing starts at step 1 and is continued until the last programmed step (LAST) or until a match is found. The input bit of the IN_BIT0 parameter is compared with the value of the mask CMP_VAL[x,0], with "x" indicating the step number. All programmed values are compared in the same manner. If a match is found, the signal state of the OUT parameter is set to "1" and the step number with the matching mask is written to the OUT_STEP parameter. Unprogrammed input bits or unprogrammed bits of the mask have the default signal state FALSE. If more than one step has a matching mask, only the first one found is indicated in the OUT_STEP parameter. If no match is found, the signal state of the OUT parameter is set to "0". In this case the value at the OUT_STEP parameter is greater by "1" than the value of the LAST parameter.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

Parameters

The following table shows the parameters of the "Compare scan matrix" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN_BIT0	Input	BOOL	I, Q, M, D, L or constant	Input bit 0 is compared with bit 0 of the mask.
IN_BIT1	Input	BOOL	I, Q, M, D, L or constant	Input bit 1 is compared with bit 1 of the mask.
IN_BIT2	Input	BOOL	I, Q, M, D, L or constant	Input bit 2 is compared with bit 2 of the mask.
IN_BIT3	Input	BOOL	I, Q, M, D, L or constant	Input bit 3 is compared with bit 3 of the mask.
IN_BIT4	Input	BOOL	I, Q, M, D, L or constant	Input bit 4 is compared with bit 4 of the mask.
IN_BIT5	Input	BOOL	I, Q, M, D, L or constant	Input bit 5 is compared with bit 5 of the mask.
IN_BIT6	Input	BOOL	I, Q, M, D, L or constant	Input bit 6 is compared with bit 6 of the mask.
IN_BIT7	Input	BOOL	I, Q, M, D, L or constant	Input bit 7 is compared with bit 7 of the mask.
IN_BIT8	Input	BOOL	I, Q, M, D, L or constant	Input bit 8 is compared with bit 8 of the mask.
IN_BIT9	Input	BOOL	I, Q, M, D, L or constant	Input bit 9 is compared with bit 9 of the mask.
IN_BIT10	Input	BOOL	I, Q, M, D, L or constant	Input bit 10 is compared with bit 10 of the mask.
IN_BIT11	Input	BOOL	I, Q, M, D, L or constant	Input bit 11 is compared with bit 11 of the mask.
IN_BIT12	Input	BOOL	I, Q, M, D, L or constant	Input bit 12 is compared with bit 12 of the mask.
IN_BIT13	Input	BOOL	I, Q, M, D, L or constant	Input bit 13 is compared with bit 13 of the mask.
IN_BIT14	Input	BOOL	I, Q, M, D, L or constant	Input bit 14 is compared with bit 14 of the mask.
IN_BIT15	Input	BOOL	I, Q, M, D, L or constant	Input bit 15 is compared with bit 15 of the mask.
OUT	Output	BOOL	I, Q, M, D, L	The signal state "1" indicates that a match was found. The signal state "0" indicates that no match was found.
ERR_CODE	Output	WORD	I, Q, M, D, L, P	Error information

Parameter	Declaration	Data type	Memory area	Description
OUT_STEP	Output	BYTE	I, Q, M, D, L, P	Contains the step number with the matching mask or the step number which is greater by "1" than the value of the LAST parameter, provided no match is found.
LAST	Static	BYTE	I, Q, M, D, L, P or constant	Specifies the step number of the last step to be scanned for a matching mask.
CMP_VAL	Static	ARRAY OF WORD	I, Q, M, D, L or constant	Comparison masks [0 to 15, 0 to 15]: The first number of the index is the step number and the second number is the bit number of the mask.

For additional information on valid data types, refer to "See also".

Parameters ERR_CODE

The following table shows the meaning of the values of the ERR_CODE parameter:

Error code* (W#16#...)	Explanation
0000	No error
000E	The value at the LAST parameter is greater than 15.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".

Overview of the valid data types (Page 1908)

LEAD_LAG: Lead and lag algorithm

Description

The "Lead and lag algorithm" instruction is used to process signals with an analog tag. The gain value at the GAIN parameter must be greater than zero. The result of the instruction "Lead and lag algorithm" is calculated using the following equation:

$$OUT = \left[\frac{LG\_TIME}{LG\_TIME + SAMPLE\_T}\right] PREV\_OUT + GAIN \left[\frac{LD\_TIME + SAMPLE\_T}{LG\_TIME + SAMPLE\_T}\right] IN - GAIN \left[\frac{LD\_TIME}{LG\_TIME + SAMPLE\_T}\right] * PREV\_IN$$

The "Lead and lag algorithm" instruction supplies plausible results only when processing is in fixed program cycles. The same units must be specified for the LD_TIME, LG_TIME, and SAMPLE_T parameters. At LG_TIME > 4 + SAMPLE_T, the instruction approaches the following function:

OUT = GAIN * ((1 + LD_TIME * s) / (1 + LG_TIME * s)) * IN

When the value of the GAIN parameter is less than or equal to zero, the calculation is not performed and an error information is output on the ERR_CODE parameter.

You can use the "Lead and lag algorithm" instruction in conjunction with loops as a compensator in dynamic feed-forward control. The instruction consists of two operations. The "Lead" operation shifts the phase of the OUT output so that the output leads the input. The "Lag" operation, on the other hand, shifts the output so that the output lags behind the input. Because the "Lag" operation is equivalent to an integration, it can be used as a noise suppressor or as a low-pass filter. The "Lead" operation is equivalent to a differentiation and can therefore be used as a high-pass filter. The two instructions together (Lead and Lag) result in the output phase lagging behind the the input at lower frequencies and leading it at higher frequencies. This means that the "Lead and lag algorithm" instruction can be used as a band pass filter.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, you will find this in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

Parameters

The following table shows the parameters of the "Lead and lag algorithm" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	REAL	I, Q, M, D, L, P or constant	The input value of the current sample time (cycle time) to be processed.
SAMPLE_T	Input	INT	I, Q, M, D, L, P or constant	Sample time
OUT	Output	REAL	I, Q, M, D, L, P	Result of the instruction
ERR_CODE	Output	WORD	I, Q, M, D, L, P	Error information
LD_TIME	Static	REAL	I, Q, M, D, L, P or constant	Lead time in the same unit as sample time.
LG_TIME	Static	REAL	I, Q, M, D, L, P or constant	Lag time in the same unit as sample time
GAIN	Static	REAL	I, Q, M, D, L, P or constant	Gain as % / % (the ratio of the change in output to a change in input as a steady state).

Parameter	Declaration	Data type	Memory area	Description
PREV_IN	Static	REAL	I, Q, M, D, L, P or constant	Previous input
PREV_OUT	Static	REAL	I, Q, M, D, L, P or constant	Previous output

For additional information on valid data types, refer to "See also".

Parameters ERR_CODE

The following table shows the meaning of the values of the ERR_CODE parameter:

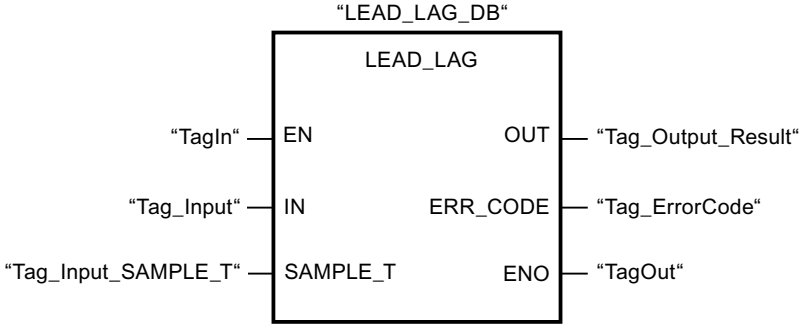
Error code* (W#16#...)	Explanation
0000	No error
0009	The value at the GAIN parameter is less than or equal to zero.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For additional information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

Note

You can initialize static parameters in the data block.



The following table shows how the instruction works using specific operand values:

Before processing

In this example the following values are used for the input parameters:

Parameters	Operand	Value
IN	Tag_Input	2.0
SAMPLE_T	Tag_InputSampleTime	10

The following values are saved in the instance data block "LEAD_LAG_DB" of the instruction:

Parameters	Address	Value
LD_TIME	DBD12	2.0
LG_TIME	DBD16	2.0
GAIN	DBD20	1.0
PREV_IN	DBD24	6.0
PREV_OUT	DBD28	6.0

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameters	Operand	Value
OUT	Tag_Output_Result	2.0

The following values are saved in the instance data block "LEAD_LAD_DB" of the instruction:

Parameters	Operand	Value
PREV_IN	DBD24	2.0
PREV_OUT	DBD28	2.0

SEG: Create bit pattern for seven-segment display

Description

The instruction "Create bit pattern for seven-segment display" is used to convert each of the four hexadecimal digits of the specified source word (IN) into an equivalent bit pattern for a seven-segment display. The result of the instruction is output in the double word on the OUT parameter.

The following relation exists between the hexadecimal digits and the assignment of the 7 segments (a, b, c, d, e, f, g):

Input digit (Binary)	**Assignment of the segments - g f e d c b a**	**Display** (Hexadecimal)	**Seven-segment display**
0000	00111111	0	0001	00000110	1	
0010	01011011	2	
0011	01001111	3	
0100	01100110	4	
0101	01101101	5	
0110	01111101	6	
0111	00000111	7	
1000	01111111	8	
1001	01100111	9	
1010	01110111	A	
1011	01111100	B	
1100	00111001	C	
1101	01011110	D	
1110	01111001	E	
1111	01110001	F	

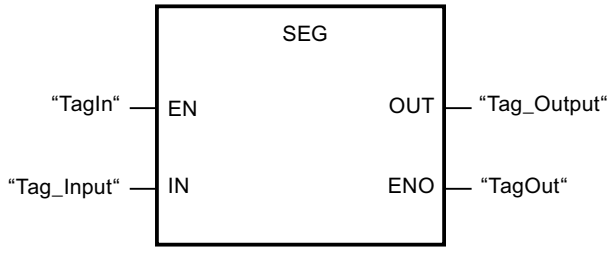
Parameters

The following table shows the parameters of the "Create bit pattern for seven-segment display" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	WORD	I, Q, M, D, L, P or constant	Source word with four hexadecimal digits
OUT	Output	DWORD	I, Q, M, D, L, P	Bit pattern for the seven-segment display

Example

The following example shows how the instruction works:



The following table shows how the instruction functions using specific values:

Parameters	Operand	Value	
Hexadecimal	Binary		
IN	Tag_Input	W#16#1234	0001 0010 0011 0100
OUT	Tag_Output	DW#16065B4F66	00000110 01011011 01001111 01100110 Display: 1234

BCDCPL: Create tens complement

Description

You can use the "Create tens complement" instruction to create the tens complement of a seven-digit BCD number specified in the IN parameter. This instruction uses the following mathematical formula to calculate:

10000000 (as BCD)

– 7-digit BCD value

Tens complement (as BCD)

Parameters

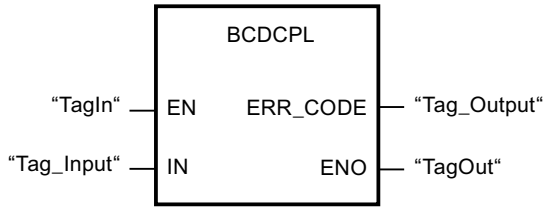
The following table shows the parameters of the "Create tens complement" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output

Parameter	Declaration	Data type	Memory area	Description
IN	Input	Bit strings	I, Q, M, D, L, P or constant	7-digit BCD number
ERR_CODE	Output	DWORD	I, Q, M, D, L, P	Result of the instruction

Example

The following example shows how the instruction works:



The following table shows how the instruction functions using specific values:

Parameter	Operand	Value*
IN	Tag_Input	DW#16#01234567
ERR_CODE	Tag_Output	DW#16#08765433
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".

BITSUM: Count number of set bits

Description

The "Count number of set bits" instruction is used to count the number of bits of an operand that is set to the signal state "1". The operand whose bits are to be counted is specified on the IN parameter. The result of the instruction is output at the RET_VAL parameter.

Parameters

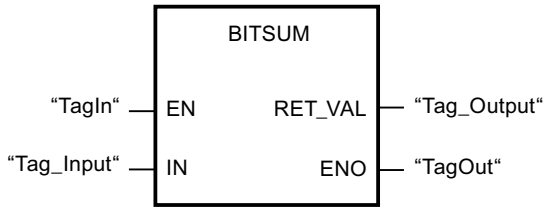
The following table shows the parameters of the "Count number of set bits" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output

Parameter	Declaration	Data type	Memory area	Description
IN	Input	DWORD	I, Q, M, D, L, P or constant	Operand whose set bits are counted.
RET_VAL	Output	INT	I, Q, M, D, L, P	Number of bits to be set

Example

The following example shows how the instruction works:



The following table shows how the instruction functions using specific values:

Parameter	Operand	Value*
IN	Tag_Input	DW#16#12345678
RET_VAL	Tag_Output	W#16#000D (13 Bits)
*The error codes can be displayed as integer or hexadecimal value in the program editor. For additional information on toggling display formats, refer to "See also".

11.6.2.3 SCL

Bit logic operations

R_TRIG:Detect positive signal edge

Description

With the "Detect positive signal edge" instruction, you can detect a state change from "0" to "1" at the CLK input. The instruction compares the current value at the CLK input with the state of the previous query (edge memory bit) that is saved in the specified instance. If the instruction detects a state change at the CLK input from "0" to "1", a positive signal edge is generated at the Q output, i.e., the output has the value TRUE or "1" for exactly one cycle.

In all other cases, the signal state at the output of the instruction is "0".

When you insert the instruction in the program, the "Call options" dialog opens automatically. In this dialog you can specify whether the edge memory bit is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface.

Syntax

The following syntax is used for the "Detect positive signal edge" instruction:

```
SCL
<Instance>(CLK := <Operand>,
           Q => <Operand>)
```

Parameters

The following table shows the parameters of the "Detect positive signal edge" instruction:

Parameter	Declaration	Data type	Memory area	Description
CLK	Input	BOOL	I, Q, M, D, L	Incoming signal, the edge of which is to be queried
Q	Output	BOOL	I, Q, M, D, L	Result of edge evaluation

Example

The following example shows how the instruction works:

```
SCL
"R_TRIG_DB"(CLK := "TagIn",
            Q => "TagOut");
```

The previous state of the tag at the CLK input is stored in the "R_TRIG_DB" tag. If a change is the signal state from "0" to "1" is detected in the "TagIn_1" and "TagIn_2" operands or in the "TagIn_3" operand, the "TagOut_Q" output has signal state "1" for one cycle.

See also

Overview of the valid data types (Page 1908)

F_TRIG:Detect negative signal edge

Description

With the "Detect negative signal edge" instruction, you can detect a state change from "1" to "0" at the CLK input. The instruction compares the current value at the CLK input with the state of the previous query (edge memory bit) that is saved in the specified instance. If the instruction detects a state change at the CLK input from "1" to "0", a negative signal edge is generated at the Q output, i.e., the output has the value TRUE or "1" for exactly one cycle.

In all other cases, the signal state at the output of the instruction is "0".

When you insert the instruction in the program, the "Call options" dialog opens automatically. In this dialog you can specify whether the edge memory bit is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface.

Syntax

The following syntax is used for the "Detect negative signal edge" instruction:

SCL

```
<Instance>(CLK := <Operand>,
           Q => <Operand>)
```

Parameters

The following table shows the parameters of the "Detect negative signal edge" instruction:

Parameter	Declaration	Data type	Memory area	Description
CLK	Input	BOOL	I, Q, M, D, L	Incoming signal, the edge of which is to be queried
Q	Output	BOOL	I, Q, M, D, L	Result of edge evaluation

Example

The following example shows how the instruction works:

SCL

```
"F_TRIG_DB"(CLK := "TagIn",
            Q => "TagOut");
```

The previous state of the tag at the CLK input is stored in the "F_TRIG_DB" tag. If a change in the signal state from "1" to "0" is detected in the "TagIn" operand, the "TagOut" output has signal state "1".

Overview of the valid data types (Page 1908)

Timer operations

TP: Generate pulse

Description

You can use the "Generate pulse" instruction to set the Q parameter for the duration PT. The instruction starts when the result of logic operation (RLO) of the IN parameter changes from "0" to "1" (positive signal edge). The programmed time PT begins when the instruction starts. The Q parameter is set for the time PT, regardless of the subsequent changes in the input signal. Even when a new positive signal edge is detected, the signal state of the Q parameter is not affected as long as the time duration PT is active.

The current time value can be queried in the ET parameter. The time value starts at T#0s and ends when the value of the time duration PT is reached. When the time duration PT is reached and the signal state at the IN parameter is "0", the ET parameter is reset.

Note

If the timer is not called in the program because it is skipped, for example, output ET returns a constant value as soon as the timer has expired.

Each call of the "Generate pulse" instruction must be assigned to an IEC timer in which the instruction data is stored.

For S7-1200 CPU

An IEC timer is a structure of the data type IEC_TIMER or TP_TIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the TP_TIME type in the "Static" section of a block (for example, #MyTP_TIMER)

For S7-1500 CPU

An IEC timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TP_TIME or TP_LTIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TP_TIME or TP_LTIME in the "Static" section of a block (for example #MyTP_TIMER)

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the IEC timer is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

The instruction data is updated both when an instruction is called and also at each access to the Q or ET outputs.

Syntax

Use the following syntax for the "Generate pulse" instruction:

- Data block of system data type IEC_Timer (global DB):

```
SCL
<IEC_Timer_DB> TP(IN := <Operand>,
                  PT := <Operand>,
                  Q => <Operand>,
                  ET => <Operand>)
```

- Local tag:

```
SCL
#myLocal_timer(IN := <Operand>,
               PT := <Operand>,
               Q => <Operand>,
               ET => <Operand>)
```

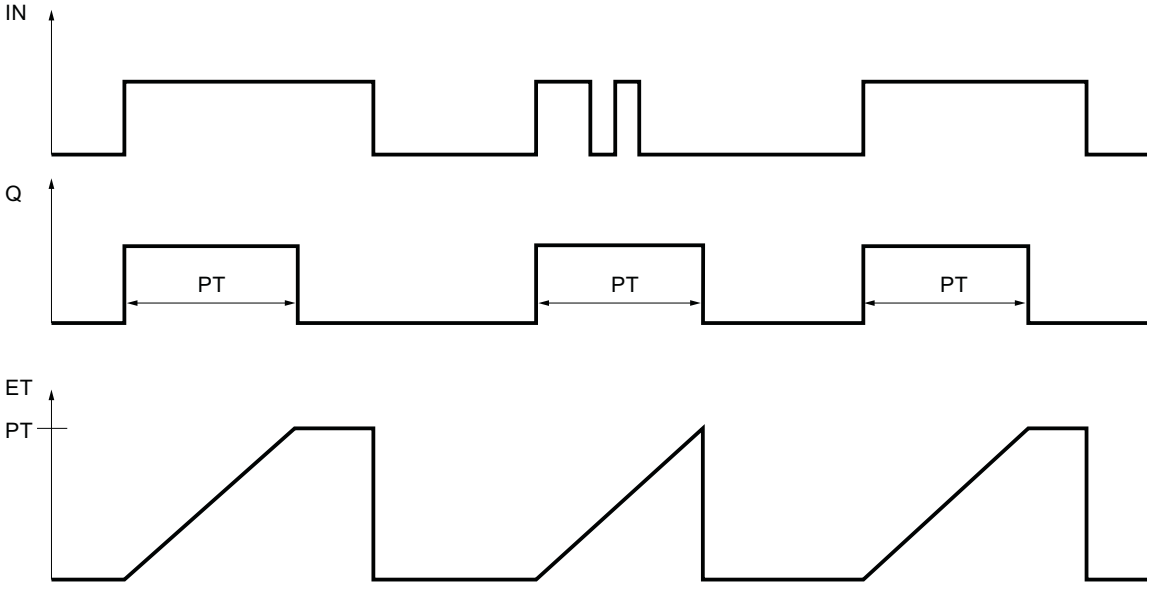
The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	BOOL	BOOL	I, Q, M, D, L, P	Start input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L, P	Duration of the pulse. The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L, P	Operand that is set for the PT duration.
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L, P	Current time value

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Generate pulse" instruction:



Example

The following example shows how the instruction works:

```
SCL
"TP_DB".TP(IN := "Tag_Start",
           PT := "Tag_PresetTime",
           Q => "Tag_Status",
           ET => "Tag_ElapsedTime");
```

When the signal state of the "Tag_Start" operand changes from "0" to "1", the time period programmed for the PT parameter is started and the "Tag_Status" operand is set to "1". The current time value is stored in the "Tag_ElapsedTime" operand.

See also

Overview of the valid data types (Page 1908)

TON: Generate on-delay

Description

You can use the "Generate on-delay" instruction to delay the setting of the Q parameter for the programmed duration PT. The instruction starts when the result of logic operation (RLO) of the IN parameter changes from "0" to "1" (positive signal edge). The programmed time PT begins when the instruction starts. When the duration PT has expired, the Q parameter returns signal state "1". The Q parameter remains set as long as the start input is still "1". If the signal state of the IN parameter changes from "1" to "0", the parameter Q will be reset. The timer function is restarted when a new positive signal edge is detected at the IN parameter.

The current time value can be queried in the ET parameter. The time value starts at T#0s and ends when the value of the time duration PT is reached. The ET parameter is reset as soon as the signal state of the IN parameter changes to "0".

Note

If the timer is not called in the program because it is skipped, for example, output ET returns a constant value as soon as the timer has expired.

Each call of the "Generate on-delay" instruction must be assigned to an IEC timer in which the instruction data is stored.

For S7-1200 CPU

An IEC timer is a structure of the data type IEC_TIMER or TON_TIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the TON_TIME type in the "Static" section of a block (for example, #MyTON_TIMER)

For S7-1500 CPU

An IEC timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TON_TIME or TON_LTIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TON_TIME or TON_LTIME in the "Static" section of a block (for example #MyTON_TIMER)

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the IEC timer is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

The instruction data is updated both when an instruction is called and also at each access to the Q or ET outputs.

Syntax

Use the following syntax for the "Generate on-delay" instruction:

- Data block of system data type IEC_Timer (global DB):

```
SCL
<IEC_Timer_DB> TON(IN := <Operand>,
                   PT := <Operand>,
                   Q => <Operand>,
                   ET => <Operand>)
```

- Local tag:

```
SCL
#myLocal_timer(IN := <Operand>,
               PT := <Operand>,
               Q => <Operand>,
               ET => <Operand>)
```

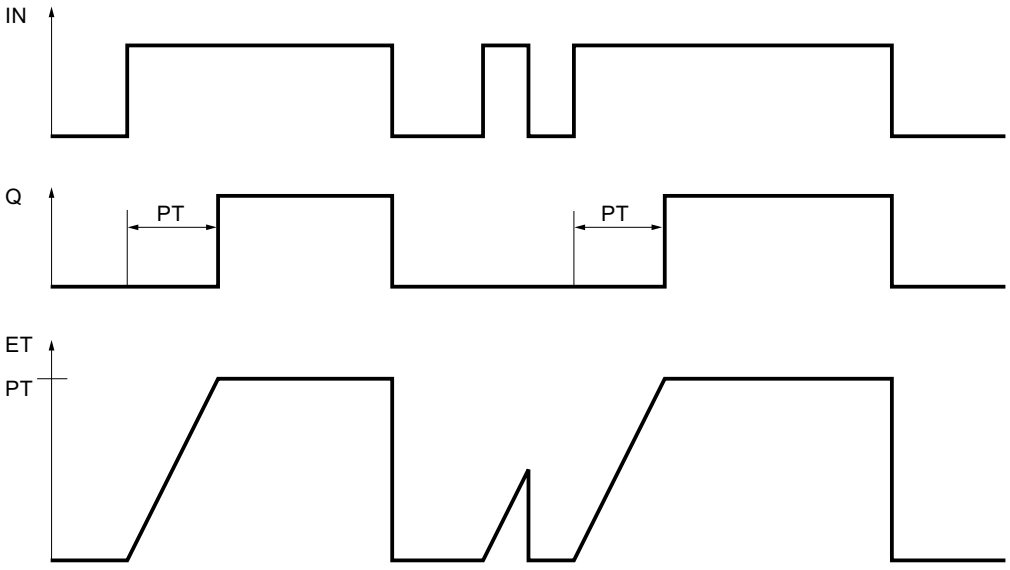
The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	BOOL	BOOL	I, Q, M, D, L, P	Start input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L, P	Duration of the on delay. The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L, P	Operand that is set when the timer PT expires.
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L, P	Current time value

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Generate on-delay" instruction:



Example

The following example shows how the instruction works:

```
SCL
"TON_DB".TON(IN := "Tag_Start",
             PT := "Tag_PresetTime",
             Q => "Tag_Status",
             ET => "Tag_ElapsedTime");
```

When the signal state of the "Tag_Start" operand changes from "0" to "1", the time programmed for the PT parameter is started. After the end of the period the "Tag_Status" operand is set to the signal state "1". The operand "Tag_Status" remains set to signal state "1" as long as the operand "Tag_Start" has signal state "1". The current time value is stored in the operand "Tag_ElapsedTime". When the signal state at the operand "Tag_Start" changes from "1" to "0", the "Tag_Status" operand is reset.

See also

Overview of the valid data types (Page 1908)

TOF: Generate off-delay

Description

You can use the "Generate off-delay" instruction to delay the resetting of the Q parameter for the programmed duration PT. The Q parameter is set when the result of logic operation (RLO) of the IN parameter changes from "0" to "1" (positive signal edge). When the signal state of the IN parameter changes back to "0", the programmed time PT starts. The Q parameter remains set as long the time duration PT is running. When the time PT expires, the Q parameter is reset. If the signal state of the IN parameter changes to "1" before the time duration PT has expired, the timer is reset. The signal state of the Q parameter remains set to "1".

The current time value can be queried in the ET parameter. The time value starts at T#0s and ends when the value of the time duration PT is reached. When the time duration PT expires, the ET parameter remains set to the current value until the IN parameter changes back to "1". If the IN parameter changes to "1" before the time PT has expired, the ET parameter is reset to the value T#0s.

Note

If the timer is not called in the program because it is skipped, for example, output ET returns a constant value as soon as the timer has expired.

Each call of the "Generate off-delay" instruction must be assigned to an IEC timer in which the instruction data is stored.

For S7-1200 CPU

An IEC timer is a structure of the data type IEC_TIMER or TOF_TIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the TOF_TIME type in the "Static" section of a block (for example, #MyTOF_TIMER)

For S7-1500 CPU

An IEC timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TOF_TIME or TOF_LTIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TOF_TIME or TOF_LTIME in the "Static" section of a block (for example #MyTOF_TIMER)

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the IEC timer is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

The instruction data is updated both when an instruction is called and also at each access to the Q or ET outputs.

Syntax

Use the following syntax for the "Generate off-delay" instruction:

- Data block of system data type IEC_Timer (global DB):

```
SCL
<IEC_Timer_DB> TOF(IN := <Operand>,
                   PT := <Operand>,
                   Q => <Operand>,
                   ET => <Operand>)
```

- Local tag:

```
SCL
#myLocal_timer(IN := <Operand>,
               PT := <Operand>,
               Q => <Operand>,
               ET => <Operand>)
```

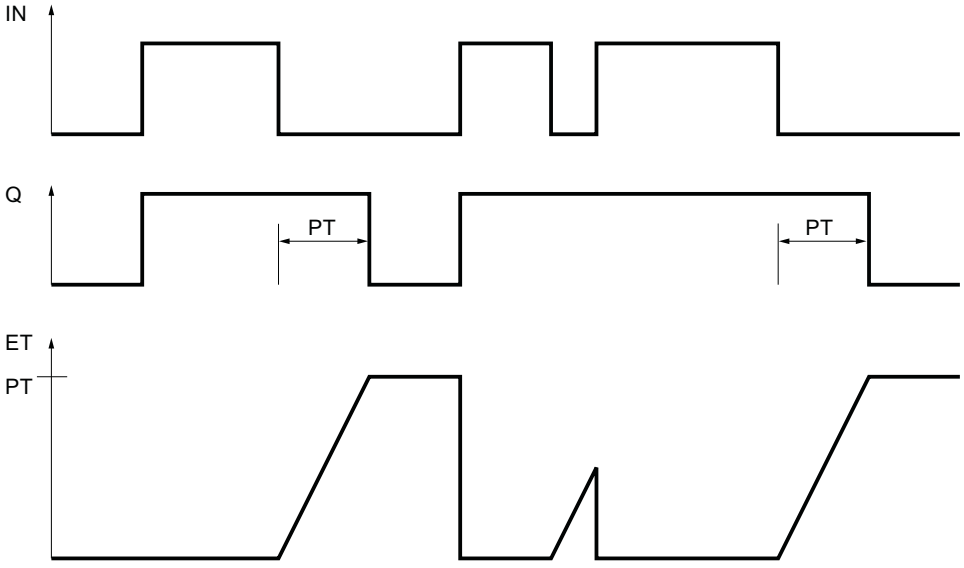
The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	BOOL	BOOL	I, Q, M, D, L, P	Start input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L, P	Duration of the off delay. The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L, P	Operand that is reset when the time PT expires.
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L, P	Current time value

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the instruction "Generate off-delay":



Example

The following example shows how the instruction works:

```
SCL
"TOF_DB".TOF(IN := "Tag_Start",
             PT := "Tag_PresetTime",
             Q => "Tag_Status",
             ET => "Tag_ElapsedTime");
```

With a change in the signal state of the "Tag_Start" operand from "0" to "1", the "Tag_Status" operand is set. When the signal state of the "Tag_Start" operand changes from "1" to "0", the time programmed for the PT parameter is started. As long as the time is running, the "Tag_Status" operand remains set. When the time has expired, the "Tag_Status" operand is reset. The current time value is stored in the operand "Tag_ElapsedTime".

See also

Overview of the valid data types (Page 1908)

TONR: Time accumulator

Description

The "Time accumulator" instruction is used to accumulate time values within a period set by the PT parameter. When the signal state of the IN parameter changes to "1", the instruction executes and the time duration PT starts. While the time duration PT is running, the time values that are recorded when the IN parameter has signal state "1" are accumulated. The accumulated time is output in the ET parameter and can be queried there. When the time duration PT is reached, the Q parameter has signal state "1". The Q parameter remains set to "1", even when the signal state at the IN parameter changes to "0".

The R parameter resets the ET and Q parameters regardless of the signal state at the IN parameter.

Each call of the "Time accumulator" instruction must be assigned to an IEC timer in which the instruction data is stored.

For S7-1200 CPU

An IEC timer is a structure of the data type IEC_TIMER or TONR_TIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the TONR_TIME type in the "Static" section of a block (for example, #MyTONR_TIMER)

For S7-1500 CPU

An IEC timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TONR_TIME or TONR_LTIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TONR_TIME or TONR_LTIME in the "Static" section of a block (for example #MyTONR_TIMER)

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the IEC timer is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

The instruction data is updated both when an instruction is called and also at each access to the Q or ET outputs.

Syntax

Use the following syntax for the "Time accumulator" instruction:

- Data block of system data type IEC_Timer (global DB):

SCL

```
<IEC_Timer_DB> TONR(IN := <Operand>,
                    R := <Operand>,
                    PT := <Operand>,
                    Q => <Operand>,
                    ET => <Operand>)
```

- Local tag:

SCL

```
#myLocal_timer(IN := <Operand>,
               R := <Operand>,
               PT := <Operand>,
               Q => <Operand>,
               ET => <Operand>)
```

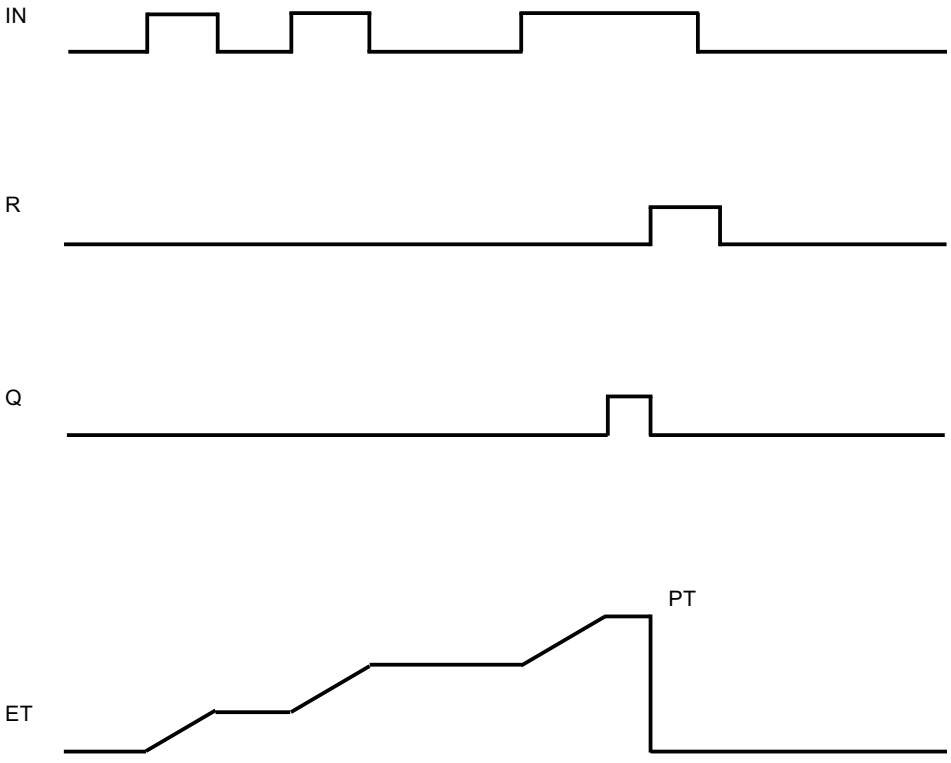
The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	BOOL	BOOL	I, Q, M, D, L, P	Start input
R	Input	BOOL	BOOL	I, Q, M, D, L, P	Reset of the ET and Q parameters
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L, P	Maximum duration of time recording. The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L, P	Operand that remains set when the timer PT has expired.
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L, P	Accumulated time

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Time accumulator" instruction:



Example

The following example shows how the instruction works:

SCL

```
"TONR_DB".TONR(IN := "Tag_Start",
               R := "Tag_Reset",
               PT := "Tag_PresetTime",
               Q => "Tag_Status",
               ET => "Tag_Time");
```

When the signal state of the "Tag_Start" operand changes from "0" to "1", the time programmed for the PT parameter is started. While the timer is running, the time values that are recorded at signal state "1" of the operand "Tag_Start" is accumulated. The accumulated times is stored in the "Tag_Time" operand. When the time value displayed at the PT parameter is reached, the "Tag_Status" operand is set to the signal state "1". The current time value is stored in the operand "Tag_Time".

Overview of the valid data types (Page 1908)

RESET_TIMER: Reset timer

Description

You can use the "Reset timer" instruction to reset an IEC timer to "0". The structure components of the timer in the specified data block are reset to "0".

The instruction does not influence the RLO. At the TIMER parameter, the "Reset timer" instruction is assigned an IEC timer declared in the program. The instruction must be programmed in an IF instruction. The instruction data is updated only when the instruction is called and not each time the assigned IEC timer is accessed. Querying the data is only identical from the call of the instruction to the next call of the instruction.

Syntax

Use the following syntax for the "Reset timer" instruction:

SCL

```
RESET_TIMER(TIMER := <IEC timer>)
```

Parameters

The following table shows the parameters of the "Reset timer" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<IEC timer>	Output	IEC_TIMER, TP_TIME, TON_TIME, TOF_TIME, TONR_TIME	IEC_TIMER, IEC_LTIMER, TP_TIME, TP_LTIME, TON_TIME, TON_LTIME, TOF_TIME, TOF_LTIME, TONR_TIME, TONR_LTIME	D, L	IEC timer that is reset

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
IF #started = false THEN
```

SCL

```
"TON_DB".TON(IN := "Tag_Start",
             PT := "Tag_PresetTime",
             Q => "Tag_Status",
             ET => "Tag_ElapsedTime");
#started := true;
END_IF;

IF "TON_DB".ET < T#25s THEN
RESET_TIMER(TIMER := "TON_DB");
#started := false;
END_IF;
```

When the tag #started has the signal state "0", the instruction "Generate on-delay" is executed when there is positive signal edge on the operand "Tag_Start". The IEC timer stored in the instance data block "TON_DB" is started with the time duration that is specified by the operand "Tag_PresetTime". The operand "Tag_Status" is set if the time duration specified by the operand "Tag_PresetTime" has expired. The parameter Q remains set as long as the operand "Tag_Start" still has the signal state "1". When the signal state of the start input changes from "1" to "0", the operand on the Q parameter is reset.

If the expired time of the IEC timer "TON_DB" is less than 25s, the "Reset timer" instruction is executed and the timer stored in the "TON_DB" instance data block is reset.

See also

Overview of the valid data types (Page 1908)

PRESET_TIMER: Load time duration

Description

You can use the "Load time duration" instruction to set the time for an IEC timer. The instruction is executed in every cycle when the result of logic operation (RLO) at the input of the instruction has the signal state "1". The instruction writes the specified time to the structure of the specified IEC timer.

Note

If the specified IEC timer is running while the instruction executes, the instruction overwrites the current time of the specified IEC timer. This can change the timer status of the IEC timer.

You assign an IEC timer declared in the program to the "Load time duration" instruction.

The instruction data is updated only when the instruction is called and each time the assigned IEC timer is accessed. The query on Q or ET (for example, "MyTimer".Q or "MyTimer".ET) updates the IEC_TIMER structure.

Syntax

Use the following syntax for the "Load time duration" instruction:

SCL

```
PRESET_TIMER(PT := <Operand>,
             TIMER := <IEC timer)
```

Parameter

The following table shows the parameters of the "Load time duration" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Time duration>	Input	TIME	TIME, LTIME	I, Q, M, D, L	Duration with which the IEC timer runs.
<IEC timer>	Output	IEC_TIMER, TP_TIME, TON_TIME, TOF_TIME, TONR_TIME	IEC_TIMER, IEC_LTIMER, TP_TIME, TP_LTIME, TON_TIME, TON_LTIME, TOF_TIME, TOF_LTIME, TONR_TIME, TONR_LTIME	D, L	IEC timer whose duration of which is set.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
IF #started = false THEN
"TON_DB".TON(IN := "Tag_Start",
             PT := "Tag_PresetTime",
             Q => "Tag_Status",
             ET => "Tag_ElapsedTime");
#started := true;
#preset = true
END_IF;

IF "TON_DB".ET < T#10s AND #preset = true THEN
```

SCL

```
PRESET_TIMER(PT := T#25s,
             TIMER := "TON_DB");
#preset := false;
END_IF;
```

When the tag #started has the signal state "0" and the operand "Tag_Start" has a positive signal edge, the instruction "Generate on-delay" is executed. The IEC timer stored in the instance data block "TON_DB" is started with the time duration that is specified by the operand "Tag_PresetTime". The operand "Tag_Status" is set if the time duration PT specified by the operand "Tag_PresetTime" has expired. The parameter Q remains set as long as the operand "Tag_Start" still has the signal state "1". When the signal state of the start input changes from "1" to "0", the operand on the Q parameter is reset.

The instruction "Load time duration" is executed when the expired time of the IEC timer "TON_DB" is less than 10s and the tag #preset has the signal state "1". The instruction writes the time duration that is specified at the parameter PT in the instance data block "TON_DB", thereby overwriting the time value of the operand "Tag_PresetTime" within the instance data block. The signal state of the timer status may therefore change at the next query or when "TON_DB".Q or "TON_DB".ET are accessed.

Legacy

S_PULSE: Assign pulse timer parameters and start

Description

The "Assign pulse timer parameters and start" instruction starts the time programmed in the T_NO parameter when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) of the S parameter. The timer runs for the programmed time (TV) as long as the signal state of the S parameter is "1".

When the signal state of the S parameter changes to "0" before the programmed time has expired, the timer is stopped and the Q parameter is reset to "0".

Internally, the time is made up of a time value and a time base and is programmed in the TV parameter. When the instruction starts, the programmed time value counts down to zero. The time base specifies the time increment by which the time value changes. The current time value is provided at the parameter BI.

If the timer is running and the signal state at input R changes to "1" then the current time value and the time base are also set to zero. If the timer is not running, the signal state "1" at the R input has no effect.

Parameter Q returns signal state "1" as long as the timer is running and the signal state at parameter S is "1". When the signal state of the S parameter changes to "0" before the

programmed time has expired, the Q parameter returns signal state "0". If the timer is reset by parameter R or if the timer has expired then parameter Q also returns signal state "0".

The instruction data is updated with each access. It is therefore possible that the query of the data at the start of the cycle returns different values from those at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Syntax

Use the following syntax for the "Assign pulse timer parameters and start" instruction:

```
SCL
S_PULSE(T_NO := <Operand>,
        S := <Operand>,
        TV := <Operand>,
        R := <Operand>,
        Q => <Operand>,
        BI => <Operand>)
```

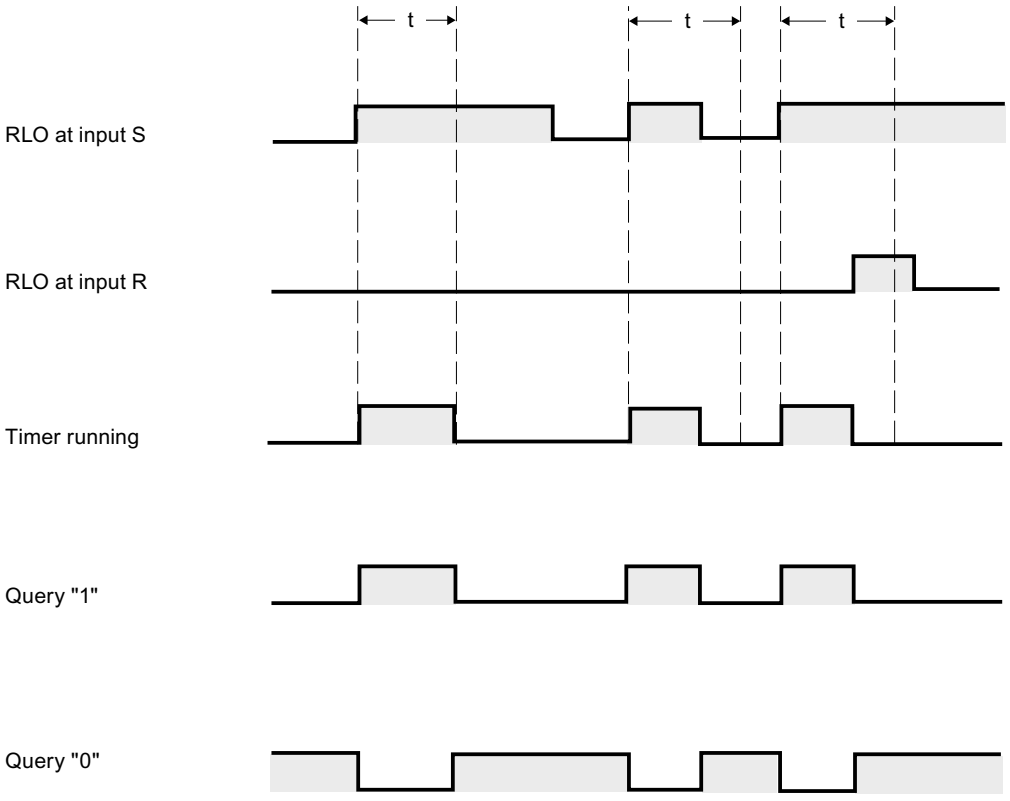
The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
T_NO	Input	TIMER, INT	T	The timer that is started. The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, D, L	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L	Preset time value
R	Input	BOOL	I, Q, M, D, L, P	Reset input
Q	Output	BOOL	I, Q, M, D, L, P	Status of the timer
BI	Output	WORD	I, Q, M, D, L, P	Current dual-coded timer value
Function value		S5TIME	I, Q, M, D, L	Current time value

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign pulse timer parameters and start" instruction:



t = programmed time

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := S_PULSE(T_NO := "Timer_1",
                        S := "Tag_1",
                        TV := "Tag_Number",
                        R := "Tag_Reset",
                        Q := "Tag_Status",
                        BI := "Tag_Value");
```

"Timer_1" starts when the signal state of the "Tag_1" operand changes from "0" to "1". The timer counts down with the time value of the operand "Tag_Number" until operand "Tag_1" returns signal state "1".

If the signal state at the S parameter changes to "0" before the programmed time has elapsed, the "Tag_Status" operand is reset to "0". If the timer is reset by the R parameter or if the timer has expired, the "Tag_Status" operand also returns signal state "0".

The current time value is stored both dual-coded at the "Tag_Value" operand and returned as a function value.

Overview of the valid data types (Page 1908)

S_PEXT: Assign extended pulse timer parameters and start

Description

The "Assign extended pulse timer parameters and start" instruction starts a programmed timer when a positive signal edge is detected at the S parameter. The timer runs for the programmed time (TV) even if the signal state at the S parameter changes to "0". As long as the timer runs, parameter Q returns the signal state "1".

When the timer has expired, parameter Q is reset to "0". If the signal state at the S parameter changes from "0" to "1" while the timer is running, the timer is restarted with the time programmed in the TV parameter.

Internally, the time is made up of a time value and a time base and is programmed in the TV parameter. When the instruction starts, the programmed time value counts down to zero. The time base specifies the time increment by which the time value changes. The current time value is provided at the parameter BI.

If the timer is running and the signal state at parameter R changes to "1" then the current time value and the time base are also set to zero. If the timer is not running then signal state "1" at parameter R has no effect.

The instruction data is updated with each access. It is therefore possible that the query of the data at the start of the cycle returns different values from those at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Syntax

Use the following syntax for the "Assign extended pulse timer parameters and start" instruction:

SCL

```
S_PEXT(T_NO := <Operand>,
       S := <Operand>,
       TV := <Operand>,
       R := <Operand>,
       Q => <Operand>,
       BI =><Operand>)
```

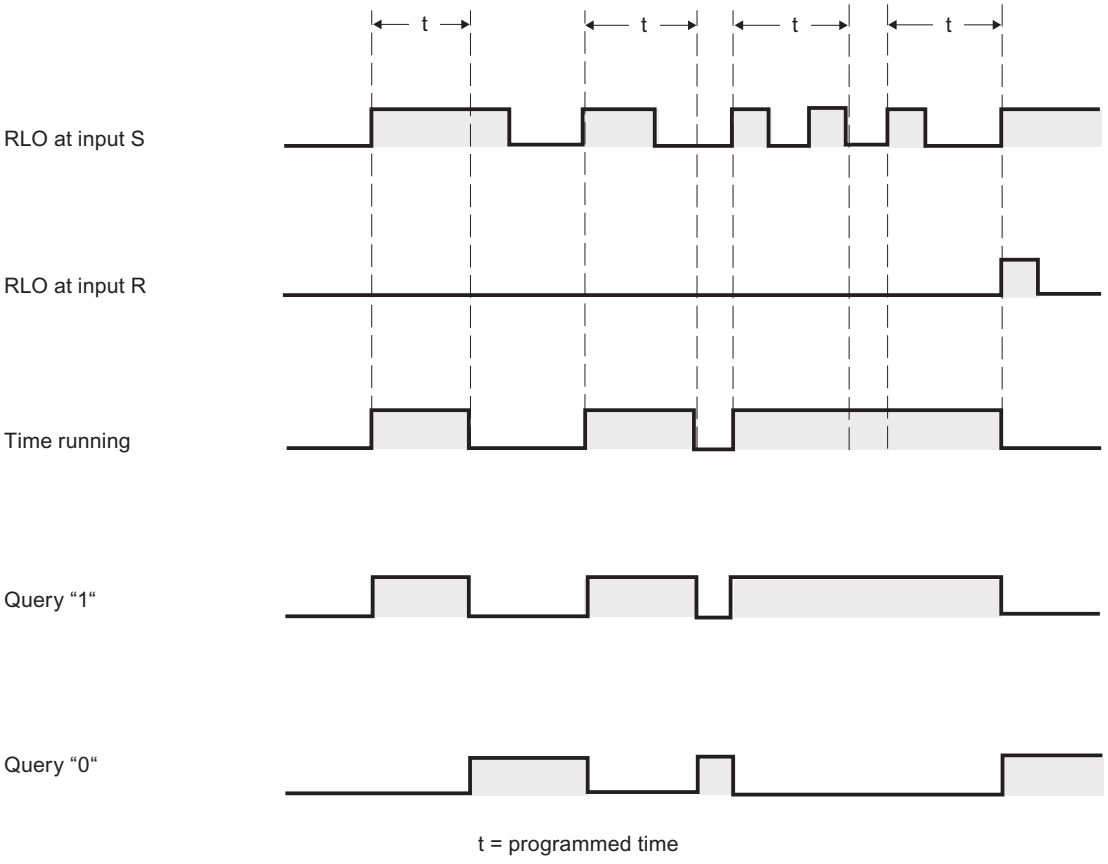
The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
T_NO	Input	TIMER, INT	T	The timer that is started. The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, D, L	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L	Preset time value
R	Input	BOOL	I, Q, M, D, L, P	Reset input
Q	Output	BOOL	I, Q, M, D, L, P	Status of the timer
BI	Output	WORD	I, Q, M, D, L, P	Current dual-coded timer value
Function value		S5TIME	I, Q, M, D, L	Current time value

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign extended pulse timer parameters and start" instruction:



t = programmed time

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := S_PEXT(T_NO := "Timer_1",
                       S := "Tag_1",
                       TV := "Tag_Number",
                       R := "Tag_Reset",
                       Q := "Tag_Status",
                       BI := "Tag_Value");
```

"Timer_1" starts when the signal state of the "Tag_1" operand changes from "0" to "1". As long as the timer runs, operand "Tag_Status" returns the signal state "1". When the timer has expired, operand "Tag_Status" is reset to "0". If the signal state at the S input changes from "0" to "1" while the timer is running, the timer is restarted with the time "Tag_Number".

The current time value is stored both dual-coded at the "Tag_Value" operand and returned as a function value.

Overview of the valid data types (Page 1908)

S_ODT: Assign on-delay timer parameters and start

Description

The "Assign on-delay timer parameters and start" instruction starts a programmed timer as on-delay when a positive signal edge is detected at the S parameter. The timer runs for the programmed time (TV) as long as the signal state of the S parameter is "1".

If the timer expires correctly and parameter S still has signal state "1" then parameter Q returns signal state "1". If the signal state at the S parameter changes from "1" to "0" while the timer is running, the timer is stopped. In this case, output Q is reset to signal state "0".

Internally, the time is made up of a time value and a time base and is programmed in the TV parameter. When the instruction starts, the programmed time value counts down to zero. The time base specifies the time increment by which the time value changes. The current time value is provided at the parameter BI.

If the time is running and the signal state at input R changes from "0" to "1" then the current time value and the time base are also set to zero. In this case, the signal state at parameter Q is "0". The timer is reset if the signal state at the R parameter is "1", even if the timer is not running and the result of logic operation (RLO) at the S parameter is "1".

The instruction data is updated with each access. It is therefore possible that the query of the data at the start of the cycle returns different values from those at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Syntax

Use the following syntax for the "Assign on-delay timer parameters and start" instruction:

SCL

```
S_ODT(T_NO := <Operand>,
      S := <Operand>,
      TV := <Operand>,
      R := <Operand>,
      Q => <Operand>,
      BI =><Operand>)
```

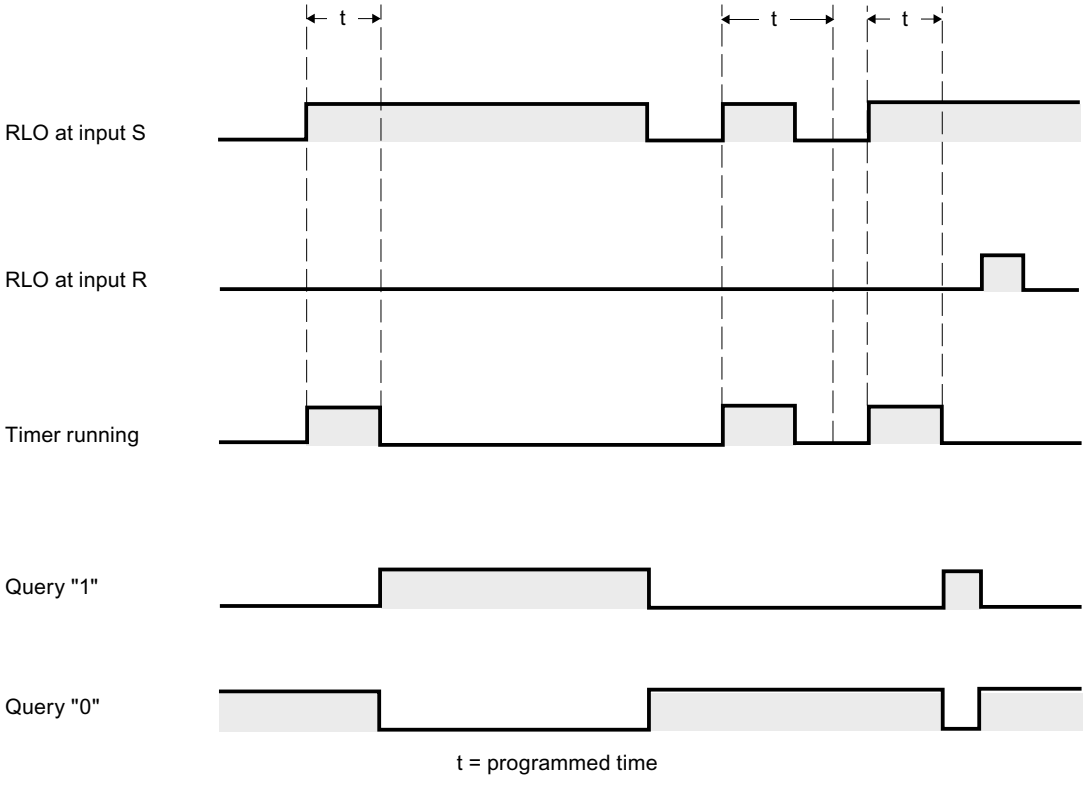
The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
T_NO	Input	TIMER, INT	T	The timer that is started. The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, D, L	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L	Preset time value
R	Input	BOOL	I, Q, M, D, L, P	Reset input
Q	Output	BOOL	I, Q, M, D, L, P	Status of the timer
BI	Output	WORD	I, Q, M, D, L, P	Current dual-coded timer value
Function value		S5TIME	I, Q, M, D, L	Current time value

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign on-delay timer parameters and start" instruction:



Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := S_ODT(T_NO := "Timer_1",
                      S := "Tag_1",
                      TV := "Tag_Number",
                      R := "Tag_Reset",
                      Q := "Tag_Status",
                      BI := "Tag_Value");
```

"Timer_1" starts when the signal state of the "Tag_1" operand changes from "0" to "1". The timer runs for the duration "Tag_Number" as long as the signal state of operand "Tag_1" is "1".

If the timer expires correctly and operand "Tag_Status" has signal state "1" then operand "Tag_Status" is reset to "1". If the signal state of the "Tag_1" operand changes from "1" to "0" while the timer is running, the timer is stopped. In this case, operand "Tag_Status" returns signal state "0".

The current time value is stored both dual-coded at the "Tag_Value" operand and returned as a function value.

Overview of the valid data types (Page 1908)

S_ODTS: Assign retentive on-delay timer parameters and start

Description

The "Assign retentive on-delay timer parameters and start" instruction starts a programmed timer when a positive signal edge is detected at the S parameter. The timer runs for the programmed time (TV) even if the signal state at the S parameter changes to "0".

If the timer expires, the Q parameter returns signal state "1" regardless of the signal state of the S parameter. If the signal state at the S parameter changes from "0" to "1" while the timer is running, the timer is restarted with the programmed time TV.

Internally, the time is made up of a time value and a time base and is programmed in the TV parameter. When the instruction starts, the programmed time value counts down to zero. The time base specifies the time increment by which the time value changes. The current time value is provided at the parameter BI.

Signal state "1" at parameter R resets the current time value and time base to "0", independent of the signal state at parameter S. In this case, the signal state at parameter Q is "0".

The instruction data is updated with each access. It is therefore possible that the query of the data at the start of the cycle returns different values from those at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Syntax

Use the following syntax for the "Assign retentive on-delay timer parameters and start" instruction:

SCL

```
S_ODTS(T_NO := <Operand>,
       S := <Operand>,
       TV := <Operand>,
       R := <Operand>,
       Q => <Operand>,
       BI =><Operand>)
```

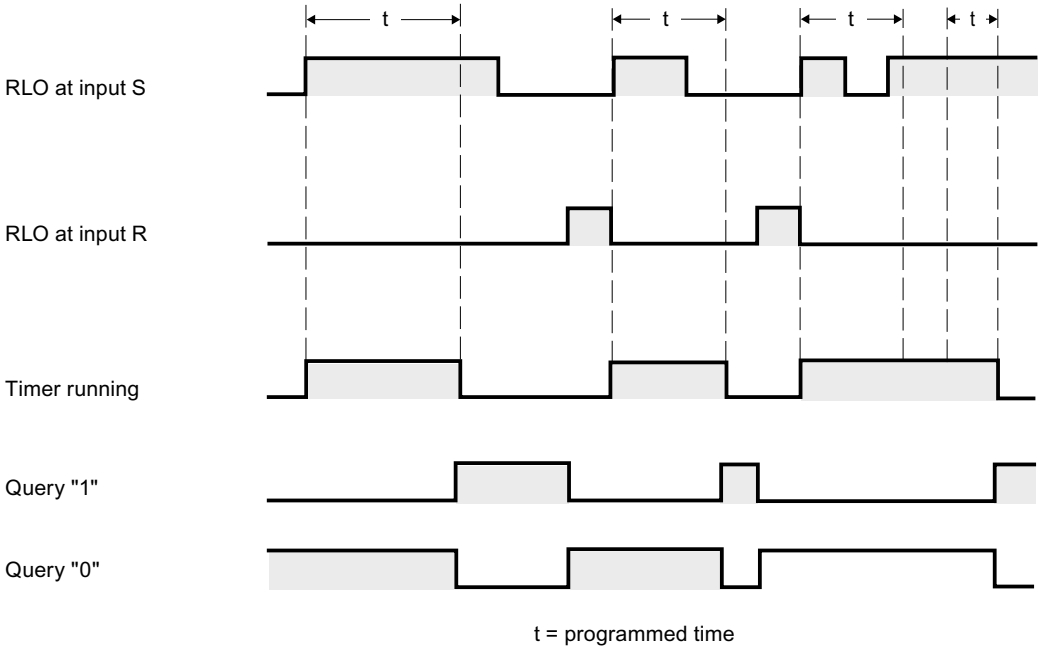
The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
T_NO	Input	TIMER, INT	T	The timer that is started. The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, D, L	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L	Preset time value
R	Input	BOOL	I, Q, M, D, L, P	Reset input
Q	Output	BOOL	I, Q, M, D, L, P	Status of the timer
BI	Output	WORD	I, Q, M, D, L, P	Current dual-coded timer value
Function value		S5TIME	I, Q, M, D, L	Current time value

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign retentive on-delay timer parameters and start" instruction:



Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := S_ODTS(T_NO := "Timer_1",
                       S := "Tag_1",
                       TV := "Tag_Number",
                       R := "Tag_Reset",
                       Q := "Tag_Status",
                       BI := "Tag_Value");
```

"Timer_1" starts when the signal state of the "Tag_1" operand changes from "0" to "1". The timer runs for the duration "Tag_Number".

If the timer expires, operand "Tag_Status" returns signal state "1" independent of the signal state of operand "Tag_1". If the signal state of the "Tag_1" operand changes from "0" to "1" while the timer is running, the timer is restarted with the time "Tag_Number".

The current time value is stored both dual-coded at the "Tag_Value" operand and returned as a function value.

Overview of the valid data types (Page 1908)

S_OFFDT: Assign off-delay timer parameters and start

Description

The "Assign off-delay timer parameters and start" instruction starts a programmed timer when a negative signal edge is detected at the S parameter. The timer runs for the programmed time (TV). As long as the timer is running or parameter S returns signal state "1", then parameter Q has signal state "1".

If the timer expires and the signal state is "0" then parameter Q is reset to signal state "0". If the signal state at parameter S changes from "0" to "1" while the timer is running, the timer is stopped. The timer is only restarted after a falling signal edge is detected at parameter S.

Internally, the time is made up of a time value and a time base and is programmed in the TV parameter. When the instruction starts, the programmed time value counts down to zero. The time base specifies the time increment by which the time value changes. The current time value is provided at the parameter BI.

Signal state "1" at parameter R resets the current time value and time base to "0". In this case, the signal state at parameter Q is "0".

The instruction data is updated with each access. It is therefore possible that the query of the data at the start of the cycle returns different values from those at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Syntax

Use the following syntax for the "Assign off-delay timer parameters and start" instruction:

SCL

```
S_OFFDT(T_NO := <Operand>,
        S := <Operand>,
        TV := <Operand>,
        R := <Operand>,
        Q => <Operand>,
        BI =><Operand>)
```

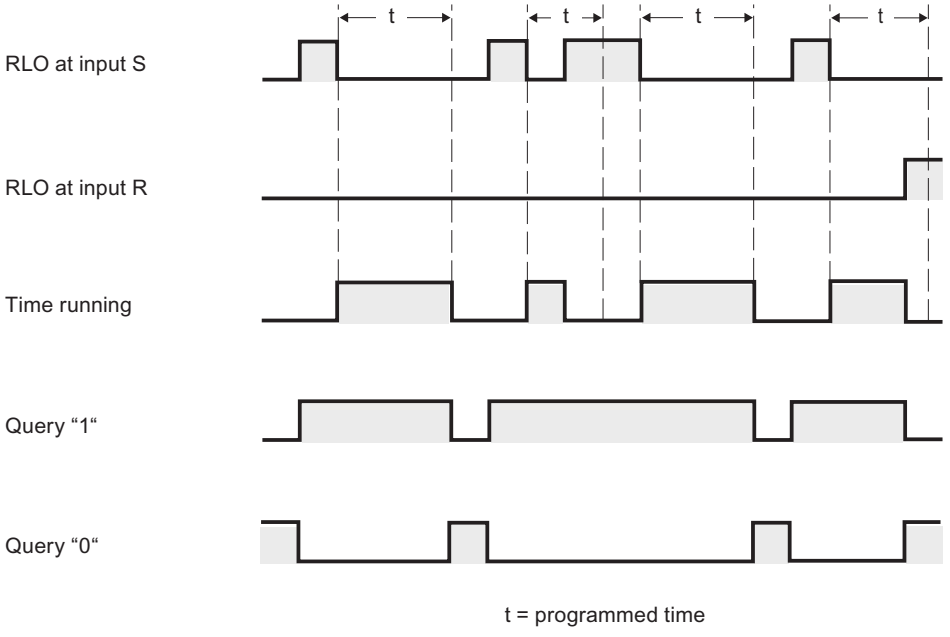
The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
T_NO	Input	TIMER, INT	T	The timer that is started. The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, D, L	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L	Preset time value
R	Input	BOOL	I, Q, M, D, L, P	Reset input
Q	Output	BOOL	I, Q, M, D, L, P	Status of the timer
BI	Output	WORD	I, Q, M, D, L, P	Current dual-coded timer value
Function value		S5TIME	I, Q, M, D, L	Current time value

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign off-delay timer parameters and start" instruction:



Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := S_OFFDT(T_NO := "Timer_1",
                        S := "Tag_1",
                        TV := "Tag_Number",
                        R := "Tag_Reset",
                        Q := "Tag_Status",
                        BI := "Tag_Value");
```

"Timer_1" starts when the signal state of the "Tag_1" operand changes from "0" to "1". The timer runs for the duration "Tag_Number". As long as the timer is running or operand "Tag_1" returns signal state "1", then operand "Tag_Status" has signal state "1".

If the timer expires and the signal state of operand "Tag_1" is "0" then operand "Tag_Status" is reset to signal state "0". If the signal state of the "Tag_1" operand changes from "0" to "1" while the timer is running, the timer is reset. The timer is only restarted after a falling edge is detected at parameter S.

The current time value is stored both dual-coded at the "Tag_Value" operand and returned as a function value.

Overview of the valid data types (Page 1908)

Counter operations

CTU: Count up

Description

You can use the "Count up" instruction to increment the value at the CV parameter. When the signal state of the parameter CU changes from "0" to "1" (positive signal edge), the instruction is executed and the current counter value of the parameter CV is incremented by one. The counter value is incremented each time a positive signal edge is detected, until it reaches the high limit of the data type specified at the CV parameter. When the high limit is reached, the signal state of the CU parameter no longer has an effect on the instruction.

You can query the count status of the Q parameter. The signal state of the Q parameter is determined by the PV parameter. When the current counter value is greater than or equal to the value of the PV parameter, the Q parameter is set to signal state "1". In all other cases, the signal state of the Q parameter is "0". You can also specify a constant for the PV parameter.

The value of the CV parameter is reset to zero when the signal state at the R parameter changes to "1". As long as the signal state of the R parameter is "1", the signal state of the CU parameter has no effect on the instruction.

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Each call of the "Count up" instruction must be assigned an IEC counter in which the instruction data is stored. An IEC counter is a structure with one of the following data types:

For S7-1200 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER	• CTU_SINT / CTU_USINT • CTU_INT / CTU_UINT • CTU_DINT / CTU_UDINT

For S7-1500 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER	• CTU_SINT / CTU_USINT • CTU_INT / CTU_UINT • CTU_DINT / CTU_UDINT • CTU_LINT / CTU_ULINT

You can declare an IEC counter as follows:

- Declaration of a data block of system data type IEC_<Counter> (for example, "MyIEC_COUNTER")
- Declaration as a local tag of the type CTU_<Data type> in the "Static" section of a block (for example, #MyCTU_COUNTER)

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the IEC counter is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

When you set up the IEC counter in a separate data block (single instance), the instance data block is created by default with "optimized block access" and the individual tags are defined as retentive. For additional information on setting retentivity in an instance data block, refer to "See also".

When you set up the IEC counter as local tag (multi-instance) in a function block with "optimized block access", it is defined as retentive in the block interface.

Syntax

The following syntax is used for the "Count up" instruction:

Table 11-28 Data block of system data type IEC_counter (global DB)

SCL

```
<IEC_Counter_DB>.CTU(CU := <Operand>,
                     R := <Operand>,
                     PV := <Operand>,
                     Q => <Operand>,
                     CV => <Operand>)
```

Table 11-29 Local tag

SCL

```
#myLocal_counter(CU := <Operand>,
                 R := <Operand>,
                 PV := <Operand>,
                 Q => <Operand>,
                 CV => <Operand>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
CU	Input	BOOL	I, Q, M, D, L	Count input
R	Input	BOOL	I, Q, M, D, L, P	Reset input
PV	Input	Integers	I, Q, M, D, L, P	Value at which the Q output is set
Q	Output	BOOL	I, Q, M, D, L	Counter status
CV	Output	Integers, CHAR, WCHAR, DATE	I, Q, M, D, L, P	Current counter value

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

SCL

```
"IEC_COUNTER_DB".CTU(CU := "Tag_Start",
                     R := "Tag_Reset",
                     PV := "Tag_PresetValue",
                     Q => "Tag_Status",
                     CV => "Tag_CounterValue");
```

When the signal state of the "Tag_Start" operand changes from "0" to "1", the "Count up" instruction is executed and the current counter value of the "Tag_CounterValue" operand is incremented by one. With each additional positive signal edge, the counter value is incremented until the high limit of the specified data type (INT = 32767) is reached.

The "Tag_Status" output has signal state "1" as long as the current counter value is greater than or equal to the value of the "Tag_PresetValue" operand. In all other cases, the

"Tag_Status" output has signal state "0". The current counter value is stored in the "Tag_CounterValue" operand.

Overview of the valid data types (Page 1908)

CTD: Count down

Description

The "Count down" instruction is used to decrement the value at the parameter CV. When the signal state of the CD parameter changes from "0" to "1" (positive signal edge), the instruction is executed and the current counter value of the CV parameter is decremented by one. Each time a positive signal edge is detected, the counter value is decremented until it reaches the low limit of the specified data type. When the low limit is reached, the signal state of the CD parameter no longer has an effect on the instruction.

You can query the count status of the Q parameter. If the current counter value is less than or equal to zero, the Q parameter is set to signal state "1". In all other cases, the signal state of the Q parameter is "0". You can also specify a constant for the PV parameter.

The value of the CV parameter is set to the value of the PV parameter when the signal state of the LD parameter changes to "1". As long as the signal state of the LD parameter is "1", the signal state of the CD parameter has no effect on the instruction.

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Each call of the "Count down" instruction must be assigned an IEC counter in which the instruction data is stored. An IEC counter is a structure with one of the following data types:

For S7-1200 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER	• CTD_SINT / CTD_USINT • CTD_INT / CTD_UINT • CTD_DINT / CTD_UDINT

For S7-1500 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER	• CTD_SINT / CTD_USINT
• IEC_COUNTER / IEC_UCOUNTER	• CTD_INT / CTD_UINT
• IEC_DCOUNTER / IEC_UDCOUNTER	• CTD_DINT / CTD_UDINT
• IEC_LCOUNTER / IEC_ULCOUNTER	• CTD_LINT / CTD_ULINT

You can declare an IEC counter as follows:

- Declaration of a data block of system data type IEC_<Counter> (for example, "MyIEC_COUNTER")
- Declaration as a local tag of the type CTD_<Data type> in the "Static" section of a block (for example, #MyCTD_COUNTER)

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the IEC counter is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

When you set up the IEC counter in a separate data block (single instance), the instance data block is created by default with "optimized block access" and the individual tags are defined as retentive. For additional information on setting retentivity in an instance data block, refer to "See also".

When you set up the IEC counter as local tag (multi-instance) in a function block with "optimized block access", it is defined as retentive in the block interface.

Syntax

The following syntax is used for the "Count down" instruction:

Table 11-30 Data block of system data type IEC_counter (global DB)

SCL

```
<IEC_Counter_DB>.CTD(CD := <Operand>,
                     LD := <Operand>,
                     PV := <Operand>,
                     Q => <Operand>,
                     CV => <Operand>)
```

Table 11-31 Local tag

SCL

```
#myLocal_counter(CD := <Operand>,
                 LD := <Operand>,
                 PV := <Operand>,
                 Q => <Operand>,
                 CV => <Operand>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
CD	Input	BOOL	I, Q, M, D, L	Count input
LD	Input	BOOL	I, Q, M, D, L, P	Load input
PV	Input	Integers	I, Q, M, D, L, P	Value to which the CV output is set with LD = 1.
Q	Output	BOOL	I, Q, M, D, L	Counter status
CV	Output	Integers, CHAR, WCHAR, DATE	I, Q, M, D, L, P	Current counter value

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

```
SCL
"IEC_SCOUNTER_DB".CTD(CD := "Tag_Start",
                      LD := "Tag_Load",
                      PV := "Tag_PresetValue",
                      Q => "Tag_Status",
                      CV => "Tag_CounterValue");
```

When the signal state of the "Tag_Start" operand changes from "0" to "1", the instruction is executed and the value of the "Tag_CounterValue" operand is decremented by one. With each additional positive signal edge, the counter value is decremented until it reaches the low limit of the specified data type (-128).

The operand "Tag_Status" has signal state "1" as long as the current counter value is less than or equal to zero. In all other cases, the "Tag_Status" output has signal state "0". The current counter value is stored in the "Tag_CounterValue" operand.

Overview of the valid data types (Page 1908)

CTUD: Count up and down

Description

Use the "Count up and down" instruction to increment or decrement the counter value at the CV parameter. When the signal state of the CU parameter changes from "0" to "1" (positive signal edge), the current counter value of the CV parameter is incremented by one. When the signal state of the CD parameter changes from "0" to "1" (positive signal edge), the counter value of the CV parameter is decremented by one. If there is a positive signal edge at the CU and CD inputs in a program cycle, the current counter value of the CV parameter remains unchanged.

The counter value can be incremented until it reaches the high limit of the data type specified at the CV parameter. When the high limit is reached, the counter value is no longer incremented

on a positive signal edge. The counter value is no longer decremented once the low limit of the specified data type has been reached.

When the signal state of the LD parameter changes to "1", the counter value of the CV parameter is set to the value of the PV parameter. As long as the LD parameter has signal state "1", the signal state of the CU and CD parameters has no effect on the instruction.

The counter value is set to zero when the signal state of the R parameter changes to "1". As long as the R parameter has signal state "1", a change in the signal state of the CU, CD and LD parameters has no effect on the "Count up and down" instruction.

You can query the status of the up counter at the QU parameter. When the current counter value is greater than or equal to the value of the PV parameter, the QU parameter is set to signal state "1". In all other cases, the signal state of the QU parameter is "0". You can also specify a constant for the PV parameter.

You can query the status of the down counter at the QD parameter. If the current counter value is less than or equal to zero, the QD parameter is set to signal state "1". In all other cases, the signal state of the QD parameter is "0".

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Each call of the "Count up and down" instruction must be assigned an IEC counter in which the instruction data is stored. An IEC counter is a structure with one of the following data types:

For S7-1200 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER	• CTUD_SINT / CTUD_USINT
• IEC_COUNTER / IEC_UCOUNTER	• CTUD_INT / CTUD_UINT
• IEC_DCOUNTER / IEC_UDCOUNTER	• CTUD_DINT / CTUD_UDINT

For S7-1500 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER	• CTUD_SINT / CTUD_USINT
• IEC_COUNTER / IEC_UCOUNTER	• CTUD_INT / CTUD_UINT
• IEC_DCOUNTER / IEC_UDCOUNTER	• CTUD_DINT / CTUD_UDINT
• IEC_LCOUNTER / IEC_ULCOUNTER	• CTUD_LINT / CTUD_ULINT

You can declare an IEC counter as follows:

- Declaration of a data block of system data type IEC_<Counter> (for example, "MyIEC_COUNTER")
- Declaration as a local tag of the type CTUD_<Data type> in the "Static" section of a block (for example, #MyCTUD_COUNTER)

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the IEC counter is stored in its own data block (single instance) or as a local tag (multi-instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

When you set up the IEC counter in a separate data block (single instance), the instance data block is created by default with "optimized block access" and the individual tags are defined as retentive. For additional information on setting retentivity in an instance data block, refer to "See also".

When you set up the IEC counter as local tag (multi-instance) in a function block with "optimized block access", it is defined as retentive in the block interface.

Syntax

The following syntax is used for the "Count up and down" instruction:

Table 11-32 Data block of system data type IEC_counter (global DB)

SCL

```
<IEC_Counter_DB>.CTUD(CU := <Operand>,
                      CD := <Operand>,
                      R := <Operand>,
                      LD := <Operand>,
                      PV := <Operand>,
                      QU=> <Operand>,
                      QD := <Operand>,
                      CV => <Operand>)
```

Table 11-33 Local tag

SCL

```
myLocal_counter(CU := <Operand>,
                CD := <Operand>,
                R := <Operand>,
                LD := <Operand>,
                PV := <Operand>,
                QU=> <Operand>,
                QD := <Operand>,
                CV => <Operand>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
CU	Input	BOOL	I, Q, M, D, L	Count up input
CD	Input	BOOL	I, Q, M, D, L	Count down input
R	Input	BOOL	I, Q, M, D, L, P	Reset input
LD	Input	BOOL	I, Q, M, D, L, P	Load input
PV	Input	Integers	I, Q, M, D, L, P	Value at which the QU output is set. / Value to which the CV output is set with LD = 1.

Parameter	Declaration	Data type	Memory area	Description
QU	Output	BOOL	I, Q, M, D, L	Status of the up counter
QD	Output	BOOL	I, Q, M, D, L	Status of the down counter
CV	Output	Integers, CHAR, WCHAR, DATE	I, Q, M, D, L, P	Current counter value

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

```
SCL
"IEC_COUNTER_DB".CTUD(CU := "Tag_Start1",
                      CD := "Tag_Start2",
                      LD := "Tag_Load",
                      R := "Tag_Reset",
                      PV := "Tag_PresetValue",
                      QU => "Tag_CU_Status",
                      QD => "Tag_CD_Status",
                      CV => "Tag_CounterValue");
```

If the "Tag_Start1" operand has a positive signal edge in the signal state, the current counter value is incremented by one and stored in the "Tag_CounterValue" operand. If the "Tag_Start2" operand has a positive signal edge in the signal state, the counter value is decremented by one and is also stored in the "Tag_CounterValue" operand. The counter value is incremented on the positive signal edge of the CU parameter until it reaches the high limit of the specified data type (INT). If the CD parameter has a positive signal edge, the counter value is decremented until it reaches the low limit of the specified data type (INT).

The operand "Tag_CU_Status" has signal state "1" as long as the current counter value is greater than or equal to the value of the operand "Tag_PresetValue". In all other cases, the "Tag_CU_Status" output has signal state "0".

The operand "Tag_CD_Status" has signal state "1" as long as the current counter value is less than or equal to zero. In all other cases, the "Tag_CD_Status" output has signal state "0".

Legacy

S_CU: Assign parameters and count up

Description

You can use the "Assign parameters and count up" instruction to increment the value of a counter. When the signal state of the parameter CU changes from "0" to "1" (positive signal edge), the current counter value is incremented by one. The current counter value is provided at the parameter CV. The counter value is incremented until the limit of "999" is reached. When the limit value is reached, the counter value is no longer incremented on a positive signal edge.

When the signal state of the parameter S changes from "0" to "1", the counter value is set to the value of the parameter PV. If the counter is set and if the result of logic operation (RLO) at the CU input is "1", the counter counts once in the next cycle, even when no signal edge change is detected.

The counter value is set to zero when the signal state of the R parameter changes to "1". As long as the parameter R has the signal state "1", a change in the signal state of the parameters CU and S has no effect on the counter value.

The signal state at parameter Q is "1" if the counter value is greater than zero. When the counter value equals zero, parameter Q returns signal state "0".

Note

To avoid counting errors, only use a counter at a single location in the program.

Syntax

The following syntax is used for the "Assign parameters and count up" instruction:

SCL

```
S_CU(C_NO := <Operand>,
     CU := <Operand>,
     S := <Operand>,
     PV := <Operand>,
     R := <Operand>,
     Q => <Operand>,
     CV => <Operand>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
C_NO	Input	COUNTER, INT	C	Counters The number of counters depends on the CPU.
CU	Input	BOOL	I, Q, M, D, L	Count up input
S	Input	BOOL	I, Q, M, D, L	Input for presetting the counter

Parameter	Declaration	Data type	Memory area	Description
PV	Input	WORD	I, Q, M, D, L	Preset counter value (C#0 to C#999) in BCD format
R	Input	BOOL	I, Q, M, D, L	Reset input
Q	Output	BOOL	I, Q, M, D, L	Status of the counter
CV	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value
Function value		WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value in BCD format

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := S_CU(C_NO := "Counter_1",
                     CU := "Tag_Start",
                     S := "Tag_1",
                     PV := "Tag_PresetValue",
                     R := "Tag_Reset",
                     Q => "Tag_Status",
                     CV => "Tag_Value");
```

If the signal state of the "Tag_Start" parameter changes from "0" to "1" (positive signal edge) and the current counter value is less than "999", the counter value is incremented by one. If the signal state of the input "Tag_1" changes from "0" to "1", the counter value in BCD format is set to the value of the operand "Tag_PresetValue". The counter value is reset to "0" when the operand "Tag_Reset" has signal state "1".

The current counter value is stored in hexadecimal form in the operand "Tag_Value".

The output "Tag_Status" has the signal state "1" as long as the current counter value is not equal to "0". The current counter value is returned in the "Tag_Value" operand and as a function value.

See also

Overview of the valid data types (Page 1908)

S_CD: Assign parameters and count down

Description

You can use the "Assign parameters and count down" instruction to decrement the value of a counter. When the signal state of the parameter CD changes from "0" to "1" (positive signal edge), the current counter value is decreased by one. The current counter value is provided at the parameter CV. The counter value is decreased until the low limit of "0" is reached. When the low limit is reached, the counter value is no longer decreased on a positive signal edge.

When the signal state of the parameter S changes from "0" to "1", the counter value is set to the value of the parameter PV. If the counter is set and if the result of logic operation (RLO) at the parameter CD is "1", the counter counts once in the next cycle, even when no signal edge change is detected.

The counter value is set to zero when the signal state of the R parameter changes to "1". As long as the parameter R has the signal state "1", a change in the signal state of the parameters CD and S has no effect on the counter value.

The signal state at parameter Q is "1" if the counter value is greater than zero. When the counter value equals zero, parameter Q returns signal state "0".

Note

To avoid counting errors, only use a counter at a single location in the program.

Syntax

The following syntax is used for the "Assign parameters and count down" instruction:

SCL

```
S_CD(C_NO:= <Operand>,
     CD := <Operand>,
     S := <Operand>,
     PV := <Operand>,
     R := <Operand>,
     Q => <Operand>,
     CV => <Operand>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
C_NO	Input	COUNTER, INT	C	Counters The number of counters depends on the CPU.
CD	Input	BOOL	I, Q, M, D, L	Count down input
S	Input	BOOL	I, Q, M, D, L	Input for presetting the counter

Parameter	Declaration	Data type	Memory area	Description
PV	Input	WORD	I, Q, M, D, L	Preset counter value (C#0 to C#999) in BCD format
R	Input	BOOL	I, Q, M, D, L	Reset input
Q	Output	BOOL	I, Q, M, D, L	Status of the counter
CV	Output	WORD, S5TIME, WORD	I, Q, M, D, L	Current counter value
Function value		WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value in BCD format

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := S_CD(C_NO := "Counter_1",
                     CD := "Tag_Start",
                     S := "Tag_1",
                     PV := "Tag_PresetValue",
                     R := "Tag_Reset",
                     Q => "Tag_Status",
                     CV => "Tag_Value");
```

When the signal state of the operand "Tag_Start" changes from "0" to "1" (positive signal edge) and the current counter value is greater than "0", the counter value is decreased by one. If the signal state of the operand "Tag_1" changes from "0" to "1", the counter value is set in BCD format to the value of the operand "Tag_PresetValue". The counter value is reset to "0" when the operand "Tag_Reset" has signal state "1".

The current counter value is stored in the operand "Tag_Value".

The operand "Tag_Status" returns signal state "1" as long as the current counter value is not equal to "0". The current counter value is returned in the "Tag_Value" operand and as a function value.

Overview of the valid data types (Page 1908)

S_CUD: Assign parameters and count up / down

Description

You can use the "Assign parameters and count up / down" instruction to increment and decrement the value of a counter. When the signal state of the parameter CU changes from "0" to "1" (positive signal edge), the current counter value is incremented by one. When the signal state of the parameter CD changes from "0" to "1" (positive signal edge), the counter value is decreased by one. The current counter value is provided at the parameter CV. If there is a positive signal edge at the parameters CU and CD in one program cycle, the counter value remains unchanged.

The counter value is incremented until the high limit of "999" is reached. When the high limit is reached, the counter value is no longer incremented on a positive signal edge. When the low limit "0" is reached, the counter value is not decremented any further.

When the signal state of the parameter S changes from "0" to "1", the counter value is set to the value of the parameter PV. If the counter is set and if the result of logic operation (RLO) of the parameters CU and CD is "1", the counter will count once in the next cycle, even if no signal edge change was detected.

The counter value is set to zero when the signal state of the R parameter changes to "1". As long as the parameter R has the signal state "1", processing of the signal state of the parameters CU, CD and S has no effect on the counter value.

The signal state at parameter Q is "1" if the counter value is greater than zero. When the counter value equals zero, parameter Q returns signal state "0".

Note

To avoid counting errors, only use a counter at a single location in the program.

Syntax

The following syntax is used for the "Assign parameters and count up / down" instruction:

SCL

```
S_CUD(C_NO:= <Operand>,
      CU := <Operand>,
      CD := <Operand>,
      S := <Operand>,
      PV := <Operand>,
      R := <Operand>,
      Q => <Operand>,
      CV => <Operand>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
C_NO	Input	COUNTER, INT	C	Counters The number of counters depends on the CPU.
CU	Input	BOOL	I, Q, M, D, L	Count up input
CD	Input	BOOL	I, Q, M, D, L	Count down input
S	Input	BOOL	I, Q, M, D, L	Input for presetting the counter
PV	Input	WORD	I, Q, M, D, L	Preset counter value (C#0 to C#999) in BCD format
R	Input	BOOL	I, Q, M, D, L	Reset input
Q	Output	BOOL	I, Q, M, D, L	Status of the counter
CV	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (hexadecimal)
Function value		WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value in BCD format

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := S_CD(C_NO := "Counter_1",
                     CU := "Tag_CU",
                     CD := "Tag_CD",
                     S := "Tag_1",
                     PV := "Tag_PresetValue",
                     R := "Tag_Reset",
                     Q => "Tag_Status",
                     CV => "Tag_Value");
```

When a positive signal edge is detected in the signal state of the operand "Tag_CU" and the current counter value is less than "999", the counter value is incremented by one. When a positive signal edge is detected in the signal state of the operand "Tag_CD" and the current counter value is greater than "0", the counter value is decremented by one.

If the signal state of the operand "Tag_1" changes from "0" to "1", the counter value is set in BCD format to the value of the operand "Tag_PresetValue". The counter value is reset to "0" when the operand "Tag_Reset" has signal state "1".

The current counter value is stored in the operand "Tag_Value".

The operand "Tag_Status" returns signal state "1" as long as the current counter value is not equal to "0". The current counter value is returned in the "Tag_Value" operand and as a function value.

Overview of the valid data types (Page 1908)

Comparator operations

TypeOf: Check data type of a VARIANT tag

Description

You can use the "Check data type of a VARIANT tag" instruction to query the data type of a tag to which a VARIANT tag is pointing. You can compare the data type of the <Operand> tag that you have declared in the block interface either to the data type of another tag or directly with a data type to determine whether they are "Equal" or "Not equal".

The operand must have the VARIANT data type. The comparison operand can be an elementary data type or a PLC data type.

You can only use the "Check data type of a VARIANT tag" instruction within an IF instruction.

Syntax

The following syntax is used for the "Check data type of a VARIANT tag" instruction:

SCL

```
TypeOf(<Operand>)
```

Parameters

The following table shows the parameters of the "Check data type of a VARIANT tag" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand>	Input	VARIANT	I, Q, M, L	First operand

For additional information on valid data types, refer to "See also".

Example

The following example shows the comparison with another tag:

SCL

```
IF TypeOf(#TagVARIANT) = TypeOf("TagBYTE") THEN
...;
END_IF;
```

The following example shows the comparison with a data type:

SCL

```
IF TypeOf(#TagVARIANT) = BYTE THEN
...;
END_IF;
```

If the operand to which the VARIANT #TagVARIANT is pointing has the BYTE data type, the comparison condition has been met.

See also

Overview of the valid data types (Page 1908)

Programming example: Programming queues (FIFO) (Page 270)

TypeOfElements: Check data type of an ARRAY element of a VARIANT tag

Description

You can use the "Check data type of an ARRAY element of a VARIANT tag" instruction to query the data type of a tag to which a VARIANT tag is pointing. You compare the data type of the tag to the data type of a tag that you have declared in the block interface to determine whether they are "Equal" or "Not equal".

The operand must have the VARIANT data type. The comparison operand can be an elementary data type or a PLC data type.

If the data type of the VARIANT tag is an ARRAY, the data type of the ARRAY elements is compared.

You can only use the instruction within an IF instruction.

Syntax

The following syntax is used for the "Check data type of an ARRAY element of a VARIANT tag" instruction:

SCL

```
TypeOfElements(<Operand>)
```

Parameters

The following table shows the parameters of the "Check data type of an ARRAY element of a VARIANT tag" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand>	Input	VARIANT	I, Q, M, L	First operand

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
IF TypeOfElements(#Tag_VARIANT) = TypeOf("GlobalDB".Product[1]) THEN
"Tag_Result" := "GlobalDB".Product[1] * 3;
END_IF;
```

The following table shows how the instruction works using specific operand values:

Operand	Value
#Tag_VARIANT	1.5
"GlobalDB".Product[1]	3.5

If the tag to which the VARIANT points and the "GlobalDB".Product[1] operand have the REAL data type, the "GlobalDB".Product[1] operand is then multiplied by 3 and the result is written to the "Tag_Result" operand.

Overview of the valid data types (Page 1908)

Programming example: Programming queues (FIFO) (Page 270)

IS_ARRAY: Check for ARRAY

Description

You can use the "Check for ARRAY" instruction to query whether the VARIANT points to a tag of the ARRAY data type.

The <Operand> must have the VARIANT data type.

You can only use the "Check for ARRAY" instruction within an IF instruction.

Syntax

The following syntax is used for the "Check for ARRAY" instruction:

SCL

```
IS_ARRAY(<Operand>)
```

Parameters

The following table shows the parameters of the "Check for ARRAY" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand>	Input	VARIANT	I, Q, M, L	Operand that is queried for ARRAY
Function value		UDINT	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
IF IS_ARRAY(#Tag_VARIANTToArray) THEN
"Tag_Result" := CountOfElements(#Tag_VARIANT);
END_IF;
```

If the tag to which the VARIANT points is an ARRAY, the number of ARRAY elements is output.

Programming example: Programming queues (FIFO) (Page 270)

Math functions

ABS: Form absolute value

Description

Use the "Form absolute value" instruction to calculate the absolute value of an input value and to save the result in the specified operands.

Syntax

Use the following syntax for the "Form absolute value" instruction:

SCL

```
ABS(<Expression>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Expression>	Input	SINT, INT, DINT, floating-point numbers	SINT, INT, DINT, LINT, floating-point numbers	I, Q, M, D, L, P	Input value
Function value		SINT, INT, DINT, floating-point numbers	SINT, INT, DINT, LINT, floating-point numbers	I, Q, M, D, L, P	Absolute value of the input value

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result1" := ABS("Tag_Value");
"Tag_Result2" := ABS("Tag_Value1"*"Tag_Value2");
```

The absolute value of the input value is returned in the format of the input value as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	-2
Tag_Result1	2
Tag_Value1	4
Tag_Value2	-1
Tag_Result2	4

See also

Overview of the valid data types (Page 1908)

MIN: Get minimum

Description

The "Get minimum" instruction compares the values of the available inputs and returns the lowest value as the result.

A minimum of two and a maximum of 32 inputs can be specified at the instruction.

The result is invalid if any of the following conditions are met:

- The implicit conversion of the data types fails during execution of the instruction.
- A floating-point number has an invalid value.

Syntax

The following syntax is used for the "Get minimum" instruction:

```
SCL
MIN(IN1:= <Operand>,
    IN2 := <Operand>)
```

Parameter

The following table shows the parameters of the "Get minimum" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	First input value
IN2	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	Second input value
INn	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	Additionally inserted inputs whose values are to be compared
Function value		Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	Result of the instruction
The data types TOD, LTOD, DATE, and LDT can only be used if the IEC test is not enabled.					

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := MIN(IN1 := "Tag_Value1",
                    IN2 := "Tag_Value2",
                    IN3 := "Tag_Value3");
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN1	Tag_Value1	12222
IN2	Tag_Value2	14444
IN3	Tag_Value3	13333
Function value	Tag_Result	12222

The instruction compares the values of the available inputs and copies the lowest value ("Tag_Value1") to operand "Tag_Result".

See also

Overview of the valid data types (Page 1908)

MAX: Get maximum

Description

The "Get maximum" instruction compares the values of the available inputs and returns the greatest value as the result.

A minimum of two and a maximum of 32 inputs can be specified at the instruction.

The result is invalid if any of the following conditions are met:

- The implicit conversion of the data types fails during execution of the instruction.
- A floating-point number has an invalid value.

Syntax

The following syntax is used for the "Get maximum" instruction:

```
SCL
MAX(IN1:= <Operand>,
    IN2 := <Operand>)
```

Parameters

The following table shows the parameters of the "Get maximum" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	First input value
IN2	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	Second input value
INn	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	Additionally inserted inputs whose values are to be compared
Function value		Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	Result of the instruction
The data types TOD, LTOD, DATE, and LDT can only be used if the IEC test is not enabled.					

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := MAX(IN1 := "Tag_Value1",
                    IN2 := "Tag_Value2",
                    IN3 := "Tag_Value3");
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN1	Tag_Value1	12 222
IN2	Tag_Value2	14 444
IN3	Tag_Value3	13 333
Function value	Tag_Result	14 444

The instruction compares the values of the specified operands and copies the greatest value ("Tag_Value2") to the operand "Tag_Result".

See also

Overview of the valid data types (Page 1908)

LIMIT: Set limit value

Description

The "Set limit value" instruction limits the value of the parameter IN to the values of the parameters MN and MX. The value of the parameter MN may not be greater than the value of the parameter MX.

If the value of the IN parameter fulfills the MN condition <=IN <= MX, it is returned as the result of the instruction. If the condition is not fulfilled and the IN input value is less than the MN low limit, the value of the MN parameter is returned as the result. If the high limit MX is exceeded, the value of the MX parameter is returned as the result.

If the value of the MN input is greater than the value of the MX input, the result is undefined.

The instruction is only executed if the operands of all parameters are of the same data type.

Syntax

The following syntax is used for the "Set limit value" instruction:

SCL

```
LIMIT(MN := <Operand>,
      IN := <Operand>,
      MX := <Operand>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
MN	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	Low limit
IN	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	Input value
MX	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	High limit
Function value		Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	Result of the instruction
The data types TOD, LTOD, DATE, and LDT can only be used if the IEC test is not enabled.					

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := LIMIT(MN := "Tag_Minimum",
                      IN := "Tag_Value",
                      MX := "Tag_Maximum");
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
MN	Tag_Minimum	12 000
IN	Tag_Value	8 000
MX	Tag_Maximum	16 000
Function value	Tag_Result	12 000

The value of operand "Tag_Value" is compared with the values of operands "Tag_Minimum" and "Tag_Maximum". Because the value of the operand "Tag_Value" is less than the low limit value, the value of operand "Tag_Minimum" will be copied to operand "Tag_Result".

Overview of the valid data types (Page 1908)

SQR: Form square

Description

Use the "Form square" instruction to square the input value and save the result in the specified operand.

Syntax

Use the following syntax for the instruction "Form square":

SCL

```
SQR(<Expression>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value
Function value		Floating-point numbers	I, Q, M, D, L, P	Square of the input value

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result1" := SQR("Tag_Value");
"Tag_Result2" := SQR((SQR("Tag_Value1"))*"Tag_Value2");
```

The square of the input value is returned in the operand "Tag_Resultxy" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	2.5
Tag_Result1	6.25
Tag_Value1	6.0
Tag_Value2	2.0
Tag_Result2	5184.0

See also

Overview of the valid data types (Page 1908)

SQRT: Form square root

Description

Use the "Form square root" instruction to calculate the square root of the input value and save the result in the specified operand. The instruction has a positive result if the input value is greater than zero. If input values are less than zero, the instruction returns an invalid floating-point number. If the input value is "0", the result is also "0".

Syntax

The following syntax is used for the "Form square root" instruction:

SCL

```
SQRT(<Expression>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value
Function value		Floating-point numbers	I, Q, M, D, L, P	Square root of the input value

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result1" := SQRT("Tag_Value");
"Tag_Result2" := SQRT((SQR("Tag_Value1"))+"Tag_Value2");
```

The square root of the input value is returned in the operand "Tag_Resultxy" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	4.0
Tag_Result1	2.0
Tag_Value1	3.0
Tag_Value2	16.0
Tag_Result2	5.0

See also

Overview of the valid data types (Page 1908)

LN: Form natural logarithm

Description

You can use the "Form natural logarithm" instruction to calculate the natural logarithm to base e (e=2.718282) from the input value. The instruction has a positive result if the input value is greater than zero. If input values are less than zero, the instruction returns an invalid floating-point number.

Syntax

The following syntax is used for the "Form natural logarithm" instruction:

SCL

```
LN(<Expression>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value
Function value		Floating-point numbers	I, Q, M, D, L, P	Natural logarithm of the input value

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result1" := LN("Tag_Value");
"Tag_Result2" := LN("Tag_Value1"+"Tag_Value2");
```

The result of the instruction is returned in the operand "Tag_Resultxy" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	2.5
Tag_Result1	0.916
Tag_Value1	1.5
Tag_Value2	3.2
Tag_Result2	1.548

See also

Overview of the valid data types (Page 1908)

EXP: Form exponential value

Description

The "Form exponential value" instruction calculates the exponent from the base e (e = 2,718282) and the input value and saves the result in the specified operand.

Syntax

The following syntax is used for the "Form exponential value" instruction:

SCL

```
EXP(<Expression>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value
Function value		Floating-point numbers	I, Q, M, D, L, P	Exponential value of the input value

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result1" := EXP("Tag_Value");
"Tag_Result2" := EXP("Tag_Value1"/"Tag_Value2");
```

The result of the instruction is returned in the operand "Tag_Resultxy" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	20.5
Tag_Result1	799 902 200
Tag_Value1	15.5
Tag_Value2	30.2
Tag_Result2	1.671

See also

Overview of the valid data types (Page 1908)

SIN: Form sine value

Description

Use the "Form sine value" instruction to calculate the sine of the input value. The input value must be given in radians.

Syntax

Use the following syntax for the "Form sine value" instruction:

SCL

```
SIN(<Expression>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value (size of an angle in radians)
Function value		Floating-point numbers	I, Q, M, D, L, P	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := SIN("Tag_Value");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	+1.570796 (π/2)
Tag_Result	1.0

See also

Overview of the valid data types (Page 1908)

COS: Form cosine value

Description

Use the "Form cosine value" instruction to calculate the cosine of the input value. The input value must be given in radians.

Syntax

Use the following syntax for the "Form cosine value" instruction:

SCL

```
COS(<Expression>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value (size of an angle in radians)
Function value		Floating-point numbers	I, Q, M, D, L, P	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := COS("Tag_Value");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	+1.570796 (π/2)
Tag_Result	0

See also

Overview of the valid data types (Page 1908)

TAN: Form tangent value

Description

Use the "Form tangent value" instruction to calculate the sine of the input value. The input value must be given in radians.

Syntax

Use the following syntax for the "Form tangent value" instruction:

SCL

```
TAN(<Expression>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value (size of an angle in radians)
Function value		Floating-point numbers	I, Q, M, D, L, P	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := TAN("Tag_Value");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	+3.141593 (π)
Tag_Result	0

See also

Overview of the valid data types (Page 1908)

ASIN: Form arcsine value

Description

You can use the "Form arcsine value" instruction to calculate the size of the angle from a sine value, which corresponds to this value. Only valid floating-point numbers within the range -1 to +1 can be specified as input values. The calculated angle size is given in radians and can range in value from -π/2 to +π/2.

Syntax

Use the following syntax for the "Form arcsine value" instruction:

SCL

```
ASIN(<Expression>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Sine value
Function value		Floating-point numbers	I, Q, M, D, L, P	Size of angle in radians

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := ASIN("Tag_Value");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	1.0
Tag_Result	+1.570796 (π/2)

See also

Overview of the valid data types (Page 1908)

ACOS: Form arccosine value

Description

You can use the "Form arccosine value" instruction to calculate the size of the angle from a cosine value, which corresponds to this value. Only valid floating-point numbers within the range -1 to +1 can be specified as input values. The calculated angle size is given in radians and can range in value from 0 to +π.

Syntax

Use the following syntax for the "Form arccosine value" instruction:

SCL

```
ACOS(<Expression>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Cosine value
Function value		Floating-point numbers	I, Q, M, D, L, P	Size of angle in radians

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := ACOS("Tag_Value");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	0
Tag_Result	+1.570796 (π/2)

See also

Overview of the valid data types (Page 1908)

ATAN: Form arctangent value

Description

You can use the "Form arctangent value" instruction to calculate the size of the angle from a tangent value, which corresponds to this value. It is only permitted to specify valid floating-point numbers (or -NaN/+NaN) as input value. The calculated angle size is given in radians and can range in value from -π/2 to +π/2.

Syntax

The following syntax is used for the "Form arctangent value" instruction:

SCL

```
ATAN(<Expression>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Tangent value
Function value		Floating-point numbers	I, Q, M, D, L, P	Size of angle in radians

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := ATAN("Tag_Value");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	1.0
Tag_Result	+0.785398 (π/4)

See also

Overview of the valid data types (Page 1908)

Invalid floating-point numbers (Page 1927)

FRAC: Return fraction

Description

The result of the instruction "Return fraction" returns the decimal places of a value. Input value 123.4567, for example, returns the value 0.4567.

Syntax

The following syntax is used for the instruction "Return fraction":

SCL

```
FRAC(<Expression>)
FRAC_<Data type>(<Expression>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value
_<Data type>		Floating-point numbers Default: REAL	-	Data type of the function value: 1. You can specify the data type of the instruction explicitly using "_". 2. If you do not specify the data type explicitly, it will be determined by the utilized tags or type-coded constants. 3. If you neither specify the data type explicitly nor specify defined tags or type-coded constants, the default data type will be used.
Function value		Floating-point numbers	I, Q, M, D, L, P	Decimal places of the input value

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result1" := FRAC("Tag_Value");
"Tag_Result2" := FRAC_LREAL("Tag_Value");
```

The following table shows how the instruction works using specific operand values:

Operand	Value	
Tag_Value	2.555	-1.4421
Tag_Result1	0.555	-0.4421

See also

Overview of the valid data types (Page 1908)

Move operations

Deserialize: Deserialize

Description

You can use the "Deserialize" instruction to convert the sequential representation of a PLC data type (UDT) back to a PLC data type and to fill its entire contents.

The memory area in which the sequential representation of a PLC data type is located must have the ARRAY of BYTE data type and be declared with standard access. The capacity of the standard memory area is 64 KB. Make sure that there is enough memory space prior to the conversion.

The instruction enables you to convert multiple sequential representations of converted PLC data types back to their original state step-by-step.

If you only want to convert back a single sequential representation of a PLC data type (UDT), you can also use the instruction "TRCV: Receive data via communication connection" directly.

Note

Applies to CPUs of the S7-1500 series

For a block with the block property "Optimized block access", the bit has a length of 1 byte.

Syntax

The following syntax is used for the "Deserialize" instruction:

SCL

```
Deserialize(SRC_ARRAY := <Operand>,
            DEST_VARIABLE:= <Operand>,
            POS := <Operand>)
```

Parameters

The following table shows the parameters of the "Deserialize" instruction:

Parameter	Declaration	Data type	Memory area	Description
SRC_ARRAY	Input	VARIANT	I, Q, M, L	Global data block in which the generated data stream is stored
DEST_VARIABLE	InOut	VARIANT	I, Q, M, L	Tag in which the returned converted PLC data type (UDT) is stored
POS	InOut	DINT	I, Q, M, D, L	Number of bytes that the converted PLC data types use. The POS parameter is calculated zero-based.
Function value		INT	I, Q, M, D, L	Error information

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B0	The memory areas for the SRC_ARRAY and DEST_VARIABLE parameters overlap.
8136	The data block at the DEST_VARIABLE parameter is not a block with standard access.
8150	The VARIANT data type at the SRC_ARRAY parameter contains no value.
8151	Code generation error at SRC_ARRAY parameter
8153	There is not enough free memory available at the SRC_ARRAY parameter.
8250	The VARIANT data type at the DEST_VARIABLE parameter contains no value.
8251	Code generation error at DEST_VARIABLE parameter
8254	Invalid data type at the DEST_VARIABLE parameter
8382	The value at the POS parameter is outside the limits of the array.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
#Tag_RetVal := Deserialize(SRC_ARRAY := "Buffer".Field,
                           DEST_VARIABLE := "Target".Client,
                           POS := #BufferPos);

#Tag_RetVal := Deserialize(SRC_ARRAY := "Buffer".Field,
                           DEST_VARIABLE := #Label,
```

SCL

```
                              POS := #BufferPos);

IF #Label = 'arti' THEN
#Tag_RetVal := Deserialize(SRC_ARRAY := "Buffer".Field,
                              DEST_VARIABLE := "Target".Article[#DeliverPos],
                              POS := #BufferPos);
ELSIF #Label = 'Bill' THEN
#Tag_RetVal := Deserialize(SRC_ARRAY := "Buffer".Field,
                              DEST_VARIABLE := "Target".Bill[#DeliverPos],
                              POS := #BufferPos);
;
ELSE
;
END_IF;
```

The "Deserialize" instruction deserializes the sequential representation of the customer data from the "Buffer" data block and writes it to the "Target" data block. The number of bytes occupied by the converted customer data is stored in the #BufferPos operand.

The "Deserialize" instruction deserializes the sequential representation of the separator sheet, which was stored in the sequential representation after the customer data, from the "Buffer" data block and writes the characters to the #Label operand. The characters are compared using comparison instructions for "arti" and "Bill". If the comparison for "arti" = TRUE, these are article data that have been deserialized and written to the "Target" data block. If the comparison for "Bill" = TRUE, these are billing data that have been deserialized and written to the "Target" data block.

The following table shows the declaration of the operands:

Operand	Data type	Declaration
DeliverPos	INT	In the "Input" section of the block interface
BufferPos	DINT	In the "Temp" section of the block interface
Error	INT	In the "Temp" section of the block interface
Label	STRING[4]	In the "Temp" section of the block interface

The following table lists the declarations of the PLC data types:

Name of the PLC data types	Name	Data type
Article	Number	DINT
	Declaration	STRING
	Colli	INT
Client	Title	INT
	First name	STRING[10]
	Surname	STRING[10]

The following table shows the declaration of the data blocks:

Name of the data blocks	Name	Data type
Target	Client	"Client" (PLC data type)
	Article	Array[0..10] of "Article" (PLC data type)
	Bill	Array[0..10] of INT
Buffer	Field	Array[0..294] of BYTE

Overview of the valid data types (Page 1908)

PLC data types (Page 1954)

Serialize: Serialize

Description

You can use the "Serialize" instruction to convert several PLC data types (UDT) to a sequential representation without losing parts of their structure.

You can use the instruction to temporarily save multiple structured data items from your program in a buffer, which should preferably be in a global data block, and send them to another CPU. The memory area in which the converted PLC data types are stored must have the ARRAY of BYTE data type and be declared with standard access. The capacity of the standard memory area is 64 KB. Make sure that there is enough memory space prior to the conversion.

The operand at the POS parameter contains information about the number of bytes used by the converted PLC data types.

If you want to send a single PLC data type (UDT), you can directly call the instruction "TSEND: Send data via communication connection".

Note

Applies to CPUs of the S7-1500 series

For a block with the block property "Optimized block access", the bit has a length of 1 byte.

Syntax

The following syntax is used for the "Serialize" instruction:

SCL

```
Serialize(SRC_VARIABLE := <Operand>,
          DEST_ARRAY := <Operand>,
          POS := <Operand>)
```

Parameters

The following table shows the parameters of the "Serialize" instruction:

Parameter	Declaration	Data type	Memory area	Description
SRC_VARIABLE	Input	VARIANT	I, Q, M, L	PLC data type (UDT) that is converted to sequential representation.
DEST_ARRAY	InOut	VARIANT	I, Q, M, L	Data block in which the generated data stream is stored.
POS	InOut	DINT	I, Q, M, D, L	Number of bytes that the converted PLC data types use. The POS parameter is calculated zero-based.
Function value		INT	I, Q, M, D, L	Error information

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B0	The memory areas for the SRC_VARIABLE and DEST_ARRAY parameters overlap.
8150	The VARIANT data type at the SRC_VARIABLE parameter contains no value.
8152	Code generation error at SRC_VARIABLE parameter
8236	The data block at the DEST_ARRAY parameter is not a block with standard access.
8250	The VARIANT data type at the DEST_ARRAY parameter contains no value.
8252	Code generation error at DEST_ARRAY parameter
8253	There is not enough free memory available at the DEST_ARRAY parameter.
8254	Invalid data type at the DEST_ARRAY parameter
8382	The value at the POS parameter is outside the limits of the array.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
#Tag_RetVal := Serialize(SRC_VARIABLE := "Source".Client,
                         DEST_ARRAY := "Buffer".Field,
                         POS := #BufferPos);

#Label := STRING_TO_WSTRING('arti');
```

SCL

```
#Tag_RetVal := Serialize(SRC_VARIABLE := #Label,
                         DEST_ARRAY := "Buffer".Field,
                         POS := #BufferPos);

#Tag_RetVal := Serialize(SRC_VARIABLE := "Source".Article[#DeliverPos],
                         DEST_ARRAY := "Buffer".Field,
                         POS := #BufferPos);
```

The "Serialize" instruction serializes the customer data from the "Source" data block and writes them in sequential representation to the "Buffer" data block. The number of bytes occupied by the sequential representation is stored in the #BufferPos operand.

A kind of separator sheet is inserted now to make it easier to deserialize the sequential representation later. The "Move character string" instruction moves the "arti" characters to the #Label operand. The "Serialize" instruction writes these characters after the customer data to the "Buffer" data block. The number of bytes that the characters need is added to the number already stored in the #BufferPos operand.

The "Serialize" instruction serializes the data of a specific article, which is calculated in runtime, from the "Source" data block and writes them in sequential representation to the "Buffer" data block after the "arti" characters.

The following table shows the declaration of the operands:

Operand	Data type	Declaration
DeliverPos	INT	In the "Input" section of the block interface
BufferPos	DINT	In the "Temp" section of the block interface
Error	INT	In the "Temp" section of the block interface
Label	STRING[4]	In the "Temp" section of the block interface

The following table lists the declarations of the PLC data types:

Name of the PLC data types	Name	Data type
Article	Number	DINT
	Declaration	STRING
	Colli	INT
Client	Title	INT
	First name	STRING[10]
	Surname	STRING[10]

The following table shows the declaration of the data blocks:

Name of the data blocks	Name	Data type
Source	Client	"Client" (PLC data type)
	Article	Array[0..10] of "Article" (PLC data type)
Buffer	Field	Array[0..294] of BYTE

MOVE_BLK: Move block

Description

You can use the "Move block" instruction to move the content of a memory area (source area) to another memory area (destination area). The number of elements to be copied to the destination area is specified with the COUNT parameter. The width of the elements to be moved is defined by the width of the first element in the source area.

The instruction can only be executed if the source area and the destination area have the same data type.

The value of the OUT output is invalid if the following condition is met:

- More data is moved than is made available at the IN parameter or OUT parameter.

Syntax

The following syntax is used for the "Move block" instruction:

SCL

```
MOVE_BLK(IN := <Operand>,
         COUNT := <Operand>,
         OUT => <Operand>)
```

Parameter

The following table shows the parameters of the "Move block" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN [1]	Input	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	The first element of the source area that is being copied
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P	Number of elements to be copied from the source area to the destination area
OUT [1]	Output	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	The first element of the destination area to which the contents of the source area are being copied
[1] The specified data types can only be used as elements of an ARRAY structure.					

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
MOVE_BLK(IN := #a_array[2],
         COUNT := "Tag_Count",
         OUT => #b_array[1]);
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	a_array[2]	The data type of the a_array operand is ARRAY [0..5] of INT. It consists of six elements of data type INT.
COUNT	Tag_Count	3
OUT	b_array[1]	The data type of the b_array operand is ARRAY [0..6] of INT. It consists of seven elements of data type INT.

Starting from the third element, the instruction selects three INT elements from the #a_array tag and copies their contents to the #b_array output tag, beginning with the second element.

See also

Overview of the valid data types (Page 1908)

MOVE_BLK_VARIANT: Move block

Description

You can use the "Move block" instruction to move the content of a memory area (source area) to another memory area (destination area). You can copy a complete ARRAY or elements of an ARRAY to another ARRAY of the same data type. The size (number of elements) of source and destination ARRAY may be different. You can copy multiple or single elements within an ARRAY.

When you use the instruction at the time to the block is created, the ARRAY does not yet have to be known, as the source and the designation are transferred per VARIANT.

Counting at the parameters SRC_INDEX and DEST_INDEX always begins with the low limit "0", regardless of the later declaration of the ARRAY.

The instruction is not executed if more data is copied than is made available.

Note

VARIANT in connection with the BOOL data type

If you want to interconnect a parameter of VARIANT data type (source or destination area) with a tag of BOOL data type or an ARRAY of BOOL, you have the following options:

1. You can address it symbolically
   Example: Parameter SRC: "Data_block".myArray
2. You can address it with help of ANY pointer. However, you must note that the specified length of the area must be dividable by 8, or the instruction will otherwise not be executed.
   Example: Parameter SRC: P#DB123.DBX456.0 BOOL 1000

Syntax

The following syntax is used for the "Move block" instruction:

SCL

```
MOVE_BLK_VARIANT(SRC := <Operand>,
                 COUNT := <Operand>,
                 SRC_INDEX := <Operand>,
                 DEST_INDEX := <Operand>,
                 DEST => <Operand>)
```

Parameters

The following table shows the parameters of the "Move block" instruction:

Parameter	Declaration	Data type	Memory area	Description
SRC	Input	VARIANT (which points to an ARRAY or an individual ARRAY element), ARRAY of <Data_type>	I, Q, M, L	Source block from which to copy
COUNT	Input	UDINT	I, Q, M, D, L	Number of elements which are copied Assign the value "1" to the parameter COUNT, if no SRC is specified at parameter DEST or at Parameter ARRAY.
SRC_INDEX	Input	DINT	I, Q, M, D, L	• The SRC_INDEX parameter is calculated zero-based. If an SRC is specified at parameter ARRAY, the integer at parameter SRC_INDEX specifies the first element within the source range from which it is to be copied. Independent of the declared ARRAY limits. • If no SRC is specified at parameter ARRAY or only one single element of an ARRAY is specified, then assign the value "0" at parameter SRC_INDEX.

Parameter	Declaration	Data type	Memory area	Description
DEST_INDEX	Input	DINT	I, Q, M, D, L	• The DEST_INDEX parameter is calculated zero-based. If an DEST is specified at parameter ARRAY, the integer at parameter DEST_INDEX specifies the first element within the target range to it is to be copied. Independent of the declared ARRAY limits. • If no DEST is specified at parameter ARRAY, then assign the value "0" at parameter DEST_INDEX.
DEST	Output 1)	VARIANT	I, Q, M, L	Destination area into which the contents of the source block are copied.
Function value (RET_VAL)		INT	I, Q, M, D, L	Error information
1) The DEST parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	Data types do not correspond
8151	Access to the SRC parameter is not possible.
8152	The operand at the SRC parameter is not typed.
8153	Code generation error at SRC parameter
8154	The operand at the SRC parameter has the data type BOOL.
8281	The COUNT parameter has an invalid value
8382	The value at the SRC_INDEX parameter is outside the limits of the VARIANT.
8383	The value at parameter SRC_INDEX is outside the high limit of the ARRAY.
8482	The value at the DEST_INDEX parameter is outside the limits of the VARIANT.
8483	The value at parameter DEST_INDEX is outside the high limit of the ARRAY.
8534	The DEST parameter is write protected
8551	Access to the DEST parameter is not possible.
8552	The operand at the DEST parameter is not typed.
8553	Code generation error at DEST parameter

Error code* (W#16#...)	Explanation
8554	The operand at the DEST parameter has the data type BOOL.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := MOVE_BLK_VARIANT(SRC := #SrcField,
                                 COUNT := "Tag_Count",
                                 SRC_INDEX := "Tag_Src_Index",
                                 DEST_INDEX := "Tag_Dest_Index",
                                 DEST => #DestField);
```

The following table shows how the instruction works using specific operand values:

Parameter	Declaration in the block interface	Operand	Value
SRC	Input	#SrcField	The local operand #SrcField uses a PLC data type that was still unknown at the time when the block was programmed. (ARRAY[0..10] of "MOVE_UDT"
COUNT	Input	Tag_Count	2
SRC_INDEX	Input	Tag_Src_Index	3
DEST_INDEX	Input	Tag_Dest_Index	3
DEST	InOut	#DestField	The local operand #DestField uses a PLC data type that was still unknown at the time when the block was programmed. (ARRAY[10..20] of "MOVE_UDT"

Two elements are moved from the source area, starting from the fourth element of the ARRAY of UDT, to the destination area. The copies are inserted in the array of UDT starting from the fourth element.

Programming example: Moving data (Page 267)

UMOVE_BLK: Move block uninterruptible

Description

You can use the "Move block uninterruptible" instruction to move the content of a memory area (source area) to another memory area (destination area). The instruction cannot be interrupted. The number of elements to be copied to the destination area is specified with the COUNT parameter. The width of the elements to be moved is defined by the width of the first element in the source area.

The instruction can only be executed if the source area and the destination area have the same data type.

Note

The move operation cannot be interrupted by other operating system activities. This is why the interrupt reaction times of the CPU increase during the execution of the "Move block uninterruptible" instruction.

The value of the OUT output is invalid if the following condition is met:

- More data is moved than is made available at the IN parameter or OUT parameter.

You can use the "Move block uninterruptible" instruction to move a maximum of 16 KB. Note the CPU-specific restrictions for this.

Syntax

The following syntax is used for the "Move block uninterruptible" instruction:

SCL

```
UMOVE_BLK(IN := <Operand>,
          COUNT := <Operand>,
          OUT => <Operand>)
```

Parameter

The following table shows the parameters of the "Move block uninterruptible" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN [1]	Input	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	The first element of the source area that is being copied
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P	Number of elements to be copied from the source area to the destination area
OUT [1]	Output	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	The first element of the destination area to which the contents of the source area are being copied
[1] The specified data types can only be used as elements of an ARRAY structure.					

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
UMOVE_BLK(IN := #a_array[2],
          COUNT := "Tag_Count",
          OUT => #b_array[1]);
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	a_array[2]	The data type of the a_array operand is ARRAY [0..5] of INT. It consists of six elements of data type INT.
COUNT	Tag_Count	3
OUT	b_array[1]	The data type of the b_array operand is ARRAY [0..6] of INT. It consists of seven elements of data type INT.

Starting from the third element, the instruction selects three INT elements from the #a_array tag and copies their contents to the #b_array output tag, beginning with the second element. The copy operation cannot be interrupted by other operating system activities.

See also

Overview of the valid data types (Page 1908)

FILL_BLK: Fill block

Description

The "Fill block" instruction is used to copy the content of a memory area (source area) to a selected memory area (target area). The number of repeated copy operations is specified with the COUNT parameter. When the instruction is executed, the source area is selected and moved to the destination area as often as specified by the value of the COUNT parameter.

The instruction can only be executed if the source area and the destination area have the same data type.

The value of the OUT output is invalid if the following condition is met:

- More data is moved than is made available at input IN or output OUT.

Syntax

The following syntax is used for the "Fill block" instruction:

SCL

```
FILL_BLK(IN := <Operand>,
         COUNT := <Operand>,
         OUT => <Operand>)
```

Parameter

The following table shows the parameters of the "Fill block" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN [1]	Input	Binary numbers, integers, floating-point numbers, timers, TOD, DATE, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	I, Q, M, D, L, P	Element used to fill the destination area
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P	Number of repeated copy operations
OUT [2]	Output	Binary numbers, integers, floating-point numbers, timers, TOD, DATE, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	Address in destination area from which filling starts
[1] The specified data types can also be used as elements of an ARRAY structure.					
[2] The specified data types can only be used as elements of an ARRAY structure.					

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
FILL_BLK(IN := #a_array[2],
         COUNT := "Tag_Count",
         OUT => #b_array[1]);
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	a_array[2]	The data type of the a_array operand is ARRAY [0..5] of INT. It consists of six elements of data type INT.
COUNT	Tag_Count	3
OUT	b_array[1]	The data type of the b_array operand is ARRAY [0..6] of INT. It consists of seven elements of data type INT.

The instruction copies the third element (#a_array[2]) of the #a_array tag three times to the #b_array output tag.

See also

Overview of the valid data types (Page 1908)

UFILL_BLK: Fill block uninterruptible

Description

The instruction "Fill block uninterruptible" is used to copy the content of a memory area (source area) to a selected memory area (target area). The number of repeated copy operations is specified with the COUNT parameter. When the instruction is executed, the value at the IN input is selected and copied to the destination area as often as specified by the value in the COUNT parameter.

The instruction can only be executed if the source area and the destination area have the same data type.

Note

The move operation cannot be interrupted by other operating system activities. This is why the interrupt reaction times of the CPU increase during the execution of the "Fill block uninterruptible" instruction.

The value of the OUT output is invalid if the following condition is met:

- More data is moved than is made available at input IN or output OUT.

You can use the "Fill block uninterruptible" instruction to move a maximum of 16 KB. Note the CPU-specific restrictions for this.

Syntax

The following syntax is used for the "Fill block uninterruptible" instruction:

SCL

```
UFILL_BLK(IN := <Operand>,
          COUNT := <Operand>,
          OUT => <Operand>)
```

Parameter

The following table shows the parameters of the "Fill block uninterruptible" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN [1]	Input	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	I, Q, M, D, L, P	Element used to fill the destination area
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P	Number of repeated copy operations
OUT [2]	Output	Binary numbers, integers, floating-point numbers, timers, TOD, DATE, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	Address in destination area from which filling starts
[1] The specified data types can also be used as elements of an ARRAY structure.					
[2] The specified data types can only be used as elements of an ARRAY structure.					

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
UFILL_BLK(IN := #a_array[2],
          COUNT := "Tag_Count",
          OUT => #b_array[1]);
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	a_array[2]	The data type of the a_array operand is ARRAY [0..5] of INT. It consists of six elements of data type INT.
COUNT	Tag_Count	3
OUT	b_array[1]	The data type of the b_array operand is ARRAY [0..6] of INT. It consists of seven elements of data type INT.

The instruction copies the third element (#a_array[2]) of the #a_array tag three times to the #b_array output tag. The copy operation cannot be interrupted by other operating system activities.

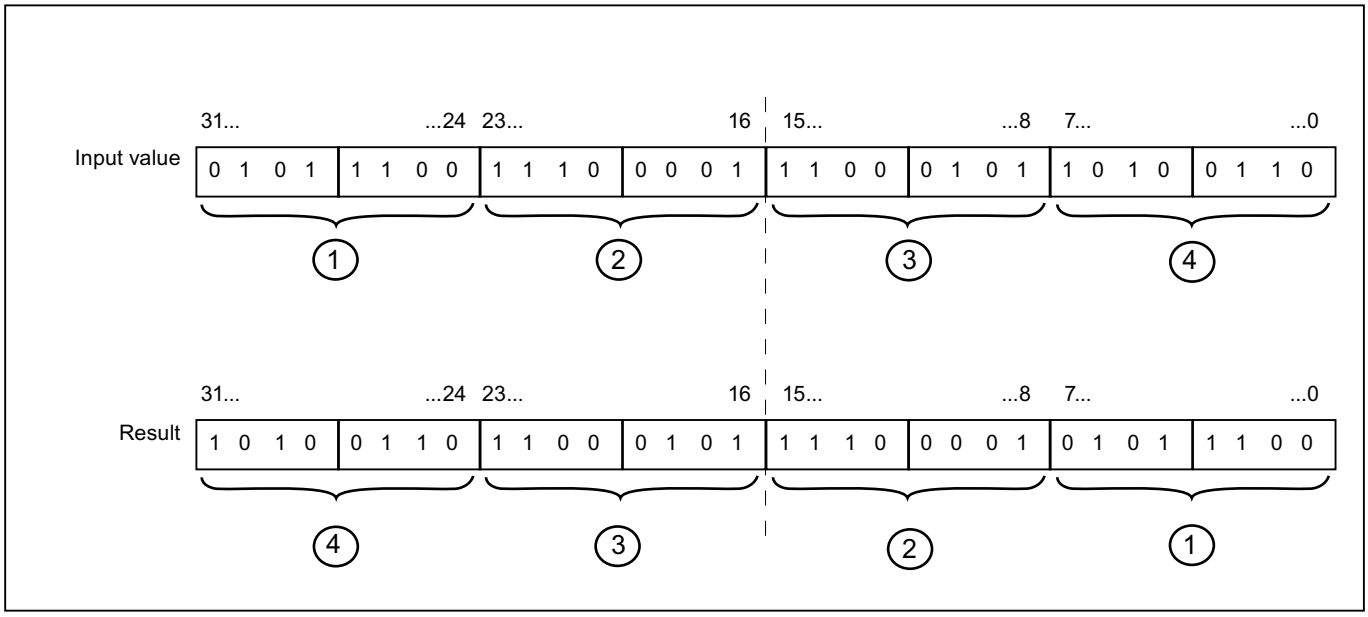
SWAP: Swap

Description

You can use the "Swap" instruction to change the arrangement of the bytes of an input value and save the result in the specified operand.

The following figure shows how the bytes of an operand of the DWORD data type are swapped using the "Swap" instruction:



Syntax

The following syntax is used for the "Swap" instruction:

SCL

```
SWAP(<Expression>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Expression>	Input	WORD, DWORD	WORD, DWORD, LWORD	I, Q, M, D, L, P	Input value
Function value		WORD, DWORD	WORD, DWORD, LWORD	I, Q, M, D, L, P	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := SWAP("Tag_Value");
```

The result of the instruction is returned as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	0000 1111 0101 0101
Tag_Result	0101 0101 0000 1111

Overview of the valid data types (Page 1908)

ARRAY DB

ReadFromArrayDB: Read from array data block

Description

The "Read from array data block" instruction is used to read data from an ARRAY data block and write it to a destination area.

An ARRAY data block is a data block that consists of exactly one ARRAY of [Data type]. The elements of the ARRAY can be of data type PLC or any other elementary data type. The

counting at the ARRAY always begins with the low limit "0", regardless of the later declaration of the ARRAY.

Syntax

The following syntax is used for the "Read from array data block" instruction:

SCL

```
ReadFromArrayDB(DB := <Operand>,
                INDEX := <Operand>,
                VALUE => <Operand>)
```

Parameters

The following table shows the parameters of the "Read from array data block" instruction:

Parameter	Declaration	Data type	Memory area	Description
DB	Input	DB_ANY	I, Q, M, D, L	Data block that is read
INDEX	Input	DINT	I, Q, M, D, L, P	Element that is read
VALUE	Output [1)]	VARIANT	I, Q, M, L	Value that is read and output
Function value (RET_VAL)		INT	I, Q, M, D, L	Result of the instruction
1) The VALUE parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
80B5	The copying was interrupted.
8132	The data block does not exist, is too short, write protected, or is located in load memory.
8135	The ARRAY data block contains invalid values.
8154	The data block has the incorrect data type.
8282	The value at parameter INDEX is outside the limits of the ARRAY.
8450	The data type VARIANT at parameter VALUE provides the value "0".
8452	Code generation error
8453	The size of the VALUE parameter does not match the element length in the ARRAY data block.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
"TagResult" := ReadFromArrayDB(DB := "ArrayDB",
                               INDEX := "ArrayDB"."THIS"[2],
                               VALUE => "TargetField[10]".Data2[1]);
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
DB	ArrayDB	The data type of the "ArrayDB" operand is Array [0 to 10] of INT.
INDEX	ArrayDB."THIS"[2]	Third element of the "ArrayDB"
VALUE	"TargetField[10]".Data2[1]	The data type of the "Target-Field" operand is Array [10 to 20] of "MOVE_UDT".

The third element is read from "ArrayDB" and written to the "TargetField[10]".Data2[1] operand.

Using ARRAY data blocks (Page 239)

WriteToArrayDB: Write to array data block

Description

The instruction "Write to array data block" is used to write data to an ARRAY data block.

An ARRAY data block is a data block that consists of exactly one ARRAY of [Data type]. The elements of the ARRAY can be of data type PLC or any other elementary data type. The counting at the ARRAY always begins with the low limit "0", regardless of the later declaration of the ARRAY.

Syntax

The following syntax is used for the "Write to array data block" instruction:

SCL

```
WriteToArrayDB(DB := <Operand>,
               INDEX := <Operand>,
               VALUE := <Operand>)
```

Parameters

The following table shows the parameters of the "Write to array data block" instruction:

Parameter	Declaration	Data type	Memory area	Description
DB	Input	DB_ANY	I, Q, M, D, L	Data block to which data is written
INDEX	Input	DINT	I, Q, M, D, L, P	Element in the DB to which data is written
VALUE	Input	VARIANT	I, Q, M, L	Value to be written
Function value (RET_VAL)		INT	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
80B5	The copying was interrupted.
8132	The data block does not exist, is too short, or is located in load memory.
8134	The data block is write protected.
8135	The data block is not an ARRAY data block.
8154	The data block has the incorrect data type.
8282	The value at parameter INDEX is outside the limits of the ARRAY.
8350	The data type VARIANT at parameter VALUE provides the value "0".
8352	Code generation error
8353	The size of the VALUE parameter does not match the element length in the ARRAY data block.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
"TagResult" := WriteToArrayDB(DB := "ArrayDB",
                              INDEX := "ArrayDB"."THIS"[2],
                              VALUE := "SourceField[1]".Data1[6]);
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
DB	ArrayDB	The data type of the "ArrayDB" operand is Array [0 to 10] of INT.
INDEX	ArrayDB."THIS"[2]	Third element of the "ArrayDB"
VALUE	"SourceField[1]".Data1[6]	The data type of the "SourceField" operand is Array [0 to 10] of "MOVE_UDT".

From the "SourceField" operand, the "Data1[6]" element from the second element is written to the "ArrayDB". The third element is written to the "ArrayDB".

Using ARRAY data blocks (Page 239)

ReadFromArrayDBL: Read from array data block in load memory

Description

The instruction "Read from array data block in load memory" is used to read data from an ARRAY data block in the load memory.

An ARRAY data block is a data block that consists of exactly one ARRAY of [Data type]. The elements of the ARRAY can be of data type PLC or any other elementary data type. The counting at the ARRAY always begins with the low limit "0", regardless of the later declaration of the ARRAY.

If the ARRAY data block has been designated with the block attribute "Only store in load memory", it will only be stored in the load memory.

The instruction is executed when a positive signal edge is detected at the REQ parameter. The BUSY parameter then has the signal state "1". The instruction is terminated if a negative signal edge is detected at the BUSY parameter. The DONE parameter has the signal state "1" for one program cycle and the read value is output at the VALUE parameter within this cycle. With all other program cycles, the value at the VALUE parameter is not changed.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

Note

The ARRAY data block must be created with the "Optimized" block property.

Syntax

The following syntax is used for the "Read from array data block in load memory" instruction:

SCL

```
"Instance DB"(REQ := <Operand>,
              DB := <Operand>,
              INDEX := <Operand>,
              VALUE := <Operand>,
              BUSY => <Operand>,
              DONE => <Operand>,
              ERROR => <Operand>)
```

Parameters

The following table shows the parameters of the "Read from array data block in load memory" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L	REQ = "1": Begin with the reading out of the ARRAY DB
DB	Input	DB_ANY	I, Q, M, D, L	Data block that is read
INDEX	Input	DINT	I, Q, M, D, L, P	Element that is read
VALUE	InOut	VARIANT	I, Q, M, L	Value that is read and output No local constants or tags from the TEMP section must be used.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = "1": The array DB is still being read
DONE	Output	BOOL	I, Q, M, D, L	DONE = "1": The instruction was executed successfully
ERROR	Output	INT	I, Q, M, D, L	Error information: If an error occurs during the execution of the instruction, an error code is output at the ERROR parameter.

For additional information on valid data types, refer to "See also".

ERROR parameter

The following table shows the meaning of the values of the ERROR parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
8230	The data block number is incorrect.

Error code* (W#16#...)	Explanation
8231	The data block does not exist.
8232	The data block is too short, or is not located in load memory.
8235	The data block is not an ARRAY DB.
8254	The data block has the incorrect data type.
8382	The value at parameter INDEX is outside the limits of the ARRAY.
8750	The data type VARIANT at parameter VALUE provides the value "0".
8751	Code generation error
8752	Code generation error
8753	The size of the VALUE parameter does not match the element length in the ARRAY data block.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

You can find descriptions of the error codes triggered by the instructions "READ_DBL: Read from data block in load memory" and "WRIT_DBL: Write to data block in the load memory" under "See also".

Example

The following example shows how the instruction works:

SCL

```
"ReadFromArrayDBL_DB"(REQ := "TagReg",
                      DB := "ArrayDB",
                      INDEX := "ArrayDB"."THIS"[2],
                      VALUE := "SourceTargetField[1]".Data1[6],
                      BUSY => "TagBusy",
                      DONE => "TagDone",
                      ERROR => "TagError");
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
REQ	TagReq	BOOL
DB	ArrayDB	The data type of the "ArrayDB" operand is Array [0 to 10] of INT.
INDEX	ArrayDB."THIS"[2]	Third element of the "ArrayDB"
VALUE	"SourceTargetField[1]".Data1[6]	The data type of the "SourceTargetField" operand is Array [0 to 10] of "MOVE_UDT".
BUSY	TagBusy	BOOL
DONE	TagDone	BOOL

If a positive edge is detected at the "TagReq" operand, the "Read from array data block in load memory" instruction is executed. The third element is read from "ArrayDB" and output at the "SourceTargetField[1]".Data1[6] operand. As soon as a negative signal edge is detected at the "TagBusy" operand, the instruction is terminated and the value at the VALUE parameter

is no longer changed. After the instruction has been processed, the "TagDone" operand the signal state "1".

WRIT_DBL: Write to data block in the load memory (Page 3353)

Using ARRAY data blocks (Page 239)

WriteToArrayDBL: Write to array data block in load memory

Description

The instruction "Write to array data block in load memory" is used to write data to an ARRAY data block in the load memory.

An ARRAY data block is a data block that consists of exactly one ARRAY of [Data type]. The elements of the ARRAY can be of data type PLC or any other elementary data type. The counting at the ARRAY always begins with the low limit "0", regardless of the later declaration of the ARRAY.

If the ARRAY data block has been designated with the block attribute "Only store in load memory", it will only be stored in the load memory.

The instruction is executed when a positive signal edge is detected at the REQ parameter. The BUSY parameter then has the signal state "1". If a negative signal edge is detected at the BUSY parameter, the instruction is terminated and the value at the VALUE parameter is written to the data block. The DONE parameter then has the signal state "1" for one program cycle.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

Note

The ARRAY data block must be created with the "Optimized" block property.

Syntax

The following syntax is used for the "Write to array data block in load memory" instruction:

SCL

```
"Instance DB"(REQ := <Operand>,
              DB := <Operand>,
              INDEX := <Operand>,
              VALUE := <Operand>,
```

SCL

```
BUSY => <Operand>,
DONE => <Operand>,
ERROR => <Operand>)
```

Parameters

The following table shows the parameters of the "Write to array data block in load memory" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L	REQ = "1": Start writing to the array DB
DB	Input	DB_ANY	I, Q, M, D, L	Data block to which data is written
INDEX	Input	DINT	I, Q, M, D, L, P	Element in the DB to which data is written
VALUE	Input	VARIANT	I, Q, M, L	Value to be written No local constants or tags from the TEMP section must be used.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = "1": The array DB is still being written
DONE	Output	BOOL	I, Q, M, D, L	DONE = "1": The instruction was executed successfully
ERROR	Output	INT	I, Q, M, D, L	Error information: If an error occurs during the execution of the instruction, an error code is output at the ERROR parameter.

For additional information on valid data types, refer to "See also".

ERROR parameter

The following table shows the meaning of the values of the ERROR parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
8230	The data block number is incorrect.
8231	The data block does not exist.
8232	The data block is too short, or is not located in load memory.
8234	The data block is write protected.
8235	The data block is not an ARRAY DB.
8254	The data block has the incorrect data type.

Error code* (W#16#...)	Explanation
8382	The value at parameter INDEX is outside the limits of the ARRAY.
8750	The data type VARIANT at parameter VALUE provides the value "0".
8751	Code generation error
8752	Code generation error
8753	The size of the VALUE parameter does not match the element length in the ARRAY data block.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

You can find descriptions of the error codes triggered by the instructions "READ_DBL: Read from data block in load memory" and "WRIT_DBL: Write to data block in the load memory" under "See also".

Example

The following example shows how the instruction works:

SCL

```
"WriteToArrayDBL_DB"(REQ := "TagReg",
                     DB := "ArrayDB",
                     INDEX := "ArrayDB"."THIS"[2],
                     VALUE := "SourceTargetField[1]".Data1[6],
                     BUSY => "TagBusy",
                     DONE => "TagDone",
                     ERROR => "TagError");
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
REQ	TagReq	BOOL
DB	ArrayDB	The data type of the "ArrayDB" operand is Array [0 to 10] of INT.
INDEX	ArrayDB."THIS"[2]	Third element of the "ArrayDB"
VALUE	"SourceTargetField[1]".Data1[6]	The data type of the "SourceTargetField" operand is Array [0 to 10] of "MOVE_UDT".
BUSY	TagBusy	BOOL
DONE	TagDone	BOOL

If a positive edge is detected at the "TagReq" operand, the "Write to array data block in load memory" instruction is executed. As soon as a negative signal edge is detected at the "TagBusy" operand, the instruction is terminated and the value at the VALUE parameter is written in the third element in the "ArrayDB". After the instruction has been processed, the "TagDone" operand the signal state "1".

Read/write access

PEEK: Read memory address

Description

The "Read memory address" instruction is used to read a memory address from a memory area without specifying a data type.

If you specify the 16#84 area for a data block at the AREA parameter, you can only access data blocks with the "Standard" block property.

Note

The instruction can only be used to access "Standard" memory areas.

Syntax

The following syntax is used for the "Read memory address" instruction:

SCL

```
PEEK(AREA:= <Operand>,
     DBNUMBER := <Operand>,
     BYTEOFFSET:= <Operand>)
```

SCL

```
PEEK_<Data type>(AREA := <Operand>,
                 DBNUMBER := <Operand>,
                 BYTEOFFSET:= <Operand>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
AREA	Input	BYTE	I, Q, M, D, L	The following areas can be selected: • 16#81: Input • 16#82: Output • 16#83: Bit memory • 16#84: DB • 16#1: Peripheral input (S7-1500 only)
DBNUM-BER	Input	DINT, DB_ANY	D	Number of the data block if AREA = DB, otherwise "0"
BYTEOFF-SET	Input	DINT	I, Q, M, D, L	Address to read from Only the 16 least significant bits are used.
_<Data type>		Bit strings default: BYTE	-	Data type of the function value: 1. You can specify the data type of the instruction explicitly using "_". 2. If you do not specify the data type explicitly, it will be determined by the utilized tags or type-coded constants. 3. If you neither specify the data type explicitly nor specify defined tags or type-coded constants, the default data type will be used.
Function value		Bit strings	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Note

If you read the memory address from the input, output or bit memory areas, you must assign the DBNUMBER parameter the value "0", as the instruction is invalid otherwise.

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result1" := PEEK(AREA := "Tag_Area",
                      DBNUMBER := "Tag_DBNumber",
                      BYTEOFFSET := "Tag_Byte");
```

SCL

```
"Tag_Result2" := PEEK_WORD(AREA := "Tag_Area",
                           DBNUMBER := "Tag_DBNumber",
```

SCL

```
                                BYTEOFFSET := "Tag_Byte");
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
AREA	Tag_Area	16#84
DBNUMBER	Tag_DBNumber	5
BYTEOFFSET	Tag_Byte	20
Function value	Tag_Result1	Byte value "20"
Function value	Tag_Result2	Word value "20"

The instruction reads the value of address "20" from the "Tag_Byte" operand at data block "5" and returns the result as a function value at the "Tag_Result" operand.

See also

Overview of the valid data types (Page 1908)

PEEK_BOOL: Read memory bit

Description

The "Read memory bit" instruction is used to read a memory bit from a memory area without specifying a data type.

If you specify the 16#84 area for a data block at the AREA parameter, you can only access data blocks with the "Standard" block property.

Note

The instruction can only be used to access "Standard" memory areas.

Syntax

The following syntax is used for the "Read memory bit" instruction:

SCL

```
PEEK_BOOL(AREA := <Operand>,
          DBNUMBER := <Operand>,
          BYTEOFFSET := <Operand>,
          BITOFFSET := <Operand>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
AREA	Input	BYTE	I, Q, M, D, L	The following areas can be selected: • 16#81: Input • 16#82: Output • 16#83: Bit memory • 16#84: DB • 16#1: Peripheral input (S7-1500 only)
DBNUM-BER	Input	DINT, DB_ANY	D	Number of the data block if AREA = DB, otherwise "0"
BYTEOFF-SET	Input	DINT	I, Q, M, D, L	Address to read from Only the 16 least significant bits are used.
BITOFFSET	Input	INT	I, Q, M, D, L	Bit to be read from
Function value		BOOL	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Note

If you read the memory bit from the input, output or bit memory areas, you must assign the DBNUMBER parameter the value "0", as the instruction is invalid otherwise.

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := PEEK_BOOL(AREA := "Tag_Area",
                          DBNUMBER := "Tag_DBNumber",
                          BYTEOFFSET := "Tag_Byte",
                          BITOFFSET := "Tag_Bit");
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
AREA	Tag_Area	16#84
DBNUMBER	Tag_DBNumber	5
BYTEOFFSET	Tag_Byte	20
BITOFFSET	Tag_Bit	3
Function value	Tag_Result	3

The instruction reads the value of memory bit "3" from the "Tag_Bit" operand at byte "20" of data block "5" and returns the result at the "Tag_Result" operand as function value.

Overview of the valid data types (Page 1908)

POKE: Write memory address

Description

The "Write memory address" instruction is used to write a memory address to a memory area without specifying a data type.

If you specify the 16#84 area for a data block at the AREA parameter, you can only access data blocks with the "Standard" block property.

Note

The instruction can only be used to access "Standard" memory areas.

Syntax

The following syntax is used for the "Write memory address" instruction:

SCL

```
POKE(AREA := <Operand>,
     DBNUMBER := <Operand>,
     BYTEOFFSET := <Operand>,
     VALUE := <Operand>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
AREA	Input	BYTE	I, Q, M, D, L	The following areas can be selected: • 16#81: Input • 16#82: Output • 16#83: Bit memory • 16#84: DB • 16#2: Peripheral output (S7-1500 only)
DBNUM-BER	Input	DINT, DB_ANY	D	Number of the data block if AREA = DB, otherwise "0"
BYTEOFF-SET	Input	DINT	I, Q, M, D, L	Address to be written Only the 16 least significant bits are used.
VALUE	Input	Bit strings	I, Q, M, D, L	Value to be written

For additional information on valid data types, refer to "See also".

Note

If you write the memory address to the input, output or bit memory areas, you must assign the DBNUMBER parameter the value "0", as the instruction is invalid otherwise.

Example

The following example shows how the instruction works:

```
SCL
POKE(AREA := "Tag_Area",
     DBNUMBER := "Tag_DBNumber",
     BYTEOFFSET := "Tag_Byte"),
     VALUE := "Tag_Value";
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
AREA	Tag_Area	16#84
DBNUMBER	Tag_DBNumber	5
BYTEOFFSET	Tag_Byte	20
VALUE	Tag_Value	16#11

The instruction overwrites the memory address "20" in the data block "5" with value "16#11".

Overview of the valid data types (Page 1908)

POKE_BOOL: Write memory bit

Description

The "Write memory bit" instruction is used to write a memory bit to a memory area without specifying a data type.

If you specify the 16#84 area for a data block at the AREA parameter, you can only access data blocks with the "Standard" block property.

Note

The instruction can only be used to access "Standard" memory areas.

Syntax

The following syntax is used for the "Write memory bit" instruction:

SCL

```
POKE_BOOL(AREA := <Operand>,
          DBNUMBER := <Operand>,
          BYTEOFFSET := <Operand>,
          BITOFFSET := <Operand>,
          VALUE := <Operand>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
AREA	Input	BYTE	I, Q, M, D, L	The following areas can be selected: • 16#81: Input • 16#82: Output • 16#83: Bit memory • 16#84: DB • 16#2: Peripheral output (S7-1500 only)
DBNUM-BER	Input	DINT, DB_ANY	D	Number of the data block if AREA = DB, otherwise "0"
BYTEOFF-SET	Input	DINT	I, Q, M, D, L	Address to be written Only the 16 least significant bits are used.
BITOFFSET	Input	INT	I, Q, M, D, L	Bit to be written
VALUE	Input	BOOL	I, Q, M, D, L	Value to be written

For additional information on valid data types, refer to "See also".

Note

If you write the memory bit to the input, output or bit memory areas, you must assign the DBNUMBER parameter the value "0", as the instruction is invalid otherwise.

Example

The following example shows how the instruction works:

SCL

```
POKE_BOOL(AREA := "Tag_Area",
          DBNUMBER := "Tag_DBNumber",
          BYTEOFFSET := "Tag_Byte",
          BITOFFSET := "Tag_Bit",
          VALUE := "Tag_Value");
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
AREA	Tag_Area	16#84
DBNUMBER	Tag_DBNumber	5
BYTEOFFSET	Tag_Byte	20
BITOFFSET	Tag_Bit	3
VALUE	Tag_Value	M0.0

The instruction overwrites the memory bit "3" in data block "5" in byte "20" with the value "M0.0".

See also

Overview of the valid data types (Page 1908)

POKE_BLK: Write memory area

Description

The "Write memory area" instruction copies the content a memory area to a different memory area without specifying a data type.

If you specify the 16#84 area for a data block at the AREA parameter, you can only access data blocks with the "Standard" block property.

Note

The instruction can only be used to access "Standard" memory areas.

Syntax

The following syntax is used for the "Write memory area" instruction:

SCL

```
POKE_BLK(AREA_SRC:= <Operand>,
         DBNUMBER_SRC:= <Operand>,
         BYTEOFFSET_SRC:= <Operand>,
         AREA_DEST:= <Operand>,
         DBNUMBER_DEST:= <Operand>,
         BYTEOFFSET_DEST:= <Operand>,
         COUNT := <Operand>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
AREA_SRC	Input	BYTE	I, Q, M, D, L	The following areas can be selected in the source memory area: • 16#81: Input • 16#82: Output • 16#83: Bit memory • 16#84: DB
DBNUMBER_SRC	Input	DINT, DB_ANY	D	Number of the data block in the source memory area, if AREA = DB, otherwise "0"
BYTEOFF-SET_SRC	Input	DINT	I, Q, M, D, L	Address in the source memory area to be written Only the 16 least significant bits are used.
AREA_DEST	Input	BYTE	I, Q, M, D, L	The following areas can be selected in the destination memory area: • 16#81: Input • 16#82: Output • 16#83: Bit memory • 16#84: DB
DBNUM-BER_DEST	Input	DINT, DB_ANY	D	Number of the data block in the destination memory area, if AREA = DB, otherwise "0"
BYTEOFF-SET_DEST	Input	DINT	I, Q, M, D, L	Address in the destination memory area to be written Only the 16 least significant bits are used.
COUNT	Input	DINT	I, Q, M, D, L	Number of bytes which are copied

For additional information on valid data types, refer to "See also".

Note

If you write the memory address to the input, output or bit memory areas, you must assign the DBNUMBER parameter the value "0", as the instruction is invalid otherwise.

Example

The following example shows how the instruction works:

```
SCL
POKE_BLK(AREA_SRC := "Tag_Source_Area",
         DBNUMBER_SRC := "Tag_Source_DBNumber",
         BYTEOFFSET_SRC := "Tag_Source_Byte"),
         AREA_DEST := "Tag_Destination_Area",
         DBNUMBER_DEST := "Tag_Destination_DBNumber",
         BYTEOFFSET_DEST := "Tag_Destination_Byte",
         COUNT := "Tag_Count");
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
AREA_SRC	Tag_Source_Area	16#84
DBNUMBER_SRC	Tag_Source_DBNumber	5
BYTEOFFSET_SRC	Tag_Source_Byte	20
AREA_DEST	Tag_Destination_Area	16#83
DBNUMBER_DEST	Tag_Destination_DBNumber	0
BYTEOFFSET_DEST	Tag_Destination_Byte	30
COUNT	Tag_Count	100

The instruction writes 100 byte from data block "5" starting with address "20" in the memory area of the bit memory starting at address "30".

Overview of the valid data types (Page 1908)

READ_LITTLE: Read data in little endian format

Description

The instruction "Read data in little endian format" is used to read data from a memory area and to write this to a single tag in the little endian byte sequence. With the little endian format, the byte with the least significant bits is saved first, which means at the lowest memory address.

The parameters SRC_ARRAY and DEST_VARIABLE are of data type VARIANT. However, there are a few restrictions regarding the data type with which the parameters can be interconnected. The VARIANT at the DEST_VARIABLE parameter must point to an elementary data type. The VARIANT at the SRC_ARRAY parameter points to the memory area to be read from, and this must be an ARRAY of BYTE.

The operand at the POS parameter determines the position in the memory area at which reading starts.

Note

Reading tag of data type VARIANT or BOOL

If you want to read a tag to which a VARIANT points, use the "Serialize" or "Deserialize" instructions.

If you want to read a tag of the data type BOOL, use a "Slice access".

Syntax

Use the following syntax for the "Read data in little endian format" instruction:

SCL

```
READ_LITTLE(SRC_ARRAY := <Operand>,
            DEST_VARIABLE => <Operand>,
            POS := <Operand>)
```

Parameters

The following table shows the parameters of the "Read data in little endian format" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
SRC_ARRAY	Input	ARRAY of BYTE	ARRAY of BYTE	I, Q, M, D, L	Memory area to be read from
DEST_VARIABLE	Output	Bit strings, integers, floating-point numbers, TOD, DATE, CHAR, WCHAR	Bit strings, integers, floating-point numbers, LDT, TOD, LTOD, DATE, CHAR, WCHAR	I, Q, M, D, L	Read value
POS	InOut	DINT	DINT	I, Q, M, D, L	Determines the position at which the reading starts. The POS parameter is calculated zero-based.
Function value (RET_VAL)		INT	INT	I, Q, M, D, L	Error information

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The data type at the SRC_ARRAY parameter is not ARRAY of BYTE.
8382	The value at the POS parameter is outside the limits of the ARRAY.
8383	The value at the POS parameter is within the limits of the ARRAY but the size of the memory area exceeds the high limit of the ARRAY.

Example

The following example shows how the instruction works:

SCL

```
#TagResult := READ_LITTLE(SRC_ARRAY := #SourceField,
                          DEST_VARIABLE => #DINTVariable,
                          POS := #TagPos);
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
SRC_ARRAY	#SourceField	ARRAY[0..3] of BYTE := 16#1A, 16#2B, 16#3C, 16#4D
DEST_VARIABLE	#DINTVariable	1295788826 16#4D3C2B1A
POS	#TagPos	0 => 4

The instruction reads the integer 1_295_788_826 from the #SourceField memory area and writes it to the #DINTVariable operand in little endian format. The data type at the DEST_VARIABLE parameter specifies how many bytes are read. The quantity 4 is stored in the #TagPos operand.

WRITE_LITTLE: Write data in little endian format

Description

You use the "Write data in little endian format" instruction to write the data of a single tag in the little endian byte sequence to a memory area. With the little endian format, the byte with the least significant bits is saved first, which means at the lowest memory address.

The parameters SRC_VARIABLE and DEST_ARRAY are of data type VARIANT. However, there are a few restrictions regarding the data type with which the parameters can be interconnected. The VARIANT at the SRC_VARIABLE parameter must point to an elementary data type. The VARIANT at the DEST_ARRAY parameter points to the memory area to which the data is written, and this must be an ARRAY of BYTE.

The operand at the POS parameter determines the position in the memory area at which writing starts.

Note

Writing tag of data type VARIANT or BOOL

If you want to write a tag to which a VARIANT points, use the "Serialize" or "Deserialize" instructions.

If you want to write a tag of the data type BOOL, use a "Slice access".

Syntax

Use the following syntax for the "Write data in little endian format" instruction:

SCL

```
WRITE_LITTLE(SRC_VARIABLE := <Operand>,
             DEST_ARRAY := <Operand>,
             POS := <Operand>)
```

Parameters

The following table shows the parameters of the "Write data in little endian format" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
SRC_VARIABLE	Input	Bit strings, integers, floating-point numbers, TOD, DATE, CHAR, WCHAR	Bit strings, integers, floating-point numbers, LDT, TOD, LTOD, DATE, CHAR, WCHAR	I, Q, M, D, L	Tag whose data are written
DEST_ARRAY	InOut	ARRAY of BYTE	ARRAY of BYTE	I, Q, M, D, L	Memory area to which the data are written
POS	InOut	DINT	DINT	I, Q, M, D, L	Determines the position at which the writing starts. The POS parameter is calculated zero-based.
Function value (RET_VAL)		INT	INT	I, Q, M, D, L	Error information

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The data type at the SRC_ARRAY parameter is not ARRAY of BYTE.
8382	The value at the POS parameter is outside the limits of the ARRAY.
8383	The value at the POS parameter is within the limits of the ARRAY but the size of the memory area exceeds the high limit of the ARRAY.

Example

The following example shows how the instruction works:

SCL

```
#TagResult := WRITE_LITTLE(SRC_VARIABLE := #DINTVariable,
                           DEST_ARRAY := #TargetField,
                           POS := #TagPos);
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
SRC_VARIABLE	#DINTVariable	1295788826 16#4D3C2B1A
DEST_ARRAY	#TargetField	ARRAY[0..10] of BYTE = 16#1A, 16#2B, 16#3C, 16#4D
POS	#TagPos	0 => 4

The instruction writes the integer 1_295_788_826 from the #DINTVariable operand to the #TargetField memory area in little endian format. The data type at the SRC_VARIABLE parameter specifies how many bytes are written. The quantity 4 is stored in the #TagPos operand.

READ_BIG: Read data in big endian format

Description

The instruction "Read data in big endian format" is used to read data from a memory area and to write this to a single tag in the big endian byte sequence. With the big endian format, the byte with the most significant bits is saved first, which means at the lowest memory address.

The parameters SRC_ARRAY and DEST_VARIABLE are of data type VARIANT. However, there are a few restrictions regarding the data type with which the parameters can be interconnected. The VARIANT at the DEST_VARIABLE parameter must point to an elementary data type. The VARIANT at the SRC_ARRAY parameter points to the memory area to be read from, and this must be an ARRAY of BYTE.

The operand at the POS parameter determines the position in the memory area at which reading starts.

Note

Reading tag of data type VARIANT or BOOL

If you want to read a tag to which a VARIANT points, use the "Serialize" or "Deserialize" instructions.

If you want to read a tag of the data type BOOL, use a "Slice access".

Syntax

Use the following syntax for the "Read data in big endian format" instruction:

SCL

```
READ_BIG(SRC_ARRAY := <Operand>,
         DEST_VARIABLE => <Operand>,
         POS := <Operand>)
```

Parameters

The following table shows the parameters of the "Read data in big endian format" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
SRC_ARRAY	Input	ARRAY of BYTE	ARRAY of BYTE	I, Q, M, D, L	Memory area to be read from
DEST_VARIABLE	Output	Bit strings, integers, floating-point numbers, TOD, DATE, CHAR, WCHAR	Bit strings, integers, floating-point numbers, LDT, TOD, LTOD, DATE, CHAR, WCHAR	I, Q, M, D, L	Read value
POS	InOut	DINT	DINT	I, Q, M, D, L	Determines the position at which the reading starts. The POS parameter is calculated zero-based.
Function value (RET_VAL)		INT	INT	I, Q, M, D, L	Error information

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The data type at the SRC_ARRAY parameter is not ARRAY of BYTE.
8382	The value at the POS parameter is outside the limits of the ARRAY.
8383	The value at the POS parameter is within the limits of the ARRAY but the size of the memory area exceeds the high limit of the ARRAY.

Example

The following example shows how the instruction works:

SCL

```
#TagResult := READ_BIG(SRC_ARRAY := #SourceField,
                       DEST_VARIABLE => #DINTVariable,
                       POS := #TagPos);
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
SRC_ARRAY	#SourceField	ARRAY[0..10] of BYTE := 16#1A, 16#2B, 16#3C, 16#4D
DEST_VARIABLE	#DINTVariable	439041101 16#1A2B3C4D
POS	#TagPos	0 => 4

The instruction reads the integer 439_041_101 from the #SourceField memory area and writes it to the #DINTVariable operand in big endian format. The data type at the DEST_VARIABLE parameter specifies how many bytes are read. The quantity 4 is stored in the #TagPos operand.

WRITE_BIG: Write data in big endian format

Description

You use the "Write data in big endian format" instruction to write the data of a single tag in the big endian byte sequence to a memory area. With the big endian format, the byte with the most significant bits is saved first, which means at the lowest memory address.

The parameters SRC_VARIABLE and DEST_ARRAY are of data type VARIANT. However, there are a few restrictions regarding the data type with which the parameters can be interconnected. The VARIANT at the SRC_VARIABLE parameter must point to an elementary data type. The VARIANT at the DEST_ARRAY parameter points to the memory area to which the data is written, and this must be an ARRAY of BYTE.

The operand at the POS parameter determines the position in the memory area at which writing starts.

Note

Writing tag of data type VARIANT or BOOL

If you want to write a tag to which a VARIANT points, use the "Serialize" or "Deserialize" instructions.

If you want to write a tag of the data type BOOL, use a "Slice access".

Syntax

Use the following syntax for the "Write data in big endian format" instruction:

SCL

```
WRITE_BIG(SRC_VARIABLE := <Operand>,
          DEST_ARRAY := <Operand>,
          POS := <Operand>)
```

Parameters

The following table shows the parameters of the "Write data in big endian format" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
SRC_VARIABLE	Input	Bit strings, integers, floating-point numbers, TOD, DATE, CHAR, WCHAR	Bit strings, integers, floating-point numbers, LDT, TOD, LTOD, DATE, CHAR, WCHAR	I, Q, M, D, L	Tag whose data are written
DEST_ARRAY	InOut	ARRAY of BYTE	ARRAY of BYTE	I, Q, M, D, L	Memory area to which the data are written
POS	InOut	DINT	DINT	I, Q, M, D, L	Determines the position at which the writing starts. The POS parameter is calculated zero-based.
Function value (RET_VAL)		INT	INT	I, Q, M, D, L	Error information

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The data type at the SRC_ARRAY parameter is not ARRAY of BYTE.
8382	The value at the POS parameter is outside the limits of the ARRAY.
8383	The value at the POS parameter is within the limits of the ARRAY but the size of the memory area exceeds the high limit of the ARRAY.

Example

The following example shows how the instruction works:

SCL

```
#TagResult := WRITE_BIG(SRC_VARIABLE := #DINTVariable,
                        DEST_ARRAY := #TargetField,
                        POS := #TagPos);
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
SRC_VARIABLE	#DINTVariable	439041101 16#1A2B3C4D
DEST_ARRAY	#TargetField	ARRAY[0..10] of BYTE = 16#1A, 16#2B, 16#3C, 16#4D
POS	#TagPos	0 => 4

The instruction writes the integer 439_041_101 from the #DINTVariable operand to the #TargetField memory area in big endian format. The data type at the SRC_VARIABLE parameter specifies how many bytes are written. The quantity 4 is stored in the #TagPos operand.

Overview of the valid data types (Page 1908)

Deserialize: Deserialize (Page 2819)

Serialize: Serialize (Page 2822)

VARIANT

VariantGet: Read out VARIANT tag value

Description

You can use the "Read out VARIANT tag value" instruction to read the value of the tag to which the VARIANT at the SRC parameter points and write it in the tag at the DST parameter.

The SRC parameter has the VARIANT data type. Any data type except for VARIANT can be specified at the DST parameter.

The data type of the tag specified at the DST parameter must match the data type to which the VARIANT points.

Note

To copy structures and ARRAYs, you can use the "MOVE_BLK_VARIANT: Move block" instruction. For additional information, refer to "See also".

Syntax

The following syntax is used for the "Read out VARIANT tag value" instruction:

SCL

```
VariantGet(SRC := <Operand>,
           DST => <Operand>)
```

Parameters

The following table shows the parameters of the "Read out VARIANT tag value" instruction:

Parameter	Declaration	Data type	Memory area	Description
SRC	Input	VARIANT	I, Q, M, L	Tag to be read
DST	Output	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY elements, PLC data types	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
VariantGet(SRC := #TagIn_Source,
           DST => "TagOut_Dest");
```

The value of the tag to which the VARIANT at the #TagIn_Source operand points is read and written to the "TagOut_Dest" operand.

See also

Overview of the valid data types (Page 1908)

VARIANT (Page 1951)

MOVE_BLK_VARIANT: Move block (Page 2827)

VariantPut: Write VARIANT tag value

Description

You can use the "Write VARIANT tag value" instruction to write the value of the tag at the SRC parameter to the tag at the DST parameter to which the VARIANT points.

The DST parameter has the VARIANT data type. Any data type except for VARIANT can be specified at the SRC parameter.

The data type of the tag at the SRC parameter must match the data type to which the VARIANT points.

Note

To copy structures and ARRAYs, you can use the "MOVE_BLK_VARIANT: Move block" instruction. For additional information, refer to "See also".

Syntax

The following syntax is used for the "Write VARIANT tag value" instruction:

SCL

```
VariantPut(SRC := <Operand>,
           DST := <Operand>)
```

Parameters

The following table shows the parameters of the "Write VARIANT tag value" instruction:

Parameter	Declaration	Data type	Memory area	Description
SRC	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY elements, PLC data types	I, Q, M, D, L	Tag to be read
DST	Input	VARIANT	I, Q, M, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
VariantPut(SRC := "TagIn_Source",
           DST := "#TagIn_Dest");
```

The value of the "TagIn_Source" operand is written to the tag to which the VARIANT at the #TagIn_Dest operand points.

See also

Overview of the valid data types (Page 1908)

VARIANT (Page 1951)

MOVE_BLK_VARIANT: Move block (Page 2827)

CountOfElements: Get number of ARRAY elements

Description

You can use the "Get number of ARRAY elements" instruction to query how many ARRAY elements a tag to which VARIANT is pointing has.

If it is a one-dimensional ARRAY, the difference between the high and low limit +1 is output as a result. If it is a multi-dimensional ARRAY, the product of all dimensions is output as the result.

The <Operand> must have the VARIANT data type.

The result is "0" if the VARIANT tag is not an ARRAY.

If the VARIANT points to an ARRAY of BOOL, the fill elements are included in the count. (For example, 8 is returned for an ARRAY[0..1] of BOOL)

Syntax

The following syntax is used for the "Get number of ARRAY elements" instruction:

SCL

```
CountOfElements(<Operand>)
```

Parameters

The following table shows the parameters of the "Get number of ARRAY elements" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand>	Input	VARIANT	I, Q, M, L	Tag to be queried
Function value		UDINT	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
IF IS_ARRAY(#Tag_VARIANTToArray) THEN
"Tag_Result" := CountOfElements(#Tag_VARIANT);
END_IF;
```

If the tag to which the VARIANT points is an ARRAY, the number of ARRAY elements is output.

Legacy

BLKMOV: Move block

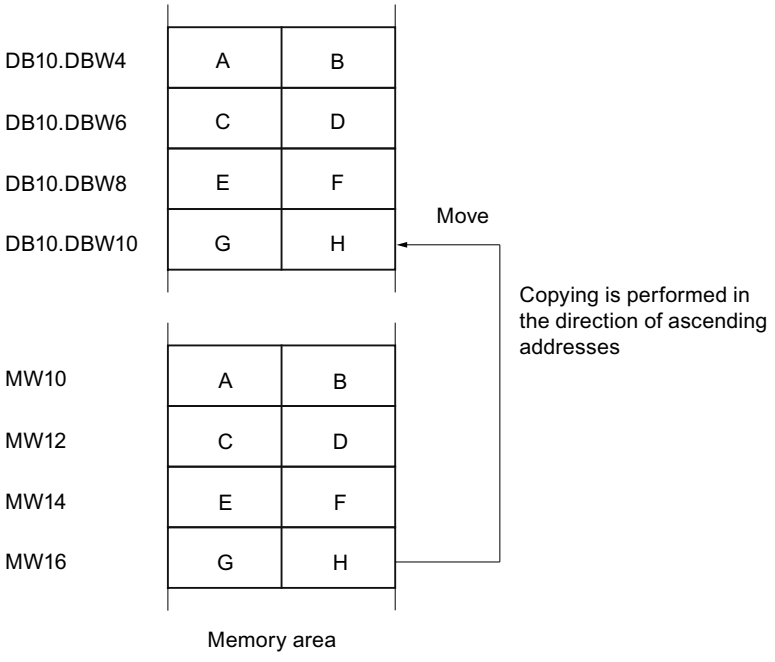
Description

You can use the "Move block" instruction to move the content of a memory area (source area) to another memory area (destination area). The move operation takes place in the direction of ascending addresses. You use VARIANT to define the source and destination areas.

Note

The tags of the instruction can only be used in data blocks in which the "Optimized block access" attribute is not set. If the tag with the retentivity setting "Set in IDB" has been declared, you can also use the tags "with optimized access".

The following figure shows the principle of the move operation:



Consistency of source and destination data

Note that while the instruction "Move block" is being executed, the source data remains unchanged; otherwise the consistency of the destination data cannot be guaranteed.

Interruptibility

There is no limit to the nesting depth.

Memory areas

You can use the "Move block" instruction to move the following memory areas:

- Areas of a data block
- Bit memory
- Process image input
- Process image output

General rules for moving

The source and destination areas must not overlap. If the source and destination areas have different lengths, only the length of the smaller area will be moved.

If the source area is smaller than the destination area, the entire source area will be written to the destination area. The remaining bytes of the destination area remain unchanged.

If the destination area is smaller than the source area, the entire destination area will be written. The remaining bytes of the source area are ignored.

If a block of data type BOOL is moved, the tag must be addressed absolutely and the specified length of the area must be divisible by 8, otherwise the instruction cannot be executed.

Rules for moving character strings

You can use the "Move block" instruction to also move source and destination areas of the STRING data type. If only the source area is STRING data type, the characters will be moved that are actually contained in the character string. Information on the actual and maximum length is also written to the destination area. If the source and destination area are both STRING data type, the current length of the character string in the destination area is set to the number of characters actually moved.

If you want to move the information on the maximum and actual length of a character string, specify the areas in bytes in the SRCBLK and DSTBLK parameters.

Syntax

The following syntax is used for the "Move block" instruction:

SCL

```
BLKMOV(SRCBLK := <Operand>,
       DSTBLK => <Operand>)
```

Parameters

The following table shows the parameters of the "Move block" instruction:

Parameter	Declaration	Data type	Memory area	Description
SRCBLK	Input	VARIANT	I, Q, M, L, P	Specifies the memory area to be moved (source area).
DSTBLK	Output [1)]	VARIANT	I, Q, M, L, P	Specifies the memory area to which the block is to be moved (destination area).
Function value (RET_VAL)		INT	I, Q, M, D, L	Error information
1) The DSTBLK parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
8092	The source or destination area is located in the load memory only.
8152	The WSTRING, WCHAR and BOOL data types are not supported at the SRCBLK parameter.
8352	The WSTRING, WCHAR and BOOL data types are not supported at the DSTBLK parameter.
General error information	See also: "GET_ERR_ID: Get error ID locally
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
"Tag_RetVal" := BLKMOV(SRCBLK := P#M100.0 BYTE 10,
                       DSTBLK => P#DB1.DBX0.0 BYTE 10);
```

The instruction copies 10 bytes starting from MB100 and writes them to DB1. If an error occurs during the move operation, its error code is output in the "Tag_RetVal" tag.

UBLKMOV: Move block uninterruptible

Description

You can use the "Move block uninterruptible" instruction to move the content of a memory area (source area) to another memory area (destination area). The move operation takes place in the direction of ascending addresses. You use VARIANT to define the source and destination areas.

The move operation cannot be interrupted by other operating system activities. As a result, the interrupt reaction time of the CPU can increase during execution of the "Move block uninterruptible" instruction.

Note

The tags of the instruction can only be used in data blocks in which the "Optimized block access" attribute is not set. If the tag with the retentivity setting "Set in IDB" has been declared, you can also use the tags "with optimized access".

Memory areas

You can use the "Move block uninterruptible" instruction to move the following memory areas:

- Areas of a data block
- Bit memory
- Process image input
- Process image output

General rules for moving

The source and destination area must not overlap during the execution of the "Move block uninterruptible" instruction. If the source area is smaller than the destination area, the entire source area will be written to the destination area. The remaining bytes of the destination area remain unchanged.

If the destination area is smaller than the source area, the entire destination area will be written. The remaining bytes of the source area are ignored.

If a source or destination area defined as a formal parameter is smaller than a destination or source area specified in the SRCBLK or DSTBLK parameter, no data is transferred.

If a block of data type BOOL is moved, the tag must be addressed absolutely and the specified length of the area must be divisible by 8, otherwise the instruction cannot be executed.

You can use the "Move block uninterruptible" instruction to move a maximum of 16 KB. Note the CPU-specific restrictions for this.

Rules for moving character strings

You can use the "Move block uninterruptible" instruction to also move source and destination areas of data type STRING. If only the source area is STRING data type, the characters will be moved that are actually contained in the character string. Information on the actual and maximum length are not written in the destination area. If the source and destination area are both STRING data type, the current length of the character string in the destination area is set to the number of characters actually moved. If areas of the STRING data type are moved, specify "1" as the area length.

Syntax

The following syntax is used for the "Move block uninterruptible" instruction:

SCL

```
UBLKMOV(SRCBLK := <Operand>,
        DSTBLK => <Operand>)
```

Parameters

The following table shows the parameters of the "Move block uninterruptible" instruction:

Parameter	Declaration	Data type	Memory area	Description
SRCBLK	Input	VARIANT	I, Q, M, L, P	Specifies the memory area to be moved (source area).
DSTBLK	Output [1]	VARIANT	I, Q, M, L, P	Specifies the memory area to which the block is to be moved (destination area).
Function value (RET_VAL)		INT	I, Q, M, D, L	Error information
1) The DSTBLK parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code (W#16#...)	Explanation
0000	No error
8091	The source or destination area is located in the load memory only.
8152	The WSTRING, WCHAR and BOOL data types are not supported at the SRCBLK parameter.
8352	The WSTRING, WCHAR and BOOL data types are not supported at the DSTBLK parameter.
General error information	See also: "GET_ERR_ID: Get error ID locally
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
"Tag_RetVal" := UBLKMOV(SRCBLK := P#M100.0 BYTE 10,
                        DSTBLK => P#DB1.DBX0.0 BYTE 10);
```

The instruction copies 10 bytes starting from MB100 and writes them to DB1. If an error occurs during the move operation, its error code is output in the "Tag_RetVal" tag.

Overview of the valid data types (Page 1908)

GET_ERR_ID: Get error ID locally (Page 2922)

FILL: Fill block

Description

You can use the "Fill block" instruction to fill a memory area (destination area) with the content of another memory area (source area). The "Fill block" instruction moves the content of the source area to the destination area until the destination area is completely written. The move operation takes place in the direction of ascending addresses.

You use VARIANT to define the source and destination areas.

Note

You can also define the source and destination areas using the ANY data type

If you use the ANY data type, you must observe the following in connection with the STRING and WSTRING data types:

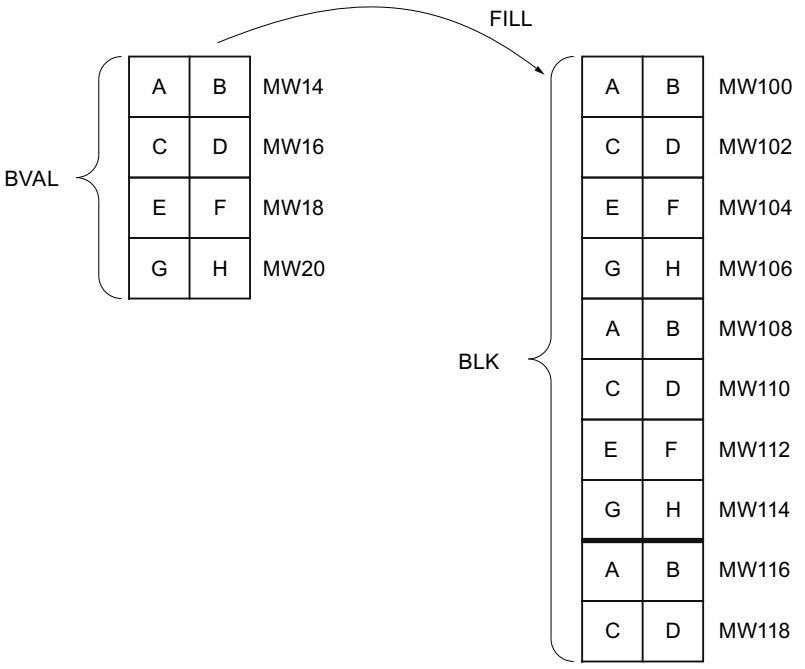
- In the case of an assignment of STRING (source area) using ANY after STRING (destination area), the content of the STRING is copied to the destination area repeatedly until it is full.
  Source area: String#'STEP7-SCL-TIA-Portal'
  Destination area: 'STEP7-SCL-TIA-PortalSTEP7-SCL-TIA-PortalSTEP7-SCL'

Note

The tags of the instruction can only be used in data blocks in which the "Optimized block access" attribute is not set. If the tag with the retentivity setting "Set in IDB" has been declared, you can also use the tags "with optimized access".

For blocks with the "Optimized block access" attribute, you can use the "FILL_BLK: Fill block" instruction.

The following figure shows the principle of the move operation:



Example: The contents of the range MW100 to MW118 are to be preassigned with the contents of the memory words MW14 to MW20.

Consistency of source and destination data

Note that while the instruction "Fill block" is being executed, the source data remains unchanged; otherwise the consistency of the destination data cannot be guaranteed.

Memory areas

You can use the "Fill block" instruction to move the following memory areas:

- Areas of a data block
- Bit memory
- Process image input
- Process image output

General rules for moving

The source and destination areas must not overlap. If the destination area to be preset is not an integer multiple of the length of the BVAL input parameter, the destination area is nevertheless written up to the last byte.

If the destination area to be preset is smaller than the source area, the function only copies as much data as can be written to the destination area.

If the destination or source area actually present is smaller than the assigned memory area for the source or destination area (BVAL, BLK parameters), no data is transferred.

If the ANY pointer (source or destination) is of the data type BOOL, it must be addressed absolutely and the length specified must be divisible by 8; otherwise the instruction is not executed.

If the destination area is STRING data type, the instruction writes the entire string including the administration information.

Syntax

The following syntax is used for the "Fill block" instruction:

```
SCL
FILL(BVAL := <Operand>,
     BLK => <Operand>)
```

Parameters

The following table shows the parameters of the "Fill block" instruction:

Parameter	Declaration	Data type	Memory area	Description
BVAL	Input	VARIANT	I, Q, M, L, P	Specification of the memory area (source area), the content of which is used to fill the destination area at the BLK parameter.
BLK	Output 1)	VARIANT	I, Q, M, L, P	Specification of the memory area that will be filled with the content of the source area.
Function value (RET_VAL)		INT	I, Q, M, D, L	Error information
1) The BLK parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

For additional information on valid data types, refer to "See also".

BVAL parameter

When you transfer a structure as an input parameter, remember that the length of a structure is always based on an even number of bytes. The structure will need one byte of additional memory space if you declare a structure with an odd number of bytes.

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code (W#16#...)	Explanation
0000	No error
8092	The source or destination area is located in the load memory only.
8152	The WSTRING, WCHAR and BOOL data types are not supported at the BVAL parameter.
8352	The WSTRING, WCHAR and BOOL data types are not supported at the BLK parameter.

Error code (W#16#...)	Explanation
General error information	See also: "GET_ERR_ID: Get error ID locally
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
"Tag_RetVal" := FILL(BVAL := P#M14.0 WORD 4,
                     BLK => P#M100.0 WORD 10);
```

The instruction copies the source area from MW14 to MW20 and fills the destination area from MW100 to MW118 with the content of the 4 words contained in the memory area in the BVAL parameter.

Conversion operations

CONVERT: Convert value

Description

Use the "Convert value" instruction to program explicit conversions. When the instruction is inserted, the "CONVERT" dialog opens. You specify the source data type and the destination data type of the conversion in this dialog. The source value is read and converted to the specified destination data type.

For information on possible conversions, refer to section "Explicit conversion" under "See also".

Syntax

The following syntax is used for the "Convert value" instruction:

SCL

```
<DestinationValue> := <???_TO_???(<SourceValue>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
<Source_value>	Input	Binary numbers, integers, floating-point numbers, times, date and time, character strings, BCD16, BCD32	I, Q, M, D, L, P or constant	Value to be converted.
???_TO_???	-	-		Function that specifies the data type to be converted .
<Target_value>	Output	Binary numbers, integers, floating-point numbers, times, date and time, character strings, BCD16, BCD32	I, Q, M, D, L, P or constant	Result of the conversion

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_INT" := REAL_TO_INT("Tag_REAL");
```

The following table shows how the instruction works using specific operand values:

Operand	Data type	Value
Tag_REAL	REAL	20.56
Tag_INT	INT	21

During the conversion, the value of the "Tag_REAL" operand will be rounded to the nearest integer and saved in the "Tag_INT" operand.

Data type conversion for S7-1200: (Page 2091)

ROUND: Round numerical value

Description

The "Round numerical value" instruction is used to round the value at input IN to the nearest integer. The instruction interprets the value at input IN as a floating-point number and converts it into an integer or floating-point number. If the input value is exactly between an even and odd number, the even number is selected.

Syntax

The following syntax is used for the "Round numerical value" instruction:

SCL

```
ROUND(<Expression>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value to be rounded.
Function value		Integers, floating-point numbers	I, Q, M, D, L, P	Result of the rounding

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := ROUND("Tag_Value");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value	
Tag_Value	1.50000000	-1.50000000
Tag_Result	2	-2

Data type conversion for S7-1200: (Page 2091)

CEIL: Generate next higher integer from floating-point number

Description

Use the "Generate next higher integer from floating-point number" instruction to round the value to the nearest integer. The instruction interprets the input value as floating-point number and converts it to the next higher integer. The function value can be greater than or equal to the input value.

Syntax

The following syntax is used for the "Generate next higher integer from floating-point number" instruction:

SCL

```
CEIL(<Expression>)
CEIL_<Data type>(<Expression>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value
_<Data type>		Integers, floating-point numbers. Default: DINT	-	Data type of the function value: 1. You can specify the data type of the instruction explicitly using "_". 2. If you do not specify the data type explicitly, it will be determined by the utilized tags or type-coded constants. 3. If you neither specify the data type explicitly nor specify defined tags or type-coded constants, the default data type will be used.
Function value		Integers, floating-point numbers	I, Q, M, D, L	Input value rounded up

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result1" := CEIL("Tag_Value");
"Tag_Result2" := CEIL_REAL("Tag_Value");
```

The following table shows how the instruction works using specific operand values:

Operand	Value	
Tag_Value	0.5	-0.5
Tag_Result1	1	0
Tag_Result2	1.0	0.0

The result of the instruction is returned in the operand "Tag_Resultxy" as a function value.

See also

Overview of the valid data types (Page 1908)

FLOOR: Generate next lower integer from floating-point number

Description

Use the "Generate next lower integer from floating-point number" instruction to round the value of a floating point number to the next lower integer. The instruction interprets the input value as floating-point number and converts it to the next lower integer. The function value can be equal or less than the input value.

Syntax

Use the following syntax for the "Generate next lower integer from floating-point number" instruction:

SCL

```
FLOOR(<Expression>)
FLOOR_<Data type>(<Expression>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value
_<Data type>		Integers, floating-point numbers. Default: DINT	-	Data type of the function value: 1. You can specify the data type of the instruction explicitly using "_". 2. If you do not specify the data type explicitly, it will be determined by the utilized tags or type-coded constants. 3. If you neither specify the data type explicitly nor specify defined tags or type-coded constants, the default data type will be used.
Function value		Integers, floating-point numbers	I, Q, M, D, L	Input value rounded

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result1" := FLOOR("Tag_Value");
"Tag_Result2" := FLOOR_REAL("Tag_Value");
```

The following table shows how the instruction works using specific operand values:

Operand	Value	
Tag_Value	0.5	-0.5
Tag_Result1	0	-1
Tag_Result2	0.0	-1.0

The result of the instruction is returned in the operand "Tag_Resultxy" as a function value.

See also

Overview of the valid data types (Page 1908)

TRUNC: Truncate numerical value

Description

The "Truncate numerical value" instruction is used to generate an integer from the input value without rounding. The instruction selects only the integer part of the input value and returns this part without decimal places as the function value.

Syntax

The following syntax is used for the "Truncate numerical value" instruction:

SCL

```
TRUNC(<Expression>)
TRUNC_<Data type>(<Expression>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L	Input value
_<Data type>		Integers, floating-point numbers Default: DINT	-	Data type of the function value: 1. You can specify the data type of the instruction explicitly using "_". 2. If you do not specify the data type explicitly, it will be determined by the utilized tags or type-coded constants. 3. If you neither specify the data type explicitly nor specify defined tags or type-coded constants, the default data type will be used.
Function value		Integers, floating-point numbers	I, Q, M, D, L	Integer component of the input value

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result1" := TRUNC("Tag_Value1");
```

SCL

```
"Tag_Result2" := TRUNC("Tag_Value2"+"Tag_Value3");
"Tag_Result3" := TRUNC_SINT("Tag_Value4");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value1	-1.5
Tag_Result1	-1
Tag_Value2	2.1
Tag_Value3	3.2
Tag_Result2	5
Tag_Result3	2
Tag_Value4	2.4

See also

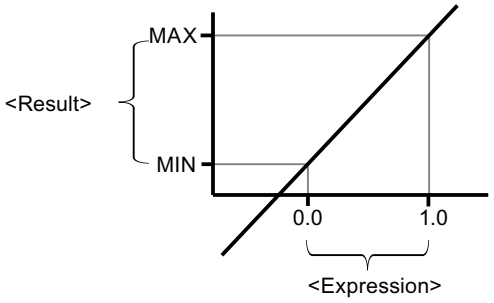
Overview of the valid data types (Page 1908)

SCALE_X: Scale

Description

Use the "Scale" instruction to scale a floating-point number by mapping it to a specific value range. You specify the value range with the MIN and MAX parameters. The result of the scaling is an integer.

The following figure shows an example of how values can be scaled:



The instruction "Scale" works with the following equation:

OUT = [VALUE * (MAX – MIN)] + MIN

Note

For more information on the conversion of analog values, refer to the respective manual.

Syntax

The following syntax is used for the "Scale" instruction:

SCL

```
SCALE_X(MIN := <Operand>,
        VALUE := <Operand>,
        MAX := <Operand>)
SCALE_X_<Data type>(MIN := <Operand>,
                    VALUE := <Operand>,
                    MAX := <Operand>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
MIN	Input	Integers, floating-point numbers	I, Q, M, D, L	Low limit of the value range
VALUE	Input	Floating-point numbers	I, Q, M, D, L	Value to be scaled. When a constant is specified, you must declare this.
MAX	Input	Integers, floating-point numbers	I, Q, M, D, L	High limit of the value range

Parameter	Declaration	Data type	Memory area	Description
_<Data type>		Integers, floating-point numbers Default: INT	-	Data type of the function value: 1. You can specify the data type of the instruction explicitly using "_". 2. If you do not specify the data type explicitly, it will be determined by the utilized tags or type-coded constants. 3. If you neither specify the data type explicitly nor specify defined tags or type-coded constants, the default data type will be used.
Function value		Integers, floating-point numbers	-	Result of scaling

For additional information on valid data types, refer to "See also".

For additional information on declaring constants, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result1" := SCALE_X(MIN := "Tag_Value1",
                         VALUE := "Tag_Real",
                         MAX := "Tag_Value2");
"Tag_Result2" := SCALE_X_REAL(MIN := "Tag_Value1",
                              VALUE := "Tag_Real",
                              MAX := "Tag_Value2");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Real	0.5
Tag_Value1	10
Tag_Value2	30
Tag_Result1	20
Tag_Result2	20.0

See also

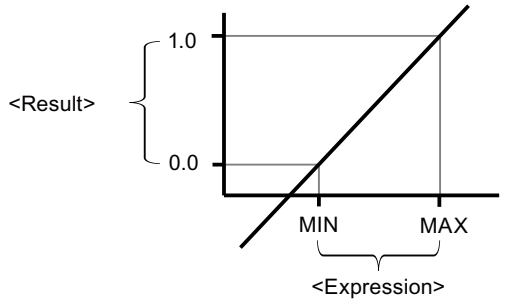
Overview of the valid data types (Page 1908)

NORM_X: Normalize

Description

You can use the instruction "Normalize" to normalize the value of the tag at the VALUE input by mapping it to a linear scale. You can use the MIN and MAX parameters to define the limits of a value range that is applied to the scale. Depending on the location of the normalized value in this value range, the result at output OUT is calculated and stored as a floating-point number. If the value to be normalized equals the value at input MIN, the instruction returns the result "0.0". If the value to be normalized equals the value at input MAX, the instruction returns the result "1.0".

The following figure shows an example of how values can be normalized:



The "Normalize" instruction works with the following equation:

OUT = (VALUE – MIN) / (MAX – MIN)

Note

For more information on the conversion of analog values, refer to the respective manual.

Syntax

The following syntax is used for the "Normalize" instruction:

```
SCL
NORM_X(MIN := <Operand>,
       VALUE := <Operand>,
       MAX := <Operand>)
```

SCL

```
NORM_X_<Data type>(MIN := <Operand>,
                   VALUE := <Operand>,
                   MAX := <Operand>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
MIN [1]	Input	Integers, floating-point numbers	I, Q, M, D, L	Low limit of the value range
VALUE [1]	Input	Integers, floating-point numbers	I, Q, M, D, L	Value to be normalized.
MAX [1]	Input	Integers, floating-point numbers	I, Q, M, D, L	High limit of the value range
_<Data type>		Floating-point numbers Default: REAL	-	Data type of the function value: 1. You can specify the data type of the instruction explicitly using "_". 2. If you do not specify the data type explicitly, it will be determined by the utilized tags or type-coded constants. 3. If you neither specify the data type explicitly nor specify defined tags or type-coded constants, the default data type will be used.
Function value		Floating-point numbers	I, Q, M, D, L	Result of the normalization
[1] If you use constants in these three parameters, you only need to declare one of them.				

For additional information on valid data types, refer to "See also".

For additional information on declaring constants, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result1" := NORM_X(MIN := "Tag_Value1",
                        VALUE := "Tag_InputValue",
                        MAX := "Tag_Value2");
"Tag_Result2" := NORM_X_LREAL(MIN := "Tag_Value1",
                              VALUE := "Tag_InputValue",
                              MAX := "Tag_Value2");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_InputValue	20
Tag_Value1	10
Tag_Value2	30
Tag_Result1	0.5
Tag_Result2	0.5

See also

Overview of the valid data types (Page 1908)

VARIANT

VARIANT_TO_DB_ANY: Convert VARIANT to DB_ANY

Description

You use the "Convert VARIANT to DB_ANY" instruction to query the data block number that the operand that is specified at the IN parameter addresses. This can be an instance data block or an ARRAY data block. The operand at the IN parameter has the data type VARIANT, which means you do not need to know the data type of the data block whose number is to be queried when the program is created. The data block number is read during runtime and written to the operand specified at the RET_VAL parameter.

Requirements

If the requirements are met, the instruction is executed. If the requirements are not met, "0" is output as data block number.

The output tag...	homed...	Conversion options
VARIANT	... a data block which is an instance data block of a PLC data type or a system data type (SDT).	The output tag can be converted to a data block number.
VARIANT	... a data block which is an ARRAY DB.	The output tag can be converted to a data block number.
VARIANT	... a tag with an elementary data type.	It is not possible to convert the output tag to a database number because a data block can never comprise only one elementary data type.
VARIANT	... a structure within a data block.	It is not possible to convert the output tags to a database number because it is only a part within the data block.

Syntax

The following syntax is used for the "Convert VARIANT To DB_ANY" instruction:

SCL

```
VARIANT_TO_DB_ANY(IN := <Operand>,
                  ERR => <Operand>)
```

Parameters

The following table shows the parameters of the "Convert VARIANT to DB_ANY" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	VARIANT	I, Q, M, L	Tag to be read
ERR	Output	INT	I, Q, M, D, L	Error information
Function value (RET_VAL)		DB_ANY	I, Q, M, D, L	Result: Number of the DB

For additional information on valid data types, refer to "See also".

ERR parameter

The following table shows the meaning of the values of the ERR parameter:

Error code* (W#16#...)	Explanation
0000	No error
252C	The VARIANT data type at the IN parameter has the value "0" and the CPU changes to STOP mode.
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
8131	The data block does not exist, is too short, or is located in load memory.
8132	The data block is too short and not an ARRAY data block.
8150	The data type VARIANT at parameter IN provides the value "0". To receive this error message, the "Handle errors within block" block property must be activated. Otherwise the CPU changes to STOP mode and sends the error code 16#252C.
8153	The VARIANT data type at the IN parameter does not point to the start of an ARRAY data block or the length of the VARIANT does not match that of the data block.
8154	The data block has the incorrect data type.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
"OutputDBNumber" := VARIANT_TO_DB_ANY(IN := "InputTag",
                                      ERR := "Tag_Error");
```

The following table shows how the instruction works using specific operand values:

Parameter	Declaration in the block interface	Operand	Value
IN	Input	#InputTag	-
<Function value>	Output	OutputDBNumber	11

The number of a data block that is specified at the #InputTag operand is read. Because the operand has the data type VARIANT, you do not need to know the data type of the tag during program creation. The number is written to the "OutputDBNumber" tag which has the data type DB_ANY.

See also

Overview of the valid data types (Page 1908)

DB_ANY_TO_VARIANT: Convert DB_ANY to VARIANT

Description

The "Convert DB_ANY to VARIANT" instruction is used to generate a VARIANT tag from a data block that meets the requirements listed below. The operand at the IN parameter has the data type DB_ANY, which means that the data block does not have to be known when the program is created. The data block number is read during runtime.

Requirements

If the requirements are met, the instruction is executed. If the requirements are not met or the data block does not exist, the value NULL is output at the RET_VAL parameter. All other accesses with the RET_VAL tag fail.

The input tag of data type ...	homed...	Conversion options
DB_ANY	...a data block which is an instance data block of a PLC data type or a system data type (SDT).	Conversion is possible
DB_ANY	...a data block which is an ARRAY DB.	Conversion is possible
DB_ANY	...a data block which is an instance data block of a function block or a global data block.	Conversion is not possible

Syntax

The following syntax is used for the "Convert DB_ANY to VARIANT" instruction:

SCL

```
DB_ANY_TO_VARIANT(IN := <Operand>,
                  ERR => <Operand>)
```

Parameters

The following table shows the parameters of the "Convert DB_ANY to VARIANT" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	DB_ANY	I, Q, M, D, L	Tag to be referenced and read
ERR	Output	INT	I, Q, M, D, L	Error information
Function value (RET_VAL) 1)		VARIANT	I, Q, M, L	Number of the data block
1) The RET_VAL parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

For additional information on valid data types, refer to "See also".

ERR parameter

The following table shows the meaning of the values of the ERR parameter:

Error code* (W#16#...)	Explanation
0000	No error
8130	The number of the data block is "0"
8131	The data block does not exist, is too short, or is located in load memory.
8132	The data block is too short and not an ARRAY data block.
8134	The data block is write protected.
8154	The data block has the incorrect data type.
8155	The data block has an unknown data type.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
#tempVARIANT := DB_ANY_TO_VARIANT(IN := "InputDB",
                                  ERR := "Tag_Error");
```

The following table shows how the instruction works using specific operand values:

Parameters	Declaration in the block interface	Operand	Value
IN	Input	InputDB	11
<Function value>	Temp	#tempVARIANT	-

The number of any data block that is specified at the "InputDB" operand is used to generate a tag of data type VARIANT that addresses the data block. Because the operand at the IN parameter has the DB_ANY data type, the data block that will be used during runtime does not have to be known when the program is created (neither the name nor the number of the

data block). Because the operand at the RET_VAL parameter has the data type VARIANT, you do not need to know the data type of the data block when the program is created.

Overview of the valid data types (Page 1908)

Legacy

SCALE: Scale

Description

The instruction "Scale" converts the integer on the parameter IN into a floating-point number, which can be scaled in physical units between a low and a high limit. You can use the LO_LIM and HI_LIM parameters to specify the low limit and high limit of the value range to which the input value is scaled. The result of the instruction is output on the OUT parameter.

The instruction "Scale" works with the following equation:

OUT = [((FLOAT (IN) – K1)/(K2–K1)) * (HI_LIM–LO_LIM)] + LO_LIM

The values of the "K1" and "K2" constants are determined by the signal state on the BIPOLAR parameter. The following signal states are possible on the BIPOLAR parameter:

- Signal state "1": It is assumed that the value at the IN parameter is bipolar and in a value range between -27648 and 27648. In this case, the constant "K1" has the value -27648.0 and the constant "K2" the value +27648.0.
- Signal state "0": It is assumed that the value at the IN parameter is unipolar and in a value range between 0 and 27648. In this case, the constant "K1" has the value 0.0 and the constant "K2" the value +27648.0.

When the value at the IN parameter is greater than the value of the "K2" constant, the result of the instruction is set to the value of the high limit (HI_LIM) and an error is output.

When the value at the IN parameter is less than the value of the "K1" constant, the result of the instruction is set to the value of the low limit value (LO_LIM) and an error is output.

When the indicated low limit is greater than the high limit (LO_LIM >HI_LIM), the result is scaled in reverse proportion to the input value.

Syntax

The following syntax is used for the "Scale" instruction:

```
SCL
SCALE(IN := <Expression>,
      HI_LIM := <Operand>,
      LO_LIM := <Operand>,
      BIPOLAR := <Operand>,
      OUT => <Operand>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	INT	I, Q, M, D, L, P	Input value to be scaled.
HI_LIM	Input	REAL	I, Q, M, D, L, P	High limit
LO_LIM	Input	REAL	I, Q, M, D, L, P	Low limit
BIPOLAR	Input	BOOL	I, Q, M, D, L	Indicates if the value at the IN parameter is to be interpreted as bipolar or unipolar. The parameter can assume the following values: 1: Bipolar 0: Unipolar
OUT	Output	REAL	I, Q, M, D, L, P	Result of the instruction
Function value (RET_VAL)		WORD	I, Q, M, D, L, P	Error information

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code (W#16#...)	Explanation
0000	No error
0008	The value of the parameter IN is greater than 27 648 or is less than 0 (unipolar) or -27 648 (bipolar).
General error information	See also: "GET_ERR_ID: Get error ID locally
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
"Tag_ErrorCode" := SCALE(IN := "Tag_InputValue",
                         HI_LIM := "Tag_HighLimit",
                         LO_LIM := "Tag_LowLimit",
                         BIPOLAR := "Tag_Bipolar",
                         OUT => "Tag_Result");
```

The error information is returned in the operand "Tag_ErrorCode" as a function value.

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	Tag_InputValue	22
HI_LIM	Tag_HighLimit	100.0
LO_LIM	Tag_LowLimit	0.0
BIPOLAR	Tag_Bipolar	1
OUT	Tag_Result	50.03978588
RET_VAL	Tag_ErrorCode	W#16#0000

See also

Overview of the valid data types (Page 1908)

GET_ERR_ID: Get error ID locally (Page 2922)

UNSCALE: Unscale

Description

The instruction "Unscale" unscales the floating-point number on the IN parameter in physical units between a low and a high limit and converts them into an integer. You can use the LO_LIM and HI_LIM parameters to specify the low limit and high limit of the value range to which the input value is unscaled. The result of the instruction is output on the OUT parameter.

The instruction "Unscale" works with the following equation:

OUT = [((IN–LO_LIM)/(HI_LIM–LO_LIM)) * (K2–K1)] + K1

The values of the "K1" and "K2" constants are determined by the signal state on the BIPOLAR parameter. The following signal states are possible on the BIPOLAR parameter:

- Signal state "1": It is assumed that the value at the IN parameter is bipolar and in a value range between -27648 and 27648. In this case, the constant "K1" has the value -27648.0 and the constant "K2" the value +27648.0.
- Signal state "0": It is assumed that the value at the IN parameter is unipolar and in a value range between 0 and 27648. In this case, the constant "K1" has the value 0.0 and the constant "K2" the value +27648.0.

When the value at the IN parameter is greater than the value of the "HI_LIM" constant, the result of the instruction is set to the value of the constant (K2) and an error is output.

When the value at the IN parameter is less than the value of the constant of the low limit (LO_LIM), the result of the instruction is set to the value of the constant (K1) and an error is output.

Syntax

The following syntax is used for the instruction "Unscale":

```
SCL
UNSCALE(IN := <Expression>,
        HI_LIM := <Operand>,
        LO_LIM := <Operand>,
        BIPOLAR := <Operand>,
        OUT => <Operand>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	REAL	I, Q, M, D, L, P	Input value to be unscaled to an integer value.
HI_LIM	Input	REAL	I, Q, M, D, L, P	High limit
LO_LIM	Input	REAL	I, Q, M, D, L, P	Low limit
BIPOLAR	Input	BOOL	I, Q, M, D, L	Indicates if the value at the IN parameter is to be interpreted as bipolar or unipolar. The parameter can assume the following values: 1: Bipolar 0: Unipolar
OUT	Output	INT	I, Q, M, D, L, P	Result of the instruction
Function value (RET_VAL)		WORD	I, Q, M, D, L, P	Error information

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code (W#16#...)	Explanation
0000	No error
0008	The value of the IN parameter is greater than the value of the high limit (HI_LIM) or less than the value of the low limit (LO_LIM).
General error information	See also: "GET_ERR_ID: Get error ID locally
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

```
"Tag_ErrorCode" := UNSCALE(IN := "Tag_InputValue",
                           HI_LIM := "Tag_HighLimit",
```

```
LO_LIM := "Tag_LowLimit",
BIPOLAR := "Tag_Bipolar",
OUT => "Tag_Result");
```

The error information is returned in the operand "Tag_ErrorCode" as a function value.

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	Tag_InputValue	50.03978588
HI_LIM	Tag_HighLimit	100.0
LO_LIM	Tag_LowLimit	0.0
BIPOLAR	Tag_Bipolar	1
OUT	Tag_Result	22
RET_VAL	Tag_ErrorCode	W#16#0000

GET_ERR_ID: Get error ID locally (Page 2922)

Program control operations

IF: Run conditionally

Description

The instruction "Run conditionally" branches the program flow depending on a condition. The condition is an expression with Boolean value (TRUE or FALSE). Logical expression or comparative expressions can be stated as conditions.

When the instruction is executed, the stated expressions are evaluated. If the value of an expression is TRUE, the condition is fulfilled; if the value is FALSE, it is not fulfilled.

Syntax

Depending on the type of branch, you can program the following forms of the instruction:

- Branch through IF:

SCL

```
IF <Condition> THEN <Instructions>
END_IF;
```

If the condition is satisfied, the instructions programmed after the THEN are executed. If the condition is not satisfied, the execution of the program continues with the next instruction after the END_IF.

- Branch through IF and ELSE:

SCL

```
IF <Condition> THEN <Instructions1>
ELSE <Instructions0>;
END_IF;
```

If the condition is satisfied, the instructions programmed after the THEN are executed. If the condition is not satisfied, the instructions programmed after the ELSE are executed. Then the execution of the program continues with the next instruction after the END_IF.

- Branch through IF, ELSIF and ELSE:

SCL

```
IF <Condition1> THEN <Instructions1>
ELSIF <Condition2> THEN <Instruction2>
ELSE <Instructions0>;
END_IF;
```

If the first condition (<Condition1>) is satisfied, the instructions (<Instructions1>) after the THEN are executed. After execution of the instructions, the execution of the program continues after the END_IF.

If the first condition is not satisfied, the second condition (<Condition2>) is checked. If the second condition (<Condition2>) is fulfilled, the instructions (<Instructions2>) after the THEN are executed. After execution of the instructions, the execution of the program continues after the END_IF.

If none of the conditions are fulfilled, the instructions (<Instructions0>) after ELSE are executed followed by the execution of the program after END_IF.

You can nest as many combinations of ELSIF and THEN as you like within the IF instruction. The programming of an ELSE branch is optional.

The syntax of the IF instruction consists of the following parts:

Parameter	Data type	Memory area	Description
<Condition>	BOOL	I, Q, M, D, L	Expression to be evaluated
<Instructions>	-		Instructions to be executed with satisfied condition. An exception are instructions programmed after the ELSE. These are executed if no condition within the program loop is satisfied.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
IF "Tag_1" = 1
THEN "Tag_Value" := 10;
ELSIF "Tag_2" = 1
THEN "Tag_Value" := 20;
ELSIF "Tag_3" = 1
THEN "Tag_Value" := 30;
ELSE "Tag_Value" := 0;
END_IF;
```

The following table shows how the instruction works using specific operand values:

Operand	Value			
Tag_1	1	0	0	0
Tag_2	0	1	0	0
Tag_3	0	0	1	0
Tag_Value	10	20	30	0

Overview of the valid data types (Page 1908)

CASE: Create multiway branch

Description

The instruction "Create multiway branch" executes one of several instruction sequences depending on the value of a numerical expression.

The value of the expression must be an integer. When the instruction is executed, the value of the expression is compared with the values of several constants. If the value of the expression agrees with the value of a constant, the instructions programmed directly after this constant are executed. The constants can assume the following values:

- An integer (for example, 5)
- A range of integers (for example, 15..20)
- An enumeration consisting of integers and ranges (for example, 10, 11, 15..20)

Syntax

The following syntax is used for the "Create multiway branch" instruction:

```
SCL
CASE <Expression> OF
<Constant1>: <Instructions1>
<Constant2>: <Instructions2>
<ConstantX>: <InstructionsX>; // X >=3
ELSE <Instructions0>;
END_CASE;
```

The syntax of the instruction consists of the following parts:

Parameter	Data type	Memory area	Description
<Expression>	Integers	I, Q, M, D, L	Value which is compared to the programmed constant values.
<Constant>	Integers	I, Q, M, D, L	Constant values which form the condition for the execution of an instruction sequence. The constants can assume the following values: • An integer (for example, 5) • A range of integers (for example, 15..20) • An enumeration consisting of integers and ranges (for example, 10, 11, 15..20)
<Instruction>	-		Any instructions which are executed if the value of the expression agrees with the value of a constant. An exception are instructions programmed after the ELSE. These instructions are executed if the values do not agree.

For additional information on valid data types, refer to "See also".

If the value of the expression agrees with the value of the first constant (<Constant1>), the instructions (<Instructions1>) which are programmed directly after the first constant are executed. Program execution subsequently resumes after the END_CASE.

If the value of the expression does not agree with the value of the first constant (<Constant1>), this value is compared to the value of the constant which is programmed next. In this way, the CASE instruction is executed until the values agree. If the value of the expression does not correspond to any of the programmed constant values, the instructions (<Instructions0>) which are programmed after the ELSE are executed. ELSE is an optional part of the syntax and can be omitted.

The CASE instruction can also be nested by replacing an instruction block with CASE. END_CASE represents the end of the CASE instruction.

Example

The following example shows how the instruction works:

```
SCL
CASE "Tag_Value" OF
     0 :
     "Tag_1" := 1;
     1,3,5 :
     "Tag_2" :=1;
     6..10 :
     "Tag_3" := 1;
     16,17,20..25 :
     "Tag_4" := 1;
ELSE "Tag_5" := 1;
END_CASE;
```

The following table shows how the instruction works using specific operand values:

Operand	Values				
Tag_Value	0	1, 3 , 5	6, 7, 8, 9, 10	16,17, 20, 21, 22, 23, 24, 25	2
Tag_1	1	-	-	-	-
Tag_2	-	1	-	-	-
Tag_3	-	-	1	-	-
Tag_4	-	-	-	1	-
Tag_5	-	-	-	-	1
1: The operand is set to the signal state "1". -: The signal state of the operand remains unaltered.					

See also

CONTINUE: Recheck loop condition (Page 2907)

Overview of the valid data types (Page 1908)

EXIT: Exit loop immediately (Page 2908)

FOR: Run in counting loop

Description

The instruction "Run in counting loop" causes repeated execution of a program loop until a loop variable lies within a specified value range.

Program loops can also be nested. Within a program loop, you can program additional program loops with other loop variables.

The current continuous run of a program loop can be ended by the instruction "Recheck loop condition" (CONTINUE). The instruction "Exit loop immediately" (EXIT) ends the entire loop execution. For additional information on this topic, refer to "See also".

Limits for FOR statements

To program "safe" FOR statements that do not run endlessly, observe the following rules and limits:

Rule

```
FOR ii := Start TO End BY Step DO
```

If ...	... then	Note
start < end	end < (PMAX step)	Run tag ii runs in a positive direction
start > end AND step < O	end > (NMAX step)	Run tag ii runs in a negative direction

Limits

Different limits apply to the possible data types:

Data type	PMAX	NMAX
ii of type SINT	127	-128
ii of type INT	32767	-32768
ii of type DINT	2147483647	-2147483648
ii of type LINT	9223372036854775807	-9223372036854775808

Syntax

The following syntax is used for the "Run in counting loop" instruction:

SCL

```
FOR<Run_tag> := <Start_value> TO<End_value> BY<Increment> DO<Instructions>
END_FOR;
```

Parameter

The following table shows the parameters of the "Run in counting loop" instruction:

Parameter	Data type		Memory area	Description
	S7-1200	S7-1500		
<Run tag>	SINT, INT, DINT	SINT, INT, DINT, LINT	I, Q, M, D, L	Operand whose value is evaluated with the loop execution. The data type of the loop variable determines the data type of the other parameters.
<Start value>	SINT, INT, DINT	SINT, INT, DINT, LINT	I, Q, M, D, L	Expression whose value is allocated at the start of the loop execution of the loop variables.

Parameter	Data type		Memory area	Description
	S7-1200	S7-1500		
<End value>	SINT, INT, DINT	SINT, INT, DINT, LINT	I, Q, M, D, L	Expression whose value defines the last run of the program loop. The value of the loop variable is checked before each loop: • End value not reached: The instructions according to DO are executed • End value is reached: The FOR loop is executed one last time • End value exceeded: The FOR loop is completed An alteration to the end value is not permitted during execution of the instruction.
<Increment>	SINT, INT, DINT	SINT, INT, DINT, LINT	I, Q, M, D, L	Expression by whose value the loop variable is increased (positive increment) or decreased (negative increment) after each loop. Specification of the increment is optional. If no increment is given, the value of the loop variable is increased by 1 after each loop. An alteration of the increment is not permitted during execution of the instruction.
<Instructions>	-	-		Instructions which are carried out with each loop, as long as the value of the loop variable lies within the value range. The value range is defined by the start and end values.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
FOR i := 2 TO 8 BY 2
    DO "a_array[i] := "Tag_Value"*"b_array[i]";
END_FOR;
```

The operand "Tag_Value" is multiplied with the elements (2, 4, 6, 8) of the ARRAY tag "b_array". The result is read in to the elements (2, 4, 6, 8) of the ARRAY tag "a_array".

See also

CONTINUE: Recheck loop condition (Page 2907)

EXIT: Exit loop immediately (Page 2908)

Overview of the valid data types (Page 1908)

WHILE: Run if condition is met

Description

The instruction "Run if condition is met" causes a program loop to be repeatedly executed until the implementation condition is satisfied. The condition is an expression with Boolean value (TRUE or FALSE). Logical expression or comparative expressions can be stated as conditions.

When the instruction is executed, the stated expressions are evaluated. If the value of an expression is TRUE, the condition is fulfilled; if the value is FALSE, it is not fulfilled.

Program loops can also be nested. Within a program loop, you can program additional program loops with other loop variables.

The current continuous run of a program loop can be ended by the instruction "Recheck loop condition" (CONTINUE). The instruction "Exit loop immediately" (EXIT) ends the entire loop execution. For additional information on this topic, refer to "See also".

Syntax

The following syntax is used for the "Run if condition is met" instruction:

```
SCL
WHILE <Condition> DO <Instructions>
END_WHILE;
```

The syntax of the WHILE instruction consists of the following parts:

Parameter	Data type	Memory area	Description
<Condition>	BOOL	I, Q, M, D, L	Expression which is evaluated before each loop.
<Instructions>	-		Instructions to be executed with satisfied condition. If the condition has not been satisfied, program execution continues after END_WHILE.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
WHILE
      "Tag_Value1" <> "Tag_Value2"
      DO "Tag_Result"
      := "Tag_Input";
END_WHILE;
```

As long as the values of the operands "Tag_Value1" and "Tag_Value2" do not match, the value of the operand "Tag_Input" is allocated to the operand "Tag_Result".

See also

EXIT: Exit loop immediately (Page 2908)

CONTINUE: Recheck loop condition (Page 2907)

Overview of the valid data types (Page 1908)

REPEAT: Run if condition is not met

Description

The instruction "Run if condition is not met" causes a program loop to be repeatedly executed until a termination condition is met. The condition is an expression with Boolean value (TRUE or FALSE). Logical expression or comparative expressions can be stated as conditions.

When the instruction is executed, the stated expressions are evaluated. If the value of an expression is TRUE, the condition is fulfilled; if the value is FALSE, it is not fulfilled.

The instructions are executed once, even if the termination condition is fulfilled.

Program loops can also be nested. Within a program loop, you can program additional program loops with other loop variables.

The current continuous run of a program loop can be ended by the instruction "Recheck loop condition" (CONTINUE). The instruction "Exit loop immediately" (EXIT) ends the entire loop execution. For additional information on this topic, refer to "See also".

Syntax

The following syntax is used for the "Run if condition is not met" instruction:

```
SCL
REPEAT <Instructions>
UNTIL <Condition>END_REPEAT;
```

The syntax of the REPEAT instruction consists of the following parts:

Parameter	Data type	Memory area	Description
<Instructions>	-		Instructions that are executed as long as the programmed condition has the value FALSE. The instructions are executed once, even if the termination condition is fulfilled.
<Condition>	BOOL	I, Q, M, D, L	Expression which is evaluated after each loop. If the expression has the value FALSE, the program loop is executed once again. If the expression has the value TRUE, the program loop continues after END_REPEAT.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
REPEAT "Tag_Result"
        := "Tag_Value";
UNTIL "Tag_Error"
END_REPEAT;
```

As long as the value of the operand "Tag_Error" has the signal state "0", the value of the operand "Tag_Value" is allocated to the operand "Tag_Result".

See also

CONTINUE: Recheck loop condition (Page 2907)

EXIT: Exit loop immediately (Page 2908)

Overview of the valid data types (Page 1908)

CONTINUE: Recheck loop condition

Description

The "Recheck loop condition" instruction ends the current program run of a FOR, WHILE or REPEAT loop.

After execution of the instruction, the conditions for the continuation of the program loop are evaluated again. The instruction affects the program loop which directly contains the instruction.

Syntax

The following syntax is used for the "Recheck loop condition" instruction:

SCL

```
CONTINUE;
```

Example

The following example shows how the instruction works:

SCL

```
FOR i
     := 1 TO 15 BY 2 DO
     IF (i < 5) THEN
     CONTINUE;
END_IF;
      "DB10".Test[i] := 1;
END_FOR;
```

For additional information on valid data types, refer to "See also".

If the condition i < 5 is satisfied, then the subsequent value allocation ("DB10".Test[i] := 1) will not be executed. The run variable (i) is increased by the increment of "2" and checked to see whether its current value lies in the programmed value range. If the run variable lies in the value range, the IF condition is evaluated again.

If the condition i < 5 is not satisfied, then the subsequent value allocation ("DB10".Test[i] := 1) will be executed and a new loop started. In this case, the run variable is also increased by the increment "2" and checked.

See also

EXIT: Exit loop immediately (Page 2908)

Overview of the valid data types (Page 1908)

EXIT: Exit loop immediately

Description

The instruction "Exit loop immediately" cancels the execution of a FOR, WHILE or REPEAT loop at any point regardless of conditions. The execution of the program is continued after the end of the loop (END_FOR, END_WHILE, END_REPEAT).

The instruction affects the program loop which directly contains the instruction.

Syntax

The following syntax is used for the "Exit loop immediately" instruction:

SCL

```
EXIT;
```

Example

The following example shows how the instruction works:

SCL

```
FOR i := 15 TO 1 BY -2 DO
IF (i < 5)
THEN EXIT;
END_IF;
"DB10".Test[i] := 1;
END_FOR;
```

For additional information on valid data types, refer to "See also".

If the condition i < 5 is satisfied, then the execution of the loop will be canceled. Program execution resumes after the END_FOR.

If the condition i < 5 is not satisfied, then the subsequent value allocation ("DB10".Test[i] := 1) will be executed and a new loop started. The run tag (i) is decreased by the increment of "-2" and it is checked whether its current value lies in the programmed value range. If the (i) run variable lies within the value range, the IF condition is evaluated again.

See also

CONTINUE: Recheck loop condition (Page 2907)

Overview of the valid data types (Page 1908)

GOTO: Jump

Description

Use the instruction "Jump" to resume the execution of a program at a given point marked with a jump label.

The jump labels and the instruction "Jump" must be in the same block. The name of a jump label can only be assigned once within a block. Each jump label can be the target of several jump instructions.

A jump from the "outside" into a program loop is not permitted, but a jump from a loop to the "outside" is possible.

Syntax

Use the following syntax for the "Jump" instruction:

SCL

```
GOTO <Jump label>
...
<Jump label>: <Instructions>
```

The syntax of the GOTO instruction consists of the following parts:

Parameter	Data type	Description
<jump label>	-	Jump label to be jumped to
<Instructions>	-	Instructions which are executed after the jump.

Example

The following example shows how the instruction works:

SCL

```
CASE "Tag_Value" OF
1 : GOTO MyLABEL1;
2 : GOTO MyLABEL2;
3 : GOTO MyLABEL3;
ELSE GOTO MyLABEL4;
END_CASE;
MyLABEL1: "Tag_1" := 1;
MyLABEL2: "Tag_2" := 1;
MyLABEL3: "Tag_3" := 1;
MyLABEL4: "Tag_4" := 1;
```

Depending on the value of the "Tag_Value" operand, the execution of the program will resume at the point identified by the corresponding jump label. If the operand "Tag_Value" has the value 2, for example, program execution will resume at the jump label "MyLABEL2". The program line identified by the jump label "MyLABEL1" will be skipped in this case.

Overview of the valid data types (Page 1908)

RETURN: Exit block

Description

The instruction "Exit block" exits the program execution in the currently edited block and continues in the calling block.

The instruction can be omitted at the end of the block.

Syntax

The following syntax is used for the "Exit block" instruction:

SCL

```
RETURN;
```

Example

The following example shows how the instruction works:

SCL

```
IF "Tag_Error" <>0 THEN RETURN;
END_IF;
```

If the signal state of the "Tag_Error" operand is not zero, execution of the program ends in the block currently being processed.

Overview of the valid data types (Page 1908)

(*...*): Insert a comment section

Description

You can use the "Insert a comment section" instruction to add a comment section. The text within the parenthesis "(*...*)" is handled as a comment.

Syntax

The following syntax is used for the "Insert a comment section" instruction:

SCL

```
(*...*)
```

Example

The following example shows how the instruction works:

SCL

```
(*This is a comment section.*)
```

Overview of the valid data types (Page 1908)

Runtime control

ENDIS_PW: Limit and enable password legitimation

Description

You use the "Limit and enable password legitimation" instruction to specify whether passwords configured for the CPU are legitimized or not. In this way, you can prevent legitimized connections, even if the correct password is known.

When you call the instruction and the REQ parameter has the signal state "0", the currently set state is displayed at the output parameters. If changes have been made to the input parameters, these are not transferred to the output parameters.

When you call the instruction and the REQ parameter has the signal state "1", the signal state is taken from the input parameters (F_PWD, FULL_PWD, R_PWD, HMI_PWD). FALSE means that legitimation per password is not permitted; TRUE means the password can be used.

Disable or enabling of the passwords can be allowed or prohibited individually. For example, all passwords can be prohibited except the fail-safe password. You can thus limit access options to a small user group. The output parameters (F_PWD_ON, FULL_PWD_ON, R_PWD_ON, HMI_PWD_ON) always show the current status of the password use, regardless of the REQ parameter.

Passwords that are not configured must have the signal state TRUE at the input and return the signal state TRUE at the output. The fail-safe password can only be configured for an F-CPU and must therefore always be interconnected with the signal state TRUE in a standard CPU. If the instruction returns an error, the call has no effect and the previous lock is still in effect.

Disabled passwords can be enabled again under the following conditions:

- The CPU is reset to its factory settings.
- The front panel of the S7-1500 CPU supports a dialog that allows you to navigate to the appropriate menu in which the passwords can be enabled again.
- When you call the "Limit and enable password legitimation" instruction, the input parameter of the desired password has the signal state "1".
- Set the operating mode switch to STOP. The restriction to password legitimation is re-established as soon as the switch is set back to RUN.
- Plugging an empty memory card (transfer card or program card) into an S7-1200 CPU.
- The transition from POWER OFF to POWER ON disables the protection in the S7-1200 CPU. The "Limit and enable password legitimation" instruction must be called once again in the program (e.g. in the startup OB).

Note

The "Limit and enable password legitimation" instruction blocks access from HMI systems if the HMI password has not been enabled.

Note

Existing legitimized connections retain their access rights and you cannot use the "Limit and enable password legitimation" instruction to restrict them.

Preventing accidental lockout of an S7-1500 CPU

The settings can be made on the front panel of the CPU and the CPU saves the most recent setting.

To prevent accidental lockout, the protection can be disabled by setting the mode switch to STOP with an S7-1500 CPU. The protection is automatically enabled again by setting mode selector to RUN without having to call the "Limit and enable password legitimation" instruction again or taking additional actions on the front panel.

Preventing accidental lockout of an S7-1200 CPU

Because the S7-1200 CPU does not have a operating mode switch, protection is disabled with POWER OFF - POWER ON. This means that it is possible and advisable to prevent accidental lockout with the help of specific program sequences within your program.

To do so, program a time control either by means of a cyclic interrupt OB or a timer in the Main OB (OB 1). This gives you the option of calling the "Limit and enable password legitimation" instruction in the respective OB (e.g., OB 1 or OB 35) relatively quickly after a transition from POWER OFF to POWER ON and the associated disabling of the protection. Call the instruction in the startup OB (OB 100) to keep the time window in which the instruction is inactive and there are no limitations for password legitimation relatively small. This procedure will give you the best possible protection from unauthorized access.

If there has been an accidental lockout, you can skip the call in the startup OB (by querying an input parameter, for example) and you have the set time (for example, 10 seconds up to 1 minute) to establish a connection to the CPU before the lock becomes active once again.

If there is no timer in your program code and a lockout has occurred, insert an empty transfer card or an empty program card into the CPU. The empty transfer card or program card deletes the internal load memory of the CPU. You must then download the user program once again from STEP 7 to the CPU.

Procedure for lost passwords with an S7-1200 CPU

If you have lost the password for a password-protected S7-1200 CPU, delete the password-protected program with an empty transfer card or program card. The empty transfer card or program card deletes the internal load memory of the CPU. You can then load a new user program from STEP 7 Basic in the CPU.

Warning

Inserting an empty transfer card

When you insert a transfer card in a CPU during runtime, the CPU goes to STOP mode. If operating states are unstable, controllers may fail and thus cause the uncontrolled operation of the controlled devices. This leads to an unforeseen operation of the automation system which can cause deadly or serious injuries and/or damage to property.

Once you have pulled the transfer card, the content of the transfer card is available in the internal load memory. Make sure that the card does not include a program at this point.

Warning

Inserting an empty program card

When you insert a program card in a CPU during runtime, the CPU goes to STOP mode. If operating states are unstable, controllers may fail and thus cause the uncontrolled operation of the controlled devices. This leads to an unforeseen operation of the automation system which can cause deadly or serious injuries and/or damage to property.

Make sure that the program card is empty. The internal load memory is copied to the empty program card. Once you have pulled the previously empty program card, the internal load memory is empty.

You must remove the transfer card or program card before you put the CPU into RUN mode.

Effects of password use on the operating modes

The following table shows what effects the password use by means of the "Limit and enable password legitimation" instruction has on the operating modes and the corresponding user actions.

Action	Password protection by means of the instruction
Basic state after • Operating mode switch to STOP • Reset memory manually (PG, switch, change of MC (Motion Control)) • Reset to factory setting	Not activated (no restrictions)
Basic state after POWER ON	• S7-1200 CPU: The lock is disabled and the instruction must be called once again in the program (e.g., in the startup OB). • S7-1500 CPU: Enabled (if a lock was activated before POWER OFF). The option of not allowing passwords is retentive.
Operating mode transition RUN/STARTUP/HOLD -> STOP (by terminating the instruction, an error or communication) or STOP -> STARTUP/RUN/HOLD	Activated Passwords still cannot be used.

Syntax

The following syntax is used for the "Limit and enable password legitimation" instruction:

SCL

```
ENDIS_PW(REQ := <Operand>,
         F_PWD := <Operand>,
         FULL_PWD := <Operand>,
         R_PWD := <Operand>,
         HMI_PWD := <Operand>,
         F_PWD_ON => <Operand>,
         FULL_PWD_ON => <Operand>,
         R_PWD_ON => <Operand>,
         HMI_PWD_ON => <Operand>)
```

Parameters

The following table shows the parameters of the "Limit and enable password legitimation" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L	When the REQ parameter has the signal state "0", the currently set signal state of the passwords is queried.
F_PWD	Input	BOOL	I, Q, M, D, L	Read/write access including fail-safe • F_PWD = "0": Do not allow password • F_PWD = "1": Allow password
FULL_PWD	Input	BOOL	I, Q, M, D, L	Read/write access • FULL_PWD = "0": Do not allow password • FULL_PWD = "1": Allow password
R_PWD	Input	BOOL	I, Q, M, D, L	Read access • R_PWD = "0": Do not allow password • R_PWD = "1": Allow password
HMI_PWD	Input	BOOL	I, Q, M, D, L	HMI access • HMI_PWD = "0": Do not allow password • HMI_PWD = "1": Allow password
F_PWD_ON	Output	BOOL	I, Q, M, D, L	Read/write access status including fail-safe • F_PWD_ON = "0": Password not allowed • F_PWD_ON = "1": Password allowed
FULL_PWD_ON	Output	BOOL	I, Q, M, D, L	Read/write access status • FULL_PWD_ON = "0": Password not allowed • FULL_PWD_ON = "1": Password allowed
R_PWD_ON	Output	BOOL	I, Q, M, D, L	Read-access status • R_PWD_ON = "0": Password not allowed • R_PWD_ON = "1": Password allowed

Parameter	Declaration	Data type	Memory area	Description
HMI_PWD_ON	Output	BOOL	I, Q, M, D, L	HMI-access status • HMI_PWD_ON = "0": Password not allowed • HMI_PWD_ON = "1": Password allowed
Function value (RET_VAL)		WORD	I, Q, M, D, L	Error information

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
8090	The "Limit and enable password legitimation" instruction is not supported
80D0	The password for fail-safe is not configured. The signal state must be TRUE for standard CPUs.
80D1	The read/write access is not configured
80D2	The read access is not configured
80D3	The HMI access is not configured
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := ENDIS_PW(REQ := 0,
                         F_PWD := 0,
                         FULL_PWD := 0,
                         R_PWD := 1,
                         HMI_PWD := 0,
                         F_PWD_ON => "Status_F_PWD",
                         FULL_PWD_ON => "Status_FULL_PWD",
                         R_PWD_ON => "Status_R_PWD",
                         HMI_PWD_ON => "Status_HMI_PWD");
```

The following table shows how the instruction works using specific operand values:

Operand	Data type	Value
REQ	BOOL	0
F_PWD	BOOL	0
FULL_PWD	BOOL	0

Operand	Data type	Value
R_PWD	BOOL	1
HMI_PWD	BOOL	0
Status_F_PWD	BOOL	0
Status_FULL_PWD	BOOL	0
Status_R_PWD	BOOL	1
Status_HMI_PWD	BOOL	0

The instruction is executed because the REQ operand has the signal state "0". The R_PWD operand has the signal state "1", which means that read access is allowed when the assigned password is entered. The R_PWD_ON status operand also has the signal state "1", thereby signaling that the R_PWD operand is activated.

RE_TRIGR: Restart cycle monitoring time

Description

The instruction "Restart cycle monitoring time" restarts the maximum cycle time of the CPU. The cycle monitoring time then restarts with the time you have set in the CPU configuration.

The "Restart cycle monitoring time" can be called, regardless of the priority, in all blocks.

If the instruction is called in a block with a higher priority, for example, a hardware interrupt, diagnostic interrupt, or cyclic interrupt, the instruction will not be executed.

The "Restart cycle monitoring time" instruction executes completely within a time span (10 times the maximum program cycle), regardless of the number of calls. Once this time has expired, the program cycle can no longer be prolonged.

Syntax

The following syntax is used for the "Restart cycle monitoring time" instruction:

```
SCL
RE_TRIGR()
```

Parameters

The "Restart cycle monitoring time" instruction has no parameters and supplies no error information.

STP: Exit program

Description

You use the "Exit program" instruction to set the CPU to STOP mode and therefore to terminate the execution of the program. The effects of changing from RUN to STOP depend on the CPU configuration.

Syntax

The following syntax is used for the instruction "Exit program":

SCL

```
STP()
```

GET_ERROR: Get error locally

Description

The "Get error locally" instruction is used to query the occurrence of errors within a block. This is usually to access error. If the system reports an error during the processing of the block, detailed information is generated for the first error to occur during the execution of the block since the last execution of the instruction.

The error information can only be saved in operands of the "ErrorStruct" system data type. The "ErrorStruct" system data type specifies the exact structure in which the information about the error is stored. Using additional instructions, you can evaluate this structure and program an appropriate response. If several errors occur in the block, the error information about the next error to occur in the instruction is output only after the first error that occurred has been remedied.

Note

The <Operand> is only changed if error information is present. To set the operand back to "0" after handling the error, you have the following options:

- Declare the operand in the "Temp" section of the block interface.
- Reset the operand to "0" before calling the instruction.

You can find an example of how you can implement the instruction in combination with other troubleshooting options under "See also".

Note

The "Get error locally" instruction enables local error handling within a block. If "Get error locally" is inserted in the program code of a block, any predefined system reactions are ignored if errors occur.

Syntax

The following syntax is used for the "Get error locally" instruction:

SCL

```
GET_ERROR(<Operand>)
```

Parameter

The following table shows the parameters of the "Get error locally" instruction:

Parameter	Data type	Memory area	Description
<Operand>	ErrorStruct	D, L	Information about errors that have occurred

Data type "ErrorStruct"

The following table shows the structure of the "ErrorStruct" data type:

Structure component		Data type	Description
ERROR_ID		WORD	Error ID
FLAGS		BYTE	Shows if an error occurred during a block call. 16#01: Error during a block call 16#00: No error during a block call
REACTION		BYTE	Default reaction: 0: Ignore (write error), 1: Continue with substitute value "0" (read error), 2: Skip instruction (system error)
CODE_ADDRESS		CREF	Information about the address and type of block
	BLOCK_TYPE	BYTE	Type of block where the error occurred: 1: OB 2: FC 3: FB
	CB_NUMBER	UINT	Number of the code block
	OFFSET	UDINT	Reference to the internal memory
MODE		BYTE	Information about the address of an operand
OPERAND_NUMBER		UINT	Operand number of the machine command
POINTER_NUMBER_LOCATION		UINT	(A) Internal pointer
SLOT_NUMBER_SCOPE		UINT	(B) Storage area in internal memory
DATA_ADDRESS		NREF	Information about the address of an operand
	AREA	BYTE	(C) Memory area: L: 16#40 – 4E, 86, 87, 8E, 8F, C0 – CE I: 16#81 Q: 16#82 M: 16#83 DB: 16#84, 85, 8A, 8B Range violations for a directly editable tag of data type DINT: 16#04

Structure component		Data type	Description
	DB_NUMBER	UINT	(D) Number of the data block
	OFFSET	UDINT	(E) Relative address of the operand

Structure component "ERROR_ID"

The following table shows the values that can be output at the structure component "ERROR_ID":

ID* (hexadecimal)	ID* (decimal)	Description
0	0	No error
2503	9475	Invalid pointer
2520	9504	Invalid STRING
2522	9506	Read error: Operand outside the valid range
2523	9507	Write error: Operand outside the valid range
2524	9508	Read error: Invalid operand
2525	9509	Write error: Invalid operand
2528	9512	Read error: Data alignment
2529	9513	Write error: Data alignment
252C	9516	Invalid pointer
2530	9520	Write error: Data block
2533	9523	Invalid pointer used
2538	9528	Access error: DB does not exist
2539	9529	Access error: Wrong DB used
253A	9530	Global data block does not exist
253C	9532	Faulty information or the function does not exist
253D	9533	System function does not exist
253E	9534	Faulty information or the function block does not exist
253F	9535	System block does not exist
2550	9552	Access error: DB does not exist
2551	9553	Access error: Wrong DB used
2575	9589	Error in the program nesting depth
2576	9590	Error in the local data distribution
2577	9591	The block property "Parameter passing via registers" is not selected.
25A0	9632	Internal error in TP
25A1	9633	Tag is write-protected
25A2	9634	Invalid numerical value of tag
2942	10562	Read error: Input
2943	10563	Write error: Output
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".		

Example

The following example shows how the instruction works:

SCL

```
LABEL: #TagOut := #Field[#index] * REAL#40.5;

GET_ERROR(#Error);

IF #Error.REACTION = 1 THEN
   GOTO LABEL;
   ;
END_IF;
```

An error occurred accessing the #Field[#index] tag. The #TagOut operand returns the signal state "1" despite the read/access error and the multiplication is performed with the value "0.0". If this error scenario occurs, we recommend that you program the "Get error locally" instruction after the multiplication to get the error. The error information supplied by the "Get error locally" instruction is evaluated with a comparison. If the #Error.REACTION structure component has the value "1", there is a read/access error and the program execution begins again at the jump label LABEL.

Querying and fixing errors in the program code (Page 228)

GET_ERR_ID: Get error ID locally

Description

The "Get error ID locally" instruction is used to query the occurrence of errors within a block. This is usually to access error. If the system reports during the block processing errors within the block execution since the last execution of the instruction, the instruction outputs the error ID of the first error that occurred.

The error ID can only be saved in operands of the WORD data type. If several errors occur in the block, the error ID of the next error to occur in the instruction is output only after the first error that occurred has been remedied.

Note

The <Operand> is only changed if error information is present. To set the operand back to "0" after handling the error, you have the following options:

- Declare the operand in the "Temp" section of the block interface.
- Reset the operand to "0" before calling the instruction.

The output of the "Get error ID locally" instruction is only set if error information is present. If one of these conditions is not fulfilled, the remaining program execution is not affected by the "Get error ID locally" instruction.

You can find an example of how you can implement the instruction in combination with other troubleshooting options under "See also".

Note

The "Get error ID locally" instruction enables local error handling within a block. If the "Get error ID locally" instruction is inserted in the program code of a block, any predefined system reactions are ignored if errors occur.

Syntax

The following syntax is used for the "Get error ID locally" instruction:

SCL

```
GET_ERR_ID()
```

Parameter

The following table shows the parameters of the "Get error ID locally" instruction:

Parameter	Data type	Memory area	Description
Function value	WORD	D, L	Error ID

Error ID

The following table shows the values that can be output:

ID* (hexadecimal)	ID* (decimal)	Description
0	0	No error
2503	9475	Invalid pointer
2520	9504	Invalid STRING
2522	9506	Read error: Operand outside the valid range
2523	9507	Write error: Operand outside the valid range
2524	9508	Read error: Invalid operand
2525	9509	Write error: Invalid operand
2528	9512	Read error: Data alignment
2529	9513	Write error: Data alignment
252C	9516	Invalid pointer
2530	9520	Write error: Data block
2533	9523	Invalid pointer used
2538	9528	Access error: DB does not exist
2539	9529	Access error: Wrong DB used
253A	9530	Global data block does not exist
253C	9532	Faulty information or the function does not exist

ID* (hexadecimal)	ID* (decimal)	Description
253D	9533	System function does not exist
253E	9534	Faulty information or the function block does not exist
253F	9535	System block does not exist
2550	9552	Access error: DB does not exist
2551	9553	Access error: Wrong DB used
2575	9589	Error in the program nesting depth
2576	9590	Error in the local data distribution
2577	9591	The block property "Parameter passing via registers" is not selected.
25A0	9632	Internal error in TP
25A1	9633	Tag is write-protected
25A2	9634	Invalid numerical value of tag
2942	10562	Read error: Input
2943	10563	Write error: Output
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".		

Example

The following example shows how the instruction works:

SCL

```
#TagOut := #Field[#index] * REAL#40.5;

#TagID := GET_ERR_ID();

IF #TagID = 16#2522 THEN
   MOVE_BLK(IN := #TagArrayIn[0],
            COUNT := 1,
            OUT => #TagArrayOut[1]);
END_IF;
```

An error occurred accessing the #Field[#index] tag. The #TagOut operand returns the signal state "1" despite the read/access error and the multiplication is performed with the value "0.0". If this error scenario occurs, we recommend that you program the "Get error ID locally" instruction after the multiplication to get the error. The error ID supplied by the "Get error ID locally" instruction is evaluated with a comparison. If the #TagID operand returns ID 16#2522, there is a read/access error and the value "100.0" of the #TagArrayIn[0] operand is written to the #TagArrayOut[1] operand.

INIT_RD: Initialize all retain data

Description

The "Initialize all retain data" instruction is used to reset the retentive data of all data blocks, bit memories and SIMATIC timers and counters at the same time. The instruction can only be executed within a startup OB because the execution exceeds the program cycle duration.

Syntax

Use the following syntax for the "Initialize all retain data" instruction:

SCL

```
INIT_RD(<Operand>)
```

Parameters

The following table shows the parameters of the "Initialize all retain data" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand>	Input	BOOL	I, Q, M, D, L	If the input "REQ" has the signal state "1", all retentive data are reset.
Function value (RET_VAL)		INT	I, Q, M, D, L	Error information: If an error occurs during the execution of the instruction, an error code is output at the RET_VAL parameter.

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B5	The instruction cannot be executed because it was not programmed within a startup OB.
General error information	See also: "GET_ERR_ID: Get error ID locally
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL
```
"Tag_Result" := INIT_RD("Tag_REQ");
```

If the operand "Tag_REQ" has the signal state "1", the instruction is executed. All retentive data of all data blocks, bit memories and SIMATIC timers and counters are reset.

GET_ERR_ID: Get error ID locally (Page 2922)

WAIT: Configure time delay

Description

The instruction "Configure time delay" pauses the program execution for a specific period of time. You indicate the period of time in microseconds on the WT parameter of the instruction.

You can configure time delays from -32768 up to 32767 microseconds (µs). The smallest possible delay time depends on the respective CPU and corresponds to the execution time of the "Configure time delay" instruction.

The execution of the instruction can be interrupted by higher priority events.

The "Configure time delay" instruction returns no error information.

Syntax

The following syntax is used for the "Configure time delay" instruction:

SCL
```
WAIT(WT:= <Operand>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
WT	Input	INT	I, Q, M, D, L, P	Time delay in microseconds (µs)

Overview of the valid data types (Page 1908)

RUNTIME: Measure program runtime

Description

The "Measure program runtime" instruction is used to measure the runtime of the entire program, individual blocks or command sequences.

If you want to measure the runtime of your entire program, call the instruction "Measure program runtime" in OB1. Measurement of the runtime is started with the first call and the output RET_VAL returns the runtime of the program after the second call. The measured runtime includes all CPU processes that can occur during the program execution, for example, interruptions caused by higher-level events or communication. The instruction "Measure program runtime" reads an internal counter of the CPU and writes the value to the in/out parameter. The instruction calculates the current program runtime according to the internal counter frequency and writes it to output RET_VAL.

If you want to measure the runtime of individual blocks or individual command sequences, you need three separate networks. Call the instruction "Measure program runtime" in an individual network within your program. You set the starting point of the runtime measurement with this first call of the instruction. Then you call the required program block or the command sequence in the next network. In another network, call the "Measure program runtime" instruction a second time and assign the same memory to the in/out parameter as you did during the first call of the instruction. The "Measure program runtime" instruction in the third network reads an internal CPU counter and calculates the current runtime of the program block or the command sequence according to the internal counter frequency and writes it to the output RET_VAL.

The following applies to S7-1200 CPUs with firmware version earlier than V4.1: The "Measure program runtime" instruction uses an internal high-frequency counter to calculate the time. If the counter overflows (this can occur up to once per minute), the instruction returns values <= 0.0. Ignore these runtime values.

Note

The runtime of a command sequence cannot be determined exactly, because the sequence of instructions within a command sequence is changed during optimized compilation of the program.

Syntax

The following syntax is used for the "Measure program runtime" instruction:

```
SCL
RUNTIME(<Operand>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
<Operand>	InOut	LREAL	I, Q, M, D, L	Saves the starting point of the runtime measurement.
Function value		LREAL	I, Q, M, D, L	Returns the measured runtime in seconds

For additional information on valid data types, refer to "See also".

Example

The following example shows the how the instruction works based on the runtime calculation of a program block:

```
SCL
"Tag_Result" := RUNTIME("Tag_Memory");

"Best_before_date_DB" ();

"Tag_Result" := RUNTIME("Tag_Memory");
```

The starting point for the runtime measurement is set with the first call of the instruction and buffered as reference for the second call of the instruction in the "TagMemory" operand.

The "Best_before_date" program block FB1 is called.

When the program block FB1 has been processed, the instruction is executed a second time. The second call of the instruction calculates the runtime of the program block and writes the result to the output "Tag_Result".

Word logic operations

DECO: Decode

Description

The instruction "Decode" sets a bit specified by the input value in the output value.

The instruction "Decode" reads the value of the parameter IN and sets the bit in the output value, whose bit position corresponds to the read value. The other bits in the output value are filled with zeroes. If the value of the IN parameter is greater than 31, a modulo 32 instruction is executed.

Syntax

The following syntax is used for the instruction "Decode":

```
SCL
DECO(IN := <Expression>)
DECO_WORD(IN := <Expression>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	UINT	I, Q, M, D, L, P	Position of the bit in the output value which is set.
_<Data type>		Bit strings default: DWORD	-	Data type of the function value: 1. You can specify the data type of the instruction explicitly using "_". 2. If you do not specify the data type explicitly, it will be determined by the utilized tags or type-coded constants. 3. If you neither specify the data type explicitly nor specify defined tags or type-coded constants, the default data type will be used.
Function value		Bit strings	I, Q, M, D, L, P	Current output value

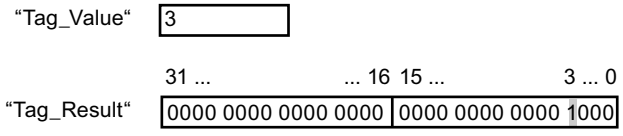
For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := DECO(IN := "Tag_Value");
"Tag_Result2" := DECO_BYTE(IN := "Tag_Value2");
```

The following figure shows how the instruction works using specific operand values:



The instruction reads the number "3" from the value of the operand "Tag_Value" and sets the third bit to the value of the operand "Tag_Result".

See also

Overview of the valid data types (Page 1908)

ENCO: Encode

Description

The instruction "Encode" reads the bit number of the lowest-value bit set in the input value and issues this as a result.

Syntax

The following syntax is used for the instruction "Encode":

SCL

```
ENCO(IN := <Expression>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	Bit strings	I, Q, M, D, L, P	Input value
Function value		INT	I, Q, M, D, L, P	Bit number of the bit in the input value that is read out.

For additional information on valid data types, refer to "See also".

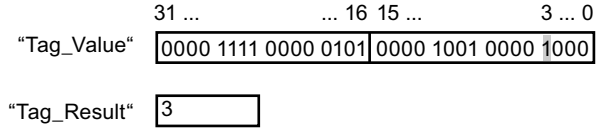
Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := ENCO(IN := "Tag_Value");
```

The following figure shows how the instruction works using specific operand values:



The instruction reads the lowest-value set bit of the operand "Tag_Value" and writes the bit position "3" in the operand "Tag_Result".

See also

Overview of the valid data types (Page 1908)

SEL: Select

Description

The instruction "Select" selects one of the parameters IN0 or IN1 depending on a switch (G parameter) and issues its content as a result. When the parameter G has the signal status "0", the value at parameter IN0 is moved. When the parameter G has the signal status "1", the value at parameter IN1 is moved and returned as a function value.

The instruction is only executed if the tags of all parameters have the same data type class.

Syntax

The following syntax is used for the "Select" instruction:

SCL

```
SEL(G := <Expression>,
    IN0 := <Expression>,
    IN1 := <Expression>)
```

The syntax of the instruction consists of the following parts:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
G	Input	BOOL	BOOL	I, Q, M, D, L	Switch
IN0	Input	Binary numbers, integers, floating-point numbers, timers, strings, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, timers, strings, DATE, TOD, LTOD, DT, LDT	I, Q, M, D, L, P	First input value
IN1	Input	Binary numbers, integers, floating-point numbers, timers, strings, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, timers, strings, DATE, TOD, LTOD, DT, LDT	I, Q, M, D, L, P	Second input value
Function value		Binary numbers, integers, floating-point numbers, timers, strings, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, timers, strings, DATE, TOD, LTOD, DT, LDT	I, Q, M, D, L, P	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := SEL(G := "Tag_Value",
                    IN0 := "Tag_0",
                    IN1 := "Tag_1");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value	
Tag_Value	0	1
Tag_0	W#16#0000	W#16#4C
Tag_1	W#16#FFFF	D#16#5E
Tag_Result	W#16#0000	D#16#5E

Overview of the valid data types (Page 1908)

MUX: Multiplex

Description

The "Multiplex" instruction copies the value of a selected input parameter and issues it. You can use the parameter K to determine the number of the input parameter whose value will be moved. Numbering starts at IN0 and is incremented continuously with each new input. You can declare a maximum of 32 inputs.

Numerical data types and time data types are permitted at the inputs. All tags with assigned parameters must be of the same data type.

The function value is invalid if any of the following conditions are met:

- Errors occurred during execution of the instruction.
- The input at the K parameter is located outside the available inputs. If the INELSE input is not used, the value of the IN0 input is assigned to the function value in this case and the ENO enable output is set to "0".

Syntax

The following syntax is used for the "Multiplex" instruction:

SCL

```
MUX(K := <Expression>,
    IN0 := <Expression>,
    IN1 := <Expression>,
    INELSE := <Expression>)
```

Parameters

The following table shows the parameters of the "Multiplex" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
K	Input	Integers	Integers	I, Q, M, D, L, P	Specifies the parameter whose content is to be transferred. • If K = 0 => Parameter IN0 • If K = 1 => Parameter IN1, etc.
IN0	Input	Binary numbers, integers, floating-point numbers, timers, STRING, CHAR, WCHAR, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, strings, TOD, LTOD, DATE, timers, DT, LDT	I, Q, M, D, L, P	First input value
IN1	Input	Binary numbers, integers, floating-point numbers, timers, STRING, CHAR, WCHAR, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, strings, TOD, LTOD, DATE, timers, DT, LDT	I, Q, M, D, L, P	Second input value
INn	Input	Binary numbers, integers, floating-point numbers, timers, STRING, CHAR, WCHAR, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, strings, TOD, LTOD, DATE, timers, DT, LDT	I, Q, M, D, L, P	Optional input values

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
INELSE	Input	Binary numbers, integers, floating-point numbers, timers, STRING, CHAR, WCHAR, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, strings, TOD, LTOD, DATE, timers, DT, LDT	I, Q, M, D, L, P	Specifies the value to be copied when K <> n.
Function value		Binary numbers, integers, floating-point numbers, timers, STRING, CHAR, WCHAR, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, strings, TOD, LTOD, DATE, timers, DT, LDT	I, Q, M, D, L, P	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := MUX(K := "Tag_Number",
                    IN0 := "Tag_1",
                    IN1 := "Tag_2",
                    INELSE := "Tag_3");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value	
Tag_Number	1	4
Tag_1	DW#16#00000000	DW#16#00000000
Tag_2	DW#16#003E4A7D	DW#16#003E4A7D
Tag_3	DW#16#FFFF0000	DW#16#FFFF0000
Tag_Result	DW#16#003E4A7D	DW#16#FFFF0000

Overview of the valid data types (Page 1908)

DEMUX: Demultiplex

Description

The "Demultiplex" instruction transfers the value of the input parameter IN to a selected output parameter. The selection of the input parameter takes place independent of the parameter value K. The K parameter specifies the output parameter number to which the value of the input parameter IN is transferred. The other output parameters are not changed. Numbering starts at OUT0 and continues consecutively with each new output. You can declare a maximum of 32 output parameters.

If the value of the K parameter is greater than the number of output parameters, the value of the ENO enable output is set to "0" and the value of the input parameter IN is transferred to the output parameter OUTELSE.

The function value is invalid if any of the following conditions are met:

- The value of the K parameter is greater than the number of available outputs.
- Errors occurred during execution of the instruction.

Syntax

The following syntax is used for the instruction "Demultiplex":

SCL

```
DEMUX(K := <Expression>,
      IN := <Expression>,
      OUT0 := <Operand>,
      OUT1 := <Operand>,
      OUTELSE := <Operand>)
```

Parameters

The following table shows the parameters of the instruction "Demultiplex":

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
K	Input	Integers	Integers	I, Q, M, D, L, P	Specifies the output to which the input value (IN) will be copied. • If K = 0 => Parameter OUT0 • If K = 1 => Parameter OUT1, etc.
IN	Input	Binary numbers, integers, floating-point numbers, timers, STRING, CHAR, WCHAR, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, strings, timers, TOD, LTOD, DATE, DT, LDT	I, Q, M, D, L, P	Input value
OUT0	Output	Binary numbers, integers, floating-point numbers, timers, STRING, CHAR, WCHAR, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, strings, timers, TOD, LTOD, DATE, DT, LDT	I, Q, M, D, L, P	First output
OUT1	Output	Binary numbers, integers, floating-point numbers, timers, STRING, CHAR, WCHAR, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, strings, timers, TOD, LTOD, DATE, DT, LDT	I, Q, M, D, L, P	Second output

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
OUTn	Output	Binary numbers, integers, floating-point numbers, timers, STRING, CHAR, WCHAR, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, strings, timers, TOD, LTOD, DATE, DT, LDT	I, Q, M, D, L, P	Optional outputs
OUTELSE	Output	Binary numbers, integers, floating-point numbers, timers, STRING, CHAR, WCHAR, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, strings, timers, TOD, LTOD, DATE, DT, LDT	I, Q, M, D, L, P	Output to which the value at input IN is copied if K > n.

For additional information on available data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
DEMUX(K := "Tag_Number",
      IN := "Tag_Value",
      OUT0 := "Tag_1",
      OUT1 := "Tag_2",
      OUTELSE := "Tag_3");
```

The following tables show how the instruction works using specific operand values:

Input values of the "Demultiplex" instruction before the network execution

Parameter	Operand	Values	
K	Tag_Number	2	4
IN	Tag_Value	DW#16#FFFFFFFF	DW#16#003E4A7D

Output values of the "Demultiplex" instruction after the network execution

Parameter	Operand	Values	
OUT0	Tag_1	Unchanged	Unchanged
OUT1	Tag_2	DW#16#FFFFFFFF	Unchanged
OUTELSE	Tag_3	Unchanged	DW#16#003E4A7D

Shift and rotate

SHR: Shift right

Description

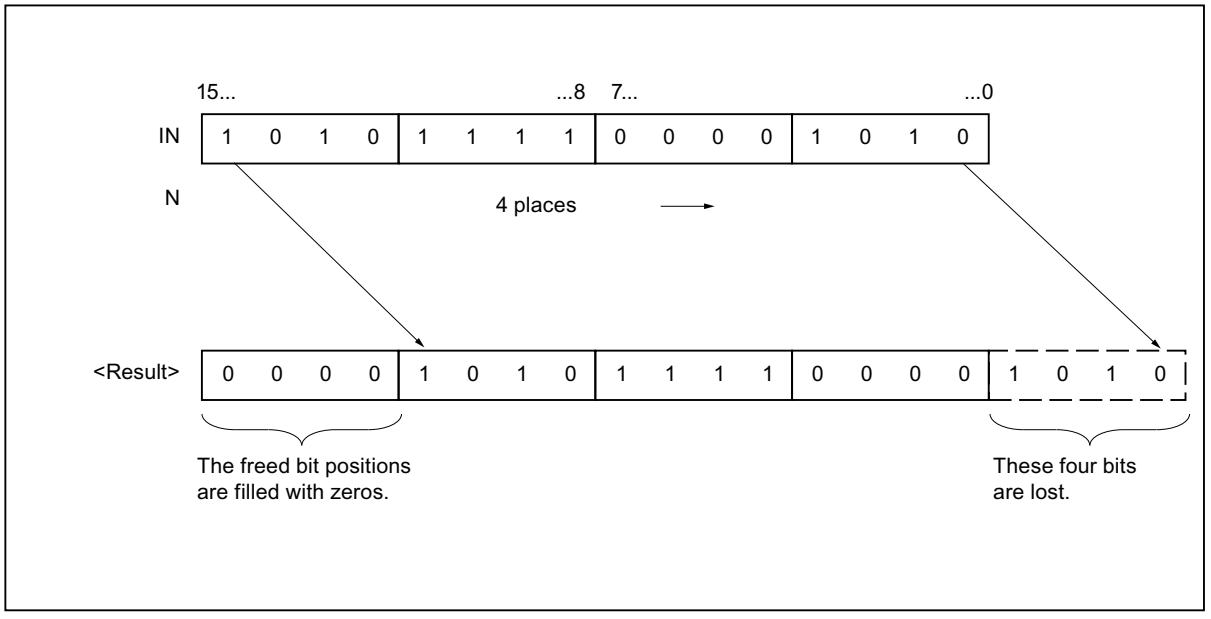
The "Shift right" instruction shifts the contents of the IN parameter bit-by-bit to the right and returns it as a function value. The parameter N is used to specify the number of bit positions by which the specified value should be shifted.

If the value of the N parameter is "0", the value of the IN parameter is given as a result.

If the value of the N parameter is greater than the number of available bit positions, then the value of the IN parameter is shifted to the right by the available number of bit positions.

The bit positions that are freed by shifting in the left operand area are filled with zeros.

The following figure shows how the content of an integer data type operand is shifted by four bit positions to the right:



Syntax

The following syntax is used for the instruction "Shift right":

SCL

```
SHR(IN := <Operand>,
    N := <Operand>)
```

Parameters

The following table shows the parameters of the "Shift right" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Value to be shifted
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L	Number of bits by which the value (IN) is shifted
Function value		Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := SHR(IN := "Tag_Value",
                    N := "Tag_Number");
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	Tag_Value	0011 1111 1010 1111
N	Tag_Number	3
Function value	Tag_Result	0000 0111 1111 010 1

The content of the "Tag_Value" operand is shifted by three bit positions to the right. The result of the instruction is returned in the operand "Tag_Result" as a function value.

See also

Overview of the valid data types (Page 1908)

SHL: Shift left

Description

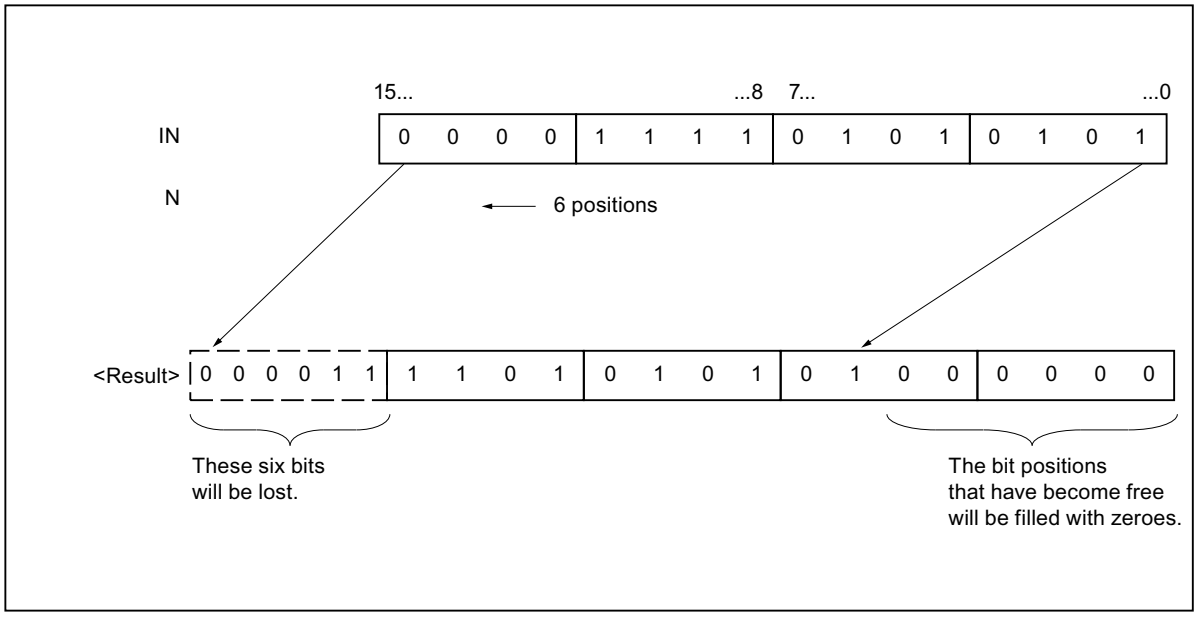
The "Shift left" instruction shifts the contents of the IN parameter bit-by-bit to the left and returns it as a function value. The parameter N is used to specify the number of bit positions by which the specified value should be shifted.

If the value of the N parameter is "0", the value of the IN parameter is given as a result.

If the value of the N parameter is greater than the number of bit positions, the value of the IN parameter is shifted to the left by the available number of bit positions.

The bit positions freed by the shift are filled with zeros in the result value.

The following figure shows how the content of an operand of the WORD data type is shifted six bit positions to the left:



Syntax

The following syntax is used for the instruction "Shift left":

```
SCL
SHL(IN := <Operand>,
    N := <Operand>)
```

Parameters

The following table shows the parameters of the "Shift left" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Value to be shifted
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L	Number of bits by which the value (IN) is shifted
Function value		Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := SHL(IN := "Tag_Value",
                    N := "Tag_Number");
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	Tag_Value	0011 1111 1010 1111
N	Tag_Number	4
Function value	Tag_Result	1111 1010 1111 0000

The value of the "Tag_Value" operand is shifted by four bit positions to the left. The result of the instruction is returned in the operand "Tag_Result" as a function value.

See also

Overview of the valid data types (Page 1908)

ROR: Rotate right

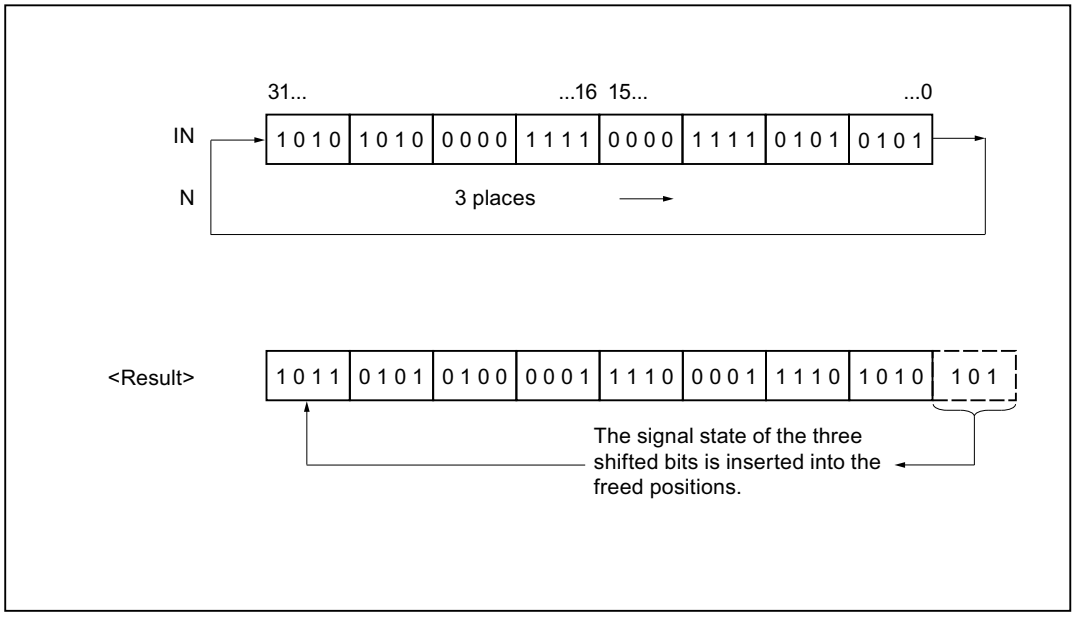
Description

The "Rotate right" instruction rotates the content of the IN parameter bit-by-bit to the right and assigns the result to the specified operand. The parameter N is used to specify the number of bit positions by which the specified value should be rotated. The bit positions freed by rotating are filled with the bit positions that are pushed out.

If the value of the N parameter is "0", the value at input IN is given as a result.

If the value at the N parameter is greater than the number of available bit positions, the operand value at the IN input is still rotated by the specified number of bit positions.

The following figure shows how the content of an operand of the DWORD data type is rotated three bit positions to the right:



Syntax

The following syntax is used for the instruction "Rotate right":

```
SCL
ROR(IN := <Operand>,
    N := <Operand>)
```

Parameters

The following table shows the parameters of the "Rotate right" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Value to be rotated
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L	Number of bit positions by which the value (IN) is rotated
Function value		Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := ROR(IN := "Tag_Value",
                    N := "Tag_Number");
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	Tag_Value	0000 1111 1001 0101
N	Tag_Number	5
Function value	Tag_Result	1010 1000 0111 1100

The content of the "Tag_Value" operand is rotated by five bit positions to the right. The result of the instruction is returned in the operand "Tag_Result" as a function value.

See also

Overview of the valid data types (Page 1908)

ROL: Rotate left

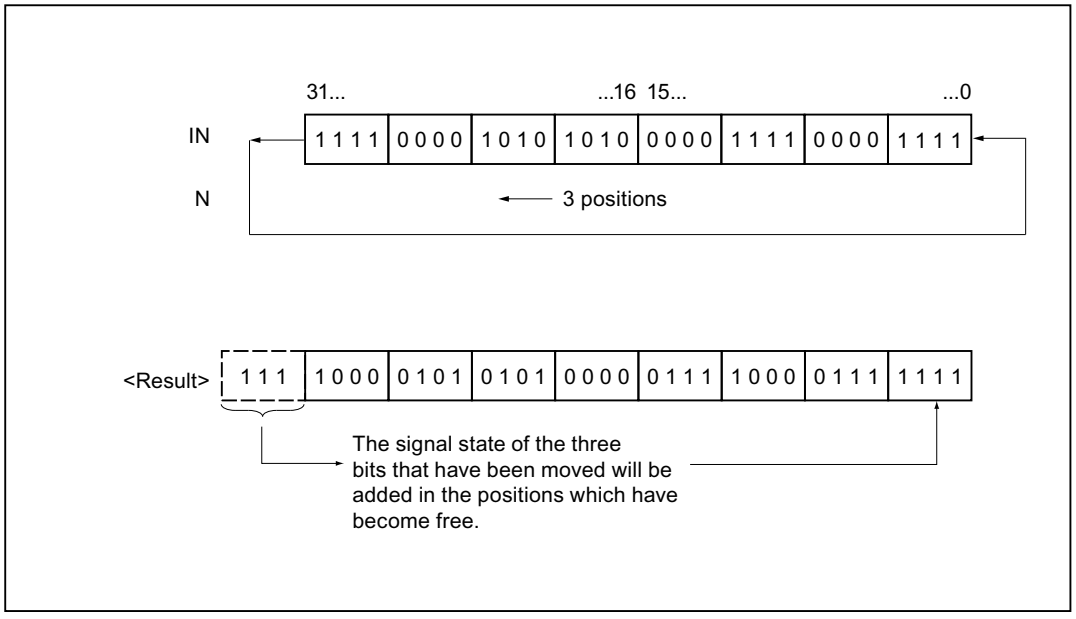
Description

The "Rotate left" instruction rotates the contents of the IN parameter bit-by-bit to the left and returns it as a function value. The parameter N is used to specify the number of bit positions by which the specified value should be rotated. The bit positions freed by rotating are filled with the bit positions that are pushed out.

If the value of the N parameter is "0", the value at input IN is given as a result.

If the value at the N parameter is greater than the number of available bit positions, the operand value at the IN input is still rotated by the specified number of bit positions.

The following figure shows how the content of an operand of the DWORD data type is rotated three bit positions to the left:



Syntax

The following syntax is used for the "Rotate left" instruction:

SCL

```
ROL(IN := <Operand>,
    N := <Operand>)
```

Parameters

The following table shows the parameters of the "Rotate left" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Value to be rotated
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L	Number of bit positions by which the value (IN) is rotated
Function value		Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
  SCL
"Tag_Result" := ROL(IN := "Tag_Value",
                    N := "Tag_Number");
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Value	1010 1000 1111 0110
N	Tag_Number	5
Function value	Tag_Result	0001 1110 1101 0101

The content of the operand "Tag_Value" is rotated five bit positions to the left. The result of the instruction is returned in the operand "Tag_Result" as a function value.

Overview of the valid data types (Page 1908)

Legacy

DRUM: Implement sequencer

Description

The "Implement sequencer" instruction is used to assign the programmed values of the OUT_VAL parameter of the corresponding step to the programmed output bits (OUT1 to OUT16) and the output word (OUT_WORD). The specific step must thereby satisfy the conditions of the programmed enable mask on the S_MASK parameter while the instruction remains at this step. The instruction advances to the next step if the event for the step is true and the programmed time for the current step elapses, or if the value at the JOG parameter changes from "0" to "1". The instruction is reset when the signal state of the RESET parameter changes to "1". The current step is hereby equated to the preset step (DSP).

The amount of time spent on a step is determined by the product of the preset timebase (DTBP) and the preset counter value (S_PRESET) for each step. At the start of a new step, this calculated value is loaded into the DCC parameter, which contains the time remaining for the current step. If, for example the value at the DTBP parameter is "2" and the preset value for the first step is "100" (100 ms), the DCC parameter has the value "200" (200 ms).

A step can be programmed with a time value, an event, or both. Steps that have an event bit and the time value "0" advance to the next step as soon as the signal state of the event bit is "1". Steps that are programmed only with a time value start the time immediately. Steps that are programmed with an event bit and a time value greater than "0" start the time when the signal state of the event bit is "1". The event bits are initialized with a signal state of "1".

When the sequencer is on the last programmed step (LST_STEP) and the time for this step has expired, the signal state on the Q parameter is set to "1"; otherwise it is set to "0". When the parameter Q is set, the instruction remains on the step until it is reset.

In the configurable mask (S_MASK) you can select the individual bits in the output word (OUT_WORD) and set or reset the output bits (OUT1 to OUT16) by means of the output values (OUT_VAL). If a bit of the configurable mask has signal state "1", the OUT_VAL value sets or resets the corresponding bit. If the signal state of a bit of the configurable mask is "0", the corresponding bit is left unchanged. All the bits of the configurable mask for all 16 steps are initialized with a signal state of "1".

The output bit on the OUT1 parameter corresponds to the least significant bit of the output word (OUT_WORD). The output bit on the OUT16 parameter corresponds to the most significant bit of the output word (OUT_WORD).

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

Syntax

The following syntax is used for the "Implement sequencer" instruction:

SCL

```
<Instance>(RESET := <Operand>,
           JOG := <Operand>,
           DRUM_EN := <Operand>,
           LST_STEP := <Operand>,
           EVENT1 - 16 := <Operand>,
           OUT1 - 16 => <Operand>,
           Q => <Operand>,
           OUT_WORD => <Operand>,
           ERR_CODE => <Operand>)
```

Parameters

The following table shows the parameters of the "Implement sequencer" instruction:

Parameter	Declaration	Data type	Memory area	Description
RESET	Input	BOOL	I, Q, M, D, L	The signal state "1" indicates a reset condition.
JOG	Input	BOOL	I, Q, M, D, L	When the signal state changes from "0" to "1", the instruction advances to the next step.
DRUM_EN	Input	BOOL	I, Q, M, D, L	The signal state "1" allows the sequencer to advance based on the event and time criteria.
LST_STEP	Input	BYTE	I, Q, M, D, L	Number of the last programmed step.

Parameter	Declaration	Data type	Memory area	Description
EVENT(i), 1 ≤ i ≤ 16	Input	BOOL	I, Q, M, D, L	Event bit (i); Initial signal state is "1".
OUT(j), 1 ≤ j ≤ 16	Output	BOOL	I, Q, M, D, L	Output bit (j)
Q	Output	BOOL	I, Q, M, D, L	The signal state "1" indicates that the time for the last step has elapsed.
OUT_WORD	Output	WORD	I, Q, M, D, L, P	Word address to which the sequencer writes the output values.
ERR_CODE	Output	WORD	I, Q, M, D, L, P	Error information
JOG_HIS	Static	BOOL	I, Q, M, D, L	JOG parameter history bit
EOD	Static	BOOL	I, Q, M, D, L	The signal state "1" indicates that the time for the last step has elapsed.
DSP	Static	BYTE	I, Q, M, D, L, P	Preset step of the sequencer
DSC	Static	BYTE	I, Q, M, D, L, P	Current step of the sequencer
DCC	Static	DWORD	I, Q, M, D, L, P	Current counter value of the sequencer
DTBP	Static	WORD	I, Q, M, D, L, P	Preset timebase of the sequencer
PrevTime	Static	TIME	I, Q, M, D, L	Previous system time
S_PRESET	Static	ARRAY[1..16] of WORD	I, Q, M, D, L	Preset counter value for each step [1 to 16] where one clock pulse = 1 ms.
OUT_VAL	Static	ARRAY[1..16, 0..15] of BOOL	I, Q, M, D, L	Output values for each step [1 to 16, 0 to 15].
S_MASK	Static	ARRAY[1..16, 0..15] of BOOL	I, Q, M, D, L	Configurable mask for each step [1 to 16, 0 to 15]. Initial signal states are "1".

For additional information on valid data types, refer to "See also".

ERR_CODE parameter

The following table shows the meaning of the values of the ERR_CODE parameter:

ERR_CODE*	Explanation
W#16#0000	No error
W#16#000B	The value at the LST_STEP parameter is less than 1 or greater than 16.
W#16#000C	The value at the DSC parameter is less than 1 or greater than the value at the LST_STEP parameter.
W#16#000D	The value at the DSP parameter is less than 1 or greater than the value at the LST_STEP parameter.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

In the following example the instruction advances from step 1 to step 2. The output bits (OUT1 to OUT16) and the output word (OUT_WORD) are set according to the mask configured for step 2 and the values of the OUT_VAL parameter.

Note

You can initialize static parameters in the data block.

SCL

```
"DRUM_DB"(RESET := "Tag_Reset"
          JOG := "Tag_Input_Jog"
          DRUM_EN := "Tag_Input_DrumEN"
          LST_STEP := "Tag_Number_LastStep"
          EVENT1 := "MyTag_Event_1"
          EVENT2 := "MyTag_Event_2"
          EVENT3 := "MyTag_Event_3"
          EVENT4 := "MyTag_Event_4"
          EVENT5 := "MyTag_Event_5"
          EVENT6 := "MyTag_Event_6"
          EVENT7 := "MyTag_Event_7"
          EVENT8 := "MyTag_Event_8"
          EVENT9 := "MyTag_Event_9"
          EVENT10 := "MyTag_Event_10"
          EVENT11 := "MyTag_Event_11"
          EVENT12 := "MyTag_Event_12"
          EVENT13 := "MyTag_Event_13"
          EVENT14 := "MyTag_Event_14"
          EVENT15 := "MyTag_Event_15"
          EVENT16 := "MyTag_Event_16"
          OUT1 => "MyTag_Output_1"
          OUT2 => "MyTag_Output_2"

          OUT11 => "MyTag_Output_11"
          OUT12 => "MyTag_Output_12"
          OUT13 => "MyTag_Output_13"
          OUT14 => "MyTag_Output_14"
          OUT15 => "MyTag_Output_15"
```

SCL

```
OUT16 => "MyTag_Output_16"
Q => "Tag_Output_Q"
OUT_WORD => "Tag_OutputWord"
ERR_CODE => "Tag_ErrorCode");
```

The following tables show how the instruction works using specific values.

Before processing

In this example, the following values are used for initializing the input parameters:

Parameter	Operand	Address	Value
RESET	Tag_Reset	M0.0	FALSE
JOG	Tag_Input_JOG	M0.1	FALSE
DRUM_EN	Tag_Input_DrumEN	M0.2	TRUE
LST_STEP	Tag_Number_LastStep	MB1	B#16#08
EVENT2	MyTag_Event_2	M20.0	FALSE
EVENT4	MyTag_Event_4	M20.1	FALSE
EVENT6	MyTag_Event_6	M20.2	FALSE
EVENT8	MyTag_Event_8	M20.3	FALSE
EVENT10	MyTag_Event_10	M20.4	FALSE
EVENT12	MyTag_Event_12	M20.5	FALSE
EVENT14	MyTag_Event_14	M20.6	FALSE
EVENT16	MyTag_Event_16	M20.7	FALSE

The following values are saved in the "DRUM_DB" instance data block of the instruction:

Parameter	Address	Value
JOG_HIS	DBX12.0	FALSE
EOD	DBX12.1	FALSE
DSP	DBB13	W#16#0001
DSC	DBB14	W#16#0001

OUT_VAL[2,12]	DBX61.4	FALSE
OUT_VAL[2,13]	DBX61.5	FALSE
OUT_VAL[2,14]	DBX61.6	FALSE
OUT_VAL[2,15]	DBX61.7	FALSE
S_MASK[2,0]	DBX92.0	FALSE
S_MASK[2,1]	DBX92.1	TRUE
S_MASK[2,2]	DBX92.2	TRUE
S_MASK[2,3]	DBX92.3	TRUE
S_MASK[2,4]	DBX92.4	TRUE
S_MASK[2,5]	DBX92.5	FALSE
S_MASK[2,6]	DBX92.6	TRUE
S_MASK[2,7]	DBX92.7	TRUE
S_MASK[2,8]	DBX93.0	FALSE
S_MASK[2,9]	DBX93.1	FALSE
S_MASK[2,10]	DBX93.2	TRUE
S_MASK[2,11]	DBX93.3	TRUE
S_MASK[2,12]	DBX93.4	TRUE
S_MASK[2,13]	DBX93.5	TRUE
S_MASK[2,14]	DBX93.6	FALSE
S_MASK[2,15]	DBX93.7	TRUE

The output parameters are set to the following values before the execution of the instruction:

Parameter	Operand	Address	Value
Q	Tag_Output_Q	M6.0	FALSE
OUTWORD	Tag_OutputWord	MW8	W#16#FFFF
OUT1	MyTag_Output_1	M4.0	TRUE
OUT2	MyTag_Output_2	M4.1	TRUE
OUT3	MyTag_Output_3	M4.2	TRUE
OUT4	MyTag_Output_4	M4.3	TRUE
OUT5	MyTag_Output_5	M4.4	TRUE
OUT6	MyTag_Output_6	M4.5	TRUE
OUT7	MyTag_Output_7	M4.6	TRUE
OUT8	MyTag_Output_8	M4.7	TRUE
OUT9	MyTag_Output_9	M5.0	TRUE
OUT10	MyTag_Output_10	M5.1	TRUE
OUT11	MyTag_Output_11	M5.2	TRUE
OUT12	MyTag_Output_12	M5.3	TRUE
OUT13	MyTag_Output_13	M5.4	TRUE
OUT14	MyTag_Output_14	M5.5	TRUE
OUT15	MyTag_Output_15	M5.6	TRUE
OUT16	MyTag_Output_16	M5.7	TRUE

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameter	Operand	Address	Value
OUT1	MyTag_Output_1	M4.0	TRUE
OUT2	MyTag_Output_2	M4.1	FALSE
OUT3	MyTag_Output_3	M4.2	FALSE
OUT4	MyTag_Output_4	M4.3	FALSE
OUT5	MyTag_Output_5	M4.4	FALSE
OUT6	MyTag_Output_6	M4.5	TRUE
OUT7	MyTag_Output_7	M4.6	FALSE
OUT8	MyTag_Output_8	M4.7	FALSE
OUT9	MyTag_Output_9	M5.0	TRUE
OUT10	MyTag_Output_10	M5.1	TRUE
OUT11	MyTag_Output_11	M5.2	FALSE
OUT12	MyTag_Output_12	M5.3	FALSE
OUT13	MyTag_Output_13	M5.4	FALSE
OUT14	MyTag_Output_14	M5.5	FALSE
OUT15	MyTag_Output_15	M5.6	TRUE
OUT16	MyTag_Output_16	M5.7	FALSE
Q	Tag_Output_Q	M6.0	FALSE

Parameter	Operand	Address	Value
OUTWORD	Tag_OutputWord	MW8	W#16#4321
ERR_CODE	Tag_ErrorCode	MW10	W#16#0000

The following values are changed in the instance data block "DRUM_DB" of the instruction after the execution of the instruction:

Parameter	Address	Value
JOG_HIS	DBX12.0	FALSE
EOD	DBX12.1	FALSE
DSC	DBB14	W#16#0002
DCC	DBD16	DW#16#000000C8

Overview of the valid data types (Page 1908)

DCAT: Discrete control-timer alarm

Description

The "Discrete control-timer alarm" instruction is used to accumulate the time from the point at which the CMD parameter issues the command to open or close. The time is accumulated until the preset time (PT) is exceeded or the information is received that the device was opened or closed (O_FB or C_FB) within the specified time. If the preset time is exceeded before the information on the opening or closing of the device is received, the corresponding alarm is activated. If the signal state on the command input changes state before the preset time, the time is restarted.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

The "Discrete control-timer alarm" instruction has the following reactions to the input conditions:

- When the signal state of the CMD parameter changes from "0" to "1", the signal states of the parameters Q, CMD_HIS, ET (only if ET < PT), OA and CA are influenced as follows:
  - The parameters Q and CMD_HIS are set to "1".
  - The parameters ET, OA and CA are reset to "0".
- When the signal state on the parameter CMD changes from "1" to "0", the parameters Q, ET (only if ET < PT), OA, CA and CMD_HIS are reset to "0".

- When the signal state of the parameters CMD and CMD_HIS is "1" and the parameter O_FB is set to "0", the time difference (ms) since the last execution of the instruction is added to the value at the parameter ET. If the value of the parameter ET exceeds the value of the parameter PT, the signal state on the parameter OA is set to "1". If the value of the parameter ET does not exceed the value of the parameter PT, the signal state on the parameter OA is reset to "0". The value at the parameter CMD_HIS is set to the value of the parameter CMD.
- If the signal state of the parameters CMD, CMD_HIS and O_FB are set to "1" and the parameter C_FB has the value "0", the signal state of the parameter OA is set to "0". The value of parameter ET is set to the value of parameter PT. If the signal state of the parameter O_FB changes to "0", the alarm is set the next time the instruction is executed. The value of parameter CMD_HIS is set to the value of parameter CMD.
- If the parameters CMD, CMD_HIS and C_FB have the value "0", the time difference (ms) since the last execution of the instruction is added to the value of the parameter ET. If the value of the parameter ET exceeds the value of the parameter PT, the signal state of the parameter CA is set to "1". If the value at the parameter PT is not exceeded, the parameter CA has the signal state "0". The value of parameter CMD_HIS is set to the value of parameter CMD.
- If the parameters CMD, CMD_HIS and O_FB have the signal state "0" and the parameter C_FB is set to "1", the parameter CA is set to "0". The value of parameter ET is set to the value of parameter PT. If the signal state of the parameter C_FB changes to "0", the alarm is set the next time the instruction is executed. The value of parameter CMD_HIS is set to the value of parameter CMD.
- If the parameters O_FB and C_FB simultaneously have the signal state "1", the signal states of both alarm outputs are set to "1".

The "Discrete control-timer alarm" instruction has no error information.

Syntax

The following syntax is used for the "Discrete control-timer alarm" instruction:

SCL

```
<Instance>(CMD := <Operand>,
           O_FB := <Operand>,
           C_FB := <Operand>,
           Q => <Operand>,
           OA => <Operand>,
           CA => <Operand>)
```

Parameter

The following table shows the parameters of the instruction:

Parameter	Declaration	Data type	Memory area	Description
CMD	Input	BOOL	I, Q, M, D, L	A signal state of "0" indicates a "close" command. A signal state of "1" indicates an "open" command.
O_FB	Input	BOOL	I, Q, M, D, L	Feedback input when opening
C_FB	Input	BOOL	I, Q, M, D, L	Feedback input when closing
Q	Output	BOOL	I, Q, M, D, L	Shows the status of the parameter CMD
OA	Output	BOOL	I, Q, M, D, L	Alarm output when opening
CA	Output	BOOL	I, Q, M, D, L	Alarm output when closing
ET	Static	DINT	D, L	Currently elapsed time, where one count = 1 ms.
PT	Static	DINT	D, L	Preset time value, where one count = 1 ms.
PREV_TIME	Static	DWORD	D, L	Previous system time
CMD_HIS	Static	BOOL	D, L	CMD history bit

For additional information on valid data types, refer to "See also".

The static parameters are not visible when calling the instruction in the program. These are saved in the instance of the instruction.

Example

In the following example the parameter CMD changes from "0" to "1". After the execution of the instruction the parameter Q is set to "1" and the two alarm outputs OA and CA have the signal state "0". The parameter CMD_HIS of the instance data block is set to the signal state "1" and the parameter ET is reset to "0".

Note

You can initialize static parameters in the data block.

SCL

```
"DCAT_DB"(CMD := "Tag_Input_CMD",
          O_FB := "Tag_Input_O_FB",
          C_FB := "Tag_Input_C_FB",
          Q => "Tag_Output_Q",
          OA => "Tag_Output_OA",
          CA => "Tag_Output_CA");
```

The following tables show how the instruction works using specific values.

Before processing

In this example the following values are used for the input and output parameters:

Parameter	Operand	Value
CMD	Tag_Input_CMD	TRUE
O_FB	Tag_Input_O_FB	FALSE
C_FB	Tag_Input_C_FB	FALSE
Q	Tag_Output_Q	FALSE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE

The following values are saved in the instance data block "DCAT_DB" of the instruction:

Parameter	Address	Value
ET	DBD4	L#12
PT	DBD8	L#222
CMD_HIS	DBX16.0	FALSE

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameter	Operand	Value
Q	Tag_Output_Q	TRUE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE

The following values are saved in the instance data block "DCAT_DB" of the instruction:

Parameter	Address	Value
ET	DBD4	L#0
CMD_HIS	DBX16.0	TRUE

Overview of the valid data types (Page 1908)

MCAT: Motor control-timer alarm

Description

The "Motor control-timer alarm" instruction is used to accumulate the time from the point at which one of the command inputs (opening or closing) is switched on. The time is accumulated until the preset time is exceeded or the relevant feedback input indicates that the device has executed the requested operation within the specified time. If the preset time is exceeded before the feedback is received, the corresponding alarm is triggered.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single

instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

Execution of the "Motor control-timer alarm" instruction

The following table shows the reactions of the "Motor control-timer alarm" instruction to the various input conditions:

Input parameters								Output parameters								
ET	O_HIS	C_HIS	O_CMD	C_CMD	S_CMD	O_FB	C_FB	OO	CO	OA	CA	ET	O_HIS	C_HIS	Q	State
X	1	1	X	X	X	X	X	0	0	1	1	PT	0	0	0	Alarm
X	X	X	X	X	X	1	1	0	0	1	1	PT	0	0	0	Alarm
X	X	X	X	X	1	X	X	0	0	0	0	X	0	0	1	Stop
X	X	X	1	1	X	X	X	0	0	0	0	X	0	0	1	Stop
X	0	X	1	0	0	X	X	1	0	0	0	0	1	0	1	Start opening
<PT	1	0	X	0	0	0	X	1	0	0	0	INC	1	0	1	Open
X	1	0	X	0	0	1	0	0	0	0	0	PT	1	0	1	Opened
>=PT	1	0	X	0	0	0	X	0	0	1	0	PT	1	0	0	Opening alarm
X	X	0	0	1	0	X	X	0	1	0	0	0	0	1	1	Start closing
<PT	0	1	0	X	0	X	0	0	1	0	0	INC	0	1	1	Close
X	0	1	0	X	0	0	1	0	0	0	0	PT	0	1	1	Closed
>=PT	0	1	0	X	0	X	0	0	0	0	1	PT	0	1	0	Closing alarm
X	0	0	0	0	0	X	X	0	0	0	0	X	0	0	1	Stopped

Legend:	
INC	Add the time difference (ms) since the last processing of the FB to ET
PT	PT is set to the same value as ET
X	Cannot be used
<PT	ET < PT
>=PT	ET >= PT

If the input parameters O_HIS and C_HIS both have the signal state "1", they are immediately set to the signal state "0". In this case, the last row in the table (X) mentioned above is valid. Because it is therefore not possible to check whether the input parameters O_HIS and C_HIS have the signal state "1", the output parameters are set as follows in this case:

OO = FALSE

CO = FALSE

OA = FALSE

CA = FALSE

ET = PT

Q = TRUE

Syntax

The following syntax is used for the "Motor control-timer alarm" instruction:

```
SCL
<Instance>(O_CMD := <Operand>,
           C_CMD := <Operand>,
           S_CMD := <Operand>,
           O_FB := <Operand>,
           C_FB := <Operand>,
           00 => <Operand>,
           C0 => <Operand>,
           OA => <Operand>,
           CA => <Operand>,
           Q => <Operand>)
```

Parameter

The following table shows the parameters of the "Motor control-timer alarm" instruction:

Parameter	Declaration	Data type	Memory area	Description
O_CMD	Input	BOOL	I, Q, M, D, L	"Open" command input
C_CMD	Input	BOOL	I, Q, M, D, L	"Close" command input
S_CMD	Input	BOOL	I, Q, M, D, L	"Stop" command input
O_FB	Input	BOOL	I, Q, M, D, L	Feedback input when opening
C_FB	Input	BOOL	I, Q, M, D, L	Feedback input when closing
OO	Output	BOOL	I, Q, M, D, L	"Open" output
CO	Output	BOOL	I, Q, M, D, L	"Close" output
OA	Output	BOOL	I, Q, M, D, L	Alarm output when opening
CA	Output	BOOL	I, Q, M, D, L	Alarm output when closing
Q	Output	BOOL	I, Q, M, D, L	A signal state of "0" indicates an error condition.
ET	Static	DINT	D, L	Currently elapsed time, where one count = 1 ms
PT	Static	DINT	D, L	Preset time value, where one count = 1 ms
PREV_TIME	Static	DWORD	D, L	Previous system time
O_HIS	Static	BOOL	D, L	"Open" history bit
C_HIS	Static	BOOL	D, L	"Close" history bit

For additional information on valid data types, refer to "See also".

The static parameters are not visible when calling the instruction in the program. These are saved in the instance of the instruction.

Example

The following example shows how the instruction works:

Note

You can initialize static parameters in the data block.

SCL

```
"MCAT_DB"(O_CMD := "Tag_Iput_O_CMD",
          C_CMD := "Tag_Input_C_CMD",
          S_CMD := "Tag_Input_S_CMD",
          O_FB := "Tag_Input_O_FB",
          C_FB := "Tag_Input_C_FB",
          OO => "Tag_OutputOpen",
          CO => "Tag_OutputClosed",
          OA => "Tag_Output_OA",
          CA => "Tag_Output_CA",
          Q => "Tag_Output_Q");
```

The following tables show how the instruction works using specific values.

Before processing

In this example the following values are used for the input and output parameters:

Parameter	Operand	Value
O_CMD	Tag_Input_O_CMD	TRUE
C_CMD	Tag_Input_C_CMD	FALSE
S_CMD	Tag_Input_S_CMD	FALSE
O_FB	Tag_Input_O_FB	FALSE
C_FB	Tag_Input_C_FB	FALSE
OO	Tag_OutputOpen	FALSE
CO	Tag_OutputClosed	FALSE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE
Q	Tag_Output_Q	FALSE

The following values are saved in the instance data block "MCAT_DB" of the instruction:

Parameter	Address	Value
ET	DBD4	L#2
PT	DBD8	L#22
O_HIS	DBX16.0	TRUE
C_HIS	DBX16.1	FALSE

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameter	Operand	Value
OO	Tag_OutputOpen	TRUE
CO	Tag_OutputClosed	FALSE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE
Q	Tag_Output_Q	TRUE

The following values are saved in the instance data block "MCAT_DB" of the instruction:

Parameter	Address	Value
ET	DBD4	L#0
O_HIS	DBX16.0	TRUE
CMD_HIS	DBX16.1	FALSE

Overview of the valid data types (Page 1908)

IMC: Compare input bits with the bits of a mask

Description

The "Compare input bits with the bits of a mask" instruction is used to compare the signal state of up to 16 programmed input bits (IN_BIT0 to IN_BIT15) with the corresponding bit of a mask. Up to 16 steps with masks can be programmed. The value of the IN_BIT0 parameter is compared with the value of the mask CMP_VAL[x,0], with "x" indicating the step number. On the CMP_STEP parameter, you specify the step number of the mask that is used for the comparison. All programmed values are compared in the same manner. Unprogrammed input bits or unprogrammed bits of the mask have a default signal state FALSE.

If a match is found in the comparison, the signal state of the OUT parameter is set to "1". Otherwise the OUT parameter is set to "0".

If the value of CMP_STEP parameter is greater than 15, the instruction is not executed. An error message is output at the ERR_CODE parameter.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

Syntax

The following syntax is used for the "Compare input bits with the bits of a mask" instruction:

SCL

```
<Instance>(IN_BIT0 - 15 := <Operand>,
           CMP_STEP := <Operand>,
           OUT => <Operand>,
           ERR_CODE => <Operand>)
```

Parameters

The following table shows the parameters of the "Compare input bits with the bits of a mask" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN_BIT0	Input	BOOL	I, Q, M, D, L	Input bit 0 is compared with bit 0 of the mask.
IN_BIT1	Input	BOOL	I, Q, M, D, L	Input bit 1 is compared with bit 1 of the mask.
IN_BIT2	Input	BOOL	I, Q, M, D, L	Input bit 2 is compared with bit 2 of the mask.
IN_BIT3	Input	BOOL	I, Q, M, D, L	Input bit 3 is compared with bit 3 of the mask.
IN_BIT4	Input	BOOL	I, Q, M, D, L	Input bit 4 is compared with bit 4 of the mask.
IN_BIT5	Input	BOOL	I, Q, M, D, L	Input bit 5 is compared with bit 5 of the mask.
IN_BIT6	Input	BOOL	I, Q, M, D, L	Input bit 6 is compared with bit 6 of the mask.
IN_BIT7	Input	BOOL	I, Q, M, D, L	Input bit 7 is compared with bit 7 of the mask.
IN_BIT8	Input	BOOL	I, Q, M, D, L	Input bit 8 is compared with bit 8 of the mask.
IN_BIT9	Input	BOOL	I, Q, M, D, L	Input bit 9 is compared with bit 9 of the mask.
IN_BIT10	Input	BOOL	I, Q, M, D, L	Input bit 10 is compared with bit 10 of the mask.
IN_BIT11	Input	BOOL	I, Q, M, D, L	Input bit 11 is compared with bit 11 of the mask.
IN_BIT12	Input	BOOL	I, Q, M, D, L	Input bit 12 is compared with bit 12 of the mask.
IN_BIT13	Input	BOOL	I, Q, M, D, L	Input bit 13 is compared with bit 13 of the mask.
IN_BIT14	Input	BOOL	I, Q, M, D, L	Input bit 14 is compared with bit 14 of the mask.
IN_BIT15	Input	BOOL	I, Q, M, D, L	Input bit 15 is compared with bit 15 of the mask.
CMP_STEP	Input	BYTE	I, Q, M, D, L, P	The step number of the mask used for the comparison.

Parameter	Declaration	Data type	Memory area	Description
OUT	Output	BOOL	I, Q, M, D, L	A signal state of "1" indicates that a match was found. A signal state of "0" indicates that no match was found.
ERR_CODE	Output	WORD	I, Q, M, D, L, P	Error information
CMP_VAL	Static	ARRAY OF WORD	I, Q, M, D, L	Comparison masks [0 to 15, 0 to 15]: The first number of the index is the step number and the second number is the bit number of the mask.

For additional information on valid data types, refer to "See also".

The static parameters are not visible when calling the instruction in the program. These are saved in the instance of the instruction.

ERR_CODE parameter

The following table shows the meaning of the values of the ERR_CODE parameter:

Error code* (W#16#...)	Explanation
0000	No error
000A	The value at the CMP_STEP parameter is greater than 15.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".

Overview of the valid data types (Page 1908)

SMC: Compare scan matrix

Description

You can use the "Compare scan matrix" instruction to compare the signal state of up to 16 programmed input bits (IN_BIT0 to IN_BIT15) with the corresponding bit of the comparison masks for each step. Processing starts at step 1 and is continued until the last programmed step (LAST) or until a match is found. The input bit of the IN_BIT0 parameter is compared with the value of the mask CMP_VAL[x,0], with "x" indicating the step number. All programmed values are compared in the same manner. If a match is found the signal state of the OUT parameter is set to "1" and the step number with the matching mask is written in the OUT_STEP parameter. Unprogrammed input bits or unprogrammed bits of the mask have a default signal state FALSE. If more than one step has a matching mask, only the first one found is indicated in the OUT_STEP parameter. If no match is found, the signal state of the OUT parameter is set to "0". In this case the value at the OUT_STEP parameter is greater by "1" than the value at the LAST parameter.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

Syntax

The following syntax is used for the "Compare scan matrix" instruction:

```
SCL
<Instance>(IN_BIT0 - 15 := <Operand>,
           OUT => <Operand>,
           OUT_STEP => <Operand>,
           ERR_CODE => <Operand>)
```

Syntax

The following table shows the parameters of the "Compare scan matrix" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN_BIT0	Input	BOOL	I, Q, M, D, L	Input bit 0 is compared with bit 0 of the mask.
IN_BIT1	Input	BOOL	I, Q, M, D, L	Input bit 1 is compared with bit 1 of the mask.
IN_BIT2	Input	BOOL	I, Q, M, D, L	Input bit 2 is compared with bit 2 of the mask.
IN_BIT3	Input	BOOL	I, Q, M, D, L	Input bit 3 is compared with bit 3 of the mask.
IN_BIT4	Input	BOOL	I, Q, M, D, L	Input bit 4 is compared with bit 4 of the mask.
IN_BIT5	Input	BOOL	I, Q, M, D, L	Input bit 5 is compared with bit 5 of the mask.
IN_BIT6	Input	BOOL	I, Q, M, D, L	Input bit 6 is compared with bit 6 of the mask.
IN_BIT7	Input	BOOL	I, Q, M, D, L	Input bit 7 is compared with bit 7 of the mask.
IN_BIT8	Input	BOOL	I, Q, M, D, L	Input bit 8 is compared with bit 8 of the mask.
IN_BIT9	Input	BOOL	I, Q, M, D, L	Input bit 9 is compared with bit 9 of the mask.
IN_BIT10	Input	BOOL	I, Q, M, D, L	Input bit 10 is compared with bit 10 of the mask.
IN_BIT11	Input	BOOL	I, Q, M, D, L	Input bit 11 is compared with bit 11 of the mask.
IN_BIT12	Input	BOOL	I, Q, M, D, L	Input bit 12 is compared with bit 12 of the mask.
IN_BIT13	Input	BOOL	I, Q, M, D, L	Input bit 13 is compared with bit 13 of the mask.

Parameter	Declaration	Data type	Memory area	Description
IN_BIT14	Input	BOOL	I, Q, M, D, L	Input bit 14 is compared with bit 14 of the mask.
IN_BIT15	Input	BOOL	I, Q, M, D, L	Input bit 15 is compared with bit 15 of the mask.
OUT	Output	BOOL	I, Q, M, D, L	A signal state of "1" indicates that a match was found. A signal state of "0" indicates that no match was found.
OUT_STEP	Output	BYTE	I, Q, M, D, L, P	Contains the step number with the matching mask, or the step number which is greater by "1" than the value at the LAST parameter, provided no match is found.
ERR_CODE	Output	WORD	I, Q, M, D, L, P	Error information
LAST	Static	BYTE	I, Q, M, D, L, P	Specifies the step number of the last step to be scanned for a matching mask.
CMP_VAL	Static	ARRAY OF WORD	I, Q, M, D, L	Comparison masks [0 to 15, 0 to 15]: The first number of the index is the step number and the second number is the bit number of the mask.

For additional information on valid data types, refer to "See also".

The static parameters are not visible when calling the instruction in the program. These are saved in the instance of the instruction.

ERR_CODE parameter

The following table shows the meaning of the values of the ERR_CODE parameter:

Error code* (W#16#...)	Explanation
0000	No error
000E	The value at the LAST parameter is greater than 15.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".

Overview of the valid data types (Page 1908)

LEAD_LAG: Lead and lag algorithm

Description

Use the "Lead and lag algorithm" instruction to process signals with an analog tag. The gain value at the GAIN parameter must be greater than zero. The result of the "Lead and lag algorithm" instruction is calculated using the following equation:

$$OUT = \left[\frac{LG\_TIME}{LG\_TIME + SAMPLE\_T}\right] PREV\_OUT + GAIN \left[\frac{LD\_TIME + SAMPLE\_T}{LG\_TIME + SAMPLE\_T}\right] IN - GAIN \left[\frac{LD\_TIME}{LG\_TIME + SAMPLE\_T}\right] * PREV\_IN$$

The instruction "Lead and lag algorithm" supplies plausible results only when processing is in fixed program cycles. The same units must be specified at the parameters LD_TIME, LG_TIME and SAMPLE_T. At LG_TIME > 4 + SAMPLE_T, the instruction approaches the following function:

OUT = GAIN * ((1 + LD_TIME * s) / (1 + LG_TIME * s)) * IN

When the value of the GAIN parameter is less than or equal to zero, the calculation is not performed and an error information is output at the ERR_CODE parameter.

You can use the "Lead and lag algorithm" instruction in conjunction with loops as a compensator in dynamic feed-forward control. The instruction consists of two operations. The "Lead" operation shifts the phase of output OUT so that the output leads the input. The "Lag" operation, on the other hand, shifts the output so that the output lags behind the input. Because the "Lag" operation is equivalent to an integration, it can be used as a noise suppressor or as a low-pass filter. The "Lead" operation is equivalent to a differentiation and can therefore be used as a high-pass filter. The two instructions together (Lead and Lag) result in the output phase lagging behind the input at lower frequencies and leading it at higher frequencies. This means that the "Lead and lag algorithm" instruction can be used as a band pass filter.

When you insert the instruction in the program, the "Call options" dialog opens in which you can specify whether the block parameters will be stored in a separate data block (single instance) or as a local tag (multiple instance) in the block interface. If you create a separate data block, you will find it in the project tree in the "Program resources" folder under "Program blocks > System blocks". For additional information on this topic, refer to "See also".

Syntax

The following syntax is used for the "Lead and lag algorithm" instruction:

SCL

```
<Instance>(IN := <Operand>,
           SAMPLE_T := <Operand>,
           OUT => <Operand>,
           ERR_CODE => <Operand>)
```

The following table shows the parameters of the instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	REAL	I, Q, M, D, L, P	The input value of the current sample time (cycle time) to be processed. Constants can also be specified at the IN parameter.
SAMPLE_T	Input	INT	I, Q, M, D, L, P	Sample time Constants can also be specified at the SAMPLE_T parameter.
OUT	Output	REAL	I, Q, M, D, L	Result of the instruction
ERR_CODE	Output	WORD	I, Q, M, D, L	Error information
LD_TIME	Static	REAL	I, Q, M, D, L, P	Lead time in the same unit as sample time.
LG_TIME	Static	REAL	I, Q, M, D, L, P	Lag time in the same unit as sample time
GAIN	Static	REAL	I, Q, M, D, L, P	Gain as % / % (the ratio of the change in output to a change in input as a steady state).
PREV_IN	Static	REAL	I, Q, M, D, L, P	Previous input
PREV_OUT	Static	REAL	I, Q, M, D, L, P	Previous output

For additional information on valid data types, refer to "See also".

The static parameters are not visible when calling the instruction in the program. These are saved in the instance of the instruction.

ERR_CODE parameter

The following table shows the meaning of the values of the ERR_CODE parameter:

Error code* (W#16#...)	Explanation
0000	No error
0009	The value at the GAIN parameter is less than or equal to zero.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

Note

You can initialize static parameters in the data block.

```
SCL
"LEAD_LAG_DB"(IN := "Tag_Input",
              SAMPLE_T := "Tag_Input_SAMPLE_T",
              OUT => "Tag_Output_Result",
              ERR_CODE => "Tag_ErrorCode");
```

The following tables show how the instruction works using specific values.

Before processing

In this example the following values are used for the input parameters:

Parameter	Operand	Value
IN	Tag_Input	2.0
SAMPLE_T	Tag_Input_SAMPLE_T	10

The following values are saved in the instance data block "LEAD_LAG_DB" of the instruction:

Parameter	Address	Value
LD_TIME	DBD12	2.0
LG_TIME	DBD16	2.0
GAIN	DBD20	1.0
PREV_IN	DBD24	6.0
PREV_OUT	DBD28	6.0

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameter	Operand	Value
OUT	Tag_Output_Result	2.0

The following values are saved in the instance data block "LEAD_LAD_DB" of the instruction:

Parameter	Operand	Value
PREV_IN	DBD24	2.0
PREV_OUT	DBD28	2.0

SEG: Create bit pattern for seven-segment display

Description

The "Create bit pattern for seven-segment display" instruction is used to convert each of the four hexadecimal digits of the specified source word (IN) into an equivalent bit pattern for a 7-segment display. The result of the instruction is output in the double word on the OUT parameter.

The following relation exists between the hexadecimal digits and the assignment of the 7 segments (a, b, c, d, e, f, g):

Input digit (Binary)	**Assignment of the segments - g f e d c b a**	**Display** (Hexadecimal)	**Seven-segment display**
0000	00111111	0	0001	00000110	1	
0010	01011011	2	
0011	01001111	3	
0100	01100110	4	
0101	01101101	5	
0110	01111101	6	
0111	00000111	7	
1000	01111111	8	
1001	01100111	9	
1010	01110111	A	
1011	01111100	B	
1100	00111001	C	
1101	01011110	D	
1110	01111001	E	
1111	01110001	F	

Syntax

Use the following syntax for the "Create bit pattern for seven-segment display" instruction:

SCL

```
SEG(IN := <Operand>,
    OUT => <Operand>)
```

Parameter

The following table shows the parameters of the "Create bit pattern for seven-segment display" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	WORD	I, Q, M, D, L, P	Source word with four hexadecimal digits
OUT	Output	DWORD	I, Q, M, D, L, P	Bit pattern for the seven-segment display
Function value		VOID		Empty function value

Example

The following example shows how the instruction works:

```
SCL
SEG(IN := "Tag_Input",
    OUT => "Tag_Output");
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value	
		Hexadecimal	Binary
IN	Tag_Input	W#16#1234	0001 0010 0011 0100
OUT	Tag_Output	DW16#065B4F66	00000110 01011011 01001111 01100110 Display: 1234

BCDCPL: Create tens complement

Description

The "Create tens complement" instruction is used to create the tens complement of a seven-digit BCD number specified by the operand. This instruction uses the following mathematical formula to calculate:

10000000 (as BCD)

– 7-digit BCD value

Tens complement (as BCD)

Syntax

The following syntax is used for the "Create tens complement" instruction:

```
SCL
BCDCPL(<Operand>)
```

Parameter

The following table shows the parameters of the "Create tens complement" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand>	Input	Bit strings	I, Q, M, D, L, P	7-digit BCD number
Function value		DWORD	I, Q, M, D, L, P	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := BCDCPL("Tag_Input");
```

The following table shows how the instruction functions using specific values:

Operand	Value*
Tag_Input	DW#16#01234567
Tag_Result	DW#16#08765433
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".

Overview of the valid data types (Page 1908)

BITSUM: Count number of set bits

Description

The "Count number of set bits" instruction is used to count the number of bits of an operand that are set to the signal state "1".

Syntax

The following syntax is used for the "Count number of set bits" instruction:

SCL

```
BITSUM(<Operand>)
```

Parameter

The following table shows the parameters of the "Count number of set bits" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand>	Input	DWORD	I, Q, M, D, L, P	Operand whose set bits are counted
Function value		INT	I, Q, M, D, L, P	Result of the instruction

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := BITSUM("Tag_Input");
```

The following table shows how the instruction functions using specific values:

Operand	Value*
Tag_Input	DW#16#12345678
Tag_Result	W#16#000D (13 bits)
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".

Overview of the valid data types (Page 1908)

11.6.3 Extended instructions

11.6.3.1 Date and time-of-day

T_COMP: Compare time tags

Description

This instruction is used to compare the contents of two tags of the "Timers" or "Date and time" data type.

The instruction supports comparisons of the following data types: DATE, TIME, LTIME, TOD (TIME_OF_DAY), LTOD (LTIME_OF_DAY), DT (DATE_AND_TIME), LDT (DATE_AND_LTIME), DTL, S5Time.

The data types must be the same length and format to carry out the comparison.

The comparison result is output at the OUT parameter as a return value. For this purpose, the parameter OUT is set to "1" if the condition used for the comparison is satisfied.

The following comparison options can be used:

Symbol	Description
EQ	The return value has the signal state “1" if the time is the same at the parameter IN1 and IN2.
NE	The return value has the signal state “1" if the time at parameters IN1 and IN2 is not identical.
GE	The return value has the signal state "1" if the time at parameter IN1 is greater (more recent) than or equal to the time at parameter IN2 .
LE	The return value has the signal state "1" if the time at parameter IN1 is less (less recent) than or equal to the time at parameter IN2.
GT	The return value has the signal state “1" if the time at parameter IN1 is greater (more recent) than the time at parameter IN2.
LT	The return value has the signal state "1" if the time at parameter IN1 is less (less recent) than the time at parameter IN2 .

Parameters

The following table shows the parameters of the instruction "T_COMP":

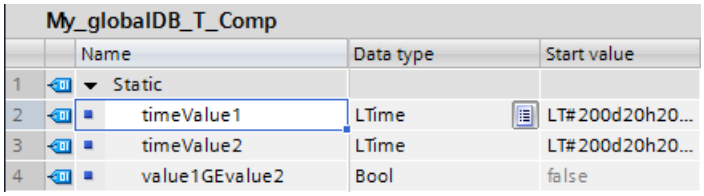
Parameter	Declaration	Data type	Memory area	Description
IN1	Input	DATE, TIME, LTIME, TOD, LTOD, DT, LDT, DTL, S5Time	I, Q, M, D, L, P or constant	First value to be compared.
IN2	Input	DATE, TIME, LTIME, TOD, LTOD, DT, LDT, DTL, S5Time	I, Q, M, D, L, P or constant	Second value to be compared.
OUT	Output	BOOL	I, Q, M, D, L, P	Return value

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

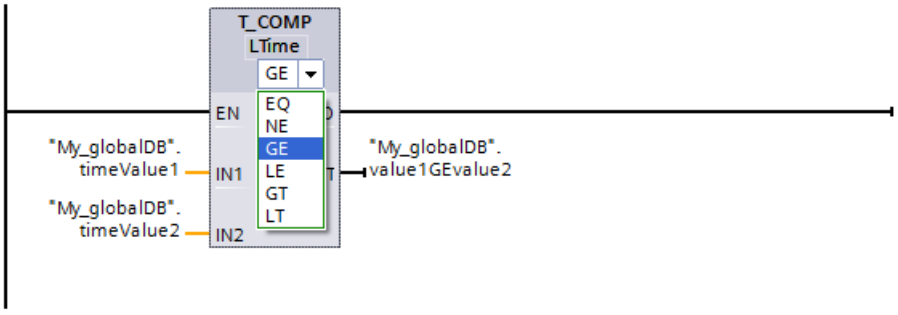
Example

In the following example, you use the "Greater or equal" comparison option to compare two times with the LTIME data type.

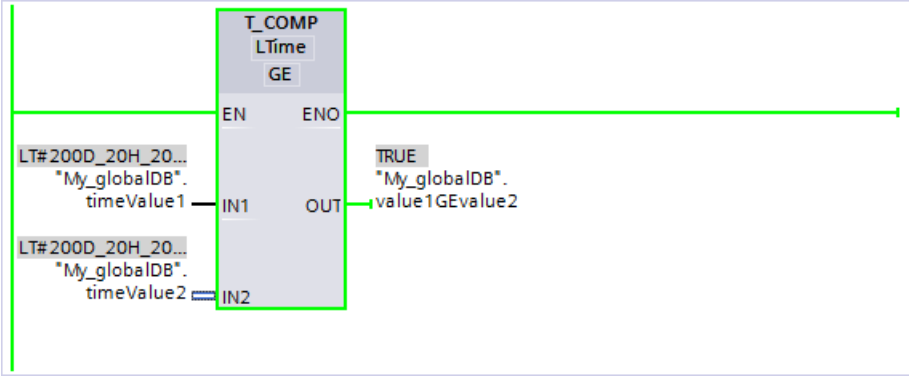
Create three tags in a global data block for storing the data.



Interconnect the parameters of the instruction as follows. Select the "GE" comparison option.



Since the time of the first value to be compared ("timeValue1") is greater than or equal to the second value ("timeValue2"), the return value ("value1GEvalue2") shows the signal state "TRUE".



T_CONV: Convert times and extract

Description

You use the instruction "T_CONV" to convert the data type of the IN input parameter to the data type that is output at the OUT output. You select the data formats for the conversion from the instruction boxes of the input and output.

Parameters

The following table shows the parameters of the instruction "T_CONV". If an input and output parameter of the same data type is used, the instruction copies the corresponding value.

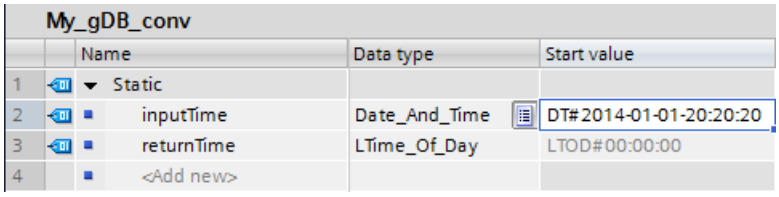
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	Integers, TIME, date and time*	WORD, integers, timers, date and time*	I, Q, M, D, L, P or constant	Value to be converted
OUT	Return	Integers, TIME, date and time*	WORD, integers, timers, date and time*	I, Q, M, D, L, P	Result of the conversion
* The range of supported data types depends on the CPU. Please refer to the overviews of valid data types for information on the data types supported by the S7-1200 and S7-1500 modules.					

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

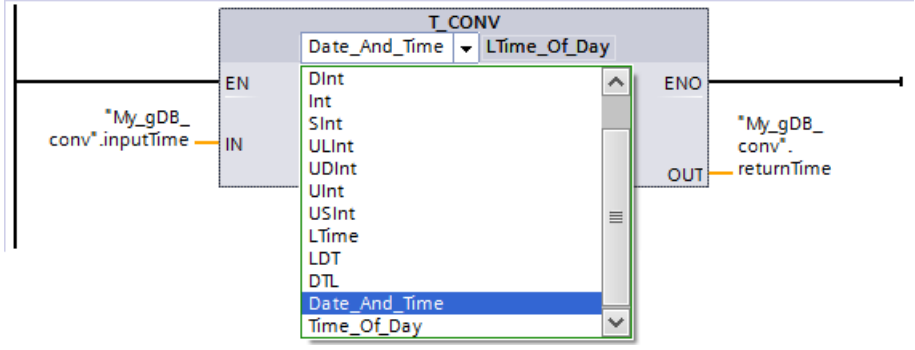
Example

In the following example, you convert a time with the DATE AND TIME data type to a time with the LTIME OF DAY data type.

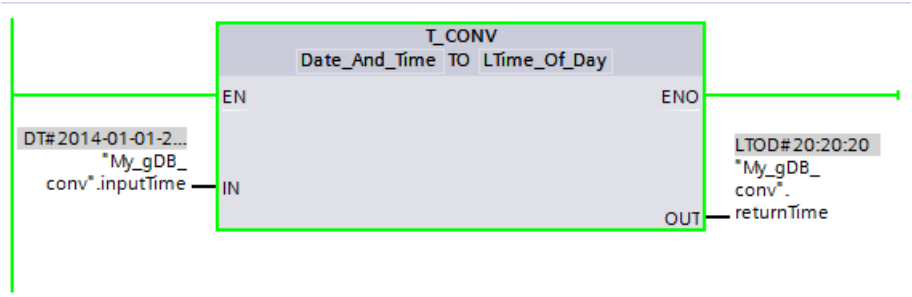
Create two tags in a global data block for storing the data.



Interconnect the parameters of the instruction as follows and select the data types.



The value to be converted ("inputTime") is output at the output parameter as a new value ("returnTime"). The information for the date is lost.



T_ADD: Add times

Description

You use this instruction to add the time information in the IN1 input to the time information in the IN2 input. You can query the result in the OUToutput parameter. You can add the following formats:

- Addition of a time period to another time period.
  Example: Addition of a TIME data type to another TIME data type.
- Addition of a time period to a time.
  Example: Addition of a TIME data type to the DTL data type.

The data type for the value at input parameter IN1 and output parameter OUT is defined by the selection in the instruction boxes of the input and output. You can only specify time information in TIME format in the IN2 input parameter (for S7-1500 modules also LTIME).

Parameters

The following tables show the parameters of the "T_ADD" instruction, according to the possible conversions:

Table 11-34 Addition of a time period to another time period

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	TIME	TIME, LTIME	I, Q, M, D, L, P or constant	First number to be added
IN2	Input	TIME	TIME, LTIME	I, Q, M, D, L, P or constant	Second number to be added
OUT	Return	DINT, DWORD, TIME, TOD	TIME, LTIME,	I, Q, M, D, L, P	Result of addition The data type selection depends on the data types selected for the IN1 and IN2 input parameters.

Table 11-35 Addition of a time period to a time

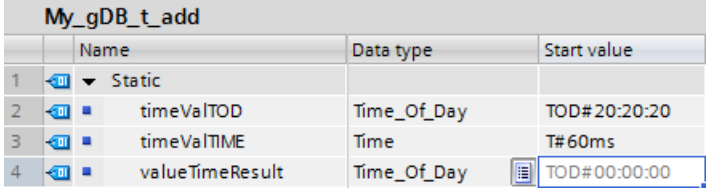
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	DTL, TOD	DT, TOD, LTOD, LDT, DTL	I, Q, M, D, L, P or constant	First number to be added For LTIME at parameter IN2, only LTOD, LDT or DTL can be used.
IN2	Input	TIME	TIME, LTIME	I, Q, M, D, L, P or constant	Second number to be added
OUT	Return	DINT, DWORD, TIME, TOD, UDINT, DTL	DT, DTL, LDT, TOD, LTOD	I, Q, M, D, L, P	Result of addition The data type selection depends on the data types selected for the IN1 and IN2 input parameters.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

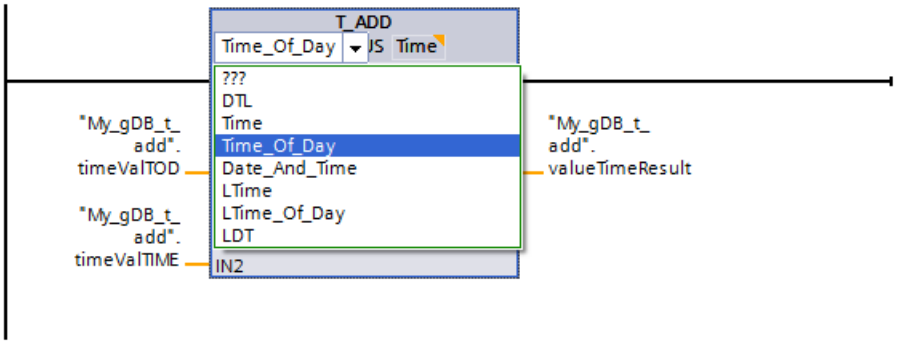
Example

In the following example, you add a time duration with the TIME data type to a time of day with the TOD data type.

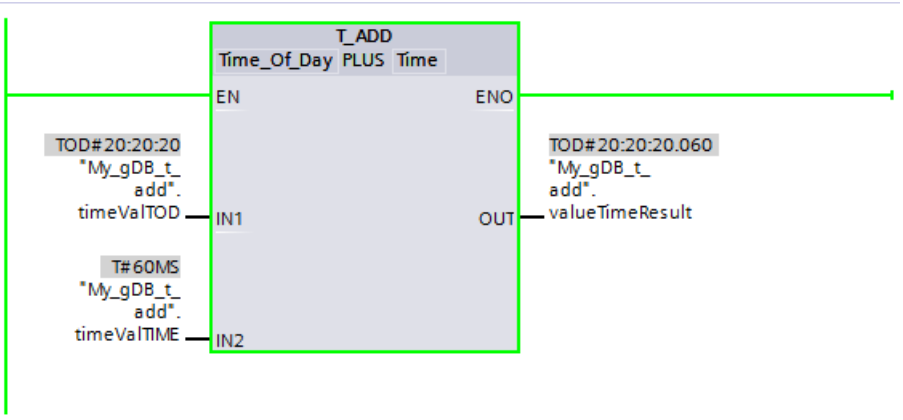
Create three tags in a global data block for storing the data.



Interconnect the parameters of the instruction as follows. You select the data types for time of day ("timeValTOD") and time period ("timeValTIME").



The time of day ("timeValTOD") and the time period ("timeValTIME") are added and the result is displayed as a time of day at output parameter OUT ("valueTimeResult").



T_SUB: Subtract times

Description

You use this instruction to subtract the time information in the IN2 input parameter from the time information in the IN1 input parameter. You can query the difference in the OUT output parameter. You can subtract the following formats:

- Subtraction of a time period from another time period
  Example: Subtraction of a time period of the data type TIME from another time period of the data type TIME. The result can be output to a tag with the TIME format.
- Subtraction of a time period from a time
  Example: Subtraction of a time period of the data type TIME from a time of the data type DTL. The result can be output to a tag with the DTL format.

You decide the formats of the values in the IN1 input parameter and the OUT output parameter by selecting the data types for the input and output parameters of the instruction.

Parameters

The following tables show the parameters of the "T_SUB" instruction, according to the possible conversions:

Table 11-36 Subtraction of a time period from another time period

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	TIME	TIME, LTIME	I, Q, M, D, L, P or constant	Minuend
IN2	Input	TIME	TIME, LTIME	I, Q, M, D, L, P or constant	Subtrahend
OUT	Return	DINT, DWORD, TIME, TOD, UDINT	TIME, LTIME	I, Q, M, D, L, P	Result of subtraction

Table 11-37 Subtraction of a time period from a time

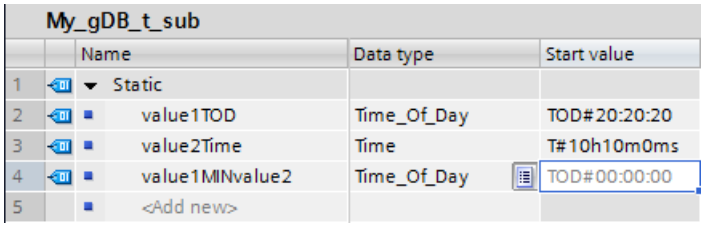
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	DTL, TOD	TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	Minuend For LTIME at parameter IN2, only LTOD, LDT or DTL can be used.
IN2	Input	TIME	TIME, LTIME	I, Q, M, D, L, P or constant	Subtrahend
OUT	Return	DTL, DINT, DWORD, TIME, TOD, UDINT	TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P	Result of subtraction

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

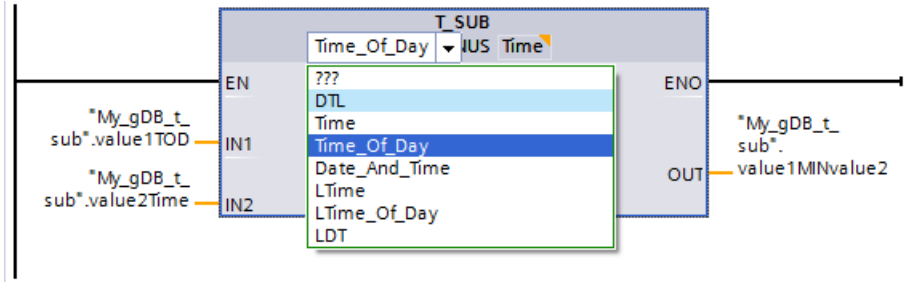
Example

In the following example, you subtract a time period with the TIME data type from a time of day with the TOD data type.

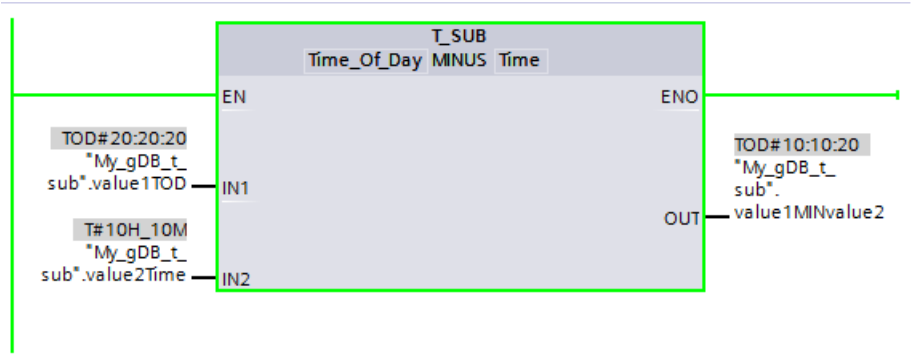
Create three tags in a global data block for storing the data.



Interconnect the parameters of the instruction as follows. You select the data type for the time of day ("value1TOD") and the data type for the time period ("value2Time").



The time of day ("value1TOD") and the time period ("value2Time") are subtracted and the result is displayed as a time of day at output parameter OUT ("value1MINvalue2").



T_DIFF: Time difference

Description

You use this instruction to subtract the time information in the IN2 input parameter from the time information in the IN1 input parameter. The result is sent at output parameter OUT.

- If the time information at the IN2 input parameter is greater than the time information at the IN1 input parameter, the result is output as a negative value at the OUT output parameter.
- If the result of the subtraction is outside the TIME range, the result is set to "0" (0:00) and the enable output ENO = "0".

Parameters

The following table shows the parameters of the "T_DIFF" instruction:

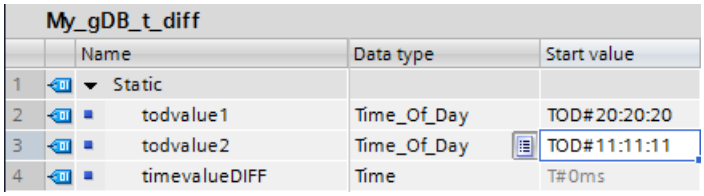
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	DTL, DATE, TOD	DTL, DATE, DT, TOD, LTOD, LDT	I, Q, M, D, L, P or constant	Minuend
IN2	Input	DTL, DATE, TOD	DTL, DATE, DT, TOD, LTOD, LDT	I, Q, M, D, L, P or constant	Subtrahend
OUT	Return	TIME, INT	TIME, LTIME, INT	I, Q, M, D, L, P	Difference of input parameters

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

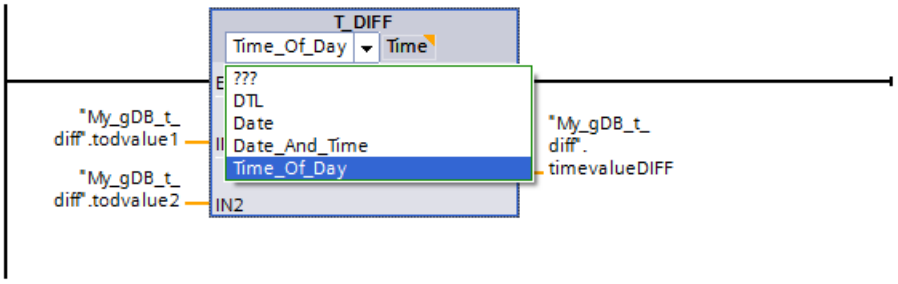
Example

In the following example, you calculate the difference between two times of day with the TOD data type. You specify the difference in the "TIME" data type.

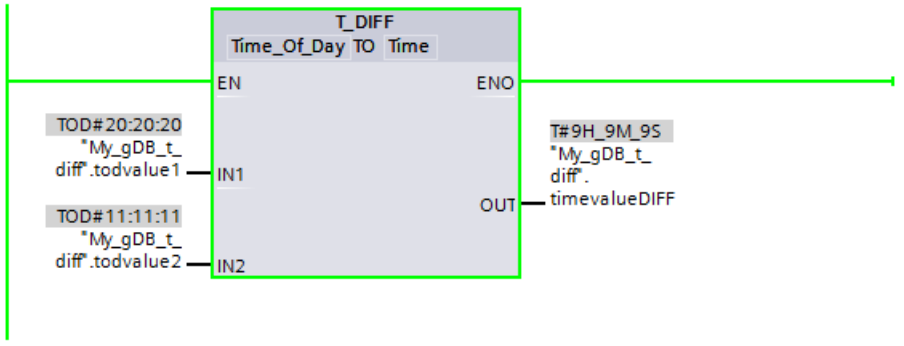
Create three tags in a global data block for storing the data.



Interconnect the parameters of the instruction as follows and select the data types. With the first selection option, you specify the data type of the points in time. With the second selection option, you specify the data type of the difference.



The first time of day ("todvalue1") and the second time of day ("todvalue2") are subtracted and the difference is displayed as a time period at output parameter OUT ("timevalueDIFF").



T_COMBINE: Combine times

Description

The instruction combines the value of a date with the value of a time and converts this into a combined date and time value.

- The date is output at the input parameter IN1. A value of between 1990-01-01 and 2089-12-31 must be used for the data type DATE (this is not checked).
- The time is input at the IN2 input value (TOD/LTOD data type).
- The combined data type for the date and time value is output at the OUT output value.

Parameters

The following table shows the parameters of the instruction "T_COMBINE":

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	DATE	DATE	I, Q, M, D, L, P or constant	Input tag of the date
IN2	Input	TOD	TOD, LTOD	I, Q, M, D, L, P or constant	Input tag of the time
OUT	Return	DTL	DT, DTL, LDT	I, Q, M, D, L, P	Return value of the date and time

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Example

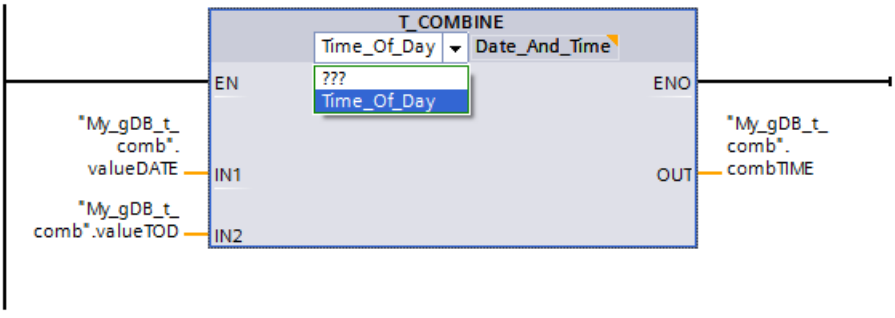
In the following example, you combine a time of day with the TOD data type and a date with the DATE data type. You specify the return value in the DT data type.

Create three tags in a global data block for storing the data.

My_gDB_t_comb

	Name	Data type	Start value
1	Static		
2	valueDATE	Date	D#2014-01-01
3	valueTOD	Time_Of_Day	TOD#20:22:20
4	combTIME	Date_And_Time	DT#1990-01-01-00:00:00

Interconnect the parameters of the instruction as follows and select the data types. With the first selection option, you specify the data type of the time of day ("valueTOD"). With the second selection option, you specify the data type of the return value ("combTIME").



The date ("valueDATE") is expanded by the specification of the time of day ("valueTOD") and the return value is displayed at output parameter OUT ("combTIME").

My_gDB_t_comb

	Name	Data type	Start value	Monitor value
1	Static			
2	valueDATE	Date	D#2014-01-01	D#2014-1-1
3	valueTOD	Time_Of_Day	TOD#20:22:20	TOD#20:22:20
4	combTIME	Date_And_Time	DT#1990-01-01-0	DT#2014-01-01-20:22:20

Time-of-day functions

WR_SYS_T: Set time-of-day

Description

You use this instruction to set the date and time-of-day of the CPU clock. Enter the date and time-of-day at the input parameter IN . The value must be in the following range:

- With DT: min. DT#1990-01-01-0:0:0, max. DT#2089-12-31-23:59:59.999
- With LDT: min. LDT#1970-01-01-0:0:0.000000000, max. LDT##2200-12-31 23:59.999
- With DTL: min. DTL#1970-01-01-00:00:00.0, max. DTL#2200-12-31 23:59.999

You can query whether errors have occurred during execution of the instruction in the RET_VAL output parameter.

The "WR_SYS_T" instruction cannot be used to pass information about the local time zone or daylight saving time.

Parameters

The following table shows the parameters of the "WR_SYS_T" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	DTL	DT, DTL, LDT	I, Q, M, D, L, P or constant *	Date and time
RET_VAL	Return	INT	INT	I, Q, M, D, L, P	Status of the instruction
* The data types DT and DTL cannot be used for the following memory areas: input, output and bit memory.					

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

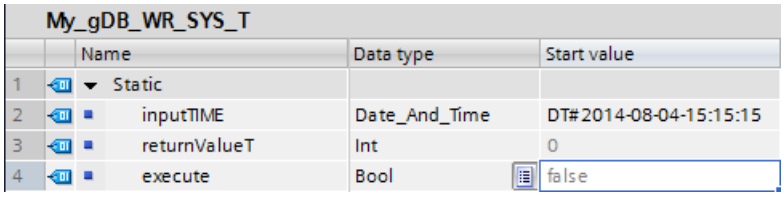
Error code* (W#16#....)	Description
0000	No error
8080	Error in date
8081	Error in time
8082	Month invalid
8083	Day invalid
8084	Hour information invalid
8085	Minute information invalid
8086	Second information invalid
8087	Nanosecond information invalid

Error code* (W#16#....)	Description
80B0	The real-time clock has failed
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

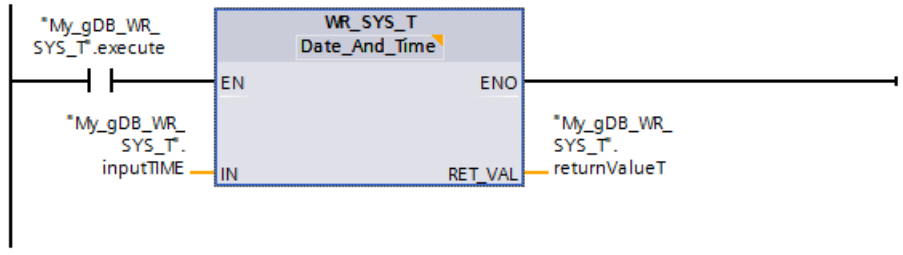
Example

In the following example, you set the date and time of the CPU clock. The data type used is DATE AND TIME.

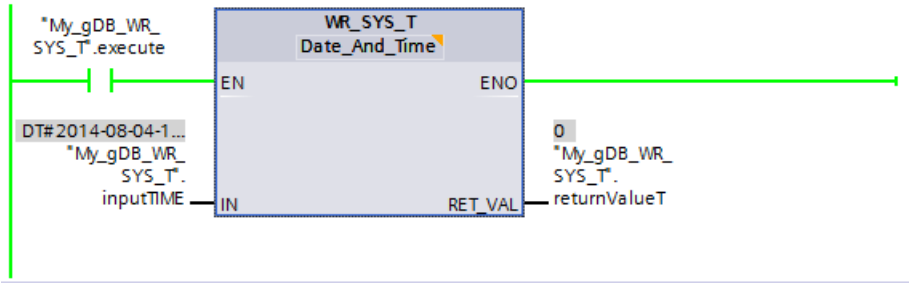
Create three tags in a global data block for storing the data.



Interconnect the parameters of the instruction as follows. Select the DATE AND TIME data type.



If the normally open contact ("execute") supplies the signal state "TRUE", the "WR_SYS_T" instruction is executed. The module time of the CPU clock is overwritten with the time to be set ("inputTIME"). The output parameter RET_VAL ("returnValueT") indicates that processing took place without errors.



You can establish whether the new module time ("inputTIME") has been correctly received by the CPU clock as follows:

- Using the display of an S7-1500 CPU: Navigate on the CPU display to "Settings > Date & Time > General".
- Using TIA Portal: Read out the module time of the CPU clock using the "RD_SYS_T (Page 2983)" instruction.
- Using TIA Portal: Navigate to the "Online & Diagnostics" entry of the CPU, and open the "Functions > Set time of day" tab.
  The Coordinated Universal Time (UTC) is set for the module time of the CPU clock. The Central European Time (local time) is set in the TIA Portal. Accordingly, an hour is added to the time to be set ("inputTIME") in the "Online & Diagnostics" entry in the TIA Portal. An additional hour is added because the settings in the TIA Portal are based on daylight saving time. The calculated local time is output in 12-hour clock format.

RD_SYS_T: Read time-of-day

Description

You use this instruction to read the current date and current time-of-day of the CPU clock.

The read dates are output at the OUT output parameter of the instruction. The provided value does not include information about the local time zone or daylight saving time.

You can query whether errors have occurred during execution of the instruction in the RET_VALoutput.

Parameters

The following table shows the parameters of the "RD_SYS_T" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
RET_VAL	Return	INT	INT	I, Q, M, D, L, P	Status of the instruction
OUT	Output	DTL	DT, DTL, LDT	I, Q, M, D, L, P	Date and time of CPU

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

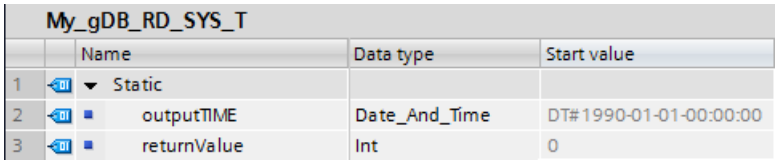
Parameter RET_VAL

Error code* (W#16#....)	Description
0000	No error
8081	Time value specified at the OUT parameter is outside the valid value range: • With DT: min. DT#1990-01-01-0:0:0, max. DT#2089-12-31-23:59:59.999 • With LDT: min. LDT#1970-01-01-0:0:0.000000000, max. LDT#2262-04-11-23:47:16.854775807 • With DTL: min. DTL#1970-01-01-00:00:00.0, max. DTL#2262-04-11-23:47:16.854775807
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Example

In the following example, you read out the module time of the CPU clock. The data type used is DATE AND TIME.

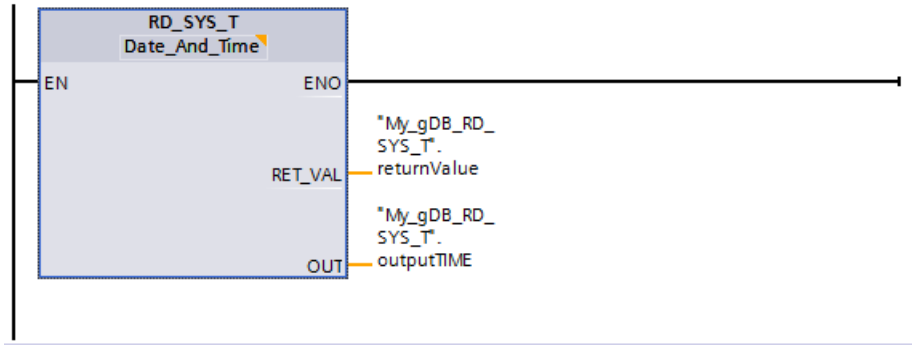
Create two tags in a global data block for storing the data.



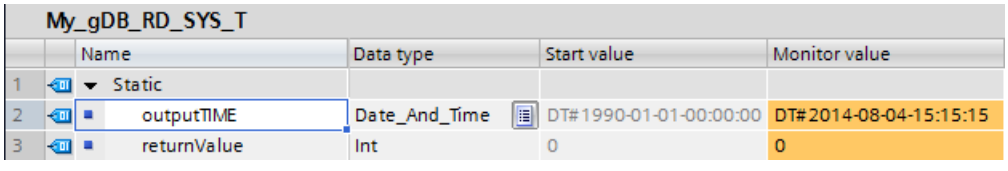
My_gDB_RD_SYS_T

	Name	Data type	Start value
1	Static		
2	outputTIME	Date_And_Time	DT#1990-01-01-00:00:00
3	returnValue	Int	0

Interconnect the parameters of the instruction as follows. Select the DATE AND TIME data type.



The module time of the CPU clock is read out and displayed at output parameter OUT ("outputTIME"). The output parameter RET_VAL ("returnValue") indicates that processing took place without errors.



My_gDB_RD_SYS_T

	Name	Data type	Start value	Monitor value
1	Static			
2	outputTIME	Date_And_Time	DT#1990-01-01-00:00:00	DT#2014-08-04-15:15:15
3	returnValue	Int	0	0

RD_LOC_T: Read local time

Description

You use this instruction to read the current local time from the CPU clock and output this at the OUT output. Information on the time zone and the start of daylight saving time and standard time, which you have set in the configuration of the CPU clock, is used to output the local time.

Parameters

The following table shows the parameters of the "RD_LOC_T" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
RET_VAL	Return	INT	INT	I, Q, M, D, L, P	Status of the instruction
OUT	Output	DTL	DT, LDT, DTL	I, Q, M, D, L, P	Local time

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

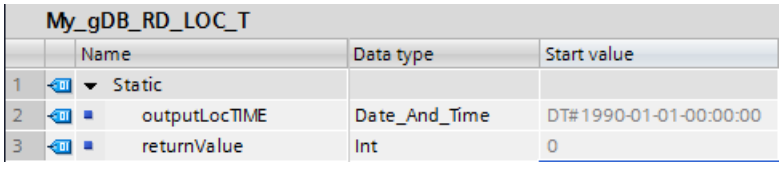
Parameter RET_VAL

Error code* (W#16#....)	Description
0000	No error
0001	No error. Local time is output as daylight saving time.
8080	Local time cannot be read.
8081	Time value specified at the OUT parameter is outside the valid value range: • With DT: min. DT#1990-01-01-0:0:0, max. DT#2089-12-31-23:59:59.999 • With LDT: min. LDT#1970-01-01-0:0:0.000000000, max. LDT#2262-04-11-23:47:16.854775807 • With DTL: min. DTL#1970-01-01-00:00:00.0, max. DTL#2262-04-11-23:47:16.854775807
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

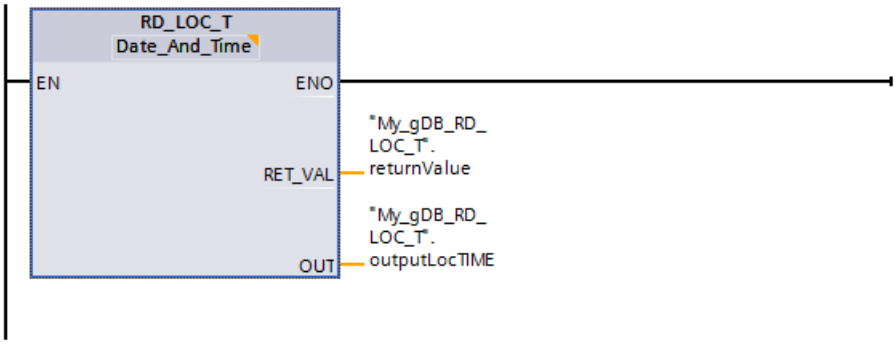
Example

In the following example, you read out the local time of the CPU clock. The data type used is DATE AND TIME.

Create two tags in a global data block for storing the data.



Interconnect the parameters of the instruction as follows. Select the DATE AND TIME data type.



The local time of the CPU clock is read out and displayed at output parameter OUT ("outputLocTIME"). Output parameter RET_VAL ("returnValue") indicates that processing took place without errors and the local time is output as daylight saving time with this call.

My_gDB_RD_LOC_T

	Name	Data type	Start value	Monitor value
1	Static			
2	outputLocTIME	Date_And_Time	DT#1990-01-01-00:00:00	DT#2014-08-04-16:15:15.001
3	returnValue	Int	0	1

WR_LOC_T: Write local time

Description

The instruction "WR_LOC_T" is used to set the date and time of the CPU clock. Enter the date and time-of-day as local time at the input parameter LOCTIME.

The value must be in the following range:

- With DT: min. DT#1990-01-01-00:00:00, max. DT#2089-12-31-23:59:59.999
- With DTL: min. DTL#1970-01-01-00:00:00.0, max. DTL#2200-12-31 23:59.999
- With LDT: min. LDT#1970-01-01-0:0:0.000000000, max. LDT#2200-12-31 23:59.999

The granularity of the time information for local time and system time is product-specific and is at least one millisecond. Input values at the LOCTIME parameter which are less than those supported by the CPU are rounded up during system time calculation.

You can query whether errors have occurred during execution of the instruction in the RET_VAL output parameter.

Use of WR_LOC_T during the time change to daylight saving or standard time

- Changeover from standard to daylight saving time
  In the following it is assumed that the time of the changeover is 2:00 am, and that the time is moved forward by one hour. This means there is no hour between 02:00:00:000000000 AM and 02:59:59:999999999 AM.
  When you specify a corresponding time for LOCTIME, the error code W#16#8089 is generated.
  DST is irrelevant.
- Changeover from daylight saving to standard time
  In the following it is assumed that the time of the changeover is 3:00 am, and that the time is moved back by one hour. This means there are two hours between 02:00:00:000000000 AM and 02:59:59:999999999 AM.
  For all times for LOCTIME that are between 02:00:00:000000000 AM and 02:59:59:999999999 AM, you therefore need to declare whether the time is before or after the time changeover. The DST parameter is used for this:
  - With DST=TRUE, the time is in the first of the two hours, i.e. still in daylight saving time.
  - With DST=FALSE, the time is in the second of the two hours, i.e. in standard time.

  For all times for LOCTIME that are outside the double hour, DST is irrelevant.

Parameters

The following table shows the parameters of the "WR_LOC_T" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
LOCTIME	Input	DTL	DT, DTL, LDT	D, L, P or constant	Local time
DST	Input	BOOL	BOOL	I, Q, M, D, L, P, T, C or constant	**D**aylight **S**aving **T**ime Is only evaluated during the "double hour" at changeover to standard time. • TRUE = daylight saving time (first hour) • FALSE = standard time (second hour)
RET_VAL	Return	INT	INT	I, Q, M, D, L, P	Error message (see "RET_VAL parameter")

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

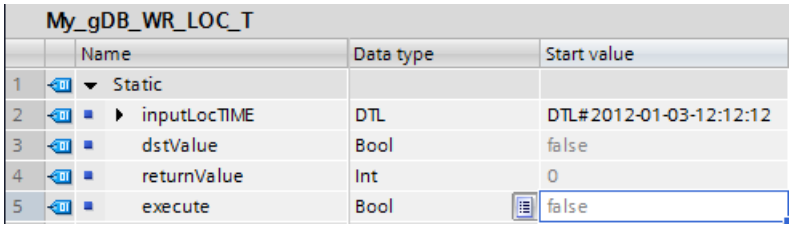
Error code* (W#16#....)	Description
0000	No error.
8080	The LOCTIME parameter has an invalid value.

Error code* (W#16#....)	Description
8081	Time value specified at the LOCTIME parameter is outside the valid value range: • With DT: min. DT#1990-01-01-00:00:00, max. DT#2089-12-31-23:59:59.999 • With DTL: min. DTL#1970-01-01-00:00:00.0, max. DTL#2200-12-31 23:59.999 • With LDT: min. LDT#1970-1-1-0:0:0.000000000, max. LDT#2200-12-31 23:59.999
8082**	Invalid value specified for the month (byte 2 in DTL format).
8083**	Invalid value specified for the day (byte 3 in DTL format).
8084**	Invalid value specified for the hour (byte 5 in DTL format).
8085**	Invalid value specified for the minute (byte 6 in format DTL).
8086**	Invalid value specified for the second (byte 7 in DTL format).
8087**	Invalid value specified for the nanosecond (byte 8 to 11 in DTL format).
8089	Time value does not exist (hour already passed upon changeover to daylight saving time).
80B0	The real-time clock has failed.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	
** Only for local time information at the LOCTIME parameter in DTL format.	

Example

In the following example, you set the local time of the CPU clock. The data type used is DTL.

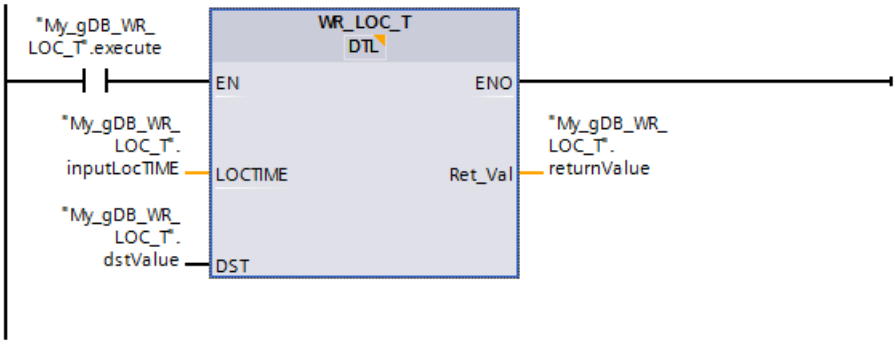
Create four tags in a global data block for storing the data.



My_gDB_WR_LOC_T

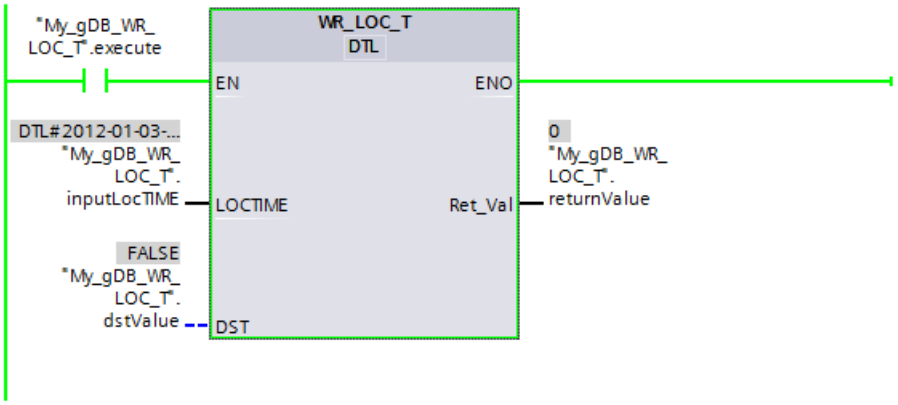
	Name	Data type	Start value
1	Static		
2	inputLocTIME	DTL	DTL#2012-01-03-12:12:12
3	dstValue	Bool	false
4	returnValue	Int	0
5	execute	Bool	false

Interconnect the parameters of the instruction as follows. Select the DTL data type.



If the normally open contact ("execute") supplies the signal state "TRUE", the "WR_LOC_T" instruction is executed. The local time of the CPU clock is overwritten with the time to be set ("inputLocTIME"). The output parameter RET_VAL ("returnValue") indicates that processing

took place without errors. Input parameter DST ("dstValue") specifies that the time information refers to standard time. This parameter is only relevant for the "double hour".



You can establish whether the new local time ("inputLocTIME") has been correctly received by the CPU clock as follows:

- Using the display of an S7-1500 CPU: Navigate on the CPU display to "Settings > Date & Time > General".
- Using TIA Portal: Read out the local time of the CPU clock using the "RD_LOC_T (Page 2985)" instruction.
- Using TIA Portal: Navigate to the "Online & Diagnostics" entry of the CPU, and open the "Functions > Set time of day" tab.
  The local time is output in 12-hour clock format.

SET_TIMEZONE: Set time zone

Description

Use the instruction "SET_TIMEZONE" to set the parameter for the local time zone and the daylight saving / standard time changeover.

The settings which are carried out with the instruction "SET_TIMEZONE" correspond with the settings for the time-of-day in the properties of the CPU. Define the corresponding parameters in the system data type TimeTransformationRule for execution of the instruction "SET_TIMEZONE".

The local time is calculated based on the system time using the settings for the time zone and the daylight saving / standard time changeover. The system time of the CPU is the UTC time. The system time is used exclusively for communication within the system.

Note

Use with CPUs of the S7-1500 series

The "SET_TIMEZONE" instruction can only be used with a CPU of the S7-1500 series starting from firmware version V1.7.

Parameters

The following table shows the parameters of the "SET_TIMEZONE" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L, P or constant	Setting of parameters that are stored at parameter TimeZone.
TimeZone	Input	TimeTransformationRule	D, L	You interconnect the TimeTransformationRule system data type (see below) at parameter TimeZone.
DONE	Output	BOOL	I, Q, M, D, L, P	Status parameter: • 0: Job not yet started or still in progress • 1: Job completed without error
BUSY	Output	BOOL	I, Q, M, D, L, P	Status parameter: • 0: Job not yet started or already completed • 1: Job not yet completed. A new job cannot be started.
ERROR	Output	BOOL	I, Q, M, D, L, P	Status parameter: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L, P	Detailed error and status information is output at the parameter STATUS. The parameter is only set for the duration of one call. To display the status, you should therefore copy the STATUS parameter to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

TimeZone parameter

You store the parameters for the local time zone and the daylight saving/standard time changeover in the TimeTransformationRule system data type

You create the TimeTransformationRule by entering TimeTransformationRule as the data type in a data block or the local interface of a function block.

The structure of the TimeTransformationRule is as follows:

Name	Data type	Description
TimeTransformationRule	STRUCT	

Name	Data type	Description
Bias	INT	Time difference between the local time and the system time (UTC) in minutes. The value must be between -720 and +780 minutes (-12 to +13 hours). The value (UTC -12 to +13 hours) corresponds to the time zones that you specify in the properties of the CPU.
DaylightBias	INT	Time difference between standard and daylight saving time in minutes. The value must be between 0 and 120 minutes. • The value "0" deactivates the changeover between daylight saving time and standard time. The values for "DaylightStart..." and "StandardStart..." are set to "0". Only the value of Bias is evaluated (time difference local time/ system time). • If the value is not "0", all tags of the TimeTransformationRule structure are evaluated. If an entry is invalid, error code 808F is output at parameter STATUS.
Specification of the time of day for changeover to daylight saving time. The following times always refer to the local time.		
DaylightStartMonth	USINT	Month in which change is made to daylight saving time: 1 = January 2 = February 3 = March ... 12 = December
DaylightStartWeek	USINT	Week in which change is made to daylight saving time. 1 = First occurrence of the weekday in the month ... 5 = Last occurrence of the weekday in the month
DaylightStartWeek-day	USINT	Weekday on which change is made to daylight saving time: 1 = Sunday ... 7 = Saturday
DaylightStartHour	USINT	Hour in which change is made to daylight saving time
DaylightStartMinute	USINT	Minute in which change is made to daylight saving time
Specification of the time of day for changeover to standard time. The following times always refer to the local time.		
StandardStartMonth	USINT	Month in which change is made to standard time: 1 = January 2 = February 3 = March ... 12 = December
StandardStartWeek	USINT	Week in which change is made to standard time: 1 = First occurrence of the weekday in the month ...

Name		Data type	Description
			5 = Last occurrence of the weekday in the month
	StandardStartWeek-day	USINT	Weekday on which change is made to standard time: 1 = Sunday ... 7 = Saturday
	StandardStartHour	USINT	Hour in which change is made to standard time
	StandardStartMinute	USINT	Minute in which change is made to standard time
	TimeZoneName	STRING[80]	Name of the time zone, for example: "(GMT+01:00) Amsterdam, Berlin, Bern, Rome, Stockholm, Vienna"

STATUS parameter

Error code* (W#16#....)	Description
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
808F	The structure, content or data types of the TimeTransformationRule at the TimeZone parameter are invalid or inconsistent.
80C3	Temporary resource error: The CPU is currently processing the maximum possible number of simultaneous block calls. "SET_TIMEZONE" cannot be executed unless at least one of the block calls is finished.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Example

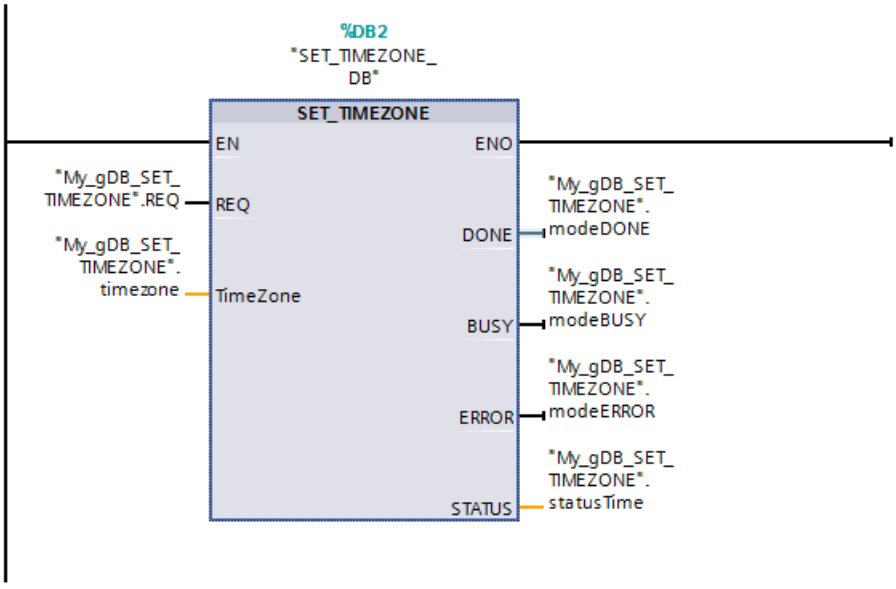
In the following example, you set the parameters for the local time zone and the daylight saving/standard time changeover.

Create the following for storing the data in a global data block: The "timezone" structure (with the TimeTransformationRule data type) and the "REQ", "modeDONE", "modeBUSY", "modeERROR", and "statusTime" tags.

My_gDB_SET_TIMEZONE

	Name	Data type	Start value
1	Static		
2	REQ	Bool	false
3	timezone	TimeTransformationRule	
4	Bias	Int	60
5	DaylightBias	Int	60
6	DaylightStartMonth	USInt	3
7	DaylightStartWeek	USInt	5
8	DaylightStartWeek...	USInt	1
9	DaylightStartHour	USInt	2
10	DaylightStartMinute	USInt	0
11	StandardStartMonth	USInt	10
12	StandardStartWeek	USInt	5
13	StandardStartWeek..	USInt	1
14	StandardStartHour	USInt	3
15	StandardStartMinute	USInt	0
16	TimeZoneName	String[80]	'My_GMT+'
17	modeDONE	Bool	false
18	modeBUSY	Bool	false
19	modeERROR	Bool	false
20	statusTime	Word	16#0

Interconnect the parameters of the instruction as follows.



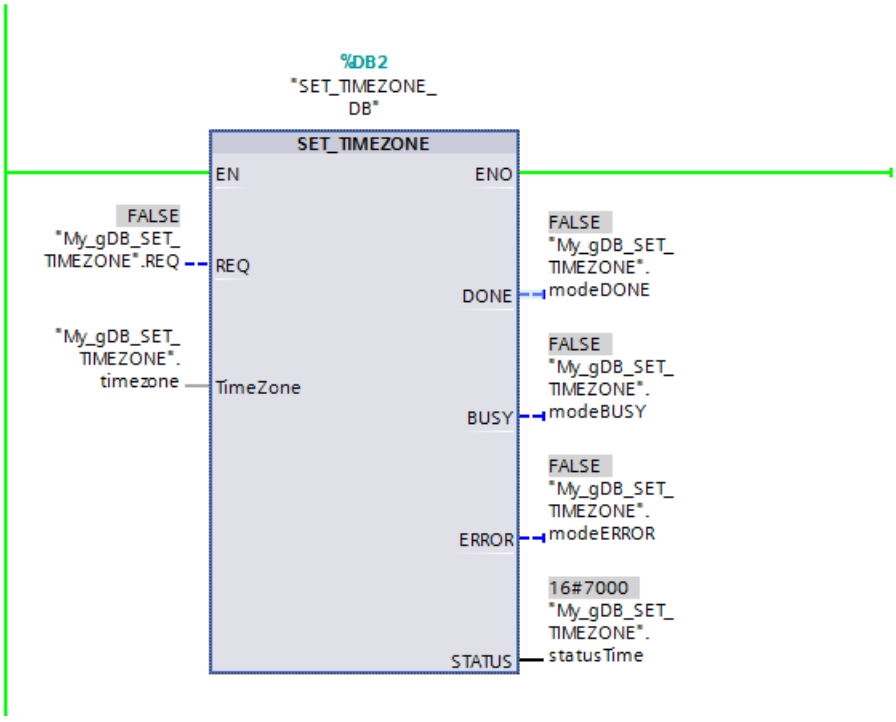
If parameter REQ supplies the signal state "TRUE", the data for the time zone of the CPU clock is overwritten with the data to be set ("timezone"). This also means:

- Output parameter BUSY ("modeBUSY") goes to signal state "TRUE". After processing, output parameter BUSY shows the value "FALSE" and output parameter DONE ("modeDONE") shows the value "TRUE".
- The output parameter STATUS ("statusTime") indicates how processing is running*. (*The job processing begins (value "7001") and the instruction is then shown as already active (value "7002").)
- The output parameter ERROR ("modeERROR") indicates that processing is running without errors (signal state is "FALSE").

My_gDB_SET_TIMEZONE

	Name	Data type	Start value	Monitor value
1	Static			
2	REQ	Bool	false	TRUE
3	timezone	TimeTransformationRule		
4	Bias	Int	60	60
5	DaylightBias	Int	60	60
6	DaylightStartMonth	USInt	3	3
7	DaylightStartWeek	USInt	5	5
8	DaylightStartWeek...	USInt	1	1
9	DaylightStartHour	USInt	2	2
10	DaylightStartMinute	USInt	0	0
11	StandardStartMonth	USInt	10	10
12	StandardStartWeek	USInt	5	5
13	StandardStartWeek..	USInt	1	1
14	StandardStartHour	USInt	3	3
15	StandardStartMinute	USInt	0	0
16	TimeZoneName	String[80]	'My_GMT+'	'My_GMT+'
17	modeDONE	Bool	false	FALSE
18	modeBUSY	Bool	false	TRUE
19	modeERROR	Bool	false	FALSE
20	statusTime	Word	16#0	16#7002

Note: The "SET_TIMEZONE" instruction is level-triggered. Only when parameter REQ supplies the signal state "TRUE" is the instruction executed.



You can establish whether the data to be set ("timezone") has been correctly received by the CPU clock as follows:

- Using the display of an S7-1500 CPU: Navigate on the CPU display to "Settings > Date & Time > Daylight Saving Time".
- Using TIA Portal: Read out the local time of the CPU clock using the "RD_LOC_T (Page 2985)" instruction.
- Using TIA Portal: Read out the module time of the CPU clock using the "RD_SYS_T (Page 2983)" instruction.

SNC_RTCB: Synchronize slave clocks

Definition: Synchronization of slave clocks

The synchronization of clock slaves refers to the transfer of the date and time-of-day from the clock master of a bus segment to all clock slaves of this bus segment.

Description

You use this instruction to synchronize all slave clocks present on a bus segment independent of the assigned synchronization interval. Successful synchronization is only possible if "SNC_RTCB" is called on a CPU whose real-time clock was assigned as the master clock for at least one bus segment.

Parameters

The following table shows the parameters of the "SNC_RTCB" instruction:

Parameter	Declaration	Data type	Memory area	Description
RET_VAL	Output	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code.

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error occurred during synchronization.
0001	The existing clock was not assigned the master clock function for any of the bus segments.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

TIME_TCK: Read system time

Description

With the "TIME_TCK" instruction, you read the system time of the CPU. The system time is a time counter that counts from 0 to a maximum of 2147483647 ms. In case of an overflow, the system time is counted again starting with "0". The time scale and the accuracy of the system time is 1 ms. The system time is only influenced by the operating modes of the CPU. You can use the system time, for example, to measure the duration of processes by comparing the results of two "TIME_TCK" calls. The instruction does not provide any error information.

The following table provides an overview of how the system time changes depending on the operating modes of the CPU.

Mode	System time ...
Startup	... is constantly updated
RUN	
STOP	... is stopped and retains the current value
Warm restart	... is deleted and restarts with "0"

Parameters

The following table shows the parameters of the instruction "TIME_TCK":

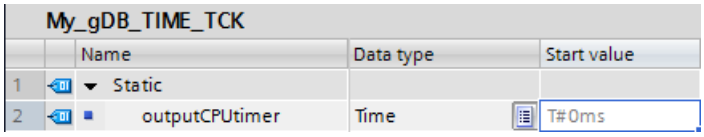
Parameter	Declaration	Data type	Memory area	Description
RET_VAL	Return	TIME	I, Q, M, D, L	The RET_VAL parameter contains the read system time in the range from 0 to 2^{31} -1 ms.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Example

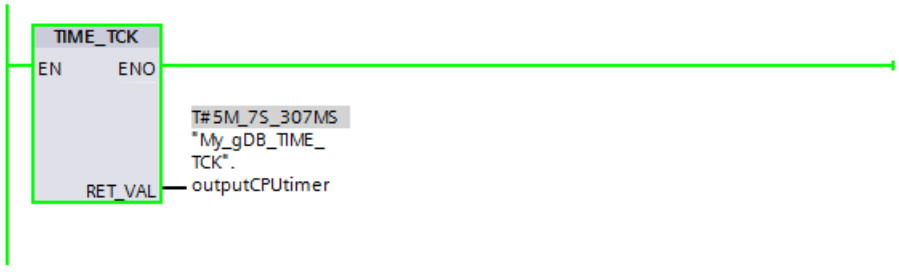
In the following example, you read out the system time of the CPU. You specify the return value in the TIME data type.

Create one tag for storing the data in a global data block.



Interconnect the parameters of the instruction as follows.

The system time of the CPU is read out and displayed at output parameter RET_VAL ("outputCPUtimer").



RTM: Runtime meters

Description

You can use this instruction to set, start, stop, and read out a 32-bit operating hours counter of your CPU.

Ensure that the operating hours counter can also be stopped or restarted during execution of the user program, which may render the saved values incorrect.

Parameters

The following table shows the parameters of the "RTM" instruction:

Parameter	Declaration	Data type	Memory area	Description
NR	Input	RTM	I, Q, M, D, L or constant	Number of the operating hours counter Numbering starts with 0. For information on the number of operating hours counters of your CPU, refer to the technical data.
MODE	Input	BYTE	I, Q, M, D, L or constant	Job ID: • 0: Read out (the status is then written to CQ and the current value to CV). After the operating hours counter has reached (2E31) -1 hours, it stops at the highest value that can be displayed and outputs an "Overflow" error message. • 1: start (at the last counter value) • 2: stop • 4: set (to the value specified in PV) • 5: set (to the value specified in PV) and then start • 6: set (to the value specified in PV) and then stop
PV	Input	DINT	I, Q, M, D, L or constant	New value for the operating hours counter
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code.
CQ	Output	BOOL	I, Q, M, D, L	Status of the operating hours counter (1: running)
CV	Output	DINT	I, Q, M, D, L	Current value of the operating hours counter

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code (W#16#...)	Explanation
0000	No error
8080	Wrong number for the operating hours counter
8081	A negative value was passed to the PV parameter.
8082	Overflow of the operating hours counter
8091	The MODE input parameter contains an invalid value.
General error information	See also: Evaluating errors with GET_ERR_ID (Page 2922)

Example

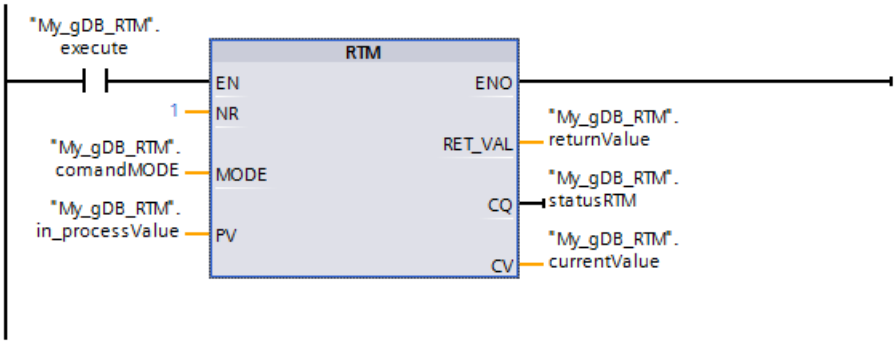
In the following example, you set the operating hours counter of the CPU and read out the value after an hour.

Create six tags in a global data block for storing the data.

My_gDB_RTM

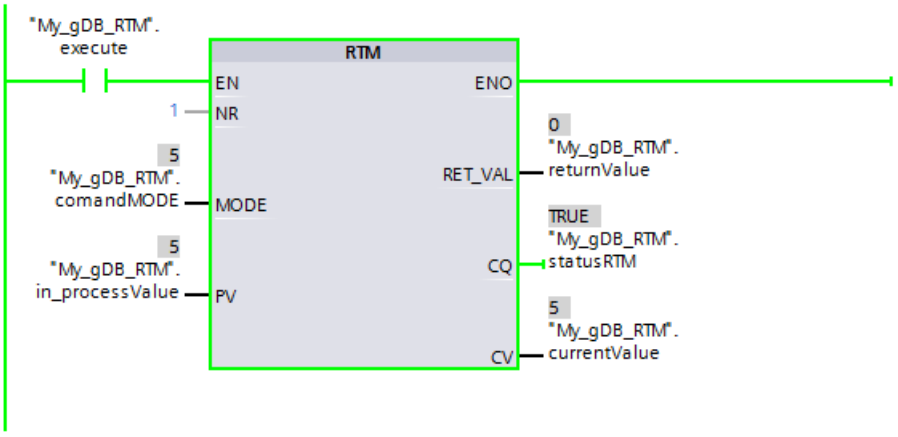
	Name	Data type	Start value
1	Static		
2	execute	Bool	false
3	in_processValue	DInt	5
4	returnValue	Int	0
5	statusRTM	Bool	false
6	currentValue	DInt	0
7	comandMODE	Byte	5

Interconnect the parameters of the instruction as follows. At input parameter NR, specify the number of the operating hours counter of the CPU.

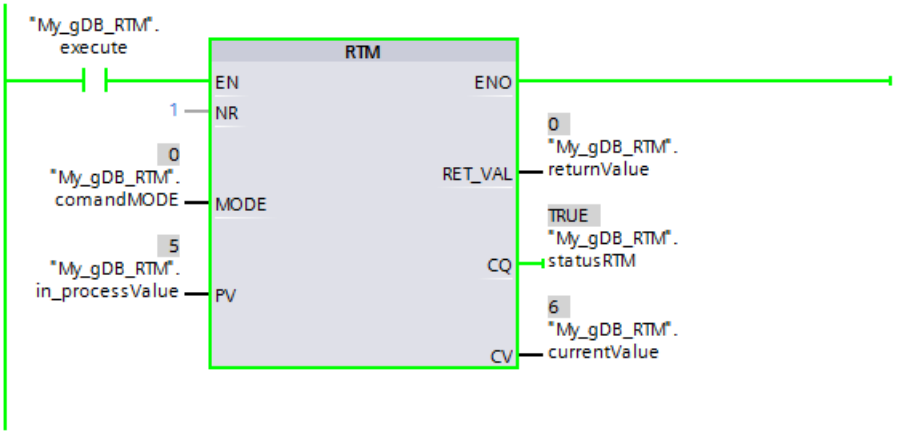


If the normally open contact ("execute") supplies the signal state "TRUE", the "RTM" instruction is executed. The operating hours counter of the CPU is set to the value to be set ("in_processValue") and started. After the start of the operating hours counter, set the value of input parameter MODE ("comandMODE") to "0". (To do so, click the parameter and select "Modify operand > Set to 0".) As a result, the "RTM" instruction only reads the current value ("currentValue") of the operating hours counter without changing it. Output parameter CQ ("statusRTM") indicates after the start of the operating hours counter that the operating hours

counter is running (value is "TRUE"). The output parameter RET_VAL ("returnValue") indicates that processing is running without errors.



After an hour, output parameter CV ("currentValue") indicates the value "6".



11.6.3.2 String + Char

S_MOVE: Move character string

Description

You can use this instruction to write the content of a character string (W)STRING from parameter IN to the data area that you specify at parameter OUT.

You can use the "MOVE_BLK" and "UMOVE_BLK" instructions to copy tags of data type ARRAY.

Parameters

The following table shows the parameters of the "S_MOVE" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	STRING, WSTRING	D, L or constant	Source string
OUT	Output	STRING, WSTRING	D, L	Destination string

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Example

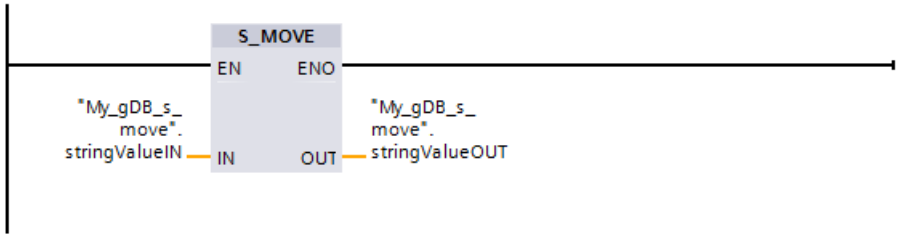
In the following example, you copy the content of a character string from input parameter IN to another character string at output parameter OUT. The data type used is STRING.

Create two tags in a global data block for storing the data.

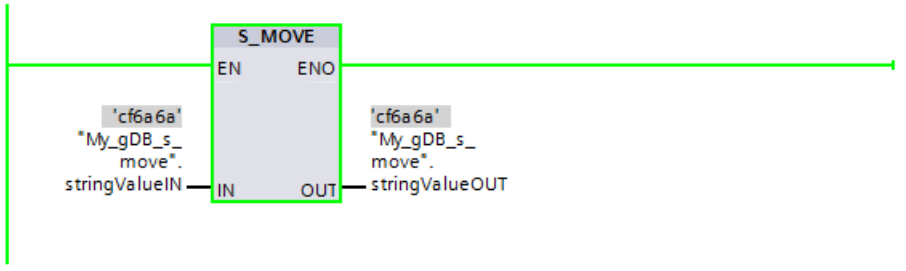
My_gDB_s_move

	Name	Data type	Start value
1	Static		
2	stringValueIN	String	'cf6a6a'
3	stringValueOUT	String	''

Interconnect the parameters of the instruction as follows.



The result of the character string to be copied ("stringValueIN") is output at output parameter OUT ("stringValueOUT").



S_COMP: Compare character strings

Description

The instruction compares the contents of two tags in the (W)STRING format and outputs the result of the comparison as a return value. The tags that are to be compared will be interconnected at the IN1 and IN2 inputs. You can only assign a symbolically defined tag for the input parameters.

Use the instruction box to select the comparison condition. If the comparison condition (for example, greater than or equal to) is satisfied, the signal state is set to "1" at the output parameter OUT .

The following comparison options can be used:

Symbol	Description
EQ	The return value has the signal state "1" if the string at the IN1 parameter is the same as the string at the IN2 parameter.
NE	The return value has the signal state "1" if the string at the IN1 parameter is not equal to the string at the IN2 parameter.
GT (1)	The return value has the signal state “1" if the string at the IN1 parameter is greater than the string at the IN2 parameter.
LT (1)	The return value has the signal state "1" if the string at the IN1 parameter is less than the string at the IN2 parameter.
GE (1)	The return value has the signal state "1" if the string at the IN1 parameter is greater than or equal to the string at the IN2 parameter.
LE (1)	The return value has the signal state "1" if the string at the IN1 parameter is less than or equal to the string at the IN2 parameter.
(1) The characters are compared by their ASCII code (for example, 'a' is greater than 'A'), starting from the left. The first character to be different decides the result of the comparison. If the first characters are the same, the longer string is greater.	

Parameters

The following table shows the parameters of the "S_COMP" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN1	Input	STRING, WSTRING*	D, L or constant	Input tag in the STRING / WSTRING format.
IN2	Input	STRING, WSTRING*	D, L or constant	Input tag in the STRING / WSTRING format.
OUT	Output	BOOL	I, Q, M, D, L	Result of comparison
* Define the maximum length of the character string if you use the data type STRING / WSTRING in the interface declaration for a temporary tag (you will find further information in the description of the data type).				

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Example

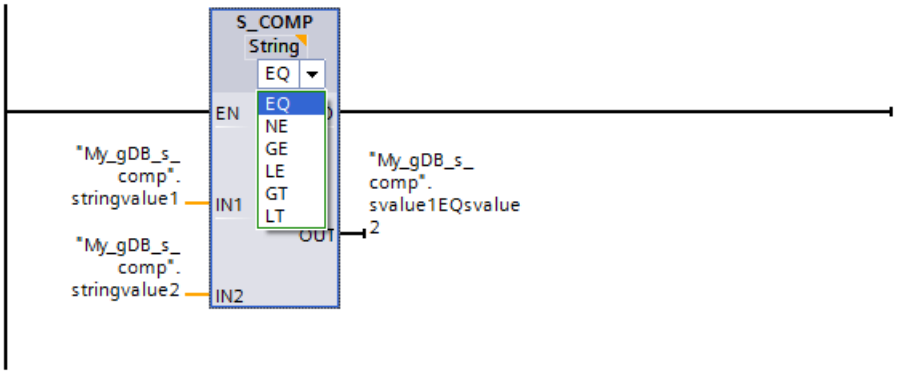
In the following example, you use the "Equal" comparison option to compare two character strings with the "STRING" data type.

Create three tags in a global data block for storing the data.

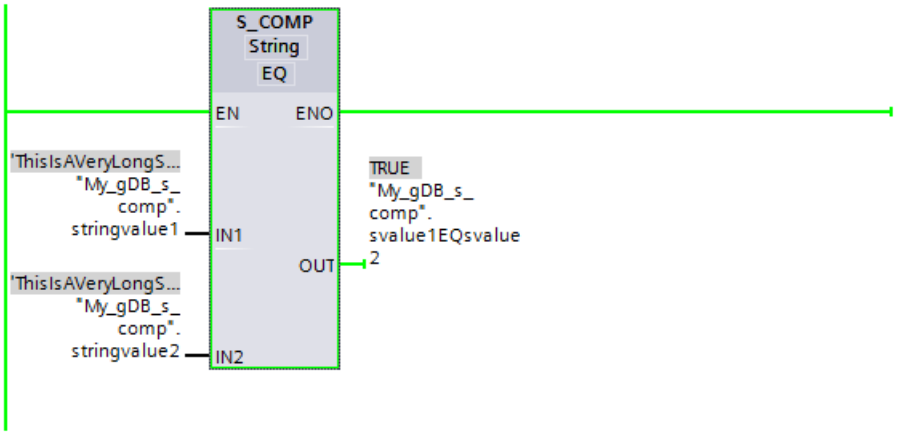
My_gDB_s_comp

	Name	Data type	Start value
1	Static		
2	stringvalue1	String	'ThisIsAVeryLongStringWithSomeNumbers646'
3	stringvalue2	String	'ThisIsAVeryLongStringWithSomeNumbers646'
4	svalue1EQsvalue2	Bool	false

Interconnect the parameters of the instruction as follows. Select the STRING data type and the EQ comparison option.



Since the value of the first character string to be compared ("stringvalue1") is equal to the second character string ("stringvalue2"), the comparison result ("svalue1EQsvalue2") shows the signal state "TRUE".



S_CONV: Convert character string

Description

You use this instruction to convert the value at the IN input to the data format you have specified in the OUT output. You decide the output format of the conversion by selecting a data type for the OUT output parameter.

The following conversions are possible:

- Conversion of a character string to:
  - Numerical value (integer or floating-point number)
    The conversion is performed for all characters of the character string specified in the IN input parameter. Permitted characters are the digits "0" to "9", the decimal point, and the plus and minus signs. The first character of the string may be a valid number or a sign. Leading spaces and exponential notations are ignored.
  - A character
    When a character string is converted to a character, the first character of the character string is transferred to parameter OUT.
  - A character string
- Conversion of a numerical value or character to a character string:
  - You decide the format of the numeric value to be converted by selecting a data type for the IN input. A valid tag of the (W)STRING data type must be specified at the OUT output. The length of the character string after conversion depends on the value at the IN input.
  - The conversion result is saved as a string starting at the third byte. The first byte of the string records the maximum length and the second byte the actual length of the character string. Positive numeric value are output without a sign.
  - If the numeric value 0, which exists as an INT or UINT data type, is converted to a string (e.g. INT_TO_STRING(0)), then the string in the result has a length of 6 characters.
  - When a numeric value is converted to a string, the first characters of the string are padded with spaces. The number of spaces depends on the length of the numerical value.
  - When a (W)CHAR character is converted, the character is written at the first position of the character string.

Note

Exponential notation during conversion from floating-point numbers

Do not use exponential notation ("e" or "E") for the conversion from floating-point numbers with the instruction "S_CONV". Instead, use the instruction "STRG_VAL (Page 3008)" for the conversion of floating-point numbers with exponential notation. You can use the FORMAT parameter of the instruction to select exponential notation as input format.

- Conversion of a character to a character

Parameters

The following tables show the parameters of the "S_CONV" instruction, according to the possible conversions:

Table 11-38 Parameters for converting a character string to a numeric value:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	STRING, WSTRING	D, L or constant	Value to be converted
OUT	Output	CHAR, WCHAR, USINT, UINT, UDINT, ULINT, SINT, INT, DINT, LINT, REAL, LREAL	I, Q, M, D, L	Result of the conversion

Table 11-39 Parameters for converting a character string to a character string:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	STRING, WSTRING	D, L or constant	Value to be converted
OUT	Output	STRING, WSTRING	D, L	Result of the conversion (possible conversions: STRING to WSTRING and vice versa)

Table 11-40 Parameters for converting a numerical value or character to a character string:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	CHAR, WCHAR, USINT, UINT, UDINT, ULINT, SINT, INT, DINT, LINT, REAL, LREAL	I, Q, M, D, L or constant	Value to be converted
OUT	Output	STRING, WSTRING	D, L	Result of the conversion

Table 11-41 Parameters for converting a character to a character:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	CHAR, WCHAR	I, Q, M, D, L or constant	Value to be converted
OUT	Output	CHAR, WCHAR	I, Q, M, D, L	Result of the conversion (possible conversions: CHAR to WCHAR and vice versa)

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Example

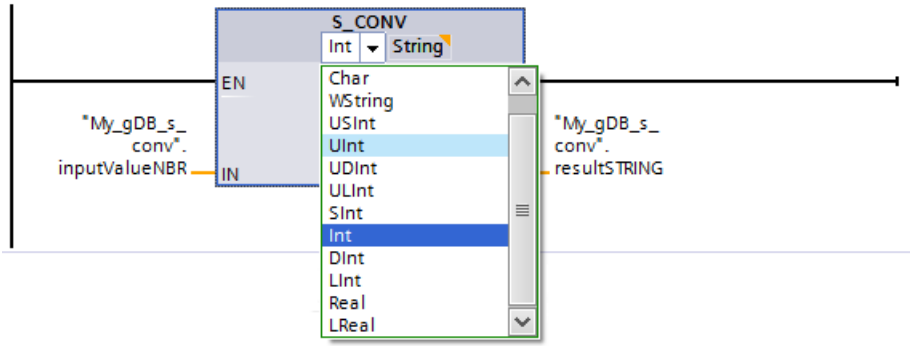
In the following example, you convert a number with the INT data type to a character string with the STRING data type.

Create two tags in a global data block for storing the data.

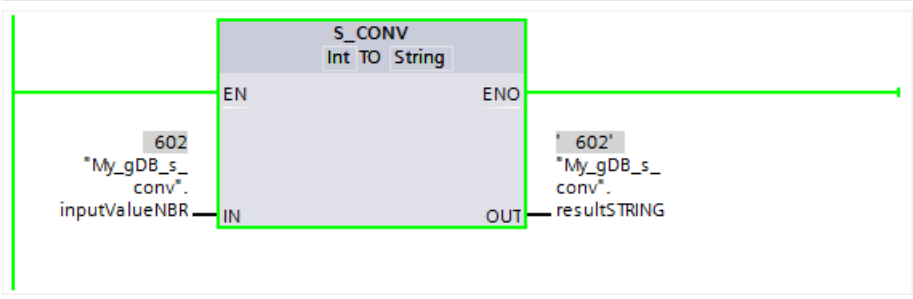
My_gDB_s_conv

	Name	Data type	Start value
1	Static		
2	inputValueNBR	Int	602
3	resultSTRING	String	''
4	<Add new>		

Interconnect the parameters of the instruction as follows. In doing so, select the data types. With the first selection option, you specify the data type of the value to be converted ("inputValueNBR"). With the second selection option, you specify the data type of the character string to be generated ("resultSTRING").



The value to be converted ("inputValueNBR") is converted to the output format. Blank spaces are written to the empty places at the start of the character string. The result of the conversion is output at output parameter OUT ("resultSTRING") as a string.



STRG_VAL: Convert character string to numerical value

Description

The "STRG_VAL" instruction converts a character string to an integer or a floating-point number:

- You specify the character string to be converted in the IN input parameter.
- You define the format of the output value by selecting a data type for the OUT output parameter.

Permitted characters for the conversion are the digits "0" to "9", the decimal point, the decimal comma, notations "E" and "e", and the plus and minus characters. The conversion can be interrupted by invalid characters.

The "STRG_VAL" instruction is not supported by the SCL programming language.

Parameters

The following table shows the parameters of the "STRG_VAL" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	STRING, WSTRING	STRING, WSTRING	D, L or constant	Number string to be converted
FORMAT	Input	WORD	WORD	I, Q, M, D, L, P or constant	Output format of the characters
P	Input	UINT	UINT	I, Q, M, D, L, P or constant	Reference to the first character to be converted (first character = 1, the value "0" or a value > length of the string is invalid)
OUT	Output	USINT, SINT, UINT, INT, UDINT, DINT, REAL, LREAL	USINT, SINT, UINT, INT, UDINT, DINT, ULINT, LINT, REAL, LREAL	I, Q, M, D, L, P	Result of the conversion

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter FORMAT

You use the FORMAT parameter to specify how the characters of a character string are to be interpreted. Exponential values can also be converted and represented with the "STRG_VAL" instruction.

The following table shows the possible values of the FORMAT parameter and their meaning:

Value (W#16#....)	Notation	Decimal representation
0000	Decimal fraction	"."
0001		","
0002	Exponential	"."
0003		","
0004 to FFFF	Invalid values	

Parameter P

The conversion starts at the character whose position you specified in the P parameter. If, for example, the value "1" is specified in the P parameter, the conversion starts at the first character of the specified character string.

Example

The following table shows examples of the conversion of a character string to a numeric value:

IN (STRING)	FORMAT (W#16#....)	OUT (data type)	OUT (value)	ENO status
'123'	0000	INT/DINT	123	1
'-00456'	0000	INT/DINT	-456	1
'123.45'	0000	INT/DINT	123	1
'+2345'	0000	INT/DINT	2345	1
'00123AB'	0000	INT/DINT	123	1
'123'	0000	REAL	123.0	1
'-00456'	0001	REAL	-456.0	1
'+00456'	0001	REAL	456.0	1
'123.45'	0000	REAL	123.45	1
'123.45'	0001	REAL	12345.0	1
'123,45'	0000	REAL	12345.0	1
'123,45'	0001	REAL	123.45	1
'.00123AB'	0001	REAL	123.0	1
'1.23e-4'	0000	REAL	1.23	1
'1.23E-4'	0000	REAL	1.23	1
'1.23E-4'	0002	REAL	1.23E-4	1
'12,345.67'	0000	REAL	12345.67	1
'12,345.67'	0001	REAL	12.345	1
'3.4e39'	0002	REAL	W#16#7F800000	1
'-3.4e39'	0002	REAL	W#16#FF800000	1
'1.1754943e-38'	0002	REAL	0.0	1
'12345'	-/-	SINT	0	0
'A123'	-/-	-/-	0	0

IN (STRING)	FORMAT (W#16#....)	OUT (data type)	OUT (value)	ENO status
''	-/-	-/-	0	0
'++123'	-/-	-/-	0	0
'+-123'	-/-	-/-	0	0

Example

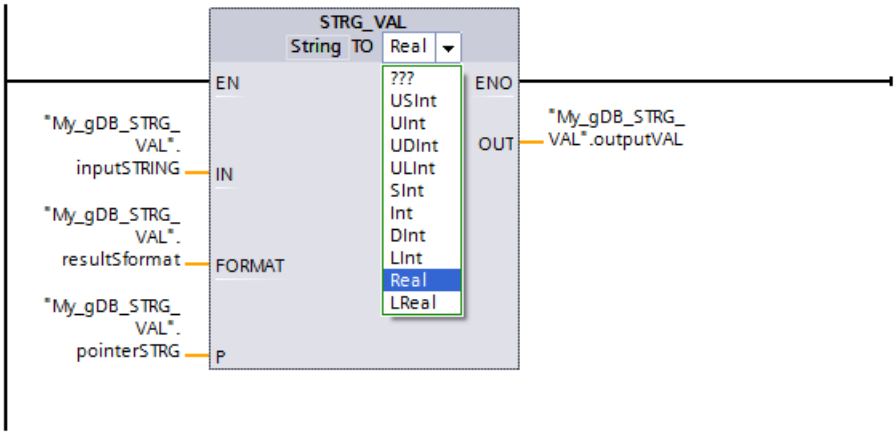
In the following example, you convert a number string with the STRING data type to a floating point number with the REAL data type. The result will have a length of 32 bits and may have a sign due to the REAL data type.

Create four tags in a global data block for storing the data.

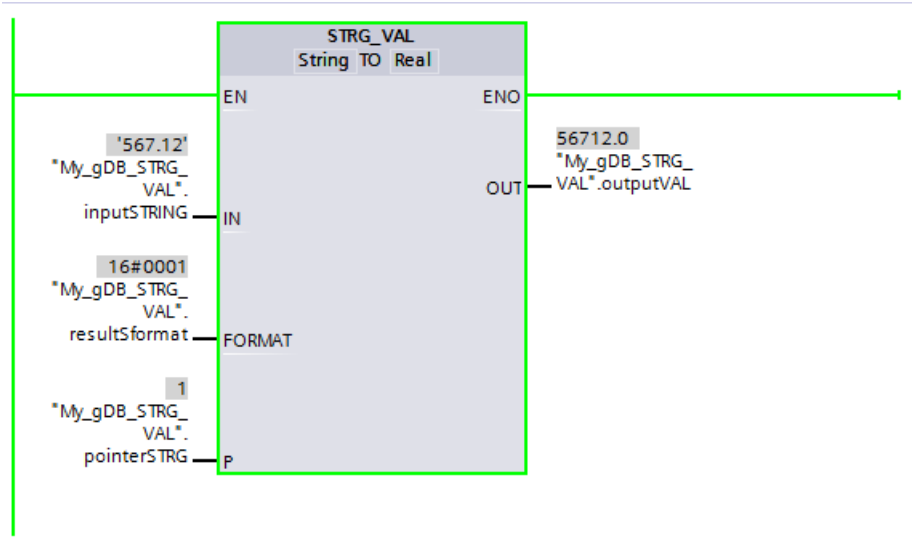
My_gDB_STRG_VAL

	Name	Data type	Start value
1	Static		
2	inputSTRING	String	'567.12'
3	resultSformat	Word	16#0001
4	pointerSTRG	UInt	1
5	outputVAL	Real	0.0

Interconnect the parameters of the instruction as follows. Using the left selection option, select the data type for the character string. Using the right selection option, select the data type for the floating-point number.



The number string is converted starting from the first character according to the value "1" of parameter P ("pointerSTRG"). The period in the number string is interpreted as a thousands delimiter due to the value "0001" of parameter FORMAT ("resultSformat"). (The comma is the decimal separator for the value "0001".) The value to be converted ("inputSTRING") is output at output parameter OUT ("outputVAL") as a floating point number.



VAL_STRG: Convert numerical value to character string

Description

The "VAL_STRG" instruction is used to convert a numerical value into a character string.

- You specify the value to be converted in the IN input parameter. You decide the format of the numeric value by selecting a data type.
- You query the result of the conversion in the OUT output parameter.

Permitted characters for the conversion are the digits "0" to "9", the decimal point, the decimal comma, notations "E" and "e", and the plus and minus characters. The conversion can be interrupted by invalid characters.

The "VAL_STRG" instruction is not supported by the SCL programming language.

Parameters

The following table shows the parameters of the "VAL_STRG" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	USINT, SINT, UINT, INT, UDINT, DINT, REAL, LREAL	USINT, SINT, UINT, INT, UDINT, DINT, ULINT, LINT, REAL, LREAL	I, Q, M, D, L, P or constant	Value to be converted
SIZE	Input	USINT	USINT	I, Q, M, D, L, P or constant	Number of character positions
PREC	Input	USINT	USINT	I, Q, M, D, L, P or constant	Number of decimal places

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
FORMAT	Input	WORD	WORD	I, Q, M, D, L, P or constant	Output format of the characters
P	InOut	UINT	UINT	I, Q, M, D, L, P or constant	Character starting at which the result is written.
OUT	Output	STRING, WSTRING	STRING, WSTRING	D, L	Result of the conversion

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter P

With the P parameter, you specify the character in the string starting at which the result is written. If, for example, the value "2" is specified in the P parameter, the converted value is saved starting at the second character of the string.

Parameters SIZE and P

Use the SIZE parameter to specify how many characters of the character string will be written. This is counted starting from the character specified in the P parameter. If the output value is shorter than the specified length, the result is written to the character string right-justified. The empty character positions are filled with blanks.

Parameter FORMAT

Use the FORMAT parameter to specify how the numerical value is interpreted during conversion and written to the character string. You can specify only tags of the FORMAT data type in the USINT parameter.

The following table shows the possible values of the FORMAT parameter and their meaning:

Value (W#16#....)	Notation	Sign	Decimal representation
0000	Decimal fraction	"-"	"."
0001			","
0002	Exponential		"."
0003			","
0004	Decimal fraction	"+" and "-"	"."
0005			","
0006	Exponential		"."
0007			","
0008 to FFFF	Invalid values		

Parameter PREC

Use the PREC parameter to define the number of decimal places when converting floating-point numbers. A maximum precision of seven numbers is supported for numerical values of the REAL data type. If the value to be converted is an integer, you use the PREC parameter to specify the position where the decimal point will be placed.

Example

The following table shows examples of the conversion of numeric values to a character string.

IN (value)	IN (data type)	P	SIZE	FORMAT (W#16#....)	PREC	OUT (STRING)	ENO status
123	UINT	16	10	0000	0	xxxxxxx123 C	1
0	UINT	16	10	0000	2	xxxxxx0.00 C	1
12345678	UDINT	16	10	0000	3	x12345.678 C	1
12345678	UDINT	16	10	0001	3	x12345.678 C	1
123	INT	16	10	0004	0	xxxxxx+123 C	1
-123	INT	16	10	0004	0	xxxxxx-123 C	1
-0.00123	REAL	16	10	0004	4	xxx-0.0012 C	1
-0.00123	REAL	16	10	0006	4	-1.2300E-3 C	1
-Inf [1]	REAL	16	10	-/-	4	xxxxxx-INF C	0
+Inf [2]	REAL	16	10	-/-	4	xxxxxx+INF C	0
NaN [3]	REAL	16	10	-/-	4	xxxxxxxNaN C	0
12345678	UDINT	16	6	-/-	3	xxxxxxxxxx C	0

"x" represents blanks
[1]-Inf: Floating-point number representing a negative infinite value.
[2]+Inf: Floating-point number representing a positive infinite value.
[3]NaN: Value returned as the result of invalid math operations.

Example

In the following example, you convert a floating-point number with the REAL data type to a character string with the STRING data type.

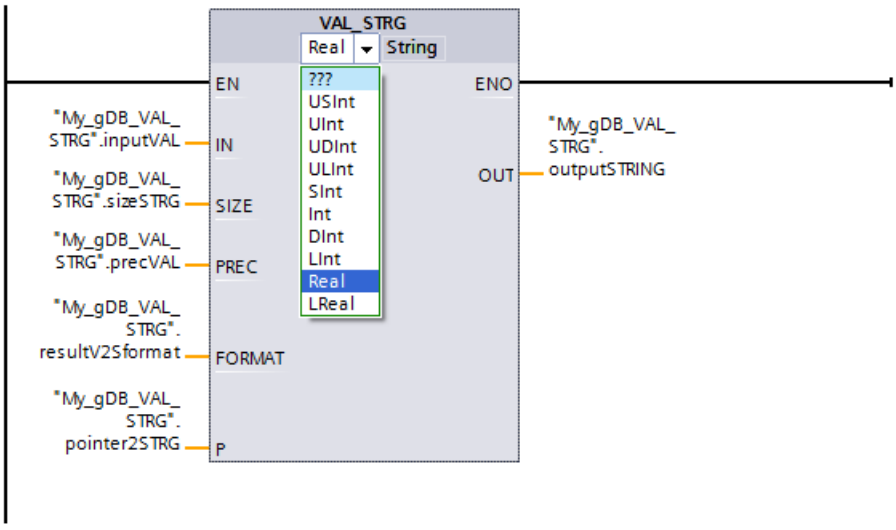
Create six tags in a global data block for storing the data.

My_gDB_VAL_STRG

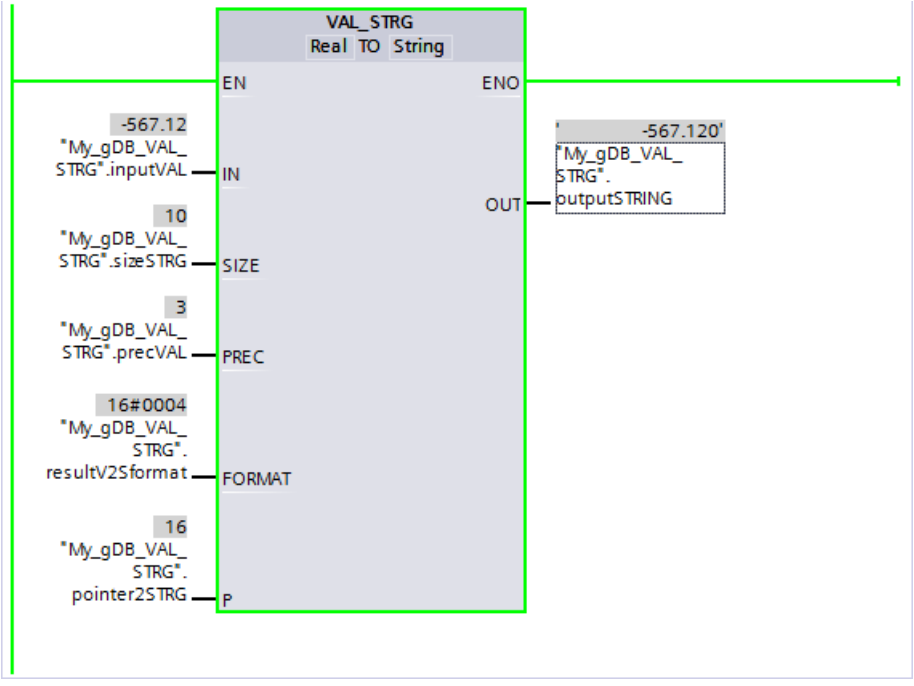
	Name	Data type	Start value
1	Static		
2	inputVAL	Real	-567.12
3	pointer2STRG	UInt	16
4	sizeSTRG	USInt	10
5	precVAL	USInt	3
6	outputSTRING	String	''
7	resultV2Sformat	Word	16#0004

Interconnect the parameters of the instruction as follows. Select the data types:

- The left selection option is for the value to be converted.
- The right selection option is for the character string to be generated.



The character string is written starting from the 16th character according to the value "16" of parameter P" ("pointer2STRG"). Starting from this point, the character string is 10 characters long, according to the value "10" of parameter SIZE ("sizeSTRG"). The point of the value to be converted ("inputVAL") is interpreted as a decimal separator due to the value "0004" of parameter FORMAT ("resultV2Sformat"). Three decimal places are written to the string according to the value "3" of parameter PREC ("precVAL"). The sign of the value to be converted is stored as a character in the string and prefixes the numbers. The remaining 10 characters of the string are written as spaces in front of the sign. The character string is output at output parameter OUT ("outputSTRING").



Strg_TO_Chars: Convert character string to Array of CHAR

Description

You use the "Strg_TO_Chars" instruction to copy a character string STRING to an Array of CHAR or an Array of BYTE or a character string WSTRING to an Array of WCHAR. Only ASCII characters are valid for the copy process.

- Specify the character string at the input parameter STRG.
- The characters are written to a data type Array of CHAR / BYTE / WCHAR at the parameter CHARS.
  - The number of characters in the destination field should be at least the same as the number copied from the source string.
  - If the destination field contains fewer characters than the source string, the characters are written up to the maximum length of the destination field.
  - If the character string contains a "$00" or W#16#0000 character, the copy operation is only carried out up to the corresponding position (see graphic).
  - The number of copied characters is output at parameter CNT.
- Use the PCHARS parameter to specify the position starting from which writing should begin in the destination field.
  - Example: If writing should take place starting from the third position, use the value "2" at parameter PCHARS:

  - The default for PCHARS is "0". When PCHAR = 0, the low index limit of the array is used (e.g. CHAR[0] for an Array [0..5] of CHAR). This also applies if the low limit of the array is negative (e.g. CHAR[-5] for an Array [-5..5] of CHAR).

Note

Use of the instruction with S7-1200 V2.0

S7-1200 up to Version 2.0 only supports Array [0 .. n] of CHAR / BYTE. Negative index limits (e.g. Array [-3..2] of CHAR) are not permissible. This restriction is not checked by the software.

Parameters

The following table shows the parameters of the instruction "Strg_TO_Chars":

Parameter	Declaration	Data type	Memory area	Description
STRG	Input	STRING, WSTRING	D, L or constant	Source of the copy operation
PCHARS	Input	DINT	I, Q, M, D, L, P or constant	Position in the structure Array of (W)CHAR / BYTE starting from which the characters of the character string are written.
CHARS	InOut	VARIANT	D, L	Destination of the copy operation The characters can be copied to a structure of the Array of (W)CHAR or Array of BYTE data type.
CNT	Output	UINT	I, Q, M, D, L, P	Number of copied characters.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Example

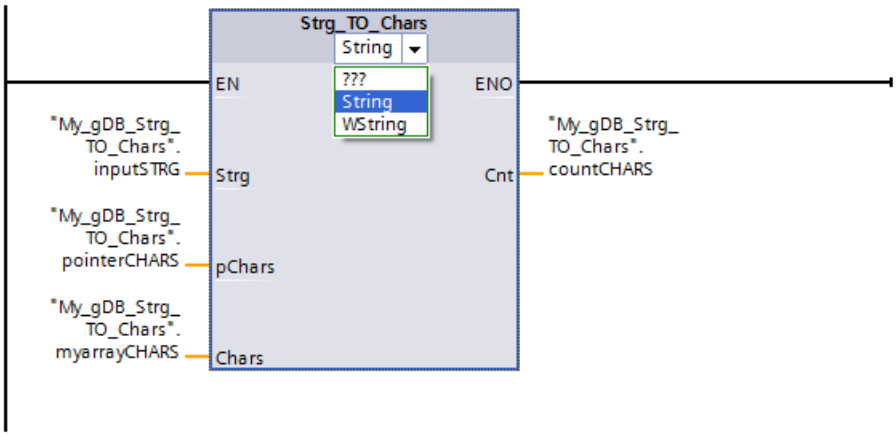
In the following example, you copy characters of a character string with the STRING data type to a structure of the Array of CHAR data type.

Create four tags in a global data block for storing the data.

My_gDB_Strg_TO_Chars

	Name	Data type	Start value
1	Static		
2	inputSTRG	String[10]	'cf7a7a#'
3	pointerCHARS	DInt	2
4	myarrayCHARS	Array[0..9] of Char	
5	myarrayCHARS[0]	Char	' '
6	myarrayCHARS[1]	Char	' '
7	myarrayCHARS[2]	Char	' '
8	myarrayCHARS[3]	Char	' '
9	myarrayCHARS[4]	Char	' '
10	myarrayCHARS[5]	Char	' '
11	myarrayCHARS[6]	Char	' '
12	myarrayCHARS[7]	Char	' '
13	myarrayCHARS[8]	Char	' '
14	myarrayCHARS[9]	Char	' '
15	countCHARS	UInt	0

Interconnect the parameters of the instruction as follows and select the data type of the character string.



A structure made up of individual characters is created due to the Array of CHAR data type. The CHARS structure ("myarrayCHARS") is ten characters long (Array ... [0..9]). According to the value "2" of parameter PCHARS ("pointerCHARS"), writing begins starting from the third character in the structure ("0" and "1" are empty, "2" contains the first character of the character string ("inputSTRG")). Once the characters of the string ("inputSTRG") are written to the structure ("myarrayCHARS"), the last character of the structure to be created is written empty. The number of characters of the character string that are moved is output at output parameter CNT ("countCHARS").

My_gDB_Strg_TO_Chars

	Name	Data type	Start value	Monitor value
1	Static			
2	inputSTRG	String[10]	'cf7a7a#'	'cf7a7a#'
3	pointerCHARS	DInt	2	2
4	myarrayCHARS	Array[0..9] of Char		
5	myarrayCHARS[0]	Char	' '	' '
6	myarrayCHARS[1]	Char	' '	' '
7	myarrayCHARS[2]	Char	' '	'c'
8	myarrayCHARS[3]	Char	' '	'f'
9	myarrayCHARS[4]	Char	' '	'7'
10	myarrayCHARS[5]	Char	' '	'a'
11	myarrayCHARS[6]	Char	' '	'7'
12	myarrayCHARS[7]	Char	' '	'a'
13	myarrayCHARS[8]	Char	' '	'#'
14	myarrayCHARS[9]	Char	' '	' '
15	countCHARS	UInt	0	7

Chars_TO_Strg: Convert Array of CHAR to character string

Description

You can use the "Chars_TO_Strg" instruction to copy characters from an Array of CHAR or Array of BYTE to a STRING or from an ARRAY of WCHAR to a WSTRING.. Only ASCII characters are valid for copying.

- Specify the characters of the Array of (W)CHAR / BYTE to be copied to a character string at the input parameter CHARS.
- The characters are written at the parameter STRG to a (W)STRING data type.
  - The number of characters in the string should be at least the same number as were copied from the source field.
  - If the character string is shorter than the number of characters in the source field, the characters are written up to the maximum length of the string.
  - If the Array of (W)CHAR / BYTE contains a "$00" character or if the Array of (W)CHAR contains a W#16#0000 character, the copy operation is only carried out up to the corresponding position (see graphic).
- Use the PCHARS parameter to specify the position of the source field starting from which the characters are to be copied. PCHARS = 0 is the default value and always specifies the low index limit of the array, even if this is negative.
  - Example: if copying is to start with the third character of the source field, use the value "2" at parameter PCHARS:

  - If an index is specified at parameter PCHARS and the index is not contained in the copy source (e.g. "7" at Array [0..5] of CHAR) then the instruction is not executed.

Note

Use of the instruction with S7-1200 V2.0

S7-1200 up to Version 2.0 only supports Array [0 .. n] of CHAR / BYTE. Negative index limits (e.g. Array [-3..2] of CHAR) are not permissible. This restriction is not checked by the software.

Parameters

The following table shows the parameters of the instruction "Chars_TO_Strg":

Parameter	Declaration	Data type	Memory area	Description
CHARS	Input	VARIANT	D, L	Source of the copy operation Array of (W)CHAR / BYTE from which the characters are copied.
PCHARS	Input	DINT	I, Q, M, D, L, P or constant	Position in the Array of (W)CHAR / Array of BYTE from which the characters are copied.
CNT	Input	UINT	I, Q, M, D, L, P	Number of characters to be copied. Use "0" to copy all characters.
STRG	Output	STRING, WSTRING	D, L	Destination of the copy operation Character string with the (W)STRING data type. Observe the maximum length of the data types: • STRING: 254 characters • WSTRING: 254 characters (default) / 16382 characters (maximum) When using WSTRING, note that you must define a length > 254 characters explicitly with square brackets (e.g., WSTRING[16382]).

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Example

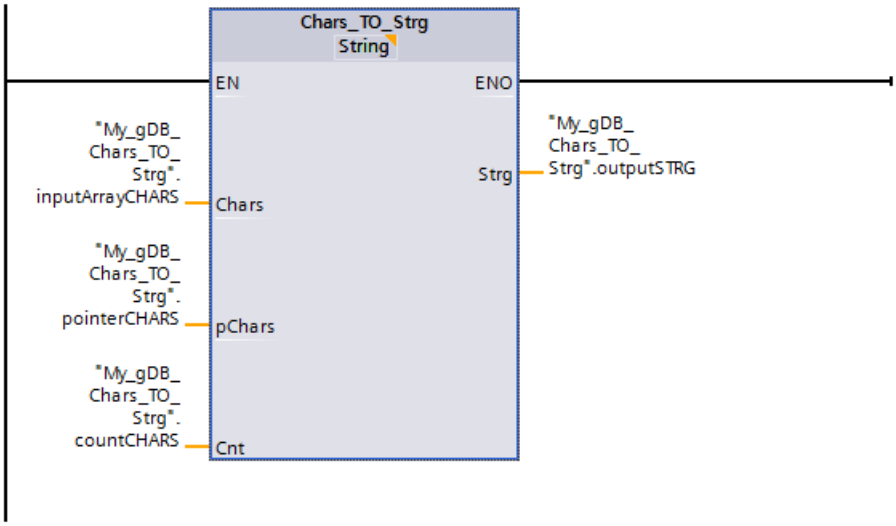
In the following example, you copy characters of a structure of the Array of CHAR data type to a character string with the STRING data type.

Create four tags in a global data block for storing the data.

My_gDB_Chars_TO_Strg

	Name	Data type	Start value
1	Static		
2	inputArrayCHARS	Array[0..9] of Char	
3	inputArrayCHARS[0]	Char	'M'
4	inputArrayCHARS[1]	Char	'y'
5	inputArrayCHARS[2]	Char	'S'
6	inputArrayCHARS[3]	Char	'7'
7	inputArrayCHARS[4]	Char	'P'
8	inputArrayCHARS[5]	Char	'L'
9	inputArrayCHARS[6]	Char	'C'
10	inputArrayCHARS[7]	Char	' '
11	inputArrayCHARS[8]	Char	' '
12	inputArrayCHARS[9]	Char	' '
13	pointerCHARS	DInt	2
14	outputSTRG	String	''
15	countCHARS	UInt	0

Interconnect the parameters of the instruction as follows and select the data type of the character string.



The CHARS structure ("inputArrayCHARS") is ten characters long (Array ... [0..9]). According to the value "2" of parameter PCHARS ("pointerCHARS"), characters are copied starting from the third position of the structure to the character string ("outputSTRG"). Starting from position "2", all characters of the structure ("inputArrayCHARS") are copied to the character string ("outputSTRG"), since parameter CNT ("countCHARS") has the value "0".

My_gDB_Chars_TO_Strg

	Name	Data type	Start value	Monitor value
1	Static			
2	inputArrayCHARS	Array[0..9] of Char		
3	inputArrayCHARS[0]	Char	'M'	'M'
4	inputArrayCHARS[1]	Char	'y'	'y'
5	inputArrayCHARS[2]	Char	'S'	'S'
6	inputArrayCHARS[3]	Char	'7'	'7'
7	inputArrayCHARS[4]	Char	'P'	'P'
8	inputArrayCHARS[5]	Char	'L'	'L'
9	inputArrayCHARS[6]	Char	'C'	'C'
10	inputArrayCHARS[7]	Char	' '	' '
11	inputArrayCHARS[8]	Char	' '	' '
12	inputArrayCHARS[9]	Char	' '	' '
13	pointerCHARS	DInt	2	2
14	outputSTRG	String	''	'S7PLC '
15	countCHARS	UInt	0	0

MAX_LEN: Determine the length of a character string

Description

A tag of the (W)STRING data type contains two lengths: the maximum length and the current length (this is the number of currently valid characters).

- The maximum length of the character string is specified for each tag in the STRING keyword in square brackets. The number of bytes occupied by a string is 2 greater than the maximum length.
- The maximum length of the character string is specified for each tag in the WSTRING keyword in square brackets. The number of words occupied by a character string is 2 greater than the maximum length.
- The current length represents the number of the character places actually used. The current length must be less than or equal to the maximum length.

You use the "MAX_LEN" instruction to query the maximum length of the character string specified at the IN input parameter and output this information as a numerical value at the OUT output parameter.

If errors occur during processing of the instruction, then an empty string will be output.

Note

Reading out the current length

You can also use the LEN (Page 3039) instruction to read out the current length of a string.

Parameters

The following table shows the parameters of the "MAX_LEN" instruction:

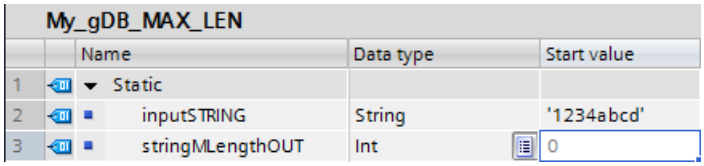
Parameter	Declaration	Data type	Memory area	Description
IN	Input	STRING, WSTRING	D, L or constant	Character string
OUT	Return	INT	I, Q, M, D, L, P	Maximum number of characters

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

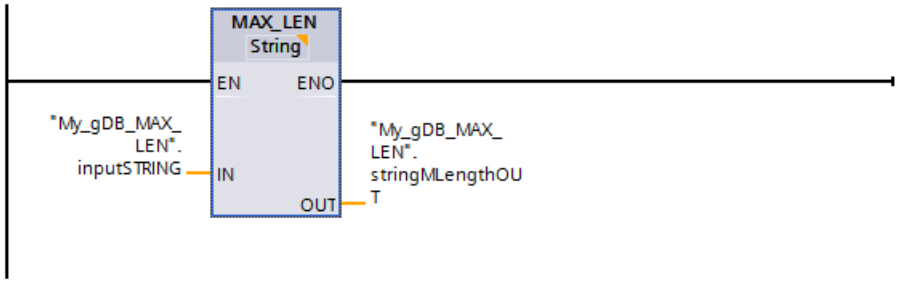
Example

In the following example, you determine the maximum length of a character string with the STRING data type.

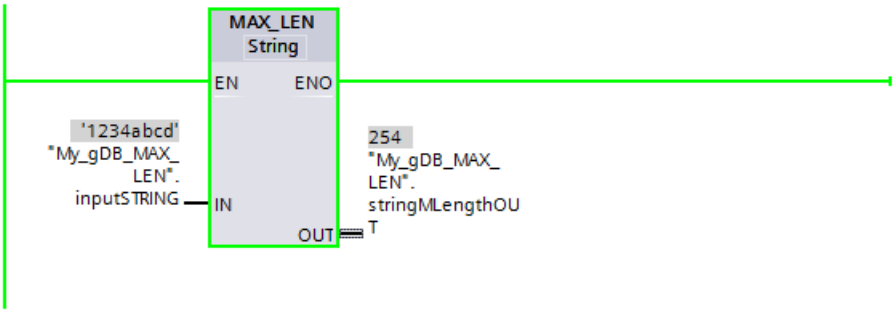
Create two tags in a global data block for storing the data.



Interconnect the parameters of the instruction as follows.



The maximum length of the specified character string ("inputSTRING") is determined and returned at output parameter OUT ("stringMLengthOUT") as a numerical value.



JOIN: Join multiple strings

Description

The "JOIN" instruction connects multiple strings into an array.

To convert multiple strings into a single one, the instruction provides the following functions:

- **Format selection**
  You can use the first bit at the Mode parameter to specify whether the sequence of the source strings for an array should be in the format CSV or FSR.
  In the following example, two source strings are specified by the two columns of the table. The maximum number of characters amounts to 4 characters for the first source string, 13 characters for the second, 10 characters for the third and 14 characters for the fourth.

1963	1974
Miller	Jackson
John	Peter
Roadname	VeryLongRoadna

  – With CSV (Comma Separated Values), the contents of the source strings are written consecutively into the destination array and separated with a delimiter. (See examples below.)

  – With FSR (Fixed Size Records), a certain number of characters is defined in the destination array for each source string. If the characters of a source string do not need the space reserved for them in the destination array, the corresponding array elements are filled with delimiters. However, if the number of characters in a source string is greater than the space reserved for them, the corresponding array elements are filled from the front, and the excess characters of the source string are truncated (see example below).

- **Selection of the delimiter for the source strings**
  You can use the RecSeparator parameter to select the delimiter to be used for each string. You should select a character based on the content of the input strings at the SrcStruct parameter. If the input strings contain a comma within a string, for example, the comma should not used as a delimiter. The data type that you use for the delimiter must correspond to the destination array at the DstArray parameter in order for the delimiter to be included in what is written in the array.

- **Selection of the delimiter for the end of all source strings**
  You can use the third bit of the Mode parameter to specify whether an additional character should be written as a delimiter at the end of the copied characters in the destination array (DstArray parameter). Specify the character to be used as a delimiter at the EndSeparator parameter. Make sure to use a character other than the one set for the RecSeparator parameter (delimiter for individual strings). If the two delimiters are indistinguishable, you will obtain unexpected results if you reverse the conversion using the "SPLIT" instruction.

- **Selection of the source strings**
  You specify the source strings at the SrcStruct parameter. For the data type, you can use Array of STRING or Array of WSTRING or structures which only contain the STRING or WSTRING data type. This also applies to user data types or nested structures. You can use these as long as they exclusively contain the data type STRING or WSTRING respectively.

- **Specification of the number of joined strings**
  If you use an Array of STRING or Array of WSTRING at the SrcStruct parameter (source string) (no nested structures), you can use the Count parameter to specify the number of source strings that have been joined to form a single string. If you use a data type other than Array of (W)STRING at the SrcStruct parameter, the Count parameter is ignored. This makes it possible to connect only a part of a large array.

- **Selection of a destination area for writing the array**
  You use the Array of (W)CHAR data type at the DstArray parameter. It is not possible to use the STRING or WSTRING data types here, because the length would be limited to 254 characters or 256 bytes for STRING.
- **Index of the position in the array (DestArray target parameter)**
  The conversion starts at this position and the instruction reads the Position parameter to determine the position at which the conversion is completed. This enables follow-up calls of the instruction for filling the array.

Parameters

The following table shows the parameters of the instruction "JOIN":

Parameter	Declaration	Data type	Memory area	Description
Mode	Input	DWORD	I, Q, M, D, L or constant	Specifies how the merger to string is performed (see Mode" parameter).
RecSeparator	Input	VARIANT	I, Q, M, D, L	Delimiter for the source strings • With CSV: Character that is used as a delimiter for the individual strings. • With FSR: Character that is used as a fill character for the individual strings.
EndSeparator	Input	VARIANT	I, Q, M, D, L or constant	Delimiter for the end of the conversion Delimiter that is written at the end of the characters if bit 3 = 1 has been set for the Mode parameter.
SrcStruct	Input	VARIANT	I, Q, M, D, L	Pointer to the source strings.
Count	Input	UDINT	I, Q, M, D, L	Number of strings that were joined. The Count parameter can only be used when an Array of (W)STRING has been used at the SrcStruct parameter.
DestArray	InOut	VARIANT	I, Q, M, D, L	Area in which the characters are written after the conversion. Use the Array [0 .. x] of CHAR/WCHAR data type at the DestArray parameter. You can set the length (x) of the array based on the length of the source strings at the SrcStruct parameter.
Position	InOut	UDINT	I, Q, M, D, L	Index the position in the total string
Ret_Val	Return	INT	I, Q, M, D, L	Status of instruction (see table "RET_VAL parameter").

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter Mode

Bit	Bit value "0"	Bit value "1"	Description
0	CSV format (Comma Separated Values)	FSR format (Fixed Size Record)	Selection of the format: • With CSV, the source strings are separated by a delimiter in the destination array. • With FSR, the source strings are written into the destination array with the fill characters defined at the RecSeparator parameter.
1	-	-	Irrelevant for the "JOIN" instruction.
2	-	-	Reserved (irrelevant for bit value)
3	Write no additional delimiters.	Write character defined by the EndSeparator parameter at the end of the read characters.	Select whether an additional character is to be written as a delimiter at the end of the characters in the array (DestArray parameter).
4	-	-	Irrelevant for the "JOIN" instruction.

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error.
0001	Additional characters are ignored.
8190	Selection at the Mode parameter is not supported.
8x20	Source strings invalid.
8x53	VARIANT points to data structure that is too short.
8x54	Invalid data type
8082	The value at parameter Count is greater than the number of source character strings in SrcStruct.
8x84	Additional characters found
8xB4	Different data types at parameters SrcStruct (source) and DestArray (destination) or at separators (parameters RecSeparator and EndSeparator).
80B5	Buffer overflow with the instruction. The characters are not completely output at parameter DestArray, or the value at parameter Position is outside of DestArray.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)

* Note the following for the error codes:

- The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".
- The "x" in the second position of the listed error codes stands for the parameter that caused the error.
  Example: Error code 8352 hex = error occurred at 3rd parameter (EndSeparator), see Parameter table.
- If the error cannot be clearly assigned to a specific parameter, "0" is output.
  Example: The CHAR data type is used for the delimiter (RecSeparator parameter). WCHAR is used as data type for the array at the DestArray parameter. Error code 80B4 is output in this case.

Two examples for the JOIN instruction when the destination ARRAY should have the format CSV

- First example:
  There are the following source strings:
  - `1963`
  - `Miller`
  - `John`
  - `Roadname`

  If you select "," as the delimiter, calling JOIN provides the following destination array:
  `1963,Miller,John,Roadname`
- Second example:
  There are the following source strings:
  - `1974`
  - `Jackson`
  - `Peter`
  - `VeryLongRoadname`

  If you select "," as the delimiter, calling JOIN provides the following destination array:
  `1974,Jackson,Peter,VeryLongRoadname`

Two examples for the JOIN instruction when the destination ARRAY should have the format FSR

- First example:
  There are the following source strings:
  - `1963`
  - `Miller`
  - `John`
  - `Roadname`

  The number of reserved characters in the destination array amounts to 4 characters for the first source string, 13 characters for the second, 10 characters for the third and 14 characters for the fourth.
  If you select "," as the fill characters, calling JOIN provides the following destination array:
  `1963Miller,,,,,,,John,,,,,,Roadname,,,,,,`
- Second example:
  There are the following source strings:
  - `1974`
  - `Jackson`
  - `Peter`
  - `VeryLongRoadname`

  The number of reserved characters in the destination array amounts to 4 characters for the first source string, 13 characters for the second, 10 characters for the third and 14 characters for the fourth.
  If you select "," as the fill characters, calling JOIN provides the following destination array:
  `1974Jackson,,,,,,Peter,,,,,VeryLongRoadna`

SPLIT: Splitting an array of characters into multiple strings

Description

The "SPLIT" instruction converts an array (Array of CHAR / WCHAR) into several separate strings (Array of STRING / WSTRING or structure).

To convert the array into several strings, specify the following information:

- **Selection of array to be read**
  You specify the array to be read at the SrcArray parameter. Make sure that the data types used for the input and output parameters match any other parameters used. If you use an array with the CHAR data type at the SrcArray parameter, for example, you must use the CHAR data type for the delimiter (Rec/EndSeparator) and the structure must only contain strings with the STRING data type at the DestStruct parameter.
- **Format selection for the source array**
  You use the first bit of the Mode parameter to specify whether the array to be read has the CSV or FSR format.
  - With CSV (Comma Separated Values), characters in the source array that belong together are separated by a delimiter from the next characters that belong together.
    Two examples of a source array:
    `1963,Miller,John,CitynameA,Roadname`
    `1974,Jackson,Peter,CitynameB,VeryLongRoadname`
  - With FSR (Fixed Size Records), a certain number of characters is defined for each item of logical information of the source array. Each item of information should fit into the space defined for it. When information does not need the space defined for it, it is filled with delimiters.
    Two examples of source arrays, whereby the length of the information is 4 characters for the first information item (year of birth), 13 characters for the second (last name), 10 characters for the third (first name), 9 characters for the fourth (city) and 16 characters for the fifth (street):
    `1963Miller,,,,,,,John,,,,,,CitynameARoadname,,,,,,,,`
    `1974Jackson,,,,,,Peter,,,,,CitynameBVeryLongRoadname`
- **Delimiter used for the array to be read**
  - If the array to be read has CSV format, specify which delimiter was used at the RecSeparator parameter.
  - If the array to be read has FSR format, specify which fill character was used at the RecSeparator parameter.
- **Selection of the delimiter for the end of the total string**
  Specify the delimiter after which the reading of the array should stop at the EndSeparator parameter. The "SPLIT" instruction stops at this position and outputs the string that has been found. It should be noted, that the EndSeparator delimiter is evaluated with higher priority than the RecSeparator delimiter. If the delimiter at the EndSeparator parameter is used in a string to be read (between two RecSeparator delimiters), all content after the EndSeparator delimiter is ignored.
- **Specification of the position starting at which the array is read**
  The conversion starts at this position in the array and the instruction reads the Position parameter to determine the position at which the conversion is completed. This enables follow-up calls of the instruction for filling the various strings at the DestStruct parameter.
- **Outputting the number of read strings**
  If you use an Array of STRING at the DestStruct parameter, you can use the Count parameter to output the number of read strings. Only strings with content are counted. If you use a data type other than Array of STRING at the DestStruct parameter, "0" is output at the Count parameter.

Parameters

The following table shows the parameters of the "SPLIT" instruction:

Parameter	Declaration	Data type	Memory area	Description
Mode	Input	DWord	I, Q, M, D, L or constant	Specifies how the split into multiple strings is performed (see "Mode" parameter).
RecSeparator	Input	Variant	I, Q, M, D, L	Delimiter or fill character • With CSV: Character that was used in the array to be read to identify the individual strings. • With FSR: Character that has been used as a fill character in the array to be read.
EndSeparator	Input	Variant	I, Q, M, D, L	Delimiter used to define the end of the total string in the array to be read.
SrcArray	Input	Variant	I, Q, M, D, L	Pointer to the array to be read (Array of CHAR/WCHAR)
DestStruct	InOut	Variant	I, Q, M, D, L	Structure which includes the converted strings (Array of STRING / WSTRING).
Position	InOut	UDInt	I, Q, M, D, L	Position from which the array is to be read at the SrcArray parameter.
Ret_Val	Return	Int	I, Q, M, D, L	Result of instruction execution / error code (see table "Ret_Val parameter")
Count	Output	UDInt	I, Q, M, D, L	Number of strings that were found.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter "Mode"

Bit	Bit value "0"	Bit value "1"	Description
0	CSV format (Comma Separated Values)	FSR format (Fixed Size Record)	Basic mode: Selection of CSV or FSR
1	• With CSV: Additional characters cause an error. • With FSR: Additional fill characters remain in string.	• With CSV: Additional characters are ignored. • With FSR: Additional fill characters are removed.	Use bit 1 to specify how you want to deal with additional characters: • With CSV: – If the bit is set, additional characters that do not fit in the destination string are ignored. Example: The instruction writes to a string with a length of 16 characters (STRING[16] data type). No delimiter is contained in the source after the first 16 characters. If bit 1 is set, the extra characters are ignored and the instruction continues to read the array. – If the bit is not set, the instruction stops in such a case and generates an error message at the Ret_Val parameter. • With FSR: – If the bit is set, the fill characters located to the right of characters containing information are not written to the destination character string when the source array is transferred to the destination character strings (see example). – If the bit is not set, the fill characters located to the right of characters containing information are written to the destination character string when the source array is transferred to the destination character strings (see example).
2	-	-	Reserved for use in future versions.
3	Separator is retained.	Separator is removed.	Specification of whether the delimiter is removed at the end of the total string.
4	Leave unwritten strings (STRING) at length.	Set unwritten strings (STRING) to length "0".	Specification of whether unused strings (STRING) at the DestStruct parameter are to be set to the length "0".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error.
0001	Additional characters are ignored.
8190	Selection at the Mode parameter is not supported.
8x20	Source strings invalid.
8x53	VARIANT points to data structure that is too short.
8x54	Invalid data type
8x84	Additional characters found.
8xB4	Different data types at parameters SrcArray (source) and DestStruct (destination) or at separators (parameters RecSeparator and EndSeparator).
80B5	Buffer overflow with the instruction. The character strings are not completely output at parameter DestStruct.

Error code* (W#16#...)	Explanation
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)

* Note the following for the error codes:

- The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".
- The "x" in the second position of the listed error codes stands for the parameter that caused the error.
  Example: Error code 8352 hex = error occurred at 3rd parameter (EndSeparator), see Parameter table.
- If the error cannot be clearly assigned to a specific parameter, "0" is output.
  Example: The CHAR data type is used for the delimiter (RecSeparator parameter). WCHAR is used as data type for the array at the DestArray parameter. Error code 80B4 is output in this case.

Two examples for the SPLIT instruction when the ARRAY to be read has the CSV format

In the first step, the source array is split into strings as specified by the delimiter (RecSeparator parameter, e.g. ",").

In the second step, the resulting strings after the split are stored in destination strings. You can use the DestStruct parameter to specify their length.

If the strings produced by the split have more characters than can fit in the destination string, the behavior of SPLIT after this point depends on the Mode parameter. With Mode=2#00, this results in an error: The associated error code is returned and no other destination strings are

filled. With Mode=2#10, the surplus characters are ignored and the next destination string is filled with the characters after the next delimiter.

- First example:
  In this example, there are these two source arrays:
  - `1963,Miller,John,Roadname`
  - `1974,Jackson,Peter,VeryLongRoadname`

  The length of the destination string amounts to 4 characters for the first destination string, 13 characters for the second, 10 characters for the third and 14 characters for the fourth. The first call for SPLIT produces the following destination strings with Mode=2#10:
  - `1963`
  - `Miller`
  - `John`
  - `Roadname`

  The second call for SPLIT produces the following destination strings with Mode=2#10:
  - `1974`
  - `Jackson`
  - `Peter`
  - `VeryLongRoadna`
- Second example:
  In this example, the logical information in the source array is not in the order expected. There are these two source arrays:
  - `1963,Miller,Roadname,John`
  - `1974,Jackson,VeryLongRoadname,Peter`

  As in the first example, the length of the destination string amounts to 4 characters for the first destination string, 13 characters for the second, 10 characters for the third and 14 characters for the fourth.
  The first call for SPLIT produces the following destination strings with Mode=2#10:
  - `1963`
  - `Miller`
  - `Roadname`
  - `John`

  The second call for SPLIT produces the following destination strings with Mode=2#10:
  - `1974`
  - `Jackson`
  - `VeryLongRo`
  - `Peter`

Two examples for the SPLIT instruction when the ARRAY to be read has format FSR

The source array is split into strings as you specified in the DestStruct parameter for the length of the destination string.

With regard to the fill characters (RecSeparator parameter e.g. ","), the behavior of SPLIT depends on the Mode parameter: With Mode=2#01, the fill characters are entered in the destination strings; with Mode=2#11, they are not entered.

- First example:
  In this example, there are these two source arrays:
  - `1963Miller,,,,,,,John,,,,,,Roadname,,,,,,`
  - `1974Jackson,,,,,,Peter,,,,,VeryLongRoadname`

  The length of the destination string amounts to 4 characters for the first destination string, 13 characters for the second, 10 characters for the third and 14 characters for the fourth. The first call for SPLIT produces the following destination strings with Mode=2#01:
  - `1963`
  - `Miller,,,,,,,`
  - `John,,,,,,`
  - `Roadname,,,,,,`

  The second call for SPLIT produces the following destination strings with Mode=2#01:
  - `1974`
  - `Jackson,,,,,,`
  - `Peter,,,,,`
  - `VeryLongRoadna`
- Second example:
  In this example, the logical information in the source array is not in the order expected. There are these two source arrays:
  - `1963Miller,,,,,,,Roadname,,,,,,John,,,,,,`
  - `1974Jackson,,,,,,VeryLongRoadnamePeter,,,,,`

  As in the first example, the length of the destination string amounts to 4 characters for the first destination string, 13 characters for the second, 10 characters for the third and 14 characters for the fourth.
  The first call for SPLIT produces the following destination strings with Mode=2#11:
  - `1963`
  - `Miller`
  - `Roadname`
  - `,,,,John`

  Explanation: The SPLIT instruction lays templates over the source array, so to speak. The length of these templates is determined by the length of the destination strings. During transfer to the destination strings, only those commas to the right of characters with information content are interpreted as fill characters. The fill characters are not entered with Mode=2#11. In the first call, the commas are to the right of the "John" fill characters. The commas to the left of "John", however, are not fill characters, because the relevant "John" characters follow before the end of the corresponding destination string is reached. Therefore, the commas to the left of "John" appear in the destination string.
  The second call for SPLIT produces the following destination strings with Mode=2#11:

- `1974`
- `Jackson`
- `VeryLongRo`
- `adnamePeter`

JOIN: Join multiple strings (Page 3022)

ATH: Convert ASCII string to hexadecimal number

Description

You use the instruction "ATH" to convert the ASCII character string specified at the IN input parameter into a hexadecimal number. The result of the conversion is output to the OUT output parameter.

- You can reference the following data types using the pointer in the IN parameter (ASCII): STRING, Array of CHAR, Array of BYTE, WSTRING, Array of WCHAR.
- You can reference the following data types using the pointer in the OUT parameter (hexadecimal): Bit strings, integers, STRING, Array of CHAR, Array of BYTE, WSTRING, Array of WCHAR.

With the N parameter, you specify the number of ASCII characters to be converted. A maximum of 32767 valid ASCII characters can be converted. Only digits "0" to "9", upper case letters "A" to "F", and lower case letters "a" to "f" can be interpreted. All other characters are converted to zeros.

Since 8 bits are required for the ASCII character and only 4 bits for the hexadecimal digit, the output word length is only half of the input word length. The ASCII characters are converted and positioned in the output in the same order as they are read in. If there is an odd number of ASCII characters, the hexadecimal number is padded with zeros in the nibble to the right of the last converted hexadecimal number.

Parameters

The following table shows the parameters of the "ATH" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	VARIANT	I, Q, D, L	Pointer to ASCII character string
N	Input	INT	I, Q, M, D, L or constant	Number of ASCII characters to be converted
RET_VAL	Return	WORD	I, Q, M, D, L	Status of the instruction
OUT	Output	VARIANT	I, Q, M, D, L	Hexadecimal number

You can find additional information on valid data types in "Overview of the valid data types (Page 1908)".

RET_VAL parameter

Error code (W#16#....)*	Description
0000	No error
0007	Invalid character. Only the following ASCII characters may be used: Digits "0" to "9", upper case letters "A" to "F", lower case letters "a" to "f".
8101	Invalid pointer in the IN parameter, e.g., because a non-existing data block is referenced.
8182	Input buffer is too small for data in the N parameter.
8120	Invalid format in the IN parameter.
8151	Non-supported data type in the IN parameter.
8401	Invalid pointer in the OUT parameter, e.g., because a non-existing data block is referenced.
8482	Output buffer is too small for data in the N parameter.
8420	Invalid format in the OUT parameter.
8451	Non-supported data type in the OUT parameter.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

ASCII characters and hexadecimal values

The following table shows the ASCII characters and the corresponding hexadecimal values:

ASCII character	ASCII-coded hexadecimal value	Hexadecimal digit
"0"	30	0
"1"	31	1
"2"	32	2
"3"	33	3
"4"	34	4
"5"	35	5
"6"	36	6
"7"	37	7
"8"	38	8
"9"	39	9
"A"	41	A
"B"	42	B
"C"	43	C
"D"	44	D
"E"	45	E
"F"	46	F

Example

The following table shows examples of the conversion of ASCII character strings to hexadecimal numbers:

IN	N	OUT	ENO status
'0123'	4	16#0123	1
'123AFx1a23'	10	16#123AF01a23	0

HTA: Convert hexadecimal number to ASCII string

Description

You use the instruction "HTA" to convert the hexadecimal number specified at the IN input into an ASCII character string. The result of the conversion is stored at the address specified in the OUT parameter.

- You can reference the following data types using the pointer in the IN parameter (hexadecimal): Bit strings, integers, STRING, Array of CHAR, Array of BYTE, WSTRING, Array of WCHAR.
- You can reference the following data types using the pointer in the OUT parameter (ASCII): STRING, Array of CHAR, Array of BYTE , WSTRING, Array of WCHAR.

With the N parameter, you specify the number of hexadecimal bytes to be converted. Since 8 bits are required for the ASCII character and only 4 bits for the hexadecimal digit, the output value is twice as long as the input value. Each nibble of the hexadecimal number is converted to a character while maintaining the original order.

A maximum of 32767 characters can be written to the ASCII character string. The result of the conversion is represented by the digits "0" to "9" and upper-case letters "A" to "F".

If the complete result of the conversion cannot be displayed in the OUT parameter, the result is will only be partially written to the parameter.

Parameters

The following table shows the parameters of the "HTA" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	VARIANT	I, Q, M, D, L	Start address of the hexadecimal digits
N	Input	UINT	I, Q, M, D, L or constant	Number of hexadecimal bytes to be converted
RET_VAL	Return	WORD	I, Q, M, D, L	Error message
OUT	Output	VARIANT	I, Q, D, L	Address at which the result is stored.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#....)	Description
0000	No error
8101	Invalid pointer at the IN parameter, e.g., because a non-existing data block is referenced.
8182	Input buffer is too small for data in the N parameter.
8120	Invalid format in the IN parameter.
8151	Non-supported data type in the IN parameter.
8401	Invalid pointer in the OUT parameter, e.g., because a non-existing data block is referenced.
8482	Output buffer is too small for data in the N parameter.
8420	Invalid format in the OUT parameter.
8451	Non-supported data type in the OUT parameter.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

ASCII characters and hexadecimal values

The following table shows the ASCII characters and the corresponding hexadecimal values:

Hexadecimal digit	ASCII-coded hexadecimal value	ASCII character
0	30	"0"
1	31	"1"
2	32	"2"
3	33	"3"
4	34	"4"
5	35	"5"
6	36	"6"
7	37	"7"
8	38	"8"
9	39	"9"
A	41	"A"
B	42	"B"
C	43	"C"
D	44	"D"
E	45	"E"
F	46	"F"

Example

The following table shows examples of the conversion of hexadecimal numbers to ASCII character strings:

IN	N	OUT	ENO status
W#16#0123	2	'0123'	1
16#123AF01023	4	'123AF010'	0

LEN: Determine the length of a character string

Description

A tag of the (W)STRING data type contains two lengths: the maximum length and the current length (this is the number of currently valid characters).

- The maximum length of the character string is specified for each tag in the STRING keyword in square brackets. The number of bytes occupied by a string is 2 greater than the maximum length.
- The maximum length of the character string is specified for each tag in the WSTRING keyword in square brackets. The number of words occupied by a character string is 2 greater than the maximum length.
- The current length represents the number of the character places actually used. The current length must be less than or equal to the maximum length.

You use the instruction "LEN" to query the current length of the character string specified at the IN input parameter and output this information as a numerical value at the OUT output parameter. An empty string ('') has the length zero.

If errors occur during processing of the instruction, then an empty string will be output.

Note

Reading out the maximum length

You can use the "MAX_LEN (Page 3021)" instruction to read the maximum length of a string.

Parameters

The following table shows the parameters of the "LEN" instruction:

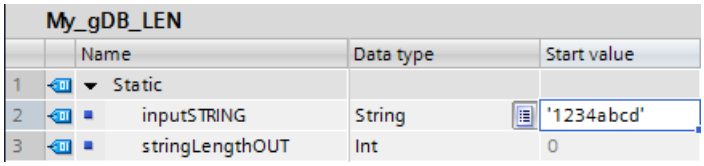
Parameter	Declaration	Data type	Memory area	Description
IN	Input	STRING, WSTRING	D, L or constant	Character string
OUT	Return	INT, DINT, REAL, LREAL	I, Q, M, D, L	Number of valid characters

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

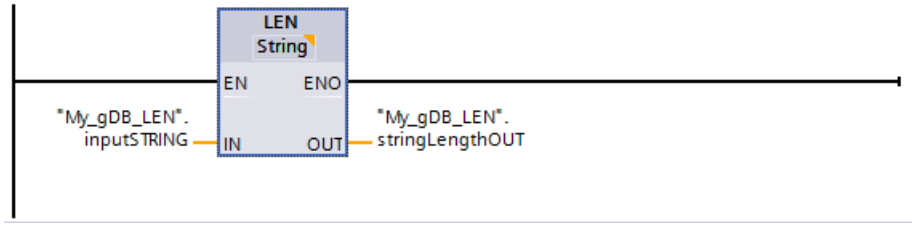
Example

In the following example, you determine the length of a character string with the STRING data type.

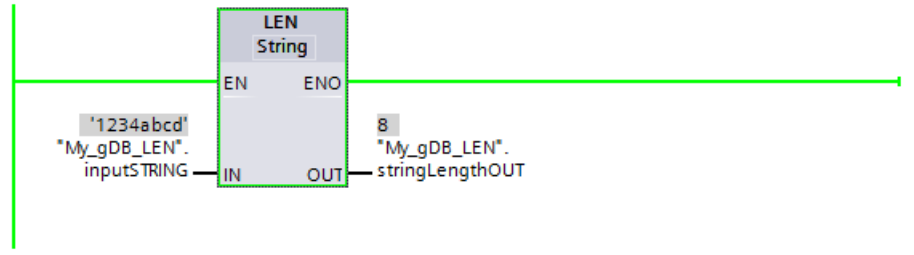
Create two tags in a global data block for storing the data.



Interconnect the parameters of the instruction as follows.



The number of actually occupied characters of the character string ("inputSTRING") is determined and returned as a numerical value at output parameter "OUT" ("stringLengthOUT").



CONCAT: Combine character strings

Description

You use the instruction "CONCAT" to combine the character string at the IN1 input parameter with the character string at the IN2 input parameter. The result is output at the OUT output parameter in (W)STRING format. If the resulting character string is longer than the tag specified in the OUT output parameter, then the resulting character string will be limited to the available length.

If errors occur during processing of the instruction and the OUT output parameter can be written, an empty string will be output.

Parameters

The following table shows the parameters of the "CONCAT" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN1	Input	STRING, WSTRING	D, L or constant	Character string
IN2	Input	STRING, WSTRING	D, L or constant	Character string
OUT	Return	STRING, WSTRING	D, L	Resulting character string

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Example

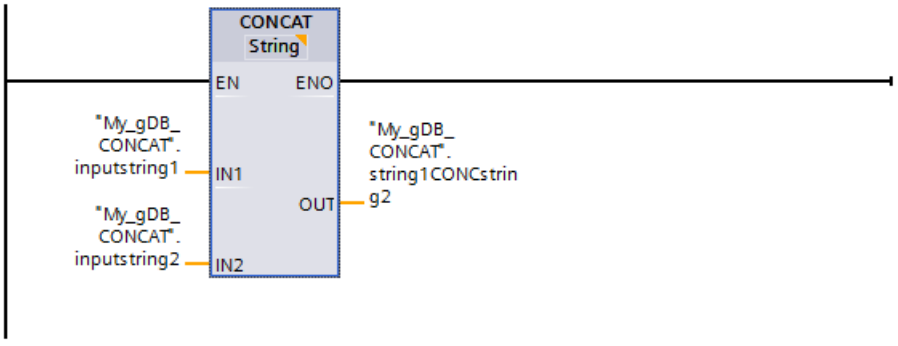
In the following example, you connect two character strings with the STRING data type.

Create three tags in a global data block for storing the data.

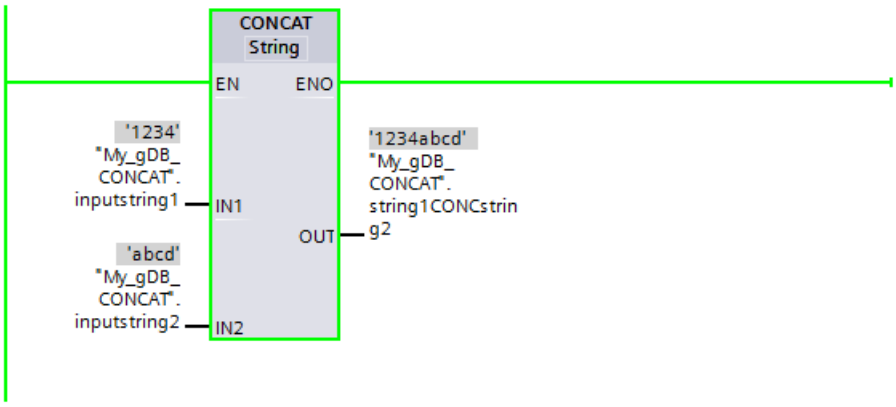
My_gDB_CONCAT

	Name	Data type	Start value
1	Static		
2	inputstring1	String	'1234'
3	inputstring2	String	'abcd'
4	string1CONCstring2	String	''

Interconnect the parameters of the instruction as follows.



The characters of the second character string ("inputstring2") are appended to the first character string ("inputstring1") and the result is output at output parameter OUT ("string1CONCstring2").



LEFT: Read the left character of a character string

Description

You use the instruction "LEFT" to extract a partial string beginning with the first character of the string at the IN input parameter. You specify the number of characters to be extracted in the L parameter. The extracted characters are output at the OUT output parameter in (W)STRING format.

If the number of characters to be extracted is greater than the current length of the character string, the OUT output parameter returns the input character string as a result. If the L parameter contains the value "0" or the input value is an empty string, an empty string will be returned. If the value in the L parameter is negative, an empty string will be output.

If errors occur during processing of the instruction and the OUT output parameter can be written, an empty string will be output.

Parameters

The following table shows the parameters of the "LEFT" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	STRING, WSTRING	D, L or constant	Character string
L	Input	BYTE, INT, SINT, USINT	I, Q, M, D, L or constant	Number of characters to be extracted
OUT	Return	STRING, WSTRING	D, L	Extracted partial string

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

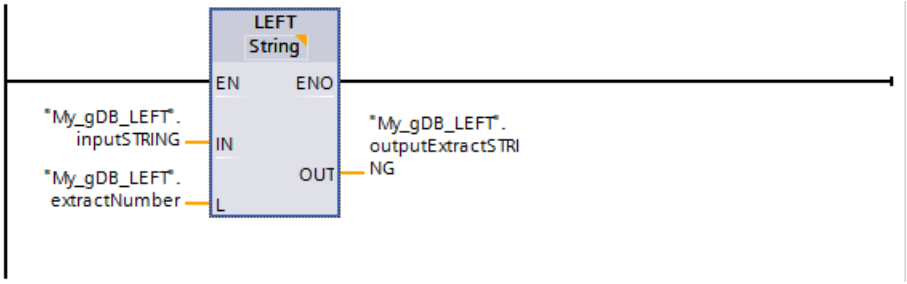
Example

In the following example, you extract a partial character string with the STRING data type from a character string starting from the first character.

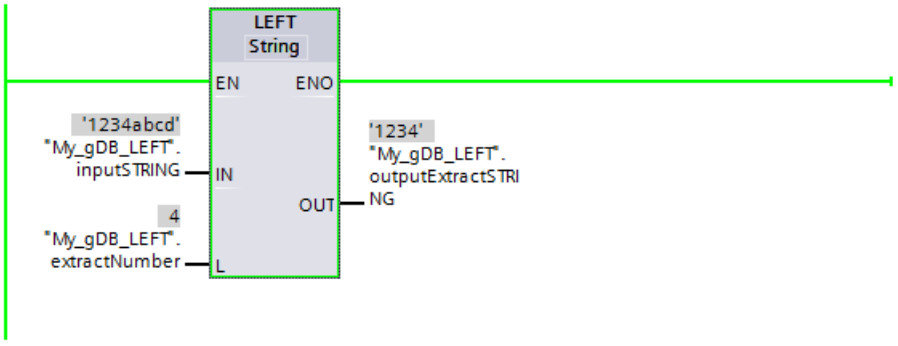
Create three tags in a global data block for storing the data.

My_gDB_LEFT			
	Name	Data type	Start value
1	Static		
2	inputSTRING	String	'1234abcd'
3	extractNumber	Int	4
4	outputExtractSTRING	String	''

Interconnect the parameters of the instruction as follows.



According to the value "4" of parameter L ("extractNumber"), you extract a four-character partial character string from the character string ("inputSTRING") starting from the first character from the left. The extracted partial character string is output at output parameter OUT ("outputExtractSTRING").



RIGHT: Read the right characters of a character string

Description

You use this instruction to extract the last L character in a character string in the input parameter IN. You specify the number of characters to be extracted in the L parameter. The extracted characters are output at the OUT output parameter in (W)STRING format.

If the number of characters to be extracted is greater than the current length of the character string, the OUT output parameter returns the input character string as a result. If the L parameter contains the value "0" or the input value is an empty string, an empty string will be returned. If the value in the L parameter is negative, an empty string will be output.

If errors occur during processing of the instruction and the OUT output parameter can be written, an empty string will be output.

Parameters

The following table shows the parameters of the "RIGHT" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	STRING, WSTRING	D, L or constant	Character string
L	Input	BYTE, INT, SINT, USINT	I, Q, M, D, L or constant	Number of characters to be extracted
OUT	Return	STRING, WSTRING	D, L	Extracted partial string

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Example

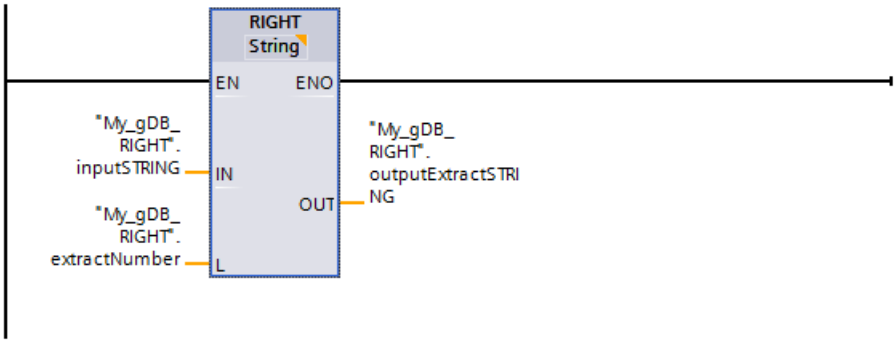
In the following example, you extract a partial character string with the STRING data type from a character string starting from the last character.

Create three tags in a global data block for storing the data.

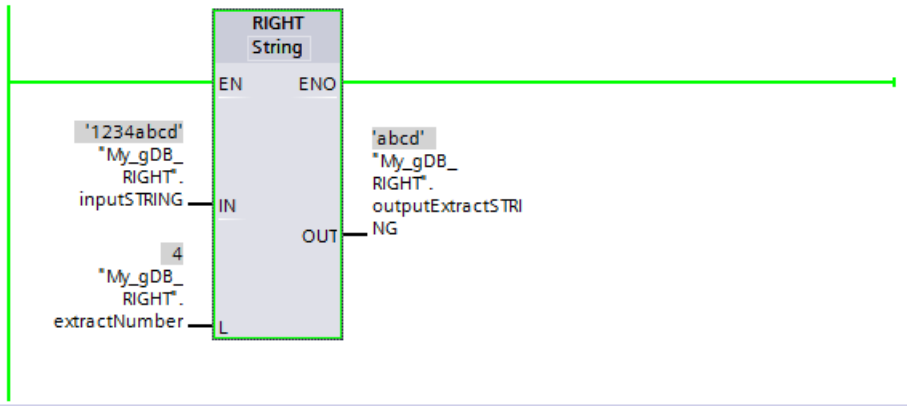
My_gDB_RIGHT

	Name	Data type	Start value
1	Static		
2	inputSTRING	String	'1234abcd'
3	extractNumber	Int	4
4	outputExtractSTRING	String	''

Interconnect the parameters of the instruction as follows.



According to the value "4" of input parameter L ("extractNumber"), you extract a four-character partial character string from the character string ("inputSTRING") starting from the first character from the right. The extracted partial character string is output at output parameter OUT ("outputExtractSTRING").



MID: Read middle characters of a character string

Description

You use this instruction to extract a portion of the character string in the IN input parameter. With the P parameter, you specify the position of the first character to be extracted. With the L parameter, you define the length of the character string to be extracted. The extracted partial character string is output to the OUT output parameter.

The following rules must be observed when executing the instruction:

- If the number of characters to be extracted exceeds the current length of the character string in the IN input parameter, a partial character string will be output, starting from character position P and continuing to the end of the character string.
- If the character position specified in the P parameter falls outside the current character string length in the IN input parameter, an empty character string will be output in the OUT output parameter.
- If the value of the P or L parameter equals zero or is negative, an empty character string will be output in the OUT output parameter.

If errors occur during processing of the instruction and the OUT output parameter can be written, an empty string will be output.

Parameters

The following table shows the parameters of the "MID" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	STRING, WSTRING	D, L or constant	Character string
L	Input	BYTE, INT, SINT, USINT	I, Q, M, D, L or constant	Length of the string to be extracted

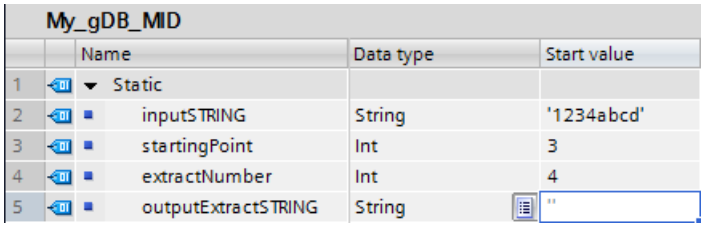
Parameter	Declaration	Data type	Memory area	Description
P	Input	BYTE, INT, SINT, USINT	I, Q, M, D, L or constant	Position of the first character to be extracted (first character = 1)
OUT	Return	STRING, WSTRING	D, L	Extracted partial string

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Example

In the following example, you extract a partial character string with the STRING data type from the middle of a character string.

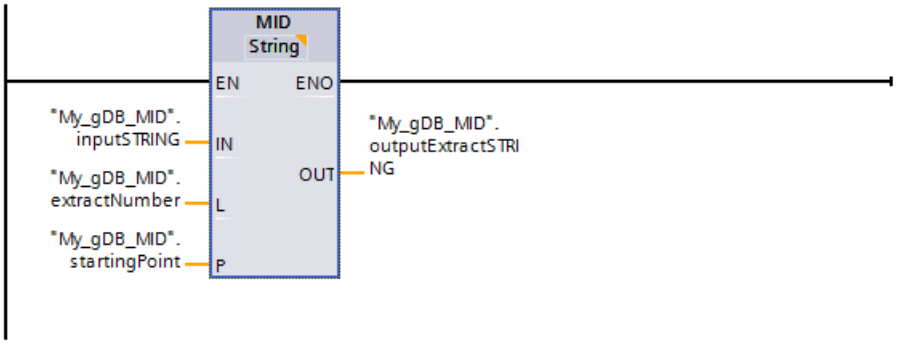
Create four tags in a global data block for storing the data.



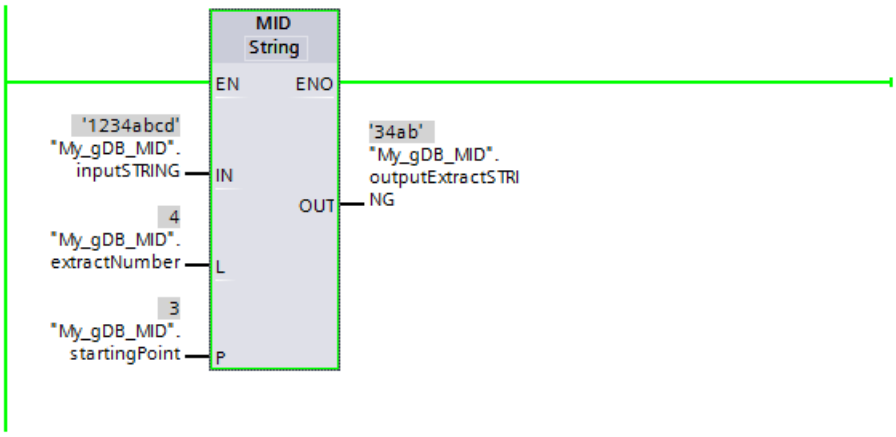
My_gDB_MID

	Name	Data type	Start value
1	Static		
2	inputSTRING	String	'1234abcd'
3	startingPoint	Int	3
4	extractNumber	Int	4
5	outputExtractSTRING	String	''

Interconnect the parameters of the instruction as follows.



According to the value "4" of input parameter L ("extractNumber"), you extract a four-character partial character string from the character string ("inputSTRING"). The extraction starts from the third character ("startingPoint" has the value "3") of the character string ("inputSTRING"). The extracted partial character string is output at output parameter OUT ("outputExtractSTRING").



DELETE: Delete characters in a character string

Description

You use this instruction to delete a portion of the character string in the IN input parameter. With the P parameter, you specify the position of the first character to be deleted. You specify the number of characters to be deleted in the L parameter. The remaining partial character string is output at the OUT output parameter in (W)STRING format.

The following rules must be observed when executing the instruction:

- If the value in the P parameter is less than or equals zero, an empty character string will be output in the OUT output parameter.
- If the value in the P parameter is greater than the current length of the character string in the IN input, the input character string will be returned in the OUT output parameter.
- If the value in the L parameter equals zero, the input character string will be returned in the OUT output parameter.
- If the number of characters to be deleted at the L parameter is greater than the length of the character string at the IN input parameter, the characters starting at the position specified by the P parameter are deleted. The string resulting from this is output.
- If the value in the L parameter is negative, an empty character string will be output.

If errors occur during processing of the instruction and the OUT output parameter can be written, an empty string will be output.

Parameters

The following table shows the parameters of the "DELETE" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	STRING, WSTRING	D, L or constant	Character string
L	Input	BYTE, INT, SINT, USINT	I, Q, M, D, L or constant	Number of characters to be deleted

Parameter	Declaration	Data type	Memory area	Description
P	Input	BYTE, INT, SINT, USINT	I, Q, M, D, L or constant	Position of first character to be deleted
OUT	Return	STRING, WSTRING	D, L	Resulting character string

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Example

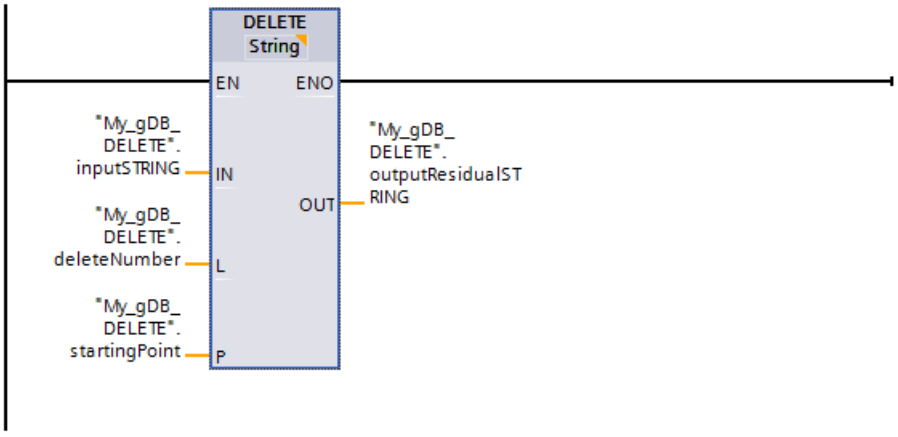
In the following example, you delete characters from a character string with the STRING data type.

Create four tags in a global data block for storing the data.

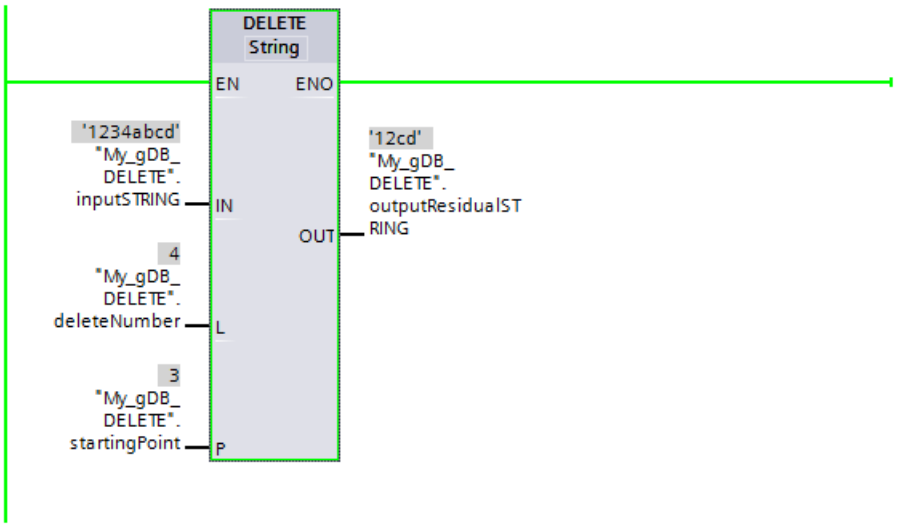
My_gDB_DELETE

	Name	Data type	Start value
1	Static		
2	inputSTRING	String	'1234abcd'
3	startingPoint	Int	3
4	deleteNumber	Int	4
5	outputResidualSTRING	String	''

Interconnect the parameters of the instruction as follows.



According to the value "4" of input parameter L ("deleteNumber"), you delete four characters from the character string ("inputSTRING") starting from the third character ("startingPoint" has the value "3"). The remaining character string is output at output parameter OUT ("outputResidualSTRING").



INSERT: Insert characters in a character string

Description

You use this instruction to insert the character string in the IN2 input parameter to the character string in the IN1 input parameter. With the P parameter, you specify the position of the character starting at which the characters are inserted. The result is output at the OUT output parameter in (W)STRING format.

The following rules must be observed when executing the instruction:

- If the value in the P parameter exceeds the current length of the character string in the IN1 input parameter, the character string of the IN2 input parameter will be appended to the character string of the IN1 input parameter.
- If the value at the P parameter is zero, the character string at the IN2 parameter followed by the character string at the IN1 parameter will be output in the OUT output parameter.
- If the value in the P parameter is negative, an empty character string will be output in the OUT output parameter.
- If the resulting character string is longer than the tag specified in the OUT output parameter, the resulting character string will be limited to the available length.

Parameters

The following table shows the parameters of the "INSERT" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN1	Input	STRING, WSTRING	D, L or constant	Character string
IN2	Input	STRING, WSTRING	D, L or constant	String to insert

Parameter	Declaration	Data type	Memory area	Description
P	Input	BYTE, INT, SINT, USINT	I, Q, M, D, L or constant	Insert position
OUT	Return	STRING, WSTRING	D, L	Resulting character string

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Example

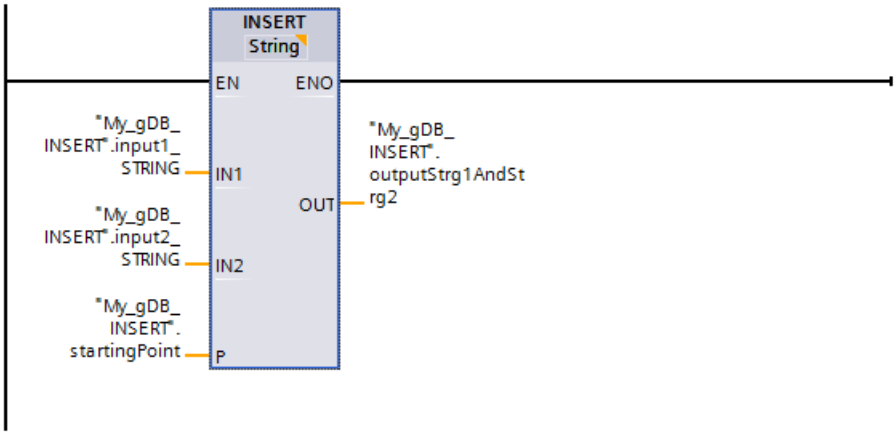
In the following example, you insert a character string in another character string. The data type used is STRING.

Create four tags in a global data block for storing the data.

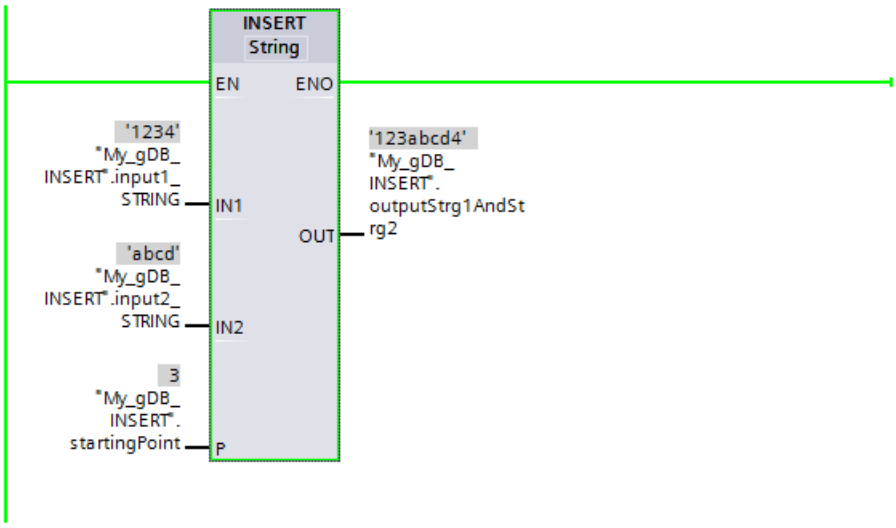
My_gDB_INSERT

	Name	Data type	Start value
1	Static		
2	input1_STRING	String	'1234'
3	input2_STRING	String	'abcd'
4	startingPoint	Int	3
5	outputStrg1AndStrg2	String	''

Interconnect the parameters of the instruction as follows.



The characters of the second character string ("input2_STRING") are inserted in the first character string ("input1_STRING"). According to the value "3" of parameter P ("startingPoint"), characters are inserted after the third character of the first character string ("input1_STRING"). The result is output at output parameter OUT ("outputStrg1AndStrg2").



REPLACE: Replace characters in a character string

Description

You use this instruction to replace a portion of the character string in the IN1 input with the character string in the IN2 input. You specify the position of the first character to be replaced in the P parameter. You specify the number of characters to be replaced in the L parameter. The result is output at the OUT output parameter in (W)STRING format.

The following rules must be observed when executing the instruction:

- If the value in the P parameter is less than or equals zero, an empty character string will be output in the OUT output parameter.
- If the value in the L parameter is less than zero, an empty character string will be output in the OUT output parameter.
- If P equals one, the character string in the IN1 input will be replaced beginning with (and including) the first character.
- If the value in the P parameter exceeds the current length of the character string in the IN1 input parameter, the character string of the IN2 input parameter will be appended to the character string of the IN1 input parameter.
- If the resulting character string is longer than the tag specified in the OUT output parameter, the resulting character string will be limited to the available length.
- If the value at parameter L is zero, characters are not replaced but inserted. Similar conditions apply as with the instruction INSERT. See also: INSERT: Insert characters in a character string (Page 3049)

Parameters

The following table shows the parameters of the "REPLACE" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN1	Input	STRING, WSTRING	D, L or constant	String with characters to be replaced.
IN2	Input	STRING, WSTRING	D, L or constant	String with characters to be inserted.
L	Input	BYTE, INT, SINT, USINT	I, Q, M, D, L or constant	Number of characters to be replaced
P	Input	BYTE, INT, SINT, USINT	I, Q, M, D, L or constant	Position of first character to be replaced
OUT	Return	STRING, WSTRING	D, L	Resulting character string

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Example

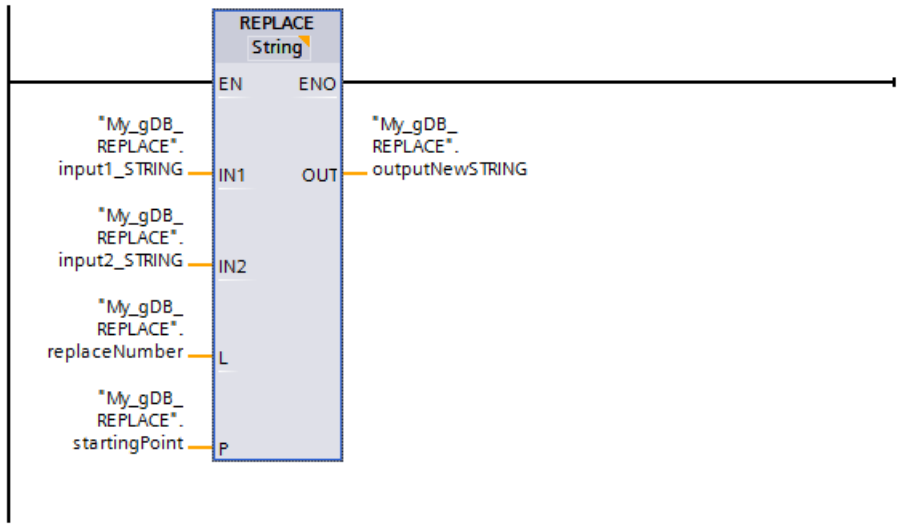
In the following example, you replace part of a character string with another character string. The data type used is STRING.

Create five tags in a global data block for storing the data.

My_gDB_REPLACE

	Name	Data type	Start value
1	Static		
2	input1_STRING	String	'1234'
3	input2_STRING	String	'abcd'
4	replaceNumber	Int	2
5	startingPoint	Int	3
6	outputNewSTRING	String	''

Interconnect the parameters of the instruction as follows.



The second character string ("input2_STRING") is added to the first character string ("input1_STRING") starting from the third character ("startingPoint" has the value "3"). According to the value "2" of parameter L ("replaceNumber"), the third and fourth characters of the first character string ("input1_STRING") are replaced in the process. The result is output at output parameter OUT ("outputNewSTRING").

My_gDB_REPLACE

	Name	Data type	Start value	Monitor value
1	Static			
2	input1_STRING	String	'1234'	'1234'
3	input2_STRING	String	'abcd'	'abcd'
4	replaceNumber	Int	2	2
5	startingPoint	Int	3	3
6	outputNewSTRING	String	''	'12abcd'

FIND: Find characters in a character string

Description

You can use this instruction to search through the character string in the IN1 input parameter for a specific character or a specific sequence of characters.

- You specify the value to be searched for in the IN2 input parameter. The search is made from left to right.
- The position of the first occurrence is output in the OUT output parameter. If the search returns no match, the value "0" will be output in the OUT output parameter.

If an invalid character is specified at the IN2 parameter or if an error occurs during processing, the value "0" is output at the OUT parameter.

Parameters

The following table shows the parameters of the "FIND" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN1	Input	STRING, WSTRING	D, L or constant	String searched through
IN2	Input	STRING, WSTRING, CHAR, WCHAR	D, L or constant (For (W)CHAR also I, Q, M)	Characters to search for
OUT	Return	INT	I, Q, M, D, L	Character position

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Example

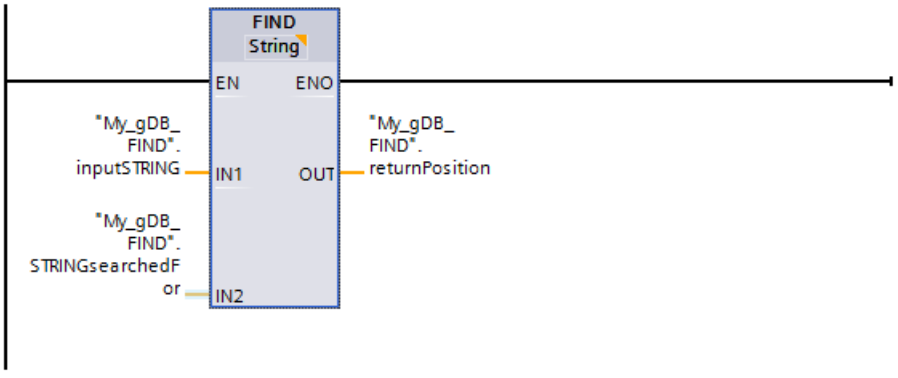
In the following example, you search for a character string in another character string. The data type used is STRING.

Create three tags in a global data block for storing the data.

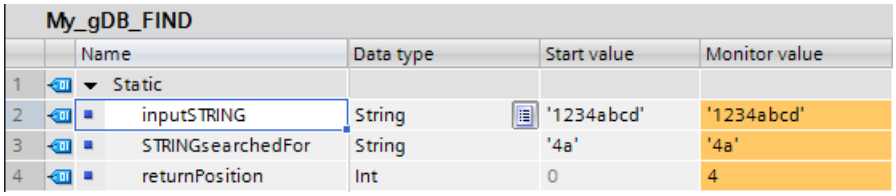
My_gDB_FIND

	Name	Data type	Start value
1	Static		
2	inputSTRING	String	'1234abcd'
3	STRINGsearchedFor	String	'4a'
4	returnPosition	Int	0

Interconnect the parameters of the instruction as follows.



The first character string ("inputSTRING") searches for the value "4a" of the second character string ("STRINGsearchedFor"). The character position ("4") at which the searched character string begins is output at output parameter OUT ("returnPosition").



My_gDB_FIND

		Name	Data type	Start value	Monitor value
1		Static			
2		inputSTRING	String	'1234abcd'	'1234abcd'
3		STRINGsearchedFor	String	'4a'	'4a'
4		returnPosition	Int	0	4

Runtime information

GetSymbolName: Read out a tag on the input parameter

Description

With the "GetSymbolName" instruction, you use the input parameter of a block to read out the name of a tag interconnected at the parameter.

If a block is used multiple times in the project and called each time by a different tag, you can use the "GetSymbolName" instruction to evaluate the name of the calling tag. The process value of the tag is irrelevant in this case.

- You specify the input parameters of the block interface at the VARIABLE parameter. Use only an interface parameter for this parameter and no PLC or data block tags.
- You can limit the length of the read tag name using the SIZE parameter. If the name has been truncated, this is indicated by the characters "..." (Unicode character 16#2026) appears at the end of the name. Note that the "..." character itself has a length of 1. If you enter 6 as the maximum length at the SIZE parameter, for example, and read the tag name "MyPLCTag" via the block interface, the following is output: "MyPLC...".
- The name read is output at the OUT parameter.

Parameters

The following table shows the parameters of the "GetSymbolName" instruction:

Parameter	Declaration	Data type	Memory area	Description
VARIABLE	Input	PARAMETER	L	Input parameters of the block interface
SIZE	Input	DINT	I, Q, M, D, L	Length limit for the read names
OUT	Return	WSTRING	I, Q, M, D, L	Name of the tag that was read via the block interface

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Example

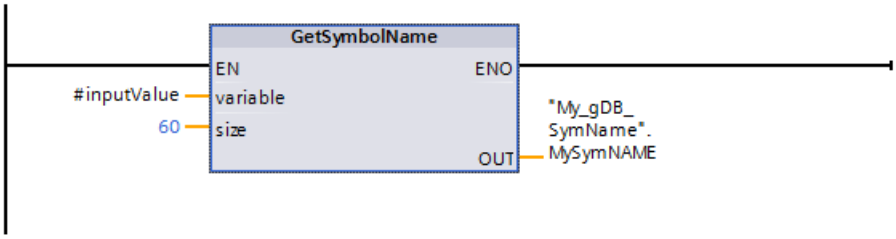
In the following example, you read out the name of a tag that is interconnected via the input parameter of a block.

Create two tags in a global data block for storing the data.

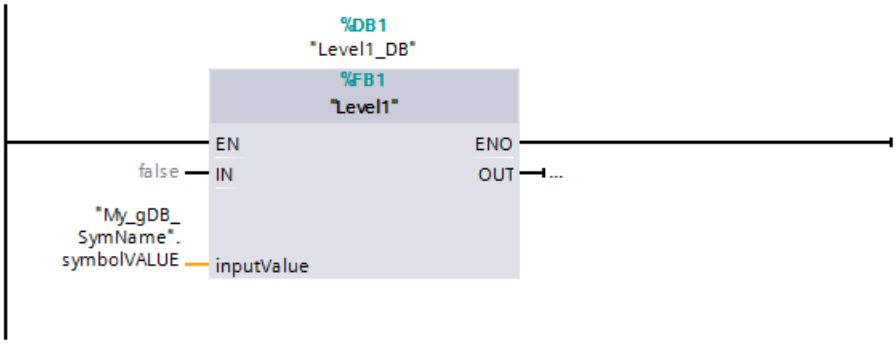
My_gDB_SymName

		Name	Data type	Start value
1		Static		
2		MySymNAME	WString	WSTRING#''
3		symbolVALUE	Byte	16#42

Create an input parameter inputValue with the BYTE data type in the "Level1" block. Call the "GetSymbolName" instruction in the "Level1" block. Interconnect the parameters of the instruction as follows.



Interconnect the inputValue parameter of the "Level1" block as follows.



The "GetSymbolName" instruction is executed in the "Level1" block. Input parameter inputValue of the "Level1" block is examined for its interconnection using input parameter VARIABLE of the instruction. In doing so, the "symbolVALUE" tag is read out and output as a character string at output parameter OUT ("MySymNAME"). According to the value of input parameter SIZE, the length of the character string is limited to 60 characters.

My_gDB_SymName

		Name	Data type	Start value	Monitor value
1		Static			
2		MySymNAME	WString	WSTRING#''	WSTRING#'"My_gDB_SymName".symbolVALUE'
3		symbolVALUE	Byte	16#42	16#42

GetSymbolPath: Query composite global name of the input parameter assignment

Description

You can use the "GetSymbolPath" instruction to read the composite global name of an input parameter at the local interface. The name consists of the storage path and the tag name.

- Specify the block interface through which the name of the input tag is to be read at the VARIABLE parameter of the instruction:
  - If the tag of a data block is used to supply the input parameters, the name of the DB, contained structures and the name of the tag are output as the path.
  - If a PLC tag is used to supply the input parameters, the name of the PLC tag is output.
  - If a constant is used to supply the input parameters, the content of the constant is output.
- You can limit the length of the read tag name using the SIZE parameter. If the name has been truncated, this is indicated by the characters "..." (Unicode character 16#2026) at the end of the name. Note that even the "..." character itself has a length of 1.
  If you enter 6 as the maximum length at the SIZE parameter, for example, and read the tag name "MyPLCTag" via the block interface, the following is output: "MyPLC...".

Parameters

The following table shows the parameters of the "GetSymbolPath" instruction:

Parameters	Declaration	Data type	Memory area	Description
VARIABLE	Input	VARIANT	L	Selection of the local interface to which you want to read the global name of the input parameter supply.
SIZE	Input	DINT	I, Q, M, D, L or constant	Limits the number of characters output at the OUT parameter. If the output of characters should not be limited, enter "0" for the SIZE parameter.
OUT	Output	WSTRING	I, Q, M, D, L	Output of the tag name of the input parameters supply.

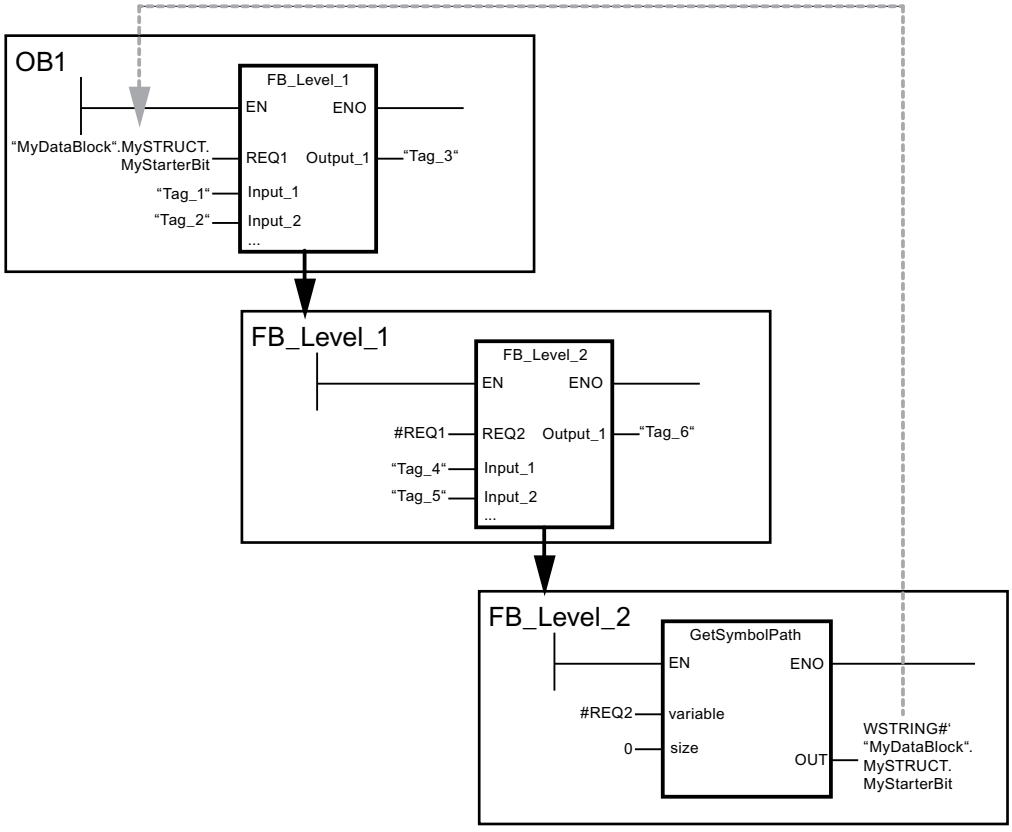
You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Example

The following example shows the use of GetSymbolPath over several call levels:

- The FB_Level_1 block is called from the organization block OB1, and from there the FB_Level_2 block is called in turn.
- GetSymbolPath is executed in the FB_Level_2 block to read the path of the parameter at the REQ2 interface.

- Since REQ2 is supplied by the REQ1 interface in turn, the instruction determines the path of the input parameter of REQ1.
- MyStarterBit is used as a parameter at the REQ1 parameter. The bit is located in the MySTRUCT structure in the MyDatablock data block.
  This information is read by GetSymbolPath and output at the OUT parameter.



GetInstanceName: Read out name of the block instance

Description

You can use the "GetInstanceName" instruction to read the name of the instance data block within a function block.

- You can specify how many characters of the instance name should be read out using the SIZE parameter. If you use the "0" value for SIZE, the entire name is read.
- The name of the instance data block is written to the OUT parameter. If the name of the instance data block is longer than the maximum length of WSTRING, the name is truncated.

Parameters

The following table shows the parameters of the "GetInstanceName" instruction:

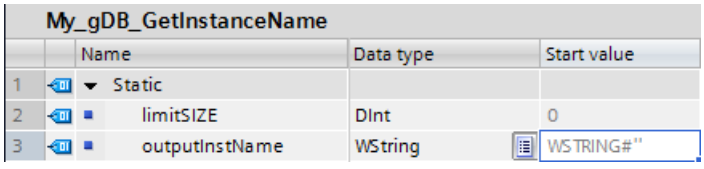
Parameter	Declaration	Data type	Memory area	Description
SIZE	Input	DINT	I, Q, M, D, L or constant	Number of characters up to which the name of the instance data block is to be read
OUT	Output	WSTRING	I, Q, M, D, L	Read name of the instance data block

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

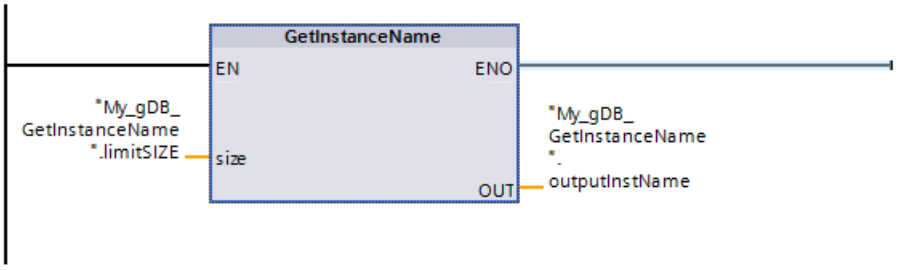
Example

In the following example, you read out the name of an instance data block.

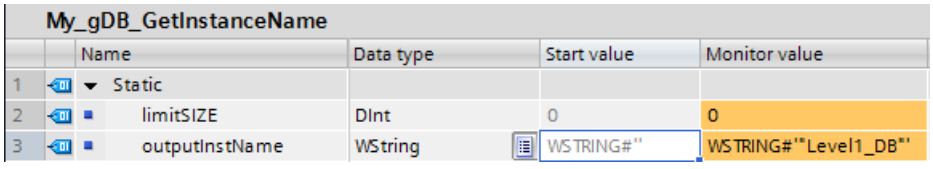
Create two tags in a global data block for storing the data.



Interconnect the parameters of the instruction as follows.



The "GetInstanceName" instruction is executed in the "Level1_gin" block. By means of the "GetInstanceName" instruction, the associated instance data block of the "Level1_gin" block is determined and output as a character string at output parameter OUT ("outputInstName"). According to the value "0" of parameter SIZE ("limitSIZE"), the length of the character string is unlimited.



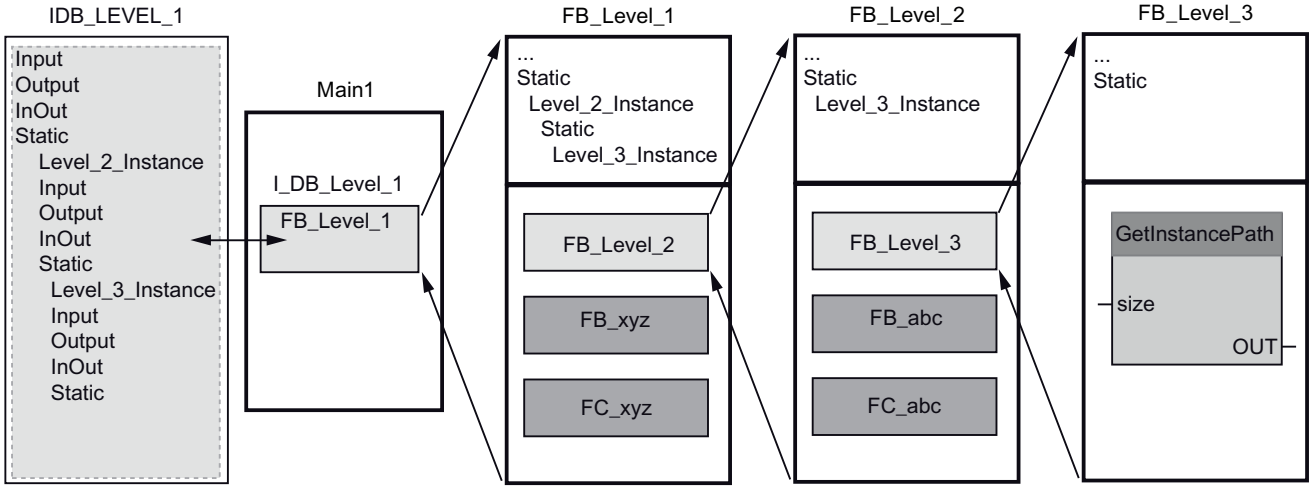
GetInstancePath: Query composite global name of the block instance

Description

You use the "GetInstancePath" instruction to read the composed global name of the block instance within a function block. The composed global name of the block instance is the path of the complete call hierarchy when multi-instances are used.

In the following example, the "GetInstancePath" instruction is called in the FB_Level_3 function block.

- The FB_Level_3 function block stores its data in the calling FB_Level_2 function block.
- The FB_Level_2 function block in turn stores its data in the calling FB_Level_1 function block.
- The FB_Level_1 function block in turn stores its data in its instance data block IDB_LEVEL_1. Through the use of multi-instances, the instance data block of FB_Level_1 contains all data of the three function blocks.



The "GetInstancePath" instruction returns the following path for this example:
'"IDB_LEVEL_1".Level_2_Instance.Level_3_Instance'

Note

Use of "GetInstancePath" in function blocks with single instance

If the function block in which you call "GetInstancePath" saves data in its own instance data block, the name of the single instance is output as the global name. The result at parameter OUT corresponds in this case to the ""GetInstanceName" instruction.

Parameters

The following table shows the parameters of the "GetInstancePath" instruction:

Parameter	Declaration	Data type	Memory area	Description
SIZE	Input	DINT	I, Q, M, D, L or constant	Number of characters up to which the global name of the block instance is to be read out. When SIZE = 0, the complete global name is output.
OUT	Output	WSTRING	I, Q, M, D, L	Read global name of the block instance. If the global name of the block instance is longer than the maximum length of WSTRING (254 characters), the name is truncated.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

See also

GetInstanceName: Read out name of the block instance (Page 3058)

GetBlockName: Read out name of the block

Description

You can use the "GetBlockName" instruction to read the name of the block in which the instruction is called.

- You can specify how many characters of the block name should be read using the SIZE parameter. If you use the "0" value for SIZE, the entire name is read.
- The name of the block is written at the OUT parameter. If the name of the block is longer than the maximum length of WSTRING, the name is truncated.

Parameters

The following table shows the parameters of the "GetBlockName" instruction:

Parameter	Declaration	Data type	Memory area	Description
SIZE	Input	UINT	I, Q, M, D, L or constant	Number of characters up to which the name of the instance data block is to be read.
RET_VAL	Output	WSTRING	I, Q, M, D, L	Read name of the instance data block

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Example

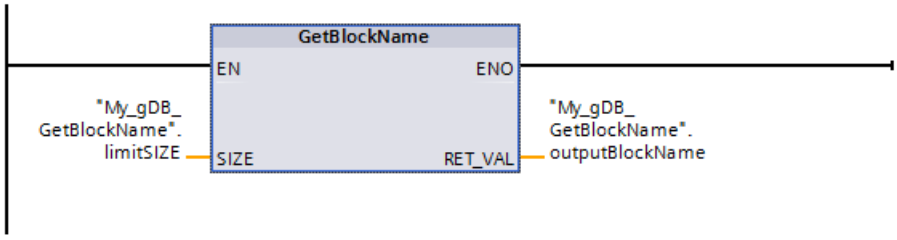
In the following example, you read out the block name.

Create two tags in a global data block for storing the data.

My_gDB_GetBlockName

		Name	Data type	Start value
1		Static		
2		limitSIZE	DInt	0
3		outputBlockName	WString	WSTRING#''

Interconnect the parameters of the instruction as follows.



The "GetBlockName" instruction is executed in the "Level1_gbn" block. By means of the "GetBlockName" instruction, the name of the "Level1_gbn" block is read out and output as a character string at output parameter OUT ("outputBlockName"). According to the value "0" of parameter SIZE ("limitSIZE"), the length of the character string is unlimited.

My_gDB_GetBlockName

		Name	Data type	Start value	Monitor value
1		Static			
2		limitSIZE	DInt	0	0
3		outputBlockName	WString	WSTRING#''	WSTRING#'"Level1_gbn"'

11.6.3.3 Process image

UPDAT_PI: Update the process image inputs

Description

With the instruction, you update the OB 1 process image (=process image partition 0) of the inputs or a process image partition of the inputs of the inputs defined by configuration.

If you have configured repeated signaling of I/O access errors for the system-side process image update, then the selected process image will be updated constantly.

Otherwise, this update will only be performed if the selected process image partition is not updated by the system, in other words:

- If you have not assigned this process image partition to an interrupt OB
  or
- If you selected process image partition 0 and have disabled updating of the OB 1 process image partition during configuration.

Note

Each logical address that you have assigned to a process image partition of the inputs per configuration no longer belongs to the OB 1 process image of the inputs.

When you update a process image partition with "UPDAT_PI", you must not perform a simultaneous update with the "SYNC_PI (Page 3066)" instruction.

System-side updating of the OB 1 process image of the inputs and the process image partitions of inputs that you have assigned to an interrupt OB takes place independently of "UPDAT_PI" calls.

Parameters

The following table shows the parameters of the "UPDAT_PI"instruction:

Parameter	Declaration	Data type	Memory area	Description
PART	Input	PIP	I, Q, M, D, L or constant	Number of the process image partition of the inputs to be updated. Maximum value range (depending on the CPU): 0 to 31 (0 means OB 1 process image, n where 1 <= n <= 31 means process image partition n).
RET_VAL	Return	INT	I, Q, M, D, L, P	Error information
FLADDR	Output	WORD	I, Q, M, D, L, P	Address of the first byte to cause an error if an access error has occurred.

You can find additional information on valid data types in "Overview of the valid data types (Page 1908)".

RET_VAL parameter

Error code* (W#16#...)	Explanation
0000	No error occurred.
8090	Illegal value for PART parameter
8091	The specified process image partition was not yet defined or is not located in the permitted process image area on the CPU.
8092	The process image partition is being updated by the system and cannot be used for the PART parameter.
8093	The process image partition update is being processed in another OB.

Error code* (W#16#...)	Explanation
80A0	An access error was detected when accessing the I/O.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

Note

If you use the instruction for process image partitions of DP standard slaves for which you have defined a consistency area greater than 32 bytes, the error codes of the "DPRD_DAT (Page 3124)" instruction are also possible.

UPDAT_PO: Update the process image outputs

Description

You use the instruction to transfer the signal states of the OB 1 process image (= process image partition 0) of the outputs or a process image partition of the outputs defined per configuration to the output modules.

If you have specified a consistency range for the selected process image partition, corresponding data is transferred as consistent data to the respective I/O module.

Note

Each logical address you have assigned to a process image partition of the outputs during configuration no longer belongs to the OB 1 process image of the outputs.

Outputs that you update with "UPDAT_PO" must not be updated simultaneously with the "SYNC_PO (Page 3067)" instruction.

The OB 1 process image of the outputs and the process image partitions of the outputs that you have assigned to an interrupt OB are transferred by the system to the output modules independently of "UPDAT_PO" calls.

Parameters

The following table shows the parameters of the "UPDAT_PO" instruction:

Parameter	Declaration	Data type	Memory area	Description
PART	Input	PIP	I, Q, M, D, L or constant	Number of the process image partition of the outputs to be transferred. Maximum value range (depending on the CPU): 0 to 31. (0 means OB 1 process image, n where 1 <= n <= 31 means process image partition n)
RET_VAL	Return	INT	I, Q, M, D, L, P	Error information
FLADDR	Output	WORD	I, Q, M, D, L, P	Address of the first byte to cause an error if an access error has occurred.

You can find additional information on valid data types in "Overview of the valid data types (Page 1908)".

RET_VAL parameter

Error code* (W#16#...)	Explanation
0000	No error occurred.
8090	Illegal value for PART parameter
8091	The specified process image partition was not yet defined or is not located in the permitted process image area on the CPU.
8092	The process image partition is being updated by the system and cannot be used for the PART parameter.
8093	The process image partition update is being processed in another OB.
80A0	An access error was detected when accessing the I/O.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

Note

If you use the instruction for process image partitions of DP standard slaves for which you have defined a consistency area greater than 32 bytes, the error codes of the "DPWR_DAT (Page 3126)" instruction are also possible.

SYNC_PI: Synchronize the process image inputs

Description

The "SYNC_PI" is used to update the process image partition of inputs in isochronous mode. A user program linked to a DP cycle or PN send cycle can use this instruction to update input data acquired in a process image partition of the inputs isochronously and consistently.

Call

"SYNC_PI" is interruptible and can only be called in OBs 61, 62, 63 and 64.

Note

A call of the "SYNC_PI" instruction in OBs 61 to 64 is only permitted if you have assigned the affected process image partition to the associated OB in the HW configuration.

A process image partition that you update with "SYNC_PI" must not be updated simultaneously with the "UPDAT_PI (Page 3062)" instruction.

Parameters

The following table shows the parameters of the "SYNC_PI" instruction:

Parameter	Declaration	Data type	Memory area	Range of values	Description
PART	Input	PIP	I, Q, M, D, L or constant	1 to 31	Number of the process image partition of the inputs to be updated isochronously.
RET_VAL	Return	INT	I, Q, M, D, L, P	-	Error information
FLADDR	Output	WORD	I, Q, M, D, L, P		Address of the first byte to cause an error if an access error has occurred.

You can find additional information on valid data types in "Overview of the valid data types (Page 1908)".

RET_VAL parameter

Error code (W#16#...)*	Explanation
0000	No error occurred.
0001	Consistency warning. The update of the process image partition was distributed over two DP or PN cycles. However, the data in one slave or IO device were consistently transferred.
8090	Illegal value on PART parameter or updating the specified process image partition of the inputs is not permitted in this OB. The process image partition of the inputs was not updated.
8091	The specified process image partition was not yet defined or is not located in the permitted process image area on the CPU. The process image partition of the inputs was not updated.
8092	The process image partition is being updated by the system and cannot be used for the PART parameter.
8093	The process image partition update is being processed in another OB.
80A0	During updating an access error was detected. The affected inputs were set to "0".

Error code (W#16#...)*	Explanation
80A1	The update time is after the permitted access window. The process image partition of the inputs was not updated. The DP or PN cycle is too short to ensure enough time for processing the instruction. You must therefore increase the TDP (also known as T_DC), Ti and To timers.
80A2	Access error with consistency warning In the case of update of the specified process image partition an access error with simultaneous consistency warning was detected. • The data of the incorrect inputs was not read by the I/O. In the process image partition of the inputs the involved inputs are set to zero. • The update of the process image partition of the not involved by an access error input data was distributed over two DP and PN cycles.
80C1	The update time is before the permitted access window. The process image partition of the inputs was not updated.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

Note

If you use the "SYNC_PI" instruction for process image partitions of DP standard slaves for which you have defined a consistency area greater than 32 bytes, the error codes of the "DPRD_DAT (Page 3124)" instruction are also possible.

SYNC_PO: Synchronize the process image outputs

Description

The instruction "SYNC_PO" is used to update a process image partition of outputs in isochronous mode. An application program linked to a DP cycle or a PN send cycle can use this instruction for the consistent isochronous transfer of the computed output data of a process image partition from outputs to the I/O devices.

Call

"SYNC_PO" is interruptible and can only be called in OBs 61, 62, 63 and 64.

Note

A call of the "SYNC_PO" instruction in OBs 61 to 64 is only permitted if you have assigned the affected process image partition to the associated OB in the HW configuration.

A process image partition that you update with "SYNC_PO" must not be updated simultaneously with the "UPDAT_PO (Page 3064)" instruction.

Parameters

The following table shows the parameters of the "SYNC_PO" instruction:

Parameter	Declaration	Data type	Memory area	Range of values	Description
PART	Input	PIP	I, Q, M, D, L or constant	1 to 31	Number of the process image partition of the outputs to be updated isochronously.
RET_VAL	Return	INT	I, Q, M, D, P	-	If an error occurs while the instruction is being executed, the return value contains an error code.
FLADDR	Output	WORD	I, Q, M, D, L, P	-	Address of the first byte that has caused the error.

You can find additional information on valid data types in "Overview of the valid data types (Page 1908)".

RET_VAL parameter

Error code (W#16#...)*	Explanation
0000	No error occurred.
0001	Consistency warning. The update of the process image partition was distributed over two DP or PN cycles. However, the data in one slave or IO device were consistently transferred.
8090	Illegal value in PART parameter, or updating the specified process image partition of the outputs is not permitted in this OB. Outputs were not transferred to the I/O. The process image partition of the outputs remains unchanged.
8091	The specified process image partition was not yet defined or is not located in the permitted process image area on the CPU. Outputs were not transferred to the I/O. The process image partition of the outputs remains unchanged.
8092	The process image partition is being updated by the system and cannot be used for the PART parameter.
8093	The process image partition update is being processed in another OB.
80A0	In the case of update of the specified process image partition of the outputs an access error was detected. Incorrect outputs were not transferred to the I/O. During process image partition of the outputs, these outputs remain unchanged.
80A1	Access error with consistency warning In the case of update of the specified process image partition of the outputs an access error with simultaneous consistency warning was detected. • The data of the incorrect outputs were not transferred to the I/O. During process image partition of the outputs, the involved outputs remain unchanged. • The update of the process image partition of the not involved by an access error input data was distributed over two DP and PN cycles.
80A2	The update time is after the permitted access window. Outputs were not transferred to the I/O. The process image partition of the outputs remains unchanged.
80C1	The update time is before the permitted access window. Outputs were not transferred to the I/O. The process image partition of the outputs remains unchanged.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

Note

If you use the "SYNC_PO" instruction for process image partitions of DP standard slaves for which you have defined a consistency area greater than 32 bytes, the error codes of the "DPWR_DAT (Page 3126)" instruction are also possible.

11.6.3.4 Distributed I/O

RDREC: Read data record

Description

You use the instruction "RDREC" to read the data record with the number INDEX from the module addressed using the ID. This may be a module in a central rack or a distributed module (PROFIBUS DP or PROFINET IO).

- Use the parameter ID to select from which module (DP/PROFINET IO) a data record is to be read. Use only the hardware identifier of the module for the "ID" parameter.
- Use the INDEX parameter to select the information to be read from the module. Which data records can be read with which data record number depends on the module. For additional information, see the manual to the specific module.
- The data records readable via "RDREC" have a different length. Use MLEN to specify the maximum number of data record bytes you want to read. If length "0" is selected at the parameter MLEN, the complete data record is written at the parameter RECORD.
- The destination area RECORD should have at least the length of MLEN bytes. If you read out the full data record with MLEN=0, use the maximum length of the data record for RECORD. The structure (configuration, data types and length) that you use at the parameter RECORD, also depends on which data record is read out by which module.
- The value TRUE for the output parameter VALID indicates that the data record was successfully transferred to the destination area RECORD. In this case, the LEN output parameter contains the length of the read data in bytes.
- If an error has occurred during transfer of the data record, this is indicated by the output parameter ERROR. In this case, the output parameter STATUS contains the error information.

Note

The interface of the "RDREC" instruction is identical to the "RDREC" FB defined in "PROFIBUS Guideline PROFIBUS Communication and Proxy Function Blocks according to IEC 61131-3".

Functional description

"RDREC" is an instruction that works asynchronously, which means its execution extends over multiple calls. You start the data record transfer by calling "RDREC" with REQ= 1.

The job status is displayed via the output parameter BUSY and the two central bytes of output parameter STATUS. The two central bytes of STATUS correspond to the RET_VAL output parameter of the instructions that operate asynchronously.

See also: Meaning of the parameters REQ, RET_VAL and BUSY with asynchronous instructions (Page 2193).

The transfer of the data record is complete when the output parameter BUSY has the value FALSE .

Parameters

The following table shows the parameters of the "RDREC" instruction:

Parameter	Declaration	Data type*	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L, T**, C** or constant	REQ = 1: Transfer data record
ID	Input	HW_IO	I, Q, M, D, L or constant	Hardware identifier of the hardware module (DP/PROFINET IO) The number is assigned automatically and is stored in the properties of the module or of the interface in the hardware configuration.
INDEX	Input	BYTE, DINT, INT, SINT, UINT, USINT, WORD	I, Q, M, D, L or constant	Data record number
MLEN	Input	BYTE, UINT, USINT	I, Q, M, D, L or constant	Maximum length in bytes of the data record information to be read
VALID	Output	BOOL	I, Q, M, D, L	New data record was received and is valid.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = 1: The reading process is not yet complete.
ERROR	Output	BOOL	I, Q, M, D, L	ERROR = 1: An error occurred during the reading process.
STATUS	Output	DWORD	I, Q, M, D, L	Block status or error information
LEN	Output	UINT	I, Q, M, D, L	Length of the read data record information
RECORD	InOut	VARIANT	I, Q, M, D, L	Destination area for the data record read.
* There is no implicit conversion in STL, which is why the range of valid data types may be limited. During programming in STL, note the permissible data types in each case in the tooltip of the parameter ** For S7-1500 only.				

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Note

If you use "RDREC" to read a data record for PROFINET IO, then negative values in the INDEX, MLEN, and LEN parameters will be interpreted as an unsigned 16-bit integer.

Parameter STATUS

For interpretation of the STATUS parameter, see Parameter STATUS (Page 3078).

WRREC: Write data record

Description

The instruction "WRREC" is used to transfer the RECORD data record to the component addressed using ID. This may be a module in a central rack or a distributed component (PROFIBUS DP or PROFINET IO).

- Use LEN to specify the length of the data record to be transmitted in bytes. The selected length of the source range RECORD should have at least the length of LEN bytes.
- The value TRUE at output parameter DONE indicates that the data record has been successfully transferred.
- If an error has occurred during transfer of the data record, this is indicated by the output parameter ERROR. In this case, the output parameter STATUS contains the error information.

Note

The interface of the "WRREC" instruction is identical to the "WRREC" FB defined in "PROFIBUS Guideline PROFIBUS Communication and Proxy Function Blocks according to IEC 61131-3".

Functional description

"The WRREC" instruction works asynchronously, that is, its execution extends over multiple calls. You start the data record transfer by calling "WRREC" with REQ = 1.

The job status is displayed via the output parameter BUSY and the two central bytes of output parameter STATUS. The two central bytes of STATUS correspond to the RET_VAL output parameter of the instructions that operate asynchronously.

See also: Meaning of the parameters REQ, RET_VAL and BUSY with asynchronous instructions (Page 2193).

Note that you must assign the same value to the actual parameter of RECORD for all "WRREC" calls that belong to one and the same job. The same applies to the actual parameters of LEN.

The transfer of the data record is complete when the output parameter BUSY has the value FALSE.

Parameters

The following table shows the parameters of the instruction "WRREC":

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L, T*, C* or constant	REQ= 1: Transfer data record
ID	Input	HW_IO	I, Q, M, D, L or constant	ID number of the hardware component (DP/ PROFINET IO) The number is assigned automatically and is stored in the properties of the component or of the interface in the hardware configuration.
INDEX	Input	DINT	I, Q, M, D, L or constant	Data record number
LEN	Input	BYTE, UINT, USINT	I, Q, M, D, L or constant	(hidden) Maximum length of the data record to be transferred in bytes
DONE	Output	BOOL	I, Q, M, D, L	Data record was transferred
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = 1: The writing process is not yet complete.
ERROR	Output	BOOL	I, Q, M, D, L	ERROR = 1: An error occurred during the writing process.
STATUS	Output	DWORD	I, Q, M, D, L	Block status or error information For interpretation of the STATUS parameter, see Parameter STATUS (Page 3078).
RECORD	InOut	VARIANT	I, Q, M, D, L	Data record
* For S7-1500 only.				

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Note

If you use "WRREC" to write a data record for PROFINET IO, negative values in the INDEX and LEN parameters will be interpreted as an unsigned 16-bit integer.

Parameter STATUS

For interpretation of the STATUS parameter, see Parameter STATUS (Page 3078).

GETIO: Read process image

Description

You use the instruction "GETIO" to consistently read out all inputs of a DP standard slave/ PROFINET IO device. The instruction "GETIO" calls the instruction "DPRD_DAT (Page 3124)". If there was no error during the data transmission, the data that have been read are entered in the target range indicated by INPUTS .

The target range must have the same length that you configured for the selected component.

If you read from a DP standard slave with a modular configuration or with several DP identifiers, you can only access the data of one component/DP identifier at the configured start address with a "GETIO" call.

Parameter

The following table shows the parameters of the instruction "GETIO":

Parameter	Declaration	Data type	Memory area	Description
ID	Input	HW_SUB-MODULE	I, Q, M, D, L or constant	Hardware ID of the DP standard slave / PROFINET IO device.
STATUS	Output	DWORD	I, Q, M, D, L	Contains the error information of "DPRD_DAT (Page 3124)" in the form DW#16#40xxxx00.
LEN	Output	INT	I, Q, M, D, L	Amount of data read in bytes
INPUTS	InOut	VARIANT	I, Q, M, D	Target range for the read data. It must have the same length as the range that you configured for the selected DP standard slave / PROFINET IO device. Only the BYTE data type is permitted.

You will find more detailed information on valid data types in "Overview of the valid data types (Page 1908)".

STATUS parameter

See also: DPRD_DAT: Read consistent data of a DP standard slave (Page 3124).

SETIO: Transfer process image

Description

You use the instruction "SETIO" to consistently transfer data from the source range defined by the parameter OUTPUTS to the addressed DP standard slave / PROFINET IO device, and, if necessary, to the process image (if you have configured the relevant address area of the DP standard slave / PROFINET IO device as a consistent range in a process image). "SETIO" calls the instruction "DPWR_DAT (Page 3126)".

The source range must have the same length that you configured for the selected component.

In the case of a DP standard slave / PROFINET IO device with modular configuration or with several DP identifiers, you can only access one DP identifier / component per "SETIO" call.

Parameters

The following table shows the parameters of the "SETIO" instruction:

Parameter	Declaration	Data type	Memory area	Description
ID	Input	HW_SUBMOD-ULE	I, Q, M, D, L or constant	Hardware ID of the DP standard slave / PROFINET IO device.
STATUS	Output	DWORD	I, Q, M, D, L	Contains the error information of "DPWR_DAT (Page 3126)" in the form DW#16#40xxxx00.
OUTPUTS	InOut	VARIANT	I, Q, M, D	Source range for the data to be written. It must have the same length as the range that you configured for the selected DP standard slave / PROFINET IO device. Only the BYTE data type is permitted.

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameter STATUS

See also: DPWR_DAT: Write consistent data of a DP standard slave (Page 3126).

GETIO_PART: Read process image area

Description

You use the instruction "GETIO_PART" to consistently read out a related part of the inputs of an IO module. "GETIO_PART" calls the instruction "DPWR_DAT (Page 3124)".

Use the ID input parameter to select the IO module by means of the hardware ID.

You use the OFFSET and LEN parameters to specify the portion of the process image area to be read. If the input area spanned by OFFSET and LEN is not completely covered by the module, the block returns the error code DW#16#40**80B7**00.

The length of the target range must be larger than or equal to the amount of bytes to be read:

- If there was no error during the data transmission, ERROR receives the value FALSE. The data that are read are written to the target range defined at the INPUTS parameter.
- If there was no error during the data transmission, ERROR receives the value TRUE. The STATUS parameter receives the error information from "DPRD_DAT".
- If the target range is greater than LEN, then the first LEN bytes of the target range will be written. ERROR receives the value FALSE.

Parameters

The following table shows the parameters of the "GETIO_PART" instruction:

Parameter	Declaration	Data type	Memory area	Description
ID	Input	HW_SUBMOD-ULE	I, Q, M, D, L or constant	Hardware identifier of the module
OFFSET	Input	INT	I, Q, M, D, L or constant	Number of the first byte to be read in the process image for the component (smallest possible value: 0).
LEN	Input	INT	I, Q, M, D, L or constant	Number of bytes to be read.
STATUS	Output	DWORD	I, Q, M, D, L	Contains the error information of "DPRD_DAT" in the form DW#16#40xxxx00, if ERROR = TRUE.
ERROR	Output	BOOL	I, Q, M, D, L	Error display: ERROR = TRUE if an error occurs when "DPRD_DAT" is called.
INPUTS	InOut	VARIANT	I, Q, M, D	Target range for read data: If the target range is greater than LEN, the first LEN bytes of the target range are written.

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameter STATUS

See "RET_VAL" parameter of the "DPRD_DAT (Page 3124)" instruction.

SETIO_PART: Transfer process image area

Description

You can use the "SETIO_PART" instruction to consistently write data from the source area spanned by OUTPUTS to the outputs of an IO module. "SETIO_PART" calls the instruction "DPWR_DAT (Page 3126)".

Use the ID input parameter to select the IO module by means of the hardware ID.
You use the OFFSET and LEN parameters to specify the portion of the process image area to be written for the components addressed by means of ID. If the output area spanned by OFFSET and LEN is not completely covered by the module, the block returns the error code DW#16#40**80B7**00.

The length of the source range must be greater than or equal to the number of bytes to be written:

- If there was no error during the data transmission, ERROR receives the value FALSE.
- If there was an error during the data transmission, ERROR receives the value TRUE, and STATUS receives the error information of "DPWR_DAT".
- If the source range is greater than LEN, the first LEN bytes from OUTPUTS are transferred. ERROR receives the value FALSE.

Parameter

The following table shows the parameters of the instruction "SETIO_PART":

Parameter	Declaration	Data type	Memory area	Description
ID	Input	HW_SUB-MODULE	I, Q, M, D, L or constant	Hardware identifier of the IO module.
OFFSET	Input	INT	I, Q, M, D, L or constant	Number of the first byte to be written in the process image for the component (smallest possible value: 0).
LEN	Input	INT	I, Q, M, D, L or constant	Number of bytes to be written.
STATUS	Output	DWORD	I, Q, M, D, L	Contains the error information of "DPWR_DAT" in the form DW#16#40xxxx00, if ERROR = TRUE.
ERROR	Output	BOOL	I, Q, M, D, L	Error display: ERROR = TRUE if an error occurs when "DPWR_DAT" is called.
OUTPUTS	InOut	VARIANT	I, Q, M, D	Source range for the data to be written: If the source range is greater than LEN, the first LEN bytes are transferred from OUT-PUTS.

You will find more detailed information on valid data types in "Overview of the valid data types (Page 1908)".

Parameters STATUS and ERROR

See instruction "DPWR_DAT (Page 3126)".

RALRM: Receive interrupt

Description RALRM

Description

The instruction receives an interrupt with all corresponding information from an I/O module (centralized configuration) or from a module of a DP slave or PROFINET IO device and supplies this information to its output parameters.

The information in the output parameters contains the start information of the called OB as well as information of the interrupt source.

For a central configuration, the configuration of the data structure of the destination area AINFO corresponds to the data structure of PROFINET IO.

Call "RALRM" only within the interrupt OB started by the CPU operating system as a result of the I/O interrupt that is to be examined.

Note

If you call "RALRM" in an OB whose start event is not an I/O interrupt, the instruction will provide correspondingly reduced information in its outputs.
Make sure to use different instance DBs when you call "RALRM" in different OBs. If you evaluate data resulting from an "RALRM" call outside of the associated interrupt OB, you should moreover use a separate instance DB per OB start event.

Note

The interface of the "RALRM" instruction is identical to the "RALRM" FB defined in "PROFIBUS Guideline PROFIBUS Communication and Proxy Function Blocks according to IEC 61131-3".

Calling RALRM

"RALRM" can be called in three operating modes (MODE parameter). These are explained in the table below.

MODE	RALRM ...
0	... shows the component that triggered the interrupt in the ID output parameter and writes TRUE in the NEW output parameter.
1	... writes all output parameters, independent of the interrupt triggering component.
2	... checks whether the component specified in the F_ID input parameter has triggered the interrupt. • If not, NEW = FALSE • If yes, NEW = TRUE and all other output parameters are written.

Parameters

The following table shows the parameters of the "RALRM" instruction:

Parameter	Declaration	Data type	Memory area	Description
MODE	Input	INT	I, Q, M, D, L or constant	Mode
F_ID	Input	HW_IO	I, Q, M, D, L or constant	Hardware identifier of the module. The number is assigned automatically and is stored in the hardware configuration properties of the component or interface.
MLEN	Input	UINT	I, Q, M, D, L or constant	Maximum length of the interrupt information to be received in bytes. With MLEN = 0, all data specified at the AINFO parameter are read.
NEW	Output	BOOL	I, Q, M, D, L	A new interrupt was received.
STATUS (Page 3078)	Output	DWORD	I, Q, M, D, L	Error code
ID	Output	HW_IO	I, Q, M, D, L	Hardware identifier of the module from which the interrupt was received.

Parameter	Declaration	Data type	Memory area	Description
LEN	Output	UINT	I, Q, M, D, L	Length of the received interrupt information
TINFO (Page 3082)	InOut	VARIANT	I, Q, M, D, L	Destination area for OB start and management information
AINFO (Page 3100)	InOut	VARIANT	I, Q, M, D, L	Destination area for header information and additional interrupt information For AINFO , you should provide a length of at least MLEN bytes.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Note

If you select a destination area (Page 3107)TINFO or AINFO that is too short, RALRM cannot enter the full information.

Parameter STATUS

Description

The STATUS output parameter contains error information. If it is interpreted as ARRAY[1...4] of BYTE, the error information has the following structure:

Field element	Name	Meaning
STATUS[1]	Function_Num	• B#16#00, if no error • Function ID from DPV1-PDU: In the event of an error, B#16#80 is output (in the event of an error reading a data record B#16#DE and writing a data record B#16#DF). If no DPV1 protocol element is used, then B#16#C0 will be output.
STATUS[2]	Error_Decode	Location of the error ID
STATUS[3]	Error_Code_1	Error ID
STATUS[4]	Error_Code_2	Manufacturer-specific error ID extension

Field element STATUS[2]

STATUS[2] can have the following values:

Error_Decode (B#16#...)	Source	Meaning
00 to 7F	CPU	No error or no warning
80	DPV1	Error according to IEC 61158-6
81 to 8F	CPU	B#16#8x shows an error in the xth call parameter of the instruction.
FE, FF	DP profile	Profile-specific error

Field element STATUS[3]

STATUS[3] can have the following values:

Error_Decode (B#16#...)	Error_Code_1 (B#16#...)	Explanation according to DVP1	Meaning
00	00		No error, no warning
70	00	reserved, reject	Initial call; no active data record transfer
	01	reserved, reject	Initial call; data record transfer has started
	02	reserved, reject	Intermediate call; data record transfer already active
80	81		The system data type at parameter TINFO does not match the call environment of the instruction. The used system data type must match the organization block in the user program (example: for a time-delay interrupt OB you need the system data type TI_Delay).
	90	reserved, pass	Invalid logical start address
	92	reserved, pass	Illegal type for VARIANT pointer
	93	reserved, pass	The DP component addressed via ID or F_ID is not configured.
	96		The "RALRM (Page 3076)" cannot supply the OB start information, management information, header information, or additional interrupt information. For OBs 4x, 55, 56, 57, 82 and 83, you can use the "DPNRM_DG (Page 3139)" instruction to read the current diagnostic frame of the relevant DP slave asynchronously (address information from OB start information).
	A0	read error	Negative acknowledgment while reading the module
	A1	write error	Negative acknowledgment when writing to the module
	A2	module failure	DP protocol error at layer 2 (e.g., slave failure or bus problems)
	A3	reserved, pass	• PROFIBUS DP: DP protocol error with Direct-Data-Link-Mapper or User-Interface/User • PROFINET IO: General CM error
	A4	reserved, pass	Communication on PBUS+ disrupted
	A5	reserved, pass	–
	A7	reserved, pass	DP slave or module is occupied (temporary error
	A8	version conflict	DP slave or module reports non-compatible versions
	A9	feature not supported	Function is not supported by DP slave or module
	AA to AF	user specific	DP slave or module reports a manufacturer-specific error in its application. Please check the documentation from the manufacturer of the DP slave or module.
	B0	invalid index	Data record not known in module Illegal data record number ≥ 256

Error_Decode (B#16#...)	Error_Code_1 (B#16#...)	Explanation according to DVP1	Meaning
	B1	write length error	Error at length specification: • With "RALRM (Page 3076)": length error in AINFO (Page 3100) • With "RDREC (Page 3069)": length error in MLEN • With "WRREC (Page 3071)": length error in LEN
	B2	invalid slot	The configured slot is not assigned.
	B3	type conflict	Actual module type does not match specified module type
	B4	invalid area	DP slave or module reports access to an invalid area
	B5	state conflict	DP slave or module not ready
	B6	access denied	DP slave or module denies access
	B7	invalid range	DP slave or module reports an invalid range for a parameter or value
	B8	invalid parameter	DP slave or module reports an invalid parameter
	B9	invalid type	DP slave or module reports an invalid type With "RDREC (Page 3069)": buffer too small (subsets cannot be read) With "WRREC (Page 3071)": buffer too small (subsets cannot be written)
	BA to BF	user specific	DP slave or module reports a manufacturer-specific error when accessing. Please check the documentation from the manufacturer of the DP slave or module.
	C0	read constrain conflict	With "WRREC (Page 3071)": the data can only be written when the CPU is in STOP mode. Note: this means that writing by the user program is not possible. You can only write the data online with PG/PC. With "RDREC (Page 3069)": the module routes the data record, but either no data is present or the data can only be read when the CPU is in STOP mode. Note: if data can only be read when the CPU is in STOP mode, then an evaluation by the user program is not possible. In this case, you can only read the data online with PG/PC.
	C1	write constrain conflict	The data of the previous write job on the module for the same data record have not yet been processed by the module.
	C2	resource busy	The module is currently processing the maximum possible number of jobs for a CPU.
	C3	resource unavailable	The required operating resources are currently occupied.
	C4		Internal temporary error. Job could not be executed. Repeat the job. If this error occurs often, check your installation for sources of electrical interference.
	C5		DP slave or module not available.
	C6		Data record transfer was canceled due to priority class cancellation
	C7		Job aborted due to warm or cold restart on the DP master

Error_Decode (B#16#...)	Error_Code_1 (B#16#...)	Explanation according to DVP1	Meaning
	C8 to CF		DP slave or module reports a manufacturer-specific resource error. Please check the documentation from the manufacturer of the DP slave or module.
	Dx	user specific	DP slave specific. Refer to the description of the DP slave.
81	00 to FF		Error in the initial call parameter (with "RALRM (Page 3076)": MODE)
	00		Illegal operating mode
82	00 to FF		Error in the second call parameter
:	:		:
88	00 to FF		Error in the eighth call parameter (with "RALRM (Page 3076)": TINFO (Page 3082))
	01		Wrong syntax ID
	23		Quantity structure exceeded or target range too small
	24		Wrong range ID
	32		DB/DI no. out of user range
	3A		DB/DI no. is NULL for area ID DB/DI or specified DB/DI does not exist
89	00 to FF		Error in the ninth call parameter (with "RALRM (Page 3076)": AINFO (Page 3100))
	01		Wrong syntax ID
	23		Quantity structure exceeded or target range too small
	24		Wrong range ID
	32		DB/DI no. out of user range
	3A		DB/DI no. is NULL for area ID DB/DI or specified DB/DI does not exist
8A	00 to FF		Error in the 10th call parameter
:	:		:
8F	00 to FF		Error in the 15th call parameter
FE, FF	00 to FF		Profile-specific error

Field element STATUS[4]

With DPV1 errors, the DP master passes on STATUS[4] to the CPU and the instruction. Without DPV1 error, this value is set to 0, with the following exceptions for "RDREC":

- STATUS[4] contains the target range length from RECORD, if MLEN > the target range length from RECORD
- STATUS[4]=MLEN, if the actual data record length < MLEN < the target range length from RECORD
- STATUS[4]=0, if STATUS[4]> 255 would have to be set

In PROFINET IO, STATUS[4] has the value "0".

Parameter TINFO

Data structure of the destination area TINFO

The data structure of the destination area TINFO contains the start information of the organization block in which "RALRM" is currently being called.

The TINFO destination area can contain the start information with standard access or optimized access. The format of the start information in the TINFO destination area must always match the start information of the corresponding organization block.

- The start information of an OB with standard access is always stored in the first 20 bytes of the "Temp" section in the block interface. Use the "TI_Classic" data structure for this.
- The start information of an OB with optimized access is always written to the "Input" section. Use a data structure for the specific OB type for these OBs.

Changing the block access (standard/optimized) also changes the block interface.

The following table provides an overview of the data structures that are used depending on the organization block at the TINFO parameter.

Name of the data structure		S7-1200 CPUs as of version	S7-1500 CPUs as of version	Data structure used for:
Data structure for organization blocks with standard access				
	TI_Classic	-	V1	Organization blocks without optimized block access.
Data structure for organization blocks with optimized block access				

Name of the data structure		S7-1200 CPUs as of version	S7-1500 CPUs as of version	Data structure used for:
	TI_ProgramCycle	V2	V1	Cycle OB (program cycle)
	TI_Startup	V2	V1	Startup OB (startup)
	TI_Delay	V2	V1	Time delay interrupt
	TI_Cyclic	V2	V1	Cyclic interrupt OB
	TI_HWInterrupt	V2	V1	Hardware interrupt OB
	TI_TimeError	V2	V1	Time error OB
	TI_DiagnosticInterrupt	V2	V1	Diagnostic error interrupt OB
	TI_PlugPullModule	V2	V1	Pull/plug of modules OB
	TI_StationFailure	V2	V1	Rack or station failure OB
	TI_ProgIOAccessError	V2	V1	• Programming error OB • I/O access error OB
	TI_TimeOfDay	V2	V1	Time-of-day interrupt OB
	TI_SynchCycle	-	V1	Synchronous cycle interrupt OB
	TI_Submodule	V2	V1	• Status interrupt OB • Update interrupt OB • OB for manufacturer or profile-specific interrupt

Data structure for organization blocks with standard access

The following shows the TI_Classic data structure:

Parameter	Data type	Byte	Description
TI_Classic			Data structure for organization blocks with optimized block access.

Parameter	Data type	Byte	Description
Bytes 0 to 19: Start information of the OB in which "RALRM" is currently being called.*			
EV_CLASS	BYTE	0	Event class Example OB1: • Bits 0-3: ID of the event (1 = incoming event) • Bits 4-7: Event class (1 = Event class 1)
EV_NUM	BYTE	1	Event number (depending on OB type) Example OB1 (SCAN_1): • SCAN_1 = 1 for first call • SCAN_1 = 3 for all additional calls
PRIORITY	BYTE	2	Priority class
NUM	BYTE	3	OB number
TYP2_3	BYTE	4	Additional information
TYP1	BYTE	5	Different information is stored in the BYTES "TYP2_3" and "TYPE 1" depending on the OB type used. What these are is described in the documentation for the organization blocks. Example (OB1): • TYP2_3: OB1_RESERVED_1 (reserved) • TYP1: OB1_RESERVED_2 (reserved)
ZI1	WORD	6 to 7	Additional information Different information is stored in "ZI1" depending on the OB type used. What these are is described in the documentation for the organization blocks. Example (OB1): • ZI1: OB1_PREV_CYCLE (runtime of previous cycle in ms)
ZI2_3	DWORD	8 to 11	Additional information Different information is stored in "ZI2_3" depending on the OB type used. What these are is described in the documentation for the organization blocks. Example (OB1): • ZI2: OB1_MIN_CYCLE (minimum cycle time (ms) since the last startup) • ZI3: OB1_MAX_CYCLE (maximum cycle time (ms) since the last startup)
OB_DATE_TIME	DATE_AND_TIME (DT)	12 to 19	Date and time-of-day when the OB was called.
Bytes 20 and 21: Address information			
address	WORD	20 and 21	Address information like S7-300/400 CPUs: • In a central configuration, the rack number (0-31):  • For a distributed configuration with PROFIBUS DP: – DP master system ID (1-31) – Station number (0-127).

Parameter	Data type	Byte	Description
			 • In a distributed configuration with PROFINET IO: – The last two positions in the PROFINET IO system ID (0-15). To obtain the complete PROFINET IO system ID, you must add 100 (decimal) to it. – Station number (0-2047). Bytes 22 to 31: Management information			
slv_prfl	BYTE	22	Slave profile like S7-300/400 CPUs: • In a central configuration: 0 (data record 0 or data record 1) • In a distributed configuration: – Bit 0 to 3: Slave type - 0000: DP (structure data record 0) - 0001: DPS7 (structure data record 0 or data record 1) - 0010: DPS7 V1 (structure data record 0 or data record 1) - 0011: DPV1 (structure according to PROFIBUS DP standard) - 0100 – 0111: Reserved - 1000: PROFINET IO (structure according to PROFINET IO standard) - from 1001: Reserved – Bit 4 to 7: Profile type (reserved)
intr_type	BYTE	23	Interrupt info type like S7-300/400 CPUs: • In a central configuration: 0 • In a distributed configuration: – Bit 0 to 3: Interrupt info type - 0000: Interrupt comes from a configured remote module - 0001: Interrupt comes from a non-DPV1 slav / non IO device or a slot that is not configured - 0010: Interrupt generated in the CPU - from 0011: Reserved – Bit 4 to 7: Structure version - 0000: Initial - from 0001: Reserved
flags1	BYTE	24	Flags of the PROFIBUS DP master interface module / PROFINET IO controller interface module like S7-300/400 CPUs: • In a central configuration: 0 • In a distributed configuration: – Bit 0 = 0: Interrupt originating from an integrated interface module (PROFINET IO or PROFIBUS DP)

Parameter		Data type	Byte	Description
				– Bit 0 = 1: Interrupt originating from an external interface module (PROFINET IO or PROFIBUS DP) – Bit 1 to 7: Reserved
	flags2	BYTE	25	Flags of the PROFIBUS DP master interface module / PROFINET IO controller interface module like S7-300/400 CPUs: • In a central configuration: 0 • For a distributed configuration with PROFIBUS DP: – Bit 0: EXT_DIAG_FLAG from the diagnostics message frame, or 0 if this bit does not exist in the interrupt The bit is 1 if the DP slave is faulty. – Bit 1 to 7: Reserved • In a distributed configuration with PROFINET IO: – Bit 0: ARDiagnosisState or 0 if there is no information in the interrupt. The bit is 1 if the IO device is faulty. – Bit 1 to 7: Reserved
	id	UINT	26 and 27	Management information • In a central configuration: 0 • For a distributed configuration with PROFIBUS DP: PROFIBUS ID number as unique identifier of the PROFIBUS DP slave • In a distributed configuration with PROFINET IO: PROFINET IO device ID number as unique identifier of the PROFINET IO device
	manufacturer	UINT	28 and 29	Manufacturer ID (only in a distributed configuration with PROFINET IO).
	instance	UINT	30 and 31	Ident number of the instance (only in a distributed configuration with PROFINET IO).
*The start information depends on the OB used. You can find the start information of each OB type at the interface or in the documentation of the OB.				

Data structures for organization blocks with optimized block access

The data structures for organization blocks with optimized block access have the following format:

- Bytes 0 to 3: Format of the start information, class and number of the called OB (same structure for all data structures).
- Bytes 4 to 19: Optimized start information (structure depends on the OB type). The data in bytes 4 to 19 correspond to the structure and content of the corresponding OB interface.
- Bytes 20 to 31: In addition, the address and management information for certain OBs. The data in bytes 20 to 31 correspond to the data of 20 to 31 bytes of the TI_Classic data structure.

The format of the data structures is described in the following tables.

Table 11-42 **Cycle OB: Data structure TI_ProgramCycle**

Parameter		Data type	Byte	Description
TI_ProgramCycle				Data structure for cycle OB
	SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
	OB_Class	USINT	1	OB class (=1)
	OB_Nr	UINT	2	OB number (1...32767).
	Initial_Call	BOOL	4	= TRUE in the first call of this OB: • Transition from STOP or HOLD to RUN • After reloading
	Remanence	BOOL	5	= TRUE, if retentive data are available.

Table 11-43 **Startup OB: Data structure TI_Startup**

Parameter		Data type	Byte	Description
TI_Startup				Data structure for startup OB
	SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
	OB_Class	USINT	1	OB class (=100)
	OB_Nr	UINT	2	OB number (1...32767).
	LostRetentive	BOOL	4	=TRUE, if the contents of retentive data areas have been lost.
	LostRTC	BOOL	5	=TRUE, if the time-of-day of the real-time clock has been lost.

Table 11-44 **Time delay interrupt OB: Data structure TI_Delay**

Parameter		Data type	Byte	Description
TI_Delay				Data structure for time delay interrupt OB
	SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
	OB_Class	USINT	1	OB class (=20)
	OB_Nr	UINT	2	OB number (1...32767).
	Sign	WORD	4	User ID: Input parameter SIGN from the call of the "SRT_DINT (Page 3230)" instruction.

Table 11-45 **Cyclic interrupt OB: Data structure TI_Cyclic**

Parameter	Data type	Byte	Description
TI_Cyclic			Data structure for cyclic interrupt OB
SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
OB_Class	USINT	1	OB class (=30)
OB_Nr	UINT	2	OB number (1...32767).
Initial_Call	BOOL	4	= TRUE in the first call of this OB • At the transition from STOP or HOLD to RUN • After reloading
Event_Count	INT	6	Number of discarded start events since the last start of this OB.

Table 11-46 **Hardware interrupt OB: Data structure TI_HWInterrupt**

Parameter	Data type	Byte	Description
TI_HWInterrupt			Data structure for hardware interrupt OB
SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
OB_Class	USINT	1	OB class (=40)
OB_Nr	UINT	2	OB number (1...32767).
LADDR	HW_IO	4	Hardware identifier of the module that triggers the hardware interrupt.
USI	WORD	6	Identifier for future extensions (not user-relevant).
IChannel	USINT	8	Number of the channel that triggered the hardware interrupt.
EventType	BYTE	9	Identifier for the event type associated with the event triggering the interrupt (e.g., rising edge). You can find this ID in the description of the respective module.
address	WORD	20	See "address" parameter for the TI_Cassic. data structure
slv_prfl	BYTE	22	See "slv_prfl" parameter for the TI_Cassic data structure.
intr_type	BYTE	23	See "intr_type" parameter for the TI_Cassic data structure.
flags1	BYTE	24	See "flags1" parameter for the TI_Cassic data structure.
flags2	BYTE	25	See "flags2" parameter for the TI_Cassic data structure.
id	UNIT	26	See "id" parameter for the TI_Cassic data structure.
manufacturer	UNIT	28	See "manufacturer" parameter for the TI_Cassic data structure.
instance	UNIT	30	See "instance" parameter for the TI_Cassic data structure.

Table 11-47 **Time error OB: Data structure TI_TimeError**

Parameter	Data type	Byte	Description
TI_TimeError			Data structure for time error OB
SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
OB_Class	USINT	1	OB class (=80)
OB_Nr	UINT	2	OB number (1...32767).
Csg_OBnr	OB_ANY	4	Number of the OB that was being executed when the time error occurred.
Fault_ID	BYTE	7	Error code. Possible values: • B#16#01: Cycle time exceeded • B#16#02: The requested OB is still being processed. • B#16#05: Expired time-of-day interrupt due to time jump. • B#16#06: Expired time-of-day interrupt upon re-entry into RUN after HOLD. • B#16#07: Overflow of the OB request buffer for the current priority class. • B#16#08: Isochronous mode interrupt - time error. • B#16#09: Interrupt loss due to high interrupt load • B#16#0B: Technology synchronization interrupt - time error
Csg_Prio	UNIT	8	Priority of the OB that was being executed when the time error occurred.

Table 11-48 **Diagnostic interrupt OB: Data structure TI_DiagnosticInterrupt**

Parameter	Data type	Byte	Description
TI_DiagnosticInterrupt			Data structure for diagnostic interrupt OB
SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
OB_Class	USINT	1	OB class (=82)
OB_Nr	UINT	2	OB number (1...32767).
LADDR	HW_ANY	4	Hardware identifier of the hardware object that triggered the diagnostic interrupt.
IO_State	WORD	6	Status of the hardware object: • Bit 0: Good • Bit 1: Disabled • Bit 2: Maintenance required • Bit 3: Maintenance demanded • Bit 4: Error • Bit 5: Not accessible • Bit 6: Qualified • Bit 7: Not available
Channel	UINT	8	Channel number
MultiError	BOOL	10	=TRUE, if there is more than one error.
address	WORD	20	See "address" parameter for the TI_Cassic. data structure
slv_prfl	BYTE	22	See "slv_prfl" parameter for the TI_Cassic data structure.
intr_type	BYTE	23	See "intr_type" parameter for the TI_Cassic data structure.
flags1	BYTE	24	See "flags1" parameter for the TI_Cassic data structure.
flags2	BYTE	25	See "flags2" parameter for the TI_Cassic data structure.
id	UINT	26	See "id" parameter for the TI_Cassic data structure.
manufacturer	UINT	28	See "manufacturer" parameter for the TI_Cassic data structure.
instance	UINT	30	See "instance" parameter for the TI_Cassic data structure.

Table 11-49 **Pull/plug interrupt OB: Data structure** TI_PlugPullModule

Parameter	Data type	Byte	Description
TI_PlugPullModule			Data structure for pull/plug interrupt OB
SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
OB_Class	USINT	1	OB class (=83)
OB_Nr	UINT	2	OB number (1...32767).
LADDR	HW_IO	4	Hardware identifier of the affected module or submodule
Event_Class	BYTE	6	• B#16#38: (Sub)module plugged • B#16#39: (Sub)module pulled or not responding
Fault_ID	BYTE	7	Error code The following table shows the events that cause the start of the pull/plug interrupt OB. • With Event_Class = B#16#38 - module/submodule plugged: – B#16#54: Submodule plugged and matches configured submodule – B#16#55: Submodule plugged, but does not match configured submodule – B#16#56: Submodule plugged, but error in module parameter assignment – B#16#57: Submodule or module plugged, but with a fault or maintenance – B#16#58: Submodule access error corrected – B#16#61: Module plugged, module type OK – B#16#63 Module plugged but module type is incorrect – B#16#64: Module plugged but faulty (module ID cannot be read) – B#16#65: Module plugged, but error in module parameter assignment – B#16#66: Module responding again, load voltage error corrected • With Event_Class = B#16#39 - module/submodule pulled or not responding: – B#16#51: Module pulled – B#16#54: Submodule pulled – B#16#61: Module pulled or not responding – B#16#66: Module not responding, load voltage error
address	WORD	20	See "address" parameter for the TI_Cassic. data structure
slv_prfl	BYTE	22	See "slv_prfl" parameter for the TI_Cassic data structure.
intr_type	BYTE	23	See "intr_type" parameter for the TI_Cassic data structure.
flags1	BYTE	24	See "flags1" parameter for the TI_Cassic data structure.
flags2	BYTE	25	See "flags2" parameter for the TI_Cassic data structure.
id	UINT	26	See "id" parameter for the TI_Cassic data structure.
manufacturer	UINT	28	See "manufacturer" parameter for the TI_Cassic data structure.
instance	UINT	30	See "instance" parameter for the TI_Cassic data structure.

Table 11-50 **Rack error OB: Data structure TI_StationFailure**

Parameter	Data type	Byte	Description
TI_StationFailure			Data structure for rack error OB

Parameter	Data type	Byte	Description
SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
OB_Class	USINT	1	OB class (=86)
OB_Nr	UINT	2	OB number (1...32767).
LADDR	HW_Device	4	Hardware identifier of the defective hardware object.
Event_Class	BYTE	6	• B#16#32: Activation of a station with the "D_ACT_DP" instruction • B#16#33: Deactivation of a station with the "D_ACT_DP" instruction • B#16#38: Outgoing event • B#16#39: Incoming event
Fault_ID	BYTE	7	Error code The error code is used to output the event that caused the start of the rack error OB. • Event_Class = B#16#39, FAULT_ID = C1: Expansion unit failure • Event_Class = B#16#38, FAULT_ID = C1: Expansion unit return • Event_Class = B#16#38, FAULT_ID = C2: Expansion unit return (outgoing expansion unit failure with discrepancy between expected and actual configuration) • Event_Class = B#16#39, FAULT_ID = C3: Distributed I/O: Failure of a DP master system • Event_Class = B#16#38, FAULT_ID = C4: Failure of a DP station • Event_Class = B#16#38, FAULT_ID = C5: Return of a DP station, but station faulty • Event_Class = B#16#38, FAULT_ID = C6: Expansion unit return, but error in module parameter assignment • Event_Class = B#16#38, FAULT_ID = C7: Return of a DP station, but error in module parameter assignment • Event_Class = B#16#38, FAULT_ID = C8: Return of a DP station, but discrepancy between expected and actual configuration • Event_Class = B#16#32/33, FAULT_ID = C9: Activation/deactivation of a DP slave with "D_ACT_DP" • Event_Class = B#16#39, FAULT_ID = CA: PROFINET IO system failure • Event_Class = B#16#39/38, FAULT_ID = CB: PROFINET IO station failure/ station return • Event_Class = B#16#38, FAULT_ID = CC: PROFINET IO station return with problem or maintenance • Event_Class = B#16#38, FAULT_ID = CD: PROFINET IO station return, expected configuration different from actual configuration • Event_Class = B#16#38, FAULT_ID = CE: PROFINET IO station return, error in module parameter assignment • Event_Class = B#16#32/33, FAULT_ID = CF: Activation/deactivation of a PROFINET IO device with the "D_ACT_DP" instruction • Event_Class = B#16#39/38, FAULT_ID = F8: Failure/return of some of the submodules of a PROFINET I-device

Parameter		Data type	Byte	Description
				• Event_Class = B#16#38, FAULT_ID = F9: Return of some of the submodules of a PROFINET I-device with a device configuration difference
	address	WORD	20	See "address" parameter for the TI_Cassic. data structure
	slv_prfl	BYTE	22	See "slv_prfl" parameter for the TI_Cassic data structure.
	intr_type	BYTE	23	See "intr_type" parameter for the TI_Cassic data structure.
	flags1	BYTE	24	See "flags1" parameter for the TI_Cassic data structure.
	flags2	BYTE	25	See "flags2" parameter for the TI_Cassic data structure.
	id	UINT	26	See "id" parameter for the TI_Cassic data structure.
	manufacturer	UINT	28	See "manufacturer" parameter for the TI_Cassic data structure.
	instance	UINT	30	See "instance" parameter for the TI_Cassic data structure.

Table 11-51 **Programming error OB / I/O access error OB: Data structure TI_ProgIOAccessError**

Parameter	Data type	Byte	Description*
TI_ProgIOAccessError			Data structure for programming error OB and I/O access error OB

Parameter	Data type	Byte	Description*
SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
OB_Class	USINT	1	OB class: • =121 for programming error OB • =122 for I/O access error OB
OB_Nr	UINT	2	OB number (1...32767).
BlockNr	UINT	4	Number of the block in which the programming error occurred.
Reaction	USINT	6	• 0: Ignore error • 1: Substitute bad value • 2: Skip command
Fault_ID	BYTE	7	Error code • B#16#21: BCD conversion error • B#16#22: Area length error when reading • B#16#23: Area length error when writing • B#16#24: Range error when reading • B#16#25: Range error when writing • B#16#26: Error in timer no. • B#16#27: Error in counter no. • B#16#28: Read access to a byte, word or double word with a pointer whose bit address is not zero • B#16#29: Write access to a byte, word or double word with a pointer whose bit address is not zero • B#16#:30: Write access to a write-protected global DB • B#16#31: Write access to a write-protected instance DB • B#16#32: DB number error when accessing a global DB • B#16#33: DB number error when accessing an instance DB • B#16#34: Number error during FC call • B#16#35: Number error during FB call • B#16#42: I/O access error, reading • B#16#43: I/O access error, writing • B#16#3A: Access to a DB that is not loaded; the DB number is located in the permitted area • B#16#3C: Access to an FC that is not loaded; the FC number is within the permissible range • B#16#3D: Access to an instruction (SFC) that is not loaded; the SFC number is within the permissible range • B#16#3E: Access to an FB that is not loaded; the FB number is within the permissible range • B#16#3F: Access to an SFB that is not available; the SFB number is within the permissible range
BlockType	USINT	8	Type of block in which the error has occurred:

Parameter		Data type	Byte	Description*
				• OB: B#16#88 • FC: B#16#8C • FB: B#16#8E
	Area	USINT	9	Memory area in which the incorrect access occurred: • Local data: B#16#40 to 4E, 86, 87, 8E, 8F, C0 to CE • Process image input: B#16#01 • Process image output: B#16#02 • Technology DB: B#16#04 • I: B#16#81 • Q: B#16#82 • M: B#16#83 • DB: B#16#84, 85, 8A, 8B
	DBNr	DB_ANY	10	DB no. if AREA = DB (global DB or instance DB) Only relevant for programming error OB.
	Csg_OBNr	OB_ANY	12	OB number: • 121: Programming error OB • 122: I/O access error OB
	Csg_Prio	USINT	14	OB priority
	Width	USINT	15	Type of access during which the error occurred: • Bit: B#16#00 • Byte: B#16#01 • Word: B#16#02 • DWord: B#16#03 • LWord: B#16#04
* Only certain output values are possible depending on the OB (I/O access error OB or programming error OB) from which information is read.				

Table 11-52 **Time-of-day interrupt OB: Data structure TI_TimeOfDay**

Parameter		Data type	Byte	Description
TI_TimeOfDay				Data structure for time-of-day interrupt OB
	SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
	OB_Class	USINT	1	OB class (=10)
	OB_Nr	UINT	2	OB number (1...32767).
	CaughtUp	BOOL	4	=TRUE if an OB call was executed subsequently because time was adjusted ahead
	SecondTime	BOOL	5	=TRUE if an OB was called a second time because time was adjusted back. Note: SecondTime is set only once in situations in which the time is set back.

Table 11-53 **Isochronous mode interrupt OB: Data structure TI_SynchCycle**

Parameter	Data type	Byte	Description
TI_SynchCycle			Data structure for isochronous mode interrupt OB
SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
OB_Class	USINT	1	OB class (=61)
OB_Nr	UINT	2	OB number (1...32767).
Initial_Call	BOOL	4	= TRUE in the first call of this OB: • Transition from STOP or HOLD to RUN • After reloading
IO _System	USINT	5	Number of the distributed I/O system triggering the interrupt
Event_Count	INT	6	• = n: Number of lost cycles • = -1: An unknown number of cycles has been lost (e.g., because cycle has changed).
PIP_Input	BOOL	10	=TRUE: The associated process image of the inputs is up-to-date
PIP_Output	BOOL	11	=TRUE: The associated process image of the outputs was transferred to the outputs in good time after the last cycle
SyncCycle-Time	LTIME	16	Calculated cycle time

Table 11-54 **Status interrupt OB / update interrupt OB for manufacturer or profile-specific interrupt: Data structure TI_Submodule**

Parameter		Data type	Byte	Description
TI_Submodule				Data structure for status interrupt OB / update interrupt OB for manufacturer or profile-specific interrupt
	SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
	OB_Class	USINT	1	OB class • =55 for status interrupt OB • =56 for update interrupt OB • =57 for manufacturer or profile-specific interrupt OB
	OB_Nr	UINT	2	OB number (1...32767).
	LADDR	HW_IO	4	Hardware address of the component triggering the interrupt
	Slot	UINT	6	Slot number of the component triggering the interrupt
	Specifier	WORD	8	Interrupt specifier from the interrupt frame
	address	WORD	20	See "address" parameter for the TI_Cassic. data structure
	slv_prfl	BYTE	22	See "slv_prfl" parameter for the TI_Cassic data structure.
	intr_type	BYTE	23	See "intr_type" parameter for the TI_Cassic data structure.
	flags1	BYTE	24	See "flags1" parameter for the TI_Cassic data structure.
	flags2	BYTE	25	See "flags2" parameter for the TI_Cassic data structure.
	id	UINT	26	See "id" parameter for the TI_Cassic data structure.
	manufacturer	UINT	28	See "manufacturer" parameter for the TI_Cassic data structure.
	instance	UINT	30	See "instance" parameter for the TI_Cassic data structure.

Parameter AINFO

Data structure of the destination area AINFO with interrupts from PROFIBUS DP

Byte	Meaning	
0 to 3	Header information, for exact description, see below	
4 to 63	Additional interrupt information: data for the respective interrupt:	
	distributed:	ARRAY[0] to ARRAY[59]

Structure of the header information with interrupts from PROFIBUS DP

Byte	Data type	Meaning	
0	BYTE	Length of the received interrupt information in bytes	
		central:	4 to 224
		distributed:	4 to 63

Byte	Data type	Meaning		
1	BYTE	central:	Reserved	
		distributed:	ID for the interrupt type	
			1: 2: 3: 4: 5: 6: 31	Diagnostics interrupt Process interrupt Pull interrupt Plug interrupt Status interrupt Update interrupt Failure of an expansion device, DP master system or DP station
			32 to 126:	Manufacturer-specific interrupt
2	BYTE	Slot number of the component that triggered the interrupt		
3	BYTE	central:	Reserved	
		distributed:	Specifier	
			Bits 0 and 1:	0: No further information; 1: Incoming event, fault at slot 2: Outgoing event, fault at slot cleared 3: Outgoing event, slot still faulty
			Bit 2:	Add_Ack
			Bits 3 to 7:	Sequence number

Data structure of the destination area AINFO with interrupts from PROFINET IO or central I/O devices

Byte	Meaning
0 to 25	Header information, for exact description, see below
26 to 1431	Additional interrupt information: Standardized diagnostic data for the respective interrupt: ARRAY[0] to ARRAY[1405] Note: The additional interrupt information may also be omitted.

Structure of the header information with interrupts from PROFINET IO or central I/O devices

Byte	Data type	Meaning
0 and 1	WORD	• Bits 0 to 7: Block type • Bits 8 to 15: Reserved
2 and 3	WORD	Block length
4 and 5	WORD	Version: • Bits 0 to 7: low byte • Bits 8 to 15: high byte

Byte	Data type	Meaning
6 and 7	WORD	ID for interrupt type: • 1: Diagnostics interrupt (incoming) • 2: Process interrupt • 3: Remove module interrupt • 4: Insert module interrupt • 5: Status interrupt • 6: Update interrupt • 7: Redundancy interrupt • 8: Controlled by supervisor • 9: Released by supervisor • 10: Configured module not inserted • 11: Return of the sub-module • 12: Diagnostics interrupt (outgoing) • 13: Slave-to-slave connection alarm • 14: Neighborhood change alarm • 15: Clock synchronization message (bus end) • 16: Clock synchronization alarm (device end) • 17: Network component alarm • 18: Time synchronization alarm (bus end) • 19 to 31: Reserved • 32 to 127: Manufacturer-specific interrupt • 128 to 65535: Reserved
8 to 11	DWORD	API (Application Process Identifier)
12 to 13	WORD	Slot number of the component triggering the interrupt (value range 0 to 65535)
14 to 15	WORD	Submodule slot number of the component triggering the interrupt (value range 0 to 65535)
16 to 19	DWORD	Module identification; specific information on the source of the interrupt

Byte	Data type	Meaning
20 to 23	DWORD	Submodule identification; specific information on the source of the interrupt
24 to 25	WORD	Interrupt specifier: • Bits 0 to 10: Sequence number (value range 0 to 2047) • Bit 11: Channel diagnostics: 0: No channel diagnostics available 1: Channel diagnostic information exists • Bit 12: Status of manufacturer-specific diagnostics: 0: No manufacturer-specific status information available 1: Manufacturer-specific status information available • Bit 13: Status of diagnostics for sub-module: 0: No status information available, all errors have been corrected 1: At least one item of channel diagnostics and/or status information is available • Bit 14: Reserved • Bit 15: Application relationship diagnosis state: – 0: None of the modules configured within this application relationship reports diagnostic information – 1: At least one of the modules configured in this AR is reporting diagnostic information

Structure of the additional interrupt information for interrupts from PROFINET IO or central I/O

The additional interrupt information for PROFINET IO depends on the format identifier. It can comprise multiple data blocks with the same or different format identifier. The following format identifiers are available:

- W#16#0000 to W#16#7FFF: Manufacturer-specific diagnostics

Byte	Data type	Meaning
0 to 1	WORD	Format identifier for the structure of the following data serving as additional interrupt information W#16#0000 to W#16#7FFF: Manufacturer-specific diagnostics
2 to n	BYTE	See manufacturer's manual.

- W#16#8000: Channel diagnostics
  Channel diagnostics is output in blocks of 6 bytes each. The additional interrupt information (without format identifier) is only output for disrupted channels.

Byte	Data type	Meaning	
0 to 1	WORD	Format identifier for the structure of the following data serving as additional interrupt information W#16#8000: Channel diagnostics	
2 to 3	WORD	Channel number of the component triggering the interrupt (value range: 0 to 65535): • W#16#0000 to W#16#7FFF: Channel number of the interface module/sub-module • W#16#8000: The generic substitute for the entire sub-module • W#16#8001 to W#16#FFFF: Reserved	
4	BYTE	Bits 0 to 2:	Reserved
		Bits 3 to 4:	Type of error: • 0: Reserved • 1: Incoming error • 2: Outgoing error • 3: Outgoing error, other errors present
		Bits 5 to 7:	Type of channel: • 0: Reserved • 1: Input channel • 2: Output channel • 3: Input/output channel

Byte	Data type	Meaning
5	BYTE	Data format: • B#16#00: Free data format • B#16#01: Bit • B#16#02: 2 bits • B#16#03: 4 bits • B#16#04: Byte • B#16#05: Word • B#16#06: Double word • B#16#07: 2 double words • B#16#08 to B#16#FF: Reserved
6 to 7	WORD	Type of error: • W#16#0000: Reserved • W#16#0001: Short circuit • W#16#0002: Undervoltage • W#16#0003: Overvoltage • W#16#0004: Overload • W#16#0005: Overtemperature • W#16#0006: Wire break • W#16#0007: High limit exceeded • W#16#0008: Low limit exceeded • W#16#0009: Error • W#16#000A to W#16#000F: Reserved • W#16#0010 to W#16#001F: Manufacturer-specific • W#16#0020 to W#16#00FF: Reserved • W#16#0100 to w#16#7FFF: Manufacturer-specific • W#16#8000: Device diagnostics available • W#16#8001 to W#16#FFFF: Reserved Not all channels support every error type. For detailed information, refer to the description of the diagnostic data for the specific device.

Note

The section from "channel number" to "type of error" can occur from 0 to n times.

- W#16#8001: MULTIPLE (different types of diagnostic information are transmitted). In this case, the additional interrupt information is transmitted as blocks of variable length.

Byte	Data type	Meaning
0 to 1	WORD	Format identifier for the structure of the following data serving as additional interrupt information W#16#8001: Manufacturer-specific diagnostics and/or channel diagnostics
2 to 3	WORD	Block type
4 to 5	WORD	Block length
6	BYTE	Version: high byte
7	BYTE	Version: low byte
8 to 11	DWORD	API (only if low byte of version = 1)
12 to 13	WORD	Slot number
14 to 15	WORD	Subslot number
16 to 17	WORD	Channel number
18 to 19	WORD	Channel properties
20 to 21	WORD	Format identifier: • W#16#0000 to W#16#7FFF: Manufacturer-specific diagnostics • W#16#8000: Channel diagnostics • W#16#8002: Extended channel diagnostics • W#16#8003: Stepped extended channel diagnostics • W#16#8004 to W#16#80FF: Reserved
22 to n	BYTE	Data depend on the format identifier

Note

The section starting from "block type" can occur from 1 to n times.

- W#16#8002: Extended channel diagnostics

Byte	Meaning
0 to 1	Format identifier W#16#8002
2 to 3	Channel number
4 to 5	Channel properties
6 to 7	Error type
8 to 9	Additional error value
10 to 13	Additional error information

- W#16#8003: Stepped extended channel diagnostics

Byte	Meaning
0 to 1	Format identifier W#16#8003
2 to 3	Channel number
4 to 5	Channel properties
6 to 7	Error type
8 to 9	Additional error value
10 to 13	Additional error information
14 to 17	Qualified channel qualifier

- W#16#8100: Maintenance information

Byte	Meaning
0 to 1	Format identifier W#16#8100
2 to 3	Block type
4 to 5	Block length
6 to 7	Block version
8 to 9	Reserved
10 to 13	Maintenance status

Note

You can find more detailed information about the structure of the additional alarm information in the *Programming Manual SIMATIC PROFINET IO from PROFIBUS DP to PROFINET IO* and the current version of IEC 61158-6-10-1.

Destination area TINFO and AINFO

Destination area TINFO and AINFO

Depending on the respective OB in which "RALRM (Page 3076)" is called, the destination areas TINFO and AINFO are only partially written. Refer to the table below to find out which information is entered respectively.

Interrupt type	OB class	TINFO OB start information	TINFO Management information	AINFO Header information	AINFO Additional interrupt information	
Process interrupt	4x	Yes	Yes	Yes	central:	No
					distributed:	as supplied by PROFIBUS DP slave/PROFINET IO device
Status interrupt	55	Yes	Yes	Yes	Yes	Yes
Update interrupt	56	Yes	Yes	Yes	Yes	Yes
Manufacturer-specific interrupt	57	Yes	Yes	Yes	Yes	Yes

Interrupt type	OB class	TINFO OB start information	TINFO Management information	AINFO Header information	AINFO Additional interrupt information	
I/O redundancy error	70	Yes	Yes	No	No	No
Diagnostics interrupt	82	Yes	Yes	Yes	central:	Structure according to PROFINET IO standard
					distributed:	as supplied by PROFIBUS DP slave/PROFINET IO device
Insert/remove interrupt	83	Yes	Yes	Yes	central:	No
					distributed:	as supplied by PROFIBUS DP slave/PROFINET IO device
Special form of the remove module interrupt: Controlled by supervisor	83	Yes	Yes	Yes	PROFINET IO only	
Special form of the insert module interrupt: Enabled by supervisor	83	Yes	Yes	Yes	PROFINET IO only	
Unconfigured module inserted	83	Yes	Yes	Yes	PROFINET IO only	
Rack failure/ station failure	86	Yes	Yes	No	No	
... all other OBs		Yes	No	No	No	

D_ACT_DP: Enable/disable DP slaves

Description

Use the "D_ACT_DP" instruction to specifically deactivate and reactivate configured DP slaves/ PROFINET IO devices. In addition, you can determine whether each assigned DP slave or PROFINET IO device is currently activated or deactivated.

If you use the instruction to deactivate an IE/PB Link PN IO type of gateway, then all connected PROFIBUS DP slaves will also cease to function. These failures will be reported.

The instruction cannot be used on PROFIBUS PA field devices that are connected by a DP/PA link to a DP master system.

Note

As long as one or more "D_ACT_DP" jobs are active, you cannot load a changed configuration from the programming device to the CPU (within the scope of CiR).
If a changed configuration is being loaded from the programming device to the CPU during ongoing operation (CiR), the CPU will reject activation of a "D_ACT_DP" job.

Several runs through the cycle control point are required to perform the disabling or enabling job. Therefore, you cannot wait for the end of such a job in a programmed loop.

Functional description

"D_ACT_DP" is an instruction that works asynchronously, which means its execution extends over multiple calls. You start the job by calling D_ACT_DP with REQ = 1.

The output parameters RET_VAL and BUSY indicate the status of the job.

See also: Meaning of the parameters REQ, RET_VAL and BUSY with asynchronous instructions (Page 2193).

Application

If you configure DP slaves/PROFINET IO devices in a CPU which are not actually present or not currently required, the CPU will nevertheless continue to access these DP slaves/PROFINET IO devices at regular intervals. After the slaves are deactivated, further CPU accessing will stop. With PROFIBUS DP, the fastest possible DP bus cycle can be achieved in this manner and the corresponding error events no longer occur.

Examples

From a machine OEM's point of view, there are numerous device options possible in series production of machines. However, each delivered machine includes only one combination of selected options.

Every one of these possible machine options is configured as a DP slave/PROFINET IO device by the manufacturer in order to create and maintain a common user program having all possible options. Use "D_ACT_DP" to deactivate all DP slaves/PROFINET IO devices not present at machine startup.

A similar situation exists for machine tools having numerous tooling options available but actually using only a few of them at any given time. These tools are implemented as DP slaves/PROFINET IO devices. With "D_ACT_DP", the user program activates the tools currently needed and deactivates those required later.

Identification of a job

If you have started a deactivation or activation job and you call "D_ACT_DP" again before the job is complete, the behavior of the instruction depends on whether or not the new call involves the same job. If the input parameter LADDR matches, then the call will be interpreted as a follow-on call.

Deactivating DP slaves/PROFINET IO devices

When you deactivate a DP slave/PROFINET IO device with "D_ACT_DP", its process outputs are set to the configured substitute values or to 0 (safe state). The assigned DP master/ PROFINET IO controller does not continue to address this component. Deactivated DP slaves/ PROFINET IO devices are not identified as faulty or missing by the error LEDs on the DP master/PROFINET IO controller or CPU.

The process image of the inputs of deactivated DP slaves/PROFINET IO devices is updated with 0, that is, it is handled just as it is for failed DP slaves/PROFINET IO devices.

If you are using your program to directly access the user data of a previously deactivated DP slave/PROFINET IO device, the I/O access error OB is called and the corresponding start event is entered in the diagnostics buffer. If you attempt to access a deactivated DP slave/ PROFINET IO device via an instruction (such as "RD_REC (Page 3118)"), you will receive the same error information in RET_VAL as for an unavailable DP slave/PROFINET IO device.

Deactivating a DP slave/PROFINET IO device does not start the program error OB, even if its inputs or outputs belong to the system-side process image to be updated. Also there is no entry in the diagnostics buffer.

If a DP station/PNIO station fails after you have deactivated it with "D_ACT_DP", the operating system does not detect the failure.

Applies to PROFIBUS DP: If you wish to deactivate DP slaves functioning as transmitters in slave-to-slave communication, we recommend that you first deactivate the receivers (listeners) that detect which input data the transmitter is transferring to its DP master. Deactivate the transmitter only after you have performed this step.

Activating DP slaves/PROFINET IO devices

When you reactivate a DP slave/PROFINET IO device with "D_ACT_DP", this component is configured and assigned parameters by the associated DP master/PROFINET IO controller (as with the return of a failed DP station/PROFINET IO station). This activation is complete when the component is able to transfer user data.

Activating a DP slave/PROFINET IO device does not start the program error OB, even if its inputs or outputs belong to the system-side process image to be updated. Also there is no entry in the diagnostics buffer.

If you try to activate a DP slave/PROFINET IO device with "D_ACT_DP" that cannot be accessed (for example, because it was physically separated from the bus), the instruction returns the error code W#16#80A7 after expiration of the configured parameter assignment time for distributed I/O. The DP slave/PROFINET IO device is activated and the fact that the activated DP slave/PROFINET IO device cannot be accessed results in a corresponding display in the system diagnostics.

If the DP slave/PROFINET IO device is accessible again afterwards, this results in standard system behavior (for example, a call of the OB configured for this purpose).

Note

Activating a DP slave/PROFINET IO device may be time-consuming. If you wish to cancel a current activation job, start "D_ACT_DP" again with the same value for LADDR and MODE = 2. Repeat the call of "D_ACT_DP" with MODE = 2 until successful cancellation of the activation job is indicated by RET_VAL = 0.

If you wish to activate DP slaves which take part in the slave-to-slave communication, we recommend that you first activate the transmitters and then the receivers (listeners).

Parameters

The following table shows the parameters of the "D_ACT_DP" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Level-triggered control parameter REQ=1: Execute activation or deactivation
MODE	Input	USINT	I, Q, M, D, L or constant	Job identifier Possible values: • 0: Request information on whether the addressed component is activated or deactivated (output via RET_VAL parameter) • 1: Activate the DP slave/PROFINET IO device • 2: Deactivate the DP slave/PROFINET IO device
LADDR	Input	HW_DEVICE	I, Q, M, D, L or constant	Hardware identifier of the DP slave (HW_DPSlave)/PROFINET IO device (HW_Device) The number can be taken from the properties of the DP slave / PROFINET IO device in the Network view or from the "System constants" tab of the standard tag table. If both the identifier for the device diagnostics as well as the ID for operating state transitions are both specified there, you must use the code for the device diagnostics.
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code.
BUSY	Output	BOOL	I, Q, M, D, L	Active code: • BUSY = 1: The job is still active. • BUSY = 0: The job was terminated.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	Job completed without error.
0001	The DP slave/PROFINET IO device is active (this error code is possible only with MODE = 0.)
0002	The DP slave/PROFINET IO device is deactivated (this error code is possible only with MODE = 0.)
7000	First call with REQ=0. The job specified with LADDR is not active; BUSY has the value "0".
7001	First call with REQ=1. The job specified with LADDR was initiated. BUSY has the value "1".
7002	Intermediate call (REQ irrelevant). The activated job is still active; BUSY has the value "1".
8090	• You have not configured a module with the address specified in LADDR. • You operate your CPU as I-Slave and you have specified in LADDR an address of this I-Slave.
8092	The deactivation of the currently addressed DP slave/PROFINET IO device (MODE=2) cannot be canceled by being activated (MODE=1). Activate the component at a later time.
8093	No DP slave / PROFINET IO device that can be activated or deactivated is assigned to the address specified in LADDR.
8094	You have attempted to activate a device which is potential partner for a tool change port. However, another device is already activated on this tool change port at this time. The activated device will remain activated.
80A0	Error during the communication between the CPU and the IO controller.
80A1	Parameters could not be assigned for the addressed component. (This error code is only available when MODE = 1.) Note: "D_ACT_DP" returns this error information only if the activated slaves/devices of this component fails again during parameter assignment. If the parameter assignment of a single module was unsuccessful, "D_ACT_DP" returns the error information W#16#0000.
80A2	The addressed DP slave does not return an acknowledgment. (This error information is not available with PROFINET IO devices. The process is not time-monitored by PROFINET.)
80A3	The DP master/PROFINET IO controller concerned does not support this function.
80A4	The CPU does not support this function for external DP masters/PROFINET IO controller.
80A6	Slot error in the DP slave/PROFINET IO device; not all user data can be accessed (this error code is only available when MODE=1). Note: "D_ACT_DP" returns this error information only if the activated component fails again after parameter assignment and before the end of "D_ACT_DP". If only a single module is unavailable, "D_ACT_DP" returns the error information W#16#0000.
80A7	Activation of a non-accessible device.
80AA	Activation with errors in the DP slave/PROFINET IO device: Differences in the configuration
80AB	Activation with errors in the DP slave/PROFINET IO device: Parameter assignment error
80AC	Activation with errors in the DP slave/PROFINET IO device: Maintenance required
80C1	"D_ACT_DP" has been started and is being continued with another address (this error code is possible when MODE=1 and MODE=2).
80C3	• Temporary resource error: The CPU is currently processing the maximum possible activation and deactivation jobs (8). (This error code is available only when MODE = 1 and MODE = 2.) • The CPU is busy receiving a modified configuration. Currently you can not enable/disable DP slaves/ PROFINET IO devices.
80C5	DP: Jobs not collected by the user are discarded at restart.
80C6	PROFINET: Jobs not collected by the user are discarded at restart.

Error code* (W#16#...)	Explanation

* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

ReconfigIOSystem: Reconfigure IO system

Description

You can use the "ReconfigIOSystem" instruction to transfer a data record to the PROFINET interface of the CPU. This data record ("CTRLREC" parameter) contains the following information for controlling the configuration:

- A list of optional IO devices to be activated
- A list of the partner ports to be specified, if you have set the "Partner is set in the user program" option in the port properties of IO devices

Note

The "ReconfigIOSystem" instruction uses the "D_ACT_DP" instruction internally in MODE 1 and MODE 3 to enable/disable IO devices. Therefore, observe the rules and notes in the description of this instruction.

See also "D_ACT_DP: Disable/enable distributed I/O devices (Page 1908)".

Functional description

"The "ReconfigIOSystem" instruction works asynchronously, that is, its execution extends over multiple calls. You start the job by calling "ReconfigIOSystem" with REQ=1.

The output parameters STATUS and BUSY indicate the status of the job.

Parameters

The following table shows the parameters of the "ReconfigIOSystem" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Edge-triggered control parameter REQ=1: Perform data transfer
MODE	Input	UINT	I, Q, M, D, L or constant	You control how the instruction works with the MODE parameter. You can find a detailed functional description in the table below. Possible values: • 1: Disable all IO devices of the IO system for the conversion phase • 2: Reconfigure the IO system according to the data record settings (CTRLREC) • 3: Enable all IO devices of the IO system again after reconfiguration
LADDR	Input	HW_INTERFACE	I, Q, M, D, L or constant	Hardware identifier of the PROFINET interface (IO controller)
CTRLREC	Input	VARIANT	I, Q, M, D, L	Data record for controlling the actual configuration of the IO system
DONE	Output	BOOL	I, Q, M, D, L	0: Instruction not yet completed 1: Instruction completed
BUSY	Output	BOOL	I, Q, M, D, L	Active code: 0: Instruction active 1: Instruction completed
ERROR	Output	BOOL	I, Q, M, D, L	0: Instruction completed without error 1: Instruction completed with error
STATUS	Output	DWORD	I, Q, M, D, L	Result/error code
ERR_INFO	Output	WORD	I, Q, M, D, L	HW ID of the most recently determined IO device that caused an error.

You can find additional information on valid data types under "Overview of valid data types (Page 1908)".

Parameter MODE

The following values are possible for the MODE input parameter:

MODE	Description
1	All IO devices of the IO system can be disabled by calling the instruction with mode 1. The "ReconfigIOSystem" instruction uses the "D_ACT_DP" instruction internally. "ReconfigIOSystem" returns errors that are detected by D_ACT_DP in the following output parameters: • STATUS (error code) • ERR_INFO (hardware identifier of the IO device causing the error). In STATUS and ERR_INFO, the CPU enters the last determined error/HW identifier and in so doing overwrites an existing error code. For this reason, additional errors can be present besides the entered error.
2	For controlling the actual configuration of the IO system, the instruction transfers the data record to the PROFINET interface, which is addressed with LADDR. See the following section for information on the structure of the data record. See the following section about the STATUS parameter for error analysis.
3	All non-optional IO devices in the IO system and optional IO devices that are listed in the control data record CTRLREC are enabled. The optional IO devices that are **not** listed in the CTRLREC data record remain disabled. If IO devices that are part of docking units are listed in the CTRLREC control data record, the PN IO system reacts as follows: • IO devices of the docking units remain disabled when ReconfigIOSystem is called with Mode 3. This reaction corresponds to the reaction of a configuration without configuration-controlled IO devices. IO devices of docking units are disabled by default and must be enabled in the user program.

Structure of the control data record

You can use the control data record ("CTRLREC" parameter) to inform the PROFINET interface of the CPU which optionally configured IO devices are available in the real IO system configuration and which port interconnections are to be set.

This requires a configuration that allows IO system configuration to be adapted:

- The IO devices listed in the control data record must be enabled as "Optional IO device" (IO device properties: PROFINET interface [X1] > Advanced options > Interface options).
- The port interconnections listed in the control data record are only possible when the partner port is set to "Partner is set by the user program" for the appropriate ports.

The data type of parameter CTRLREC is "VARIANT". The "CTRLREC" control data record must have the following structure:

- Array from elements of the Word data type.

Below, the basic structural composition of "CTRLREC" is described with the Word element data type.

You read the required hardware identifiers directly in the "System constants" tab in the network view or in the device view. To do this, select the object in the network view (IO device) or in the device view (PROFINET interface).

Recommendation: Use the symbolic addressing of the HW identifiers by using the names of the HW identifiers.

Name	Data type	Comment
Version_High, Version_Low	Word	Version of the control data record(High Byte: 01 Low Byte: 00
Number_of_opt_Devices_used	Word	Number of optional IO devices that are used in the real IO system configuration. Optional IO devices that are not listed below remain disabled.
Activate_opt_Device_1	Word / Hw_Device	The optional IO devices that are present in the real configuration must be listed with their hardware identifiers. Use the system constant of the IO device object. Example: The IO device object has the name "IO-Device_4~IO-Device" and its type is "Hw_Device".
Activate_opt_Device_2	Word / Hw_Device	2nd optional IO device (e.g. with value 262)
...	...	...
Activate_opt_Device_n	Word / Hw_Device	nth optional IO device (e.g. with value 282)
Number_of_Port_Interconnections_used	Word	Number of port interconnections listed below. If you do not specify port interconnections, enter "0". For all the ports for which you have configured "Partner is set by the user program" and that are not listed below, the CPU uses the "Any partner" setting.
Port_Interconnection_1_Local	Word / Hw_Interface	1st port interconnection, HW identifier of local port Use the system constant of the port object. Example: The port object has the name "IO-Device_2~PROFINET_interface~Port_2" and its type is "Hw_Interface".
Port_Interconnection_1_Remote	Word / Hw_Interface	1st port interconnection, HW identifier of partner port
Port_Interconnection_2_Local	Word / Hw_Interface	2nd port interconnection, HW identifier of local port
Port_Interconnection_2_Remote	Word / Hw_Interface	2nd port interconnection, HW identifier of partner port
...	...	...
Port_Interconnection_n_Local	Word / Hw_Interface	nth port interconnection, HW identifier of local port
Port_Interconnectio_n_Remote	Word / Hw_Interface	nth port interconnection, HW identifier of local port

STATUS parameter

The STATUS output parameter contains error information. You can find a detailed list of possible error codes in the next section. If STATUS is interpreted as ARRAY[1...4] of BYTE, the error information has the following structure:

Field element	Name	Meaning
STATUS[1]	Function_Num	B#16#DF: Error writing data record, otherwise B#16#00.
STATUS[2]	Error_Decode	B#16#80 is output for an error (corresponding to IEC 61158-6 in the context of reading and writing data records).

Field element	Name	Meaning
STATUS[3]	Error_Code_1	B#16#AA in the case of an error in the structure of the data record
STATUS[4]	Error_Code_2	Manufacturer-specific error ID extension: • B#16#00 Error in the data record (e.g. incorrect padding byte values (not equal to 0) • B#16#01 Reserved • B#16#02 At least one station number for an IO device in the data record is invalid (not configured, points to a non-optional IO device or has the value 0 for an IO controller) • B#16#03 At least one partner port specified in the data record is invalid: Examples: – Subslot address of a partner port is not available – Partner port is configured incorrectly (the correct setting is: "Partner is set by the user program") – Partner port belongs to an IO device that is disabled • B#16#10 Version of the CTRLREC control data record invalid (specified version is not supported) • B#16#11 The number of optional IO devices to be activated in the CTRLREC control data record is not supported • B#16#12 The number of specified interconnections ("Partner set in the user program") in the CTRLREC control data record is not supported • B#16#13 Internal conversion of the hardware identifier to device number failed. The ERR_INFO output parameter contains the hardware identifier of the device causing the error. • B#16#14 Consistency error: The length of the CTRLREC control data record does not match the information in the control data record. Example: 20 optional IO devices are specified, but the control data record only has a length of 10 bytes.

Error codes (STATUS parameter)

Error code	Description
16#0000_0000	Job completed without error
16#0070_0000	No job active
16#0070_0100	First call of the instruction
16#0070_0200	Following call of the instruction (instruction is still running, BUSY = 1)
16#0080_8000	MODE is not supported
16#0084_5100	Incorrect data type of CRTLREC data record. Use an Array of Word.
16#0080_9100	The LADDR parameter is not addressing any PROFINET interface (does not exist or wrong type, e.g. PROFIBUS interface). The PROFINET interface does not support configuration control of IO systems.
16#0080_Cx00	Temporary error, e.g., due to temporary lack of resources.

Error code	Description
16#DF80_AAxy	Error in the structure of the data record (MODE 2). For the meaning of "xy", see the definition of STATUS[4] Error_Code_2 above.
16#DF80_B600	Configuration control not possible because no optional IO device was configured and no port was assigned with "Partner is set in the user program". This configuration is a prerequisite for calling the instruction.
16#0080_9400 16#0080_A000 16#0080_A700 16#0080_AA00 16#0080_AB00 16#0080_AC00	Forwarded error codes of the internally called D_ACT_DP instruction. For the meaning of these error codes, see "D_ACT_DP (Page 3108)". The hardware identifiers of IO devices causing errors are entered in ERR_INFO (entry is consecutively overwritten by subsequent errors). If more than one IO device is involved, online diagnostics with STEP 7 is recommended. With IRT configuration: The device numbers of the IO devices should follow from the IO controller in ascending order of their topological interconnection, see here.

Others

RD_REC: Read data record from I/O

Description

Use the instruction to read the data record with the number RECNUM from the addressed module. You start the read process by assigning the value "1" to the input parameter REQ during the call. If the read process could be executed immediately, the instruction returns the value "0" at the output parameter BUSY . If BUSY has the value "1", reading is not yet complete.

See also: Meaning of the parameters REQ, RET_VAL and BUSY with asynchronous instructions (Page 2193). The data record read is entered in the destination area spanned by the RECORD parameter, providing the data transfer was free of errors.

Note

When you read out a data record with a number greater than one from an FM or a CP you have purchased prior to February 1997 (below referred to as "old modules"), "RD_REC" responds differently than it does in new modules. This special situation is covered in the section "Using old S7-300 FMs and CPs with data record numbers >1" (see below).

If a DPV1 slave is configured via GSD file (GSD rev. 3 and higher) and the DP interface of the DP master is set to "S7 compatible", then you may not read any data records from the I/O modules in the user program with "RD_REC". In this case, the DP master addresses the wrong slot (configured slot + 3).

Remedy: Set the interface of the DP master to "DPV1".

Parameters

The following table shows the parameters of the "RD_REC" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = 1: Read request
LADDR	Input	HW_IO	I, Q, M, D, L or constant	Hardware identifier of the module.
RECNUM	Input	BYTE	I, Q, M, D, L or constant	Data record number (permitted values: 0 to 240)
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code. In addition: the length of the data record actually transferred in bytes (possible values: +1 to +240), if the destination area is greater than the transferred data record and if no error occurred during the transfer.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = 1: The reading process is not yet complete.
RECORD	Output	ANY	I, Q, M, D, L	destination area for the data record read. With asynchronous execution of "RD_REC", make sure that the actual parameters of RECORD have the same length information for all calls. Only the BYTE data type is permitted. Note: Note that for S7-300 CPUs the parameter RECORD always requires the full specification of the DB parameters (for example, P#DB13.DBX0.0 byte 100). The omission of an explicit DB number is only permitted for S7-300 CPUs and leads to an error message in the user program.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter RECORD

Note

If you want to ensure that the entire data record is always read, select a destination area with a length of 241 bytes. If the data transfer is without error, RET_VAL contains the actual data record length.

Using old S7-300 FMs and CPs with data record numbers > 1

If you want to use the instruction "RD_REC" to read out a data record with a number greater than one from an old S7-300 FM or old S7-300 CP, remember the following points:

- If the destination area is greater than the actual length of the required data record, no data is entered in RECORD . RET_VAL is written with W#16#80B1.
- If the destination area is smaller than the actual length of the required data record, the CPU reads as many bytes beginning at the start of the record as are specified in the length information of RECORD and enters this number of bytes inRECORD . RET_VAL has the value "0".
- If the length specified in RECORD is the same as the actual length of the required data record, the CPU reads the data record and enters it in RECORD . RET_VAL is written with "0".

Parameter RET_VAL

- If an error has occurred while the function was being executed, the return value contains an error code.
- If no error occurred during the transfer, RET_VAL contains the following:
  - 0, if the entire destination area was filled with data from the selected data record (the data record can also be incomplete).
  - The length of the data record actually transferred in bytes (possible values: +1 to +240) if the destination area is greater than the transferred data record.

Note

If the general error W#16#8745 occurs, this only indicates that access to at least one byte of the process image was blocked. The data record was read by the module correctly and written to the I/O memory area.

When looking at the "real" error information (error codes W#16#8xyz) in the following table, we distinguish between two cases:

- Temporary errors (error codes W#16#80A2 to 80A3, 80Cx):
  This type of error can possibly be eliminated without user action, meaning it is helpful to call the instruction again (multiple calls, if necessary).
  Example of a temporary error: Resources required are currently in use (W#16#80C3).
- Permanent errors (error codes W#16#809x, 80A0, 80A1, 80Bx):
  This type of error does not correct itself. A new call of the instruction will not be successful until you have eliminated the error. Example of a permanent error: Wrong length specification in RECORD (W#16#80B1).

Note

If you transfer data records to a DPV1 slave with "WR_REC (Page 3123)" or if you read data records from a DPV1 slave with RD_REC and if this DPV1 slave operates in DPV1 mode, the DP master evaluates the error information it received from the slave as follows:

If the error information lies within the range from W#16#8000 to W#16#80FF or W#16#F000 to W#16#FFFF, the DP master passes the error information to the instruction. If the error information is outside this range, the DP master passes the value W#16#80A2 to the instruction and suspends the slave.

For a description of the error information originating from DPV1 slaves, refer to STATUS[3] Parameter STATUS (Page 3078).

Parameter RET_VAL for WR_REC and RD_REC

Error code* (W#16#...)	Explanation	Restriction
0000	No error	-
7000	First call with REQ=0: No data transfer active; BUSY has the value 0.	-
7001	First call with REQ=1: Data transfer started; BUSY has the value 1.	Distributed I/O
7002	Intermediate call (REQ irrelevant): Data transfer already active; BUSY has the value 1.	Distributed I/O
8090	Address specified at parameter ADDR is invalid.	-
8092	A type other than BYTE is specified in the ANY reference.	-
8093	This instruction is not permitted for the module selected by means of LADDR and IOID .	-
80A0	Negative acknowledgment when reading from the module: Module was removed during the reading process or is defective	With "RD_REC" only
80A1	Negative acknowledgment when writing to the module: Module was removed during the writing process or is defective	With "WR_REC (Page 3123)" only
80A2	• DP protocol error at layer 2 (for example, slave failure or bus problems) • For ET 200S, data record cannot be read in DPV0 mode.	Distributed I/O
80A3	DP protocol error with user interface/user	Distributed I/O
80A4	Communication on PROFIBUS disrupted.	-

Error code* (W#16#...)	Explanation	Restriction
80B0	• Instruction not possible for module type. • The module does not recognize the data record. • Data record number 241 not permitted. • With "WR_REC (Page 3123)", data records 0 and 1 are not permitted.	-
80B1	The length specified in parameter RECORD is incorrect.	• With "WR_REC (Page 3123)": Length incorrect • With "RD_REC" (only when using old S7-300 FMs and S7-300 CPs): specified length > data record length • With DPNRM_DG: specified length < data record length
80B2	The configured slot is not assigned.	-
80B3	Actual module type does not match specified module type	-
80B5	DP slave or module is not ready.	-
80B7	DP slave or module reports an invalid range for a parameter or value.	With "RD_REC" only
80C0	With "WR_REC (Page 3123)": the data can only be written when the CPU is in STOP mode. Note: this means that writing by the user program is not possible. You can only write the data online with PG/PC. With "RD_REC": the module routes the data record, but either no data is present or the data can only be read when the CPU is in STOP mode. Note: if data can only be read when the CPU is in STOP mode, then an evaluation by the user program is not possible. In this case, you can only read the data online with PG/PC. With "DPNRM_DG (Page 3139)": There are no diagnostic data available.	With "WR_REC (Page 3123)" or "RD_REC" or "DPNRM_DG (Page 3139)"
80C1	The data of the previous write job on the module for the same data record have not yet been processed by the module.	-
80C2	The module is currently processing the maximum possible number of jobs for a CPU.	-
80C3	The required resources (memory, etc.) are currently occupied.	-
80C4	Internal temporary error. Job could not be executed. Repeat the job. If this error occurs often, check your installation for sources of electrical interference.	-
80C5	Distributed I/O not available.	Distributed I/O
80C6	Data record transfer stopped due to priority class abort (restart or background)	Distributed I/O

Error code* (W#16#...)	Explanation	Restriction
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)	-
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".		

WR_REC: Write data record to I/O

Description

Use the instruction "WR_REC" to transfer the data record RECORD to the addressed module.

The data to be transferred are read from the RECORD parameter during the first call. If the transfer of the data record takes longer than the duration of one call, the contents of the RECORD parameter are no longer relevant for the subsequent instruction calls (for the same job).

You start the writing process by assigning the value "1" to the input parameter REQ during the call. If the writing process could be executed immediately, the instruction returns the value "0" at the output parameter BUSY. If BUSY has the value "1", writing is not yet complete.

Parameters

The following table shows the parameters of the instruction "WR_REC":

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L, T, C or constant	REQ = 1: Write request
LADDR	Input	HW_IO	I, Q, M, D, L or constant	Hardware identifier of the module.
RECNUM	Input	BYTE	I, Q, M, D, L or constant	Data record number
RECORD	Input	VARIANT	I, Q, M, D, L	Data record
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = 1: The writing process is not yet completed.

You will find more detailed information on valid data types in "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

See also: RD_REC: Read data record from I/O (Page 3118)

Note

If the general error W#16#8544 occurs, it only indicates that access to at least one byte of the I/O memory area containing the data record was denied. The data transfer was continued.

DPRD_DAT: Read consistent data of a DP standard slave

Description

Use the instruction "DPRD_DAT" to read out consistent data from an I/O module.

The instruction can be used for the central modules as well as for the DP standard slaves and PROFINET IO devices.

You require "DPRD_DAT" because you can only read out a maximum of four continuous bytes using the load commands that access the I/O or the process image input table. If required, you can also read consistent data via the process image of the inputs. Refer to the related documentation to find out if your CPU supports this functionality. For additional information on consistent data of a DP standard slave/PROFINET IO device, refer to Section "Data consistency (Page 3608)".

If necessary, the instruction "DPRD_DAT" can also be used for a data area of 1 byte or larger. For information on the maximum length of the data, refer to the documentation of your CPU (e.g. 64 bytes for an S7-1214).

- Use the parameter LADDR to select the module of the DP normslave/PROFINET IO device. If an access error occurs, the error code W#16#8090 is output.
- Use the RECORD parameter to define the target range of the read data:
  - The target range has to be at least as long as the inputs of the selected module. Only the inputs are transferred, the other bytes are not considered. If you read from a DP standard slave with a modular configuration or with several DP identifiers, you can only access the data of a module of the configured hardware identifier per "DPRD_DAT" call. If you select a target range that is too small, the error code 80B1 is output at the RET_VAL parameter.
  - All bit strings and all integers can be used as data type. It is also possible to use these data types in a data structure of the ARRAY type . The data type STRING is not supported.
- If there was no error during the data transmission, the data that have been read are entered in the target range defined at the RECORD parameter.

Parameters

The following table shows the parameters of the instruction "DPRD_DAT":

Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_IO	I, Q, M, L or constant	Hardware ID of the module from which the data is to be read. The hardware ID can be found in the properties of the module in the device view or system constants.
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code.
RECORD	Output	VARIANT	I, Q, M, D, L	Destination area for the user data that were read.

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

RET_VAL parameter

Error code* (W#16#...)	Explanation
0000	No error occurred.
8090	• You have not configured a module for the specified hardware identifier or • You have ignored the restriction concerning the length of consistent data, or • you have not specified a hardware identifier as an address at parameter LADDR .
8092	A data type other than (Array of) bit string or integer was specified at the RECORD parameter.
8093	No DP module/PROFINET IO device from which you can read consistent data exists for the hardware identifier specified in LADDR . This error code also occurs if the module addressed by means of LADDR does not have inputs.
80A0	An access error was detected when accessing the I/O.
80B1	The length of the specified target range at parameter RECORD is shorter than the configured user data length.
80C0	The data have not been read yet.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

See also

Parameter STATUS (Page 3078)

DPWR_DAT: Write consistent data of a DP standard slave

Description

Use the instruction "DPWR_DAT" to transfer the data at the parameters RECORD consistently to the addressed module of the central module or of the DP standard slave/PROFINET IO device and if necessary to the process image (i.e. if the affected address range of the DP standard slaves is projected as consistency range in a process image).

You require "DPWR_DAT" because you can only write a maximum of four continuous bytes using the transfer commands that access the I/O or process image output. If required, you can also write consistent data via the process image outputs. Refer to the related documentation to find out if your CPU supports this functionality. Do not use both possibilities concurrently when writing consistent data: Either use "DPWR_DAT" or write via the process image output table. For additional information on consistent data of a DP standard slave/PROFINET IO device, refer to Section "Data consistency (Page 3608)". If the DP standard slave has a modular design, you can only access one module of the DP slave.

Caution

I/O access

When using "DPWR_DAT", avoid accessing I/O areas that have process image partitions with OB6x connections (isochronous mode interrupts) assigned to them.

If necessary, the instruction "DPRD_DAT" can also be used for a data area of 1 byte or larger. For information on the maximum length of the data, refer to the documentation of your CPU (e.g. 64 bytes for an S7-1214).

- Use the LADDR parameter to select the DP standard slave / PROFINET IO device. If an access error occurs on the addressed module, the error code 8090 is output.
- Use the RECORD parameter to define the source range of the data to be written:
  - The source range has to be at least as long as the outputs of the selected module. Only the outputs are transferred, the other bytes are not considered. If the source range at parameter RECORD is longer than the outputs of the configured module, only the data up to the maximum length of the outputs is transferred. If the source range at parameter RECORD is shorter than the outputs of the configured module, the error code 80B1 is output.
  - The following data types can be used: Byte, Char, Word, LWord, DWord, Int, UInt, USInt, SInt, LInt, ULInt, DInt, UDInt. The use of these data types in a data structure of the type ARRAY or STRUCT is also permissible.
  - The data type STRING is not supported.

The data is transferred synchronously, that is, the write process is completed when the instruction is completed.

Parameters

The following table shows the parameters of the instruction "DPWR_DAT":

Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_IO	I, Q, M, L or constant	Hardware ID of the module to which the data is to be written. The hardware ID can be found in the properties of the module in the device view or system constants.
RECORD	Input	VARIANT	I, Q, M, D, L	Source area for the user data to be written.
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code.

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

RET_VAL parameter

Error code* (W#16#...)	Explanation
0000	No error occurred.
8090	• You have not configured a module for the specified hardware identifier or • You have ignored the restriction concerning the length of consistent data, or • you have not specified a hardware identifier at parameter LADDR .
8092	A data type other than (Array of) bit string or integer was specified at the RECORD parameter.
8093	No DP module /PROFINET IO device to which you can write consistent data exists at the HW ID specified in LADDR . This error code also occurs if the DP standard slave / PROFINET IO device addressed via LADDR does not have outputs.
80A1	Access error detected while I/O devices were being accessed.
80B1	The length of the specified source range at the RECORD parameter is shorter than the outputs of the configured DP standard slave / PROFINET IO device.
80C1	The data of the previous write job have not yet been processed by the DP standard slave / PROFINET IO device.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".

Parameter STATUS (Page 3078)

iDevice / iSlave

RCVREC: Receive data record

Description

An I-device can receive a data record from a superordinate controller. The receipt takes place in the user program with the instruction "RCVREC" (receive record).

The instruction has the following operating modes:

- Check whether the I-device has a request for a data record receipt.
- Make the data record available to the output parameters.
- Send an answer to the superordinate controller.

You can determine the operating mode executed by the instruction using the input parameter MODE (see below).

The I-device must be in the RUN or STARTUP mode.

With MLEN, you specify the maximum number of bytes you want to receive. The selected length of the target range RECORD should have at least the length of MLEN bytes.

If a data record was received (MODE=1 or MODE=2), the output parameter NEW will indicate that the data record was stored in RECORD. Note that RECORD has a sufficient length. The output parameter LEN contains the actual length of the data record received in bytes.

Set CODE1 and CODE2 to zero for the positive answer to the superordinate controller. If the received data record is to be rejected, enter the negative answer to the superordinate controller in Error Code 1 of the CODE1 and in Error Code 2 of the CODE2.

Note

If the I-device has received a request for a data record receipt, you must recognize the delivery of this request within a certain duration. After recognition, you must send an answer to the superordinate controller within this time period. Otherwise the I-device will experience a timeout error which causes the operating system of the I-device to send a negative answer to the superordinate controller. For information on the value for the time period, refer to the specifications of your CPU.

The output parameter STATUS receives the error information after the occurrence of an error.

Operating modes

You can determine the operating mode of the instruction "RCVREC" with the input parameter MODE. This step will be explained in the following table.

MODE	Meaning
0	Check whether a request for a data record receipt exists If a data record from a higher-level controller exists on the I-device, the instruction will only write the output parameters NEW, SLOT, SUBSLOT, INDEX and LEN. If you call the instruction several times with MODE=0, then the output parameter will only refer to one and the same request.
1	Receiving a data record for any subslot of the I-device If a data record from a superordinate controller exists on the I-device for any subslot of the I-device, the instruction will write the output parameter and transfer the data record to the parameter RECORD.
2	Receiving a data record for a specific subslot of the I-device If a data record from a superordinate controller exists on the I-device for a specific subslot of the I-device, the instruction will write the output parameter and transfer the data record to the parameter RECORD.
3	Sending a positive answer to the superordinate controller The instruction checks the request of the superordinate controller to receive a data record, accepts the existing data record and sends a positive acknowledgment to the superordinate controller.
4	Sending a negative answer to the superordinate controller The instruction checks the request of the superordinate controller to receive a data record, rejects the existing data record and sends a negative acknowledgment to the superordinate controller. Enter the reason for the rejection in the input parameters CODE1 and CODE2.

Note

After the receipt of a data record (NEW=1) you must call "RCVREC" twice to ensure complete processing. You must do this in the following order:

- First call with MODE=1 or MODE=2
- Second call with MODE=3 or MODE=4

Parameters

The following table shows the parameters of the "RCVREC" instruction:

Parameter	Declaration	Data type	Memory area	Description
MODE	Input	INT	I, Q, M, D, L or constant	Mode
F_ID	Input	HW_SUBMODULE	I, Q, M, D, L or constant	Subslot in the transfer area of the I-device for the data record to be received (only relevant for MODE=2). The high word is always set to zero.
MLEN	Input	INT*	I, Q, M, D, L or constant	Maximum length of the data record to be received in bytes
CODE1	Input	BYTE	I, Q, M, D, L or constant	Zero (for MODE=3) and/or Error Code 1 (for-MODE=4)
CODE2	Input	BYTE	I, Q, M, D, L or constant	Zero (for MODE=3) and/or Error Code 2 (for-MODE=4)

Parameter	Declaration	Data type	Memory area	Description
NEW	Output	BOOL	I, Q, M, D, L	• MODE = 0: New data record was received • MODE=1 or 2: Data record was transferred to RECORD
STATUS	Output	DWORD	I, Q, M, D, L	Error information
SLOT	Output	HW_SUB-MODULE	I, Q, M, D, L	Identical to F_ID
SUBSLOT	Output	HW_SUB-MODULE	I, Q, M, D, L	Identical to F_ID
INDEX	Output	UINT	I, Q, M, D, L	Number of the data record received
LEN	Output	UINT	I, Q, M, D, L	Length of the data record received
RECORD	InOut	VARIANT	I, Q, M, D, L	Target range for the data record received. Note: Note that for S7-300 CPUs the parameter RECORD always requires the full specification of the DB parameters (for example, P#DB13.DBX0.0 Byte 100). The omission of an explicit DB number is not permitted for S7-300 CPUs and results in an error message in the user program.
* Use the data type UINT in the STL programming language.				

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameter STATUS

For interpretation of the parameter STATUS refer to section: Parameter STATUS (Page 3078)

PRVREC: Make data record available

Description

An I-device can receive a request from a superordinate controller to make a data record available. The I-device makes the data record available in the user program with the instruction "PRVREC" (provide record).

The instruction has the following operating modes:

- Check whether the I-device has a request for making a data record available.
- Transfer the requested data record to the superordinate controller.
- Sending an answer to the superordinate controller.

You can determine the operating mode executed by the instruction using the input parameter MODE (see below).

The I-device must be in the RUN or STARTUP mode.

Enter the maximum number of bytes the data record to be sent should have with LEN. The selected length of the target range RECORD should have at least the length of LEN bytes.

If a request to make a data record available exists, (MODE=0), the output parameter NEW will be set to TRUE.

If the request for making a data record available is accepted, write RECORD for the positive answer to the superordinate controller with the requested data record and write zero for CODE1 and CODE2. If the request for making a data record available is to be rejected, enter the negative answer to the superordinate controller in Error Code 1 of the CODE1 and in Error Code 2 of theCODE2.

Note

If the I-device has received a request for making a data record available, you must recognize the delivery of this request within a certain time period. After recognition, you must send an answer to the superordinate controller within this time period. Otherwise the I-device will experience a timeout error which causes the operating system of the I-device to send a negative answer to the superordinate controller. For information on the value for the time period, refer to the specifications of your CPU.

The output parameter STATUS receives the error information after the occurrence of an error.

Operating modes

You can determine the operating mode of the instruction "PRVREC" with the input parameter MODE. This step will be explained in the following table.

MODE	Meaning
0	Check whether a request for making a data record available exists If a request from a higher-level controller for making a data record available exists on the I-device, the instruction will only write the output parameters NEW, SLOT, SUBSLOT, INDEX and RLEN. If you call the instruction several times with MODE=0, then the output parameter will only refer to one and the same request.
1	Receiving a request for making a data record available for any subslot of the I-device If such a request from a superordinate controller for any subslot of the I-device exists on the I-device, the instruction will write the output parameter.
2	Receiving a request for making a data record available for a specific subslot of the I-device If such a request from a superordinate controller for a specific subslot of the I-device exists on the I-device, the instruction will write the output parameter.
3	Make the data record available and send a positive answer to the superordinate controller The instruction checks the request of the superordinate controller to make a data record available, makes the request data record available to RECORD and sends a positive acknowledgement to the superordinate controller.
4	Sending a negative answer to the superordinate controller The instruction checks the request of the superordinate controller to make a data record available, rejects this request and sends a negative acknowledgement to the superordinate controller. Enter the reason for the rejection in the input parameters CODE1 and CODE2.

Note

After the receipt of a request (NEW=1) you must call the instruction twice to ensure complete processing. You must do this in the following order:

- First call with MODE=1 or MODE=2
- Second call with MODE=3 or MODE=4

Parameters

The following table shows the parameters of the "PRVREC" instruction:

Parameter	Declaration	Data type	Memory area	Description
MODE	Input	INT	I, Q, M, D, L or constant	Mode
F_ID	Input	HW_SUBMODULE	I, Q, M, D, L or constant	Subslot in the transfer area of the I-device for the data record to be sent (only relevant for MODE=2). The high word is always set to zero.
CODE1	Input	BYTE	I, Q, M, D, L or constant	Zero (for MODE=3) and/or Error Code 1 (for-MODE=4)
CODE2	Input	BYTE	I, Q, M, D, L or constant	Zero (for MODE=3) and/or Error Code 2 (for-MODE=4)
LEN	Input	UINT	I, Q, M, D, L or constant	Maximum length of the data record to be sent in bytes
NEW	Output	BOOL	I, Q, M, D, L	The new data record was requested by the superordinate controller.
STATUS	Output	DWORD	I, Q, M, D, L	Error information
SLOT	Output	HW_SUBMODULE	I, Q, M, D, L	Identical to F_ID
SUBSLOT	Output	HW_SUBMODULE	I, Q, M, D, L	Identical to F_ID
INDEX	Output	UINT	I, Q, M, D, L	Number of the data record to be sent
RLEN	Output	UINT	I, Q, M, D, L	Length of the data record to be sent
RECORD	InOut	VARIANT	I, Q, M, D, L	Data record made available Note: Note that for S7-300 CPUs the parameter RECORD always requires the full specification of the DB parameters (for example, P#DB13.DBX0.0 Byte 100). The omission of an explicit DB number is not permitted for S7-300 CPUs and results in an error message in the user program.

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameter STATUS

For interpretation of the parameter STATUS refer to section: Parameter STATUS (Page 3078)

PROFIBUS

DPSYC_FR: Synchronize DP slaves / Freeze inputs

Description

You use the instruction to synchronize one or more groups of DP slaves.

The function involves sending one of the control commands below, or a combination of them, to the relevant groups:

- SYNC (simultaneous output and freezing of output states on the DP slaves)
- UNSYNC (cancels the SYNC control command)
- FREEZE (freeze the input states on the DP slaves and read in the frozen inputs)
- UNFREEZE (cancels the FREEZE control command)

Before you send the control commands listed above, you must assign the DP slaves to groups per configuration. You must know which DP slave is assigned to which group, with which number and know the reactions of the various groups to SYNC/FREEZE.

Note

Note that the control commands SYNC and FREEZE also remain valid when you perform a warm/cold restart.

Please note also that you may initiate only one SYNC/UNSYNC job or only one FREEZE/ UNFREEZE job at a time.

Functional description

"DPSYC_FR" works asynchronously, that is, its execution extends over multiple calls. You start the job by calling "DPSYC_FR" with REQ=1.

The output parameters RET_VAL and BUSY indicate the status of the job.

See also: Meaning of the parameters REQ, RET_VAL and BUSY with asynchronous instructions (Page 2193).

Identification of a job

If you have triggered a SYNC/FREEZE job and called "DPSYC_FR" again before the first job was completed, the response of the instruction depends on whether the new call is for the same job. If the input parameters LADDR, GROUP and MODE match, the call is interpreted as a follow-on call.

Writing outputs of DP modules

The writing of outputs of DP modules is triggered as follows:

- By transfer commands to the DP I/O
- By writing the process image of the outputs to the modules (by the operating system at the end of OB 1 or by calling the instruction "UPDAT_PO (Page 3064)")
- Calling the "DPWR_DAT (Page 3126)" instruction.

In normal operation, the DP master transfers the output bytes cyclically (within the cycle of the PROFIBUS DP bus) to the outputs of the DP slaves.

If you want to have certain output data (possibly distributed on several slaves) applied to the outputs to the process at exactly the same time, you can send the SYNC control command to the relevant DP master using the "DPSYC_FR" instruction.

What are the effects of SYNC?

With the SYNC control command, the DP slaves of the selected groups are switched to Sync mode. In other words, the DP master transfers the current output data and instructs the DP slaves involved to freeze their outputs. With the following output message frames, the DP slaves enter the output data in an internal buffer and the state of the outputs remains unchanged.

Following each SYNC control command, the DP slaves of the selected groups apply the output data of their internal buffer to the outputs on the process.

The outputs are only updated cyclically again when you send the UNSYNC control command using the "DPSYC_FR" instruction.

Note

If the DP slaves of the selected group(s) are not currently connected to the network or have failed when the control command was sent, they will not be switched to SYNC mode. This information will not be communicated in the return value of the instruction.

Reading input data of DP modules

The input data of the DP modules are read as follows:

- Using load commands to the DP I/O
- When the process image of the inputs is updated (by the operating system at the start of OB 1 or by calling the "UPDAT_PI (Page 3062)" instruction)
- By calling the "DPRD_DAT (Page 3124)" instruction.

In normal operation, the DP master receives this input data cyclically (within the cycle of the PROFIBUS DP bus) from its DP slaves and makes them available to the CPU.

If you want to have certain input data (possibly distributed on several slaves) to be read from the process at exactly the same time, send the FREEZE control command to the relevant DP master using the "DPSYC_FR" instruction.

What are the effects of FREEZE?

With the FREEZE control command, the DP slaves involved are switched to Freeze mode, in other words the DP master instructs the DP slaves to freeze the current state of the inputs. It then transfers the frozen data to the input area of the CPU.

Following each FREEZE control command, the DP slaves freeze the state of their inputs again.

The DP master only receives the current state of the inputs cyclically again after you have sent the UNFREEZE control command with the "DPSYC_FR" instruction.

Note

If the DP slaves of the selected group(s) are not currently connected to the network or have failed when the control command has been sent, they will not be switched to FREEZE mode. This information will not be communicated in the return value of the instruction.

Data consistency

Because the DPSYC_FR functions are asynchronous and can be interrupted by higher priority classes, you should make sure that the process images are consistent with the actual inputs and outputs of the I/O when using the "DPSYC_FR" instruction.

This is guaranteed if you comply with the following consistency rules:

- Define suitable process image partitions for the "SYNC outputs" and the "FREEZE inputs" (only possible on the S7-400). Call the "UPDAT_PO (Page 3064)" instruction immediately before each first call of a SYNC job. Call the "UPDAT_PI (Page 3062)" instruction immediately after the respective last call of a FREEZE job.
- As an alternative: Use only direct I/O access for outputs involved in a SYNC job and for inputs involved in a FREEZE job. Do not write to these outputs when a SYNC job is active and do not read in these inputs when a FREEZE job is active.

Use of DPWR_DAT and DPRD_DAT

If you use the "DPWR_DAT (Page 3126)" instruction, it must be complete before you send a SYNC job for the outputs involved.

If you use the "DPRD_DAT (Page 3124)" instruction, it must be complete before you send a FREEZE job for the inputs involved.

Startup and "DPSYC_FR"

The user alone must take responsibility for sending the SYNC and FREEZE control commands in the startup OBs.

If you want the outputs of one or more groups to be in SYNC mode when the user program starts, you must initialize these outputs during startup and completely execute the "DPSYC_FR" instruction with the SYNC control command.

If you want the inputs of one or more groups to be in FREEZE mode when the user program starts, you must execute the "DPSYC_FR" instruction with the FREEZE control command completely for these inputs during startup.

Parameters

The following table shows the parameters of the "DPSYC_FR" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Level-triggered control parameter REQ = 1: Triggering of the SYNC/FREEZE job
LADDR	Input	HW_DPMASTER	I, Q, M, D, L or constant	Hardware identifier of the DP master interface The number can be taken from the properties of the DP master interface in the Network view or from the "System constants" tab of the standard tag table.
GROUP	Input	BYTE	I, Q, M, D, L or constant	Group selection Bit 0 = 1: group 1 selected Bit 1 = 1: group 2 selected : Bit 7 = 1: group 8 selected You can select several groups per job. The value B#16#0 is invalid.

Parameter	Declaration	Data type	Memory area	Description
MODE	Input	BYTE	I, Q, M, D, L or constant	Job ID (coding complies with EN 50 170 Volume 2, PROFIBUS) Bit 0: reserved (value 0) Bit 1: reserved (value 0) Bit 2: • = 1: UNFREEZE will be executed • = 0: no meaning Bit 3: • = 1: FREEZE will be executed • = 0: no meaning Bit 4: • = 1: UNSYNC will be executed • = 0: no meaning Bit 5: • = 1: SYNC will be executed • = 0: no meaning Bit 6: reserved (value 0) Bit 7: reserved (value 0) Possible values: • with exactly one ID per job: – B#16#04 (UNFREEZE) – B#16#08 (FREEZE) – B#16#10 (UNSYNC) – B#16#20 (SYNC) • with more than one ID per job: – B#16#14 (UNSYNC, UNFREEZE) – B#16#18 (UNSYNC, FREEZE) – B#16#24 (SYNC, UNFREEZE) – B#16#28 (SYNC, FREEZE)
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code. Make sure that you evaluate RET_VAL each time the block has been executed.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY=1: The SYNC/FREEZE job is not yet complete.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Note

If you access DPV1 slaves, error information of these slaves can be forwarded from the DP master to the instruction. For a description of this error information, refer to STATUS[3], STATUS (Page 3078) parameter.

Error code* (W#16#...)	Explanation
0000	Job completed without error.
7000	First call with REQ=0. The job specified with LADDR, GROUP and MODE is not active; BUSY has the value 0.
7001	First call with REQ=1. The job specified with LADDR, GROUP and MODE was triggered; BUSY has the value 1.
7002	Intermediate call (REQ irrelevant). The activated SYNC/FREEZE job is still running; BUSY has the value 1.
8090	The module selected with LADDR is not a DP master.
8093	This instruction is not permitted for the module selected with LADDR (configuration or version of the DP master).
8094	GROUP parameter is incorrect
8095	MODE parameter is incorrect
80A4	Communication on PROFIBUS disrupted.
80B0	The group selected with GROUP is not configured.
80B1	The group selected with GROUP is not assigned to this CPU.
80B2	The SYNC job specified with MODE is not permitted on the group selected with GROUP.
80B3	The FREEZE job specified with MODE is not permitted on the group selected with GROUP .
80C2	Temporary shortage of resources on the DP master: The DP master is currently processing the maximum number of jobs for a CPU.
80C3	This SYNC/UNSYNC job cannot be activated at present because only one SYNC/UNSYNC job can be triggered at a time. Check your user program.
80C4	This FREEZE/UNFREEZE job cannot be activated at present because only one FREEZE/UNFREEZE job can be triggered at a time. Check your user program.
80C5	Short circuit directly at DP interface
80C6	Job aborted due to I/O disconnection by CPU
80C7	Job aborted due to warm or cold restart on the DP master
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

DPNRM_DG: Read diagnostics data from a DP slave

Description

You use the "DPNRM_DG" instruction to read the current diagnostic data of a DP slave in the form specified in EN 50 170 Volume 2, PROFIBUS.

Refer to the following table for the basic structure of the slave diagnostic data and to the manuals of the DP slaves for further information.

Byte	Meaning
0	Station status 1
1	Station status 2
2	Station status 3
3	Master station number
4	Vendor ID (high byte)
5	Vendor ID (low byte)
6 ...	Additional slave-specific diagnostic information

The data that has been read is entered in the destination area indicated by RECORD following without error data transfer. You start the read process by assigning the value "1" to the REQ input parameter when the "DPNRM_DG" instruction is called.

Functional description

The reading process is executed asynchronously, in other words, it can extend over several calls. The output parameters RET_VAL and BUSY indicate the status of the job.

See also: Meaning of the parameters REQ, RET_VAL and BUSY with asynchronous instructions (Page 2193).

Parameters

The following table shows the parameters of the "DPNRM_DG" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = 1: Read request
LADDR	Input	HW_DPSLAVE	I, Q, M, D, L or constant	Configured diagnostic address of the DP slave Note: Address must be specified in hexadecimal form, for example, diagnostic address 1022 means: LADDR:=W#16#3FE.
RET_VAL	Return	DINT, INT, LREAL, REAL	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code. If no error has occurred, the length of the data actually transferred is entered in RET_VAL .

Parameter	Declaration	Data type	Memory area	Description
RECORD	Output	VARIANT	I, Q, M, D, L	Destination area for the diagnostic data that were read. Only the BYTE data type is permitted. The minimum length of the data record to be read or the destination area is 6. The maximum length of the data record to be sent is 240. Standard slaves can provide more than 240 bytes of diagnostic data up to a maximum of 244 bytes. In this case, the first 240 bytes are transferred to the destination area and the overflow bit is set in the data.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = 1: The reading process is not yet complete.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

You can find information on data type conversion in the different programming languages under "Overview of data type conversion (Page 2157)".

Parameter RECORD

The CPU evaluates the actual length of the read diagnostic data:

If the length specified for RECORD

- is less than the number of data bytes supplied, the data is discarded and a corresponding error code is entered in RET_VAL.
- is greater than or equal to the number of data bytes supplied, the data is accepted in the destination area and the actual length is entered in RET_VAL as a positive value.

Note

You must ensure that the actual parameters of RECORD correspond in all calls belonging to a job.

A job is uniquely identified by the LADDR input parameter.

Standard slaves with more than 240 bytes of diagnostic data

With standard slaves on which the number of standard diagnostic data is between 241 and 244 bytes, note the following points:

If the length specified for RECORD

- is less than 240 bytes, the data is discarded and a corresponding error code is entered in RET_VAL.
- If the length specified for RECORD is greater than or equal to 240 bytes, the first 240 bytes of the standard diagnostic data is transferred to the destination area and the overflow bit is set in the data.

Parameter RET_VAL

- If an error occurs while the function is being executed, the return value contains an error code.
- If no errors have occurred during data transfer, RET_VAL contains the length of the data read in bytes as a positive number.

Note

The amount of data read in a DP slave depends on its diagnostics status.

For the evaluation of the error information of the RET_VAL parameter, refer to the following table.

Error code (W#16#...)	Explanation	Restriction
7000	First call with REQ = 0: No data transfer active; BUSY has the value "0".	-
7001	First call with REQ = 1: Data transfer triggered; BUSY has the value "1".	Distributed I/O
7002	Intermediate call (REQ irrelevant): Data transfer already active; BUSY has the value "1".	Distributed I/O
8090	Address specified at parameter LADDR is invalid.	-
8093	This instruction is not permitted for the module selected by means of LADDR and IOID.	-
80A2	• DP protocol error at layer 2 (for example, slave failure or bus problems) • For ET 200S, data record cannot be read in DPV0 mode.	Distributed I/O
80A3	DP protocol error with user interface/user	Distributed I/O
80A4	Communication on PROFIBUS disrupted.	Distributed I/O
80B0	• Instruction not possible for module type. • The module does not recognize the data record. • Data record number 241 not permitted. • With "WR_REC (Page 3071)", data records 0 and 1 are not permitted.	-
80B1	The length specified in parameter RECORD is incorrect.	specified length < data record length
80B2	The configured slot is not assigned.	-
80B3	Actual module type does not match specified module type	-
80C0	There are no diagnostic data available.	-
80C1	The data of the previous write job on the module for the same data record have not yet been processed by the module.	-
80C2	The module is currently processing the maximum possible number of jobs for a CPU.	-
80C3	The required resources (memory, etc.) are currently occupied.	-

Error code (W#16#...)	Explanation	Restriction
80C4	Internal temporary error. Job could not be executed. Repeat the job. If this error occurs often, check your installation for sources of electrical interference.	-
80C5	Distributed I/O not available.	Distributed I/O
80C6	Data record transfer stopped due to priority class abort (restart or background)	Distributed I/O
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)	-

DP_TOPOL: Determine topology for DP master system

Description

You use the instruction to trigger the topology determination for a selected DP master system. Calling the instruction will address all diagnostics repeaters on a DP master system.

Note

The topology can only be determined for one DP master system at a time.

Topology determination is the prerequisite for the detailed display of the error location if line errors occur. After configuration and after every change to the physical configuration of a DP master system, you must repeat the topology determination with "DP_TOPOL".

Changes to the physical configuration are:

- Changes in line lengths
- Adding or removing stations or components with repeater function
- Changing station addresses

If an error is reported by a diagnostics repeater, "DP_TOPOL" writes the DPR and DPRI outputs for the duration of one "DP_TOPOL pass. If errors are reported by multiple diagnostics repeaters of the selected DP master system, "DP_TOPOL" writes DPR and DPRI with information regarding the first diagnostics repeater reporting the error. You can read out the entire diagnostic information on the programming device or using the "DPNRM_DG (Page 3139)" instruction. If no diagnostics repeater reports an error, the DPR and DPRI outputs have the value NULL.

If you want to repeat a topology determination after an error occurs, you must first reset "DP_TOPOL". This is done by calling "DP_TOPOL" with REQ=0 and R=1.

Functional description

"DP_TOPOL" works asynchronously, that is, its execution extends over multiple calls. You start determining the bus topology by calling "DP_TOPOL" with REQ=1 . If you want to cancel the process, call "DP_TOPOL" with R=1 .

The output parameters RET_VAL and BUSY indicate the status of the job.

See also: Meaning of the parameters REQ, RET_VAL and BUSY with asynchronous instructions (Page 2193).

Note

Determining the topology may take several minutes.

Identification of a job

The input parameter DP_ID uniquely specifies a job.

If you have called "DP_TOPOL" and you call this instruction again before the topology is re-determined, the manner in which the instruction reacts depends on whether the new call involves the same job: If the DP_ID parameter matches a job that has not yet been completed, then the call is interpreted as a follow-up call and the value W#16#7002 will be entered in RET_VAL. On the other hand, if another job is involved, the CPU rejects it.

Parameters

The following table shows the parameters of the "DP_TOPOL" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ=1: Trigger topology determination
R	Input	BOOL	I, Q, M, D, L or constant	R=1: Cancel topology determination
DP_ID	Input	HW_IOSYSTEM	I, Q, M, D, L or constant	DP master system ID of those master systems for which the topology will be determined
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY=1: Topology determination is not yet complete.
DPR	Output	BYTE	I, Q, M, D, L	PROFIBUS address of the diagnostics repeater reporting the error.
DPRI	Output	BYTE	I, Q, M, D, L	Measuring segment diagnostics repeater reporting the error: • Bit 0 = 1: Temporary faults on segment DP2 • Bit 1 = 1: Permanent faults on segment DP2 • Bit 4 = 1: Temporary faults on segment DP3 • Bit 5 = 1: Permanent faults on segment DP3

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

When looking at the "real" error information (error codes W#16#8xyz) in the following table, we distinguish between two cases:

- Temporary errors (error codes W#16#80A2 to 80A4, 80C3, 80C5):
  It is possible to eliminate this type of error without user action; in other words, it is advisable to call "DP_TOPOL" again (multiple calls, if necessary).
  Example of a temporary error: Resources required are currently in use (W#16#80C3).
- Permanent errors (error codes W#16#8082, 80B0, 80B2):
  This type of error does not correct itself. A new call of "DP_TOPOL" is only advisable after you have eliminated the error. Example of a permanent error: The DP master/CPU does not support this service. (W#16#80B0).

Error code* (W#16#...)	Explanation
0000	Job completed without error.
7000	First call with REQ=0. Topology determination is not triggered. BUSY has the value "0".
7001	First call with REQ=1. The request to execute topology determination was sent. BUSY has the value "1".
7002	Intermediate call (REQ irrelevant): Topology determination is not yet complete. BUSY has the value "1".
7010	You have attempted to cancel topology identification. But there is no running job with the specified DP_ID. BUSY has the value "0".
7011	First call with R=1. The cancellation of the topology determination was triggered. BUSY has the value "1".
7012	Intermediate call: The cancellation of the topology determination is not yet complete. BUSY has the value "1".
7013	Final call: The topology determination was cancelled. BUSY has the value "0".
8082	No DP master system is configured with the specified DP_ID.
80A2	Error during topology determination; for more detailed information, refer to output parameters DPR and DPRI.
80A3	Error during topology determination: Monitoring time has elapsed (timeout).
80A4	Communication on PROFIBUS disrupted.
80B0	The DP master/CPU does not support this service.
80B2	Error during topology determination: No diagnostics repeater was found at the selected DP master system.
80C3	Resources required are currently in use. Possible cause: You have initiated a second topology determination (only one topology determination is permitted at one time).
80C5	The DP master system is currently not available.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

ASi

ASI_CTRL

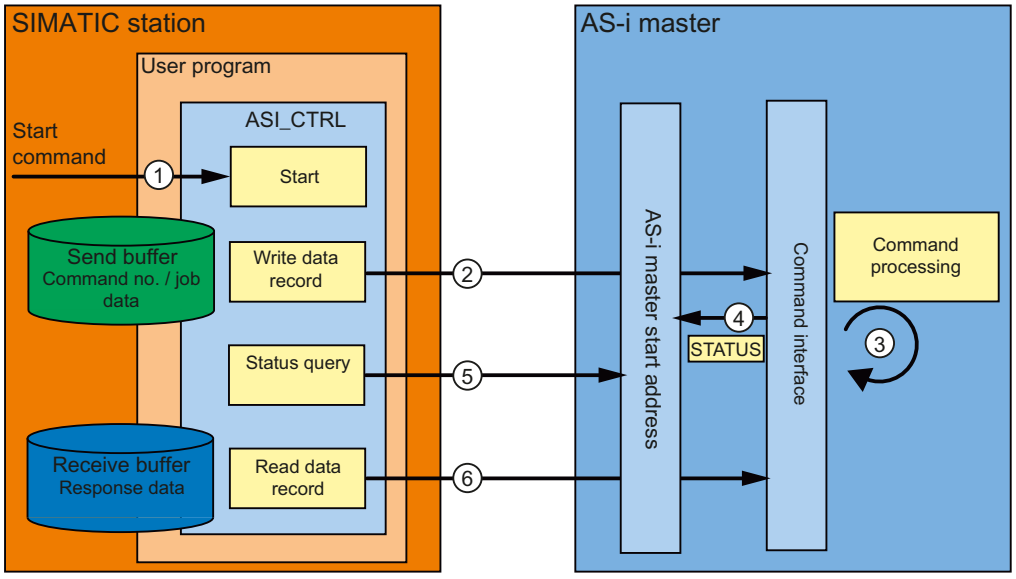
Description of ASI_CTRL

Description

Using the instruction "ASI_CTRL", you can control the behavior of the AS-i master from the user program of the PLC. The instruction processes the command protocol automatically. It also enables parameter assignment on SIMATIC AS-i masters and reading out information data. The functions and operation of the command interface are detailed in the manual for the AS-i master.

Both centrally inserted AS-i masters and distributed AS-i masters via PROFIBUS DP are supported. Combinations with PROFINET IO (e.g. IE/PB Link PN IO) are also possible.

The schematic diagram below shows the functions of the "ASI_CTRL" instruction:



① Start of processing at the REQ parameter.

② The program sends the required command to the AS-i master via the instruction "RDREC".

③ The AS-i master processes the command.

④ The current status of the AS-i master is stored in the input area of the binary data (logical start address).

⑤ The instruction "ASI_CTRL" cyclically queries and evaluates the 4 status bits.

⑥ Once command processing is complete, the command job is completed with "RDREC". Depending on the command, the data field of "RDREC" may contain the response data for the command or additional status information.

Differences in the command call between IE/ AS-i Link and DP/AS-i Links

There are significant differences in how a controller exchanges commands with an AS-i master.

- **IE/AS-i Link** (PROFINET) used the data record interface. The different commands are called with either "Write data record" ("WRREC" instruction) or "Read data record" ("RDREC" instruction) by various data record numbers.
- **DP/AS-i Links** (PROFIBUS) use the command interface. All commands are called by data record number 2 with "Write data record" ("WRREC" instruction) plus "Read data record" ("RDREC" instruction). The type of command is defined by the data content in the write job.

Changes compared to the instruction "ASi_3422".

The "ASI_CTRL" instruction is a revised version of the "ASi_3422" instruction (for S7-300/400 CPUs only) and provides improved functionality and compatibility. The specific changes are as follows:

- For writing and reading diagnostic data records, the instructions "WR_REC (Page 3123)" and "RD_REC (Page 3118)" have been replaced by the instructions "RDREC (Page 3069)" and "WRREC (Page 3071)". Their function is identical; however, they support data transfer via PROFINET IO.
- The block type of the instruction has been changed from a function (FC) to a function block (FB). "ASI_CTRL" has an instance data block and is multi-instance-capable.
- The designation of the formal parameters of "ASI_CTRL" complies with the SIMATIC system blocks. There is no STARTUP input parameter. The definition of the STATUS parameter is based on the instructions "RDREC (Page 3069)" and "WRREC (Page 3071)". The status identifiers for the parameter DONE and the new parameter BUSY have also been adjusted.

Operation of the "ASI_CTRL" instruction

The instruction "ASI_CTRL" is an asynchronous function block; in other words, its processing extends over multiple calls.

- A job is started with REQ = TRUE.
- The job status is displayed via the BUSY output parameters and the two central bytes of the output parameter STATUS.
- The BUSY parameter is set during job processing. Upon the first call, STATUS is assigned the value 00700100_H. Upon all subsequent calls for this job, it is assigned the value 00700200_H. When the job is complete, the result is output at the parameters DONE or ERROR.
  - If no errors have occurred, DONE is set. For jobs with response data from the AS-i master, this data is provided in the specified receive buffer. In such cases, the STATUS parameter also displays the volume of data supplied in bytes. For jobs without response data, the value 00000000_H is entered in STATUS.
  - If an error occurs during job processing, ERROR is set. The content of the receive buffer is invalid in such a case. An error code is entered in the STATUS parameter for a more detailed description of the error which has occurred.

Number of command calls

If you use the instruction "ASI_CTRL" to send commands, you may not simultaneously send other commands to the same AS-i master with "RDREC (Page 3069)" or "WRREC (Page 3071)". This also applies to multiple calls of the instruction for the same AS-i master.

The instruction "ASI_CTRL" cannot be run with interruptions. Calls therefore cannot be programmed in program priority classes which interrupt each other (for example with calls in OB 1 and in OB 35).

Parameters

The following table shows the parameters of the instruction "ASI_CTRL":

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L, constant	REQ = TRUE starts a new job unless a job is already in progress. No edge evaluation takes place.
LADDR	Input	WORD	I, Q, M, D, L, constant	Hardware identifier of the AS-i master. You can obtain the address from the module properties.
SD	Input	VARIANT	I, Q, M, D, L	Send buffer The parameter refers to a memory area in which the command is to be specified (see " ASi commands (Page 3148)").
RD	Input	VARIANT	I, Q, M, D, L	Receive buffer This buffer is only relevant for commands which deliver answer data. The parameter refers to a memory area in which a command response is stored (see "ASi commands (Page 3148)").
DONE	Output	BOOL	I, Q, M, D, L	DONE = TRUE: Job completed without errors.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = TRUE: Job in progress.
ERROR	Output	BOOL	I, Q, M, D, L	ERROR = TRUE: Job aborted with error.
STATUS	Output	DWORD	I, Q, M, D, L	Job status / error code See the "STATUS parameter" description.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Note

Parameters LADDR, SD, and RD

The parameters LADDR, SD, and RD must not be changed in any block cycle when a job is in progress: they must remain constant.

Parameter STATUS

The following table shows the possible STATUS displays dependent upon DONE and ERROR.

DONE	ERROR	STATUS	Meaning
0	0	00700000_H	First call with REQ = FALSE; no active job.
0	0	00700100_H	First call with REQ = TRUE; job has started.
0	0	00700200_H	Subsequent call (REQ irrelevant); job is still in progress.
1	0	00000000_H	Job completed without errors. No response data.
1	0	$0000xx00_H$	Job completed without errors. Number of xx bytes of response data.
0	1	$C0818400_H$	Data type of formal operand RD invalid.
0	1	$C0818500_H$	Error in communication with AS-i master (incorrect address configured at the LADDR parameter).
0	1	$C0838100_H$	Incorrect AS-i slave address.
0	1	$C0838200_H$	AS-i slave is not enabled (not in LAS).
0	1	$C0838300_H$	Error at the AS interface (the SD parameter may have been set too small).
0	1	$C0838400_H$	The command is not valid with the current AS-i master status.
0	1	$C0838500_H$	There is no AS-i slave with the address "0".
0	1	$C0838600_H$	The AS-i slave has invalid configuration data (I/O or ID codes).
0	1	$C083A100_H$	The AS-i slave addressed has not been found at the AS interface.
0	1	$C083A200_H$	There is no AS-i slave with the address "0".
0	1	$C083A300_H$	There is already an AS-i slave with the new address at the AS interface.
0	1	$C083A400_H$	The AS-i slave address cannot be deleted.
0	1	$C083A500_H$	The AS-i slave address cannot be set.
0	1	$C083A600_H$	The AS-i slave address cannot be permanently saved.
0	1	$C083A700_H$	Error during reading of the extended ID1 code.
0	1	$C083A800_H$	The target address is not plausible (e.g. a B slave address has been used for a standard slave).
0	1	$C083B100_H$	A length error has occurred during string transfer.
0	1	$C083B200_H$	A protocol error has occurred during string transfer.
0	1	$C083F800_H$	Unknown job number or job parameter.
0	1	$C083F900_H$	The AS-i master has detected an EEPROM error.

GET_ERR_ID: Get error ID locally (Page 2417)

ASi commands

Description

The command interface allows the controller and AS-i master to exchange parameter assignment and information data.

These commands

- provide the complete functionality of the M4 master profile of the AS-i master specifications.
- enable the AS-i master to be completely configured from the controller.

Note

AS-i commands supported

Please see the manual of the relevant AS-i master for the AS-i commands supported and a detailed description.

General structure of the send buffer

The general structure of the send buffer for commands and job data is set out in the table below. The area for the command number must always be filled. The number of bytes for the job data can be found in the description of the command (see AS-i master documentation). "q" is the start address of the send buffer.

Byte	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
	Meaning							
q + 0	Command number							
q + 1	Job data							
q + 2	Job data							
q + ...	Job data							

General structure of the receive buffer

The general structure of the receive buffer for the command response data is set out in the table below. The number of bytes for the response data depends on the command. Some commands do not return response data, and therefore only require the definition of a virtual receive buffer which is not filled with data. "n" is the start address of the receive buffer.

Byte	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
	Meaning							
n + 0	Command number (echo)							
n + 1	Response data							
n + 2	Response data							
n + ...	Response data							

Caution

Memory areas can be overwritten

If the receive buffer of the "ASI_CTRL" instruction is too short, neighboring memory areas may be overwritten. The length specified in the ANY pointer of the RD parameter when the instruction "ASI_CTRL" is called is irrelevant. The required length for the receive buffer can be found in the description of the command.

The following applies for command numbers 39_H, 41_H, 42_H, 43_H and 44_H:

The receive buffer must be 221 bytes long (bytes 0 to 220), even if the command returns less data. Depending on the command, the highest bytes in the receive buffer may be overwritten with zero values by the AS-i master.

AS-i commands

A selection of possible AS-i commands is set out in the table below.

Name	Parameter	Return	Coding
Set_permanent_parameter (Set_Permanent_Parameter)	Slave address, parameter		00_H
Get_permanent_parameter (Get_Permanent_Parameter)	Slave address	Parameter	01_H
Write_parameter (Write_Parameter)	Slave address, parameter	Parameter echo	02_H
Read_parameter (Read_Parameter)	Slave address	Parameter value	03_H
Store_actual_parameters (Store_Actual_Parameters)			04_H
Set_configuration_data	Slave address, configuration		25_H
Get_configuration_data	Slave address	set configuration data	26_H
Store_actual_configuration (Store_Actual_Configuration)			07_H
Get_actual_configuration	Slave address	Actual configuration data	28_H
Configure_LPS	LPS		29_H
Set_offline_mode	Mode		$0A_H$
Select_auto-program	Mode		$0B_H$
Set_mode	Mode		$0C_H$
Change_AS–iSlave_address (Change_AS–iSlave_Address)	Address1, Address2		$0D_H$
Get_AS-iSlave_status	Slave address	Error record of the AS-i slave	$0F_H$
Read_lists_and_flags		LDS, LAS, LPS, flags	30_H
Get_overall_configuration		Actual configuration data, current parameters, LAS, flags	39_H

Name	Parameter	Return	Coding
Set_overall_configuration	Overall configuration		3A $_H$
Write_parameter_list	Parameter list		3C $_H$
Read_parameter_echo_list		Parameter echo list	33 $_H$
Write_CTT2_request	Slave address CTT2 string	CTT2 string	44 $_H$
Read_version_identifier		Version string	14 $_H$
Read_AS-i_slave	Slave address	ID code	17 $_H$
Read_AS-i_slave_extended_ID1	Slave address	Extended ID1 code	37 $_H$
Write_AS-iSlave_extended_ID1	Extended ID1 code		3F $_H$
Read_AS-iSlave_extended_ID2	Slave address	Extended ID2 code	38 $_H$
Read_AS-iSlave_IO	Slave address	I/O configuration	18 $_H$
Read_I/O_error_list		LPF	3E $_H$
Write_AS–i-slave_parameter_string	Slave address, parameter string		40 $_H$
Read_AS–iSlave_parameter_string	Slave address	Parameter string	41 $_H$
Read_AS-iSlave_ID_string	Slave address	ID string	42 $_H$
Read_AS-iSlave_diagnostic_string	Slave address	Diagnostic string	43 $_H$
Read_AS-i_line_error_counter			4A $_H$
Read_and_clear_AS-i_line_error_counter			4B $_H$
Read_AS-iSlave_error_counter	Slave address		4C $_H$
Read_and_clear_AS-iSlave_error_counter	Slave address		4D $_H$
Additional command for DP/ AS-i F-Link:			
AS–i_status/diag_of_F_slaves		Status/diagnostics of all AS-i safe slaves	51 $_H$

Note

Re-initializing the AS-i master command interface

Another command which is not mentioned in the table is command 77 $_H$. This call re-initializes the command interface of the AS-i master. Any command which the AS-i master specified is currently processing will be terminated.

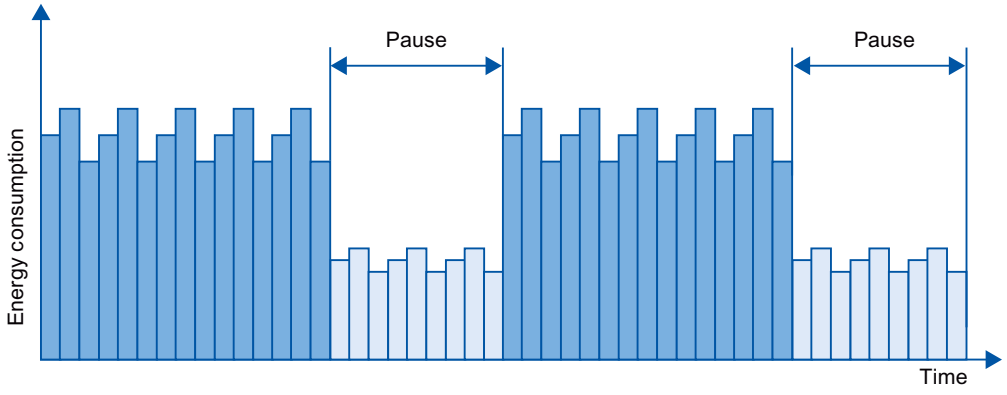
As of version V2.1.20 of DP/AS-i LINK Advanced, command 0E $_H$ is also available. This call enables you to release and block the ground fault monitoring function for a line.

11.6.3.5 PROFIenergy

Description of PROFIenergy

PROFIenergy

PROFIenergy is a manufacturer- and device-neutral profile for energy management with PROFINET. PROFIenergy enables central, coordinated device shutdown to reduce electricity consumption during breaks in production and unplanned interruptions.



The PROFINET devices/power modules are switched off via special commands in the user program of the PROFINET IO controller. No additional hardware is required. The PROFINET devices interpret the PROFIenergy commands directly.

PROFIenergy controller (PE controller)

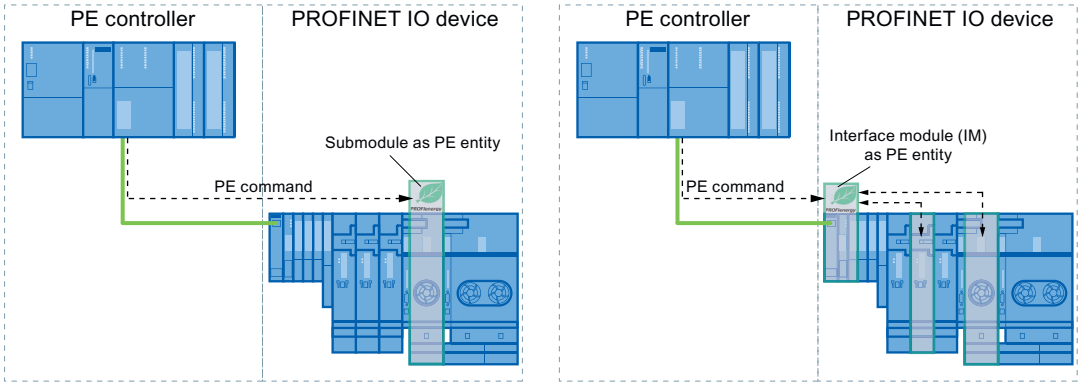
The PE controller is a PLC which enables/disables the idle state in lower-level devices. Individual production components and entire production lines are switched off and reactivated from the user program. Commands (e.g. "Start_Pause" and "End_Pause") are sent to the lower-level device using corresponding instructions (function blocks). The commands are sent via the PROFINET communication protocol.

PROFIenergy entity (PE entity)

The PE entity receives the PROFIenergy commands of the PE controller and executes these accordingly (for example, by returning a measured value or activating an energy saving mode). Implementation of the PE entity in a PROFIenergy-capable device is device- and manufacturer-specific.

The PE entity can, for example, be executed:

- Within the proxy of a submodule: The PE commands are valid for the addressed submodule and any existing lower-level submodules.
- Within the proxy of a module: The PE commands are valid for different submodules within the module.



- For networked submodules without a proxy function: The PE commands in this case are only valid for the respective submodule.

PROFIenergy instructions

- Instructions for IO controller
  - The "PE_START_END (Page 3154)" instruction represents the simplest way to activate or deactivate the idle state of the PROFINET devices (PROFIenergy commands "Start_Pause" and "End_Pause"). This is done using a positive and negative signal edge in the instruction.
  - The "PE_CMD (Page 3159)" instruction allows you to transmit all PROFIenergy commands, including "Start_Pause" and "End_Pause". With other commands, you can query the current status of the PROFINET devices or the behavior during breaks, for example.
  - The instruction "PE_DS3_Write_ET200S (Page 3164)" is used to define the switching characteristic of up to 8 slots of ET 200S. The instruction is not a PROFIenergy instruction; however, it supplements the PROFIenergy functions for an ET 200S.
- Instruction for iDevices
  The "PE_I_DEV (Page 3189)" instruction allows you to implement PROFIenergy on iDevices as well. The instruction receives PROFIenergy commands on the iDevice and forwards these to the user program for processing. After processing the command, the user program calls the "PE_I_DEV (Page 3189)" instruction again in order to send the acknowledgement to the IO controller. For these replies, each command offers you a corresponding auxiliary block that supplies the response data to the instruction "PE_I_DEV (Page 3189)".

PROFIenergy commands (PE commands)

The PE controller transmits PE commands to the PE entity. The PE command can be either a control command to switch a PE entity to the energy-saving mode, or a command to read a status or measured value:

- PI commands for control
  PROFIenergy supports two control commands that can be executed using either the "PE_Start_End (Page 3154)" instruction or the "PE_CMD (Page 3159)" instruction:
  - Start_Pause: Starting a suitable energy-saving mode (PE Energy-saving mode)
  - End_Pause: Exiting the energy-saving mode (switch to PE_ready_to_operate mode)
- PI commands for reading a status or measured value
  Certain condition information can be read by the control system using the following status commands with the instruction "PE_CMD (Page 3159)":
  - PE_Identify: Read out which PE commands are supported by the PE entity.
  - PEM_Status: Read out the currently active mode of a PE entity (e. g. PE_ready_to_operate).
  - Query_Modes: Output an overview of all supported energy-saving modes, including the time and energy information
  - Query_Measurement: Output the measured values of a PE entity

Example applications

Examples for use of PROFIenergy instructions can be found in the Industry Online Support in the entry "PROFIenergy - Saving Energy with SIMATIC S7 (http://support.automation.siemens.com/WW/view/en/41986454)".

Service and Support (http://support.automation.siemens.com/)

IO controller

PE_START_END: Start and exit energy-saving mode

Description

The instruction "PE_START_END" is used to start and exit the energy-saving mode of a specified PE entity (e.g. ET 200S).

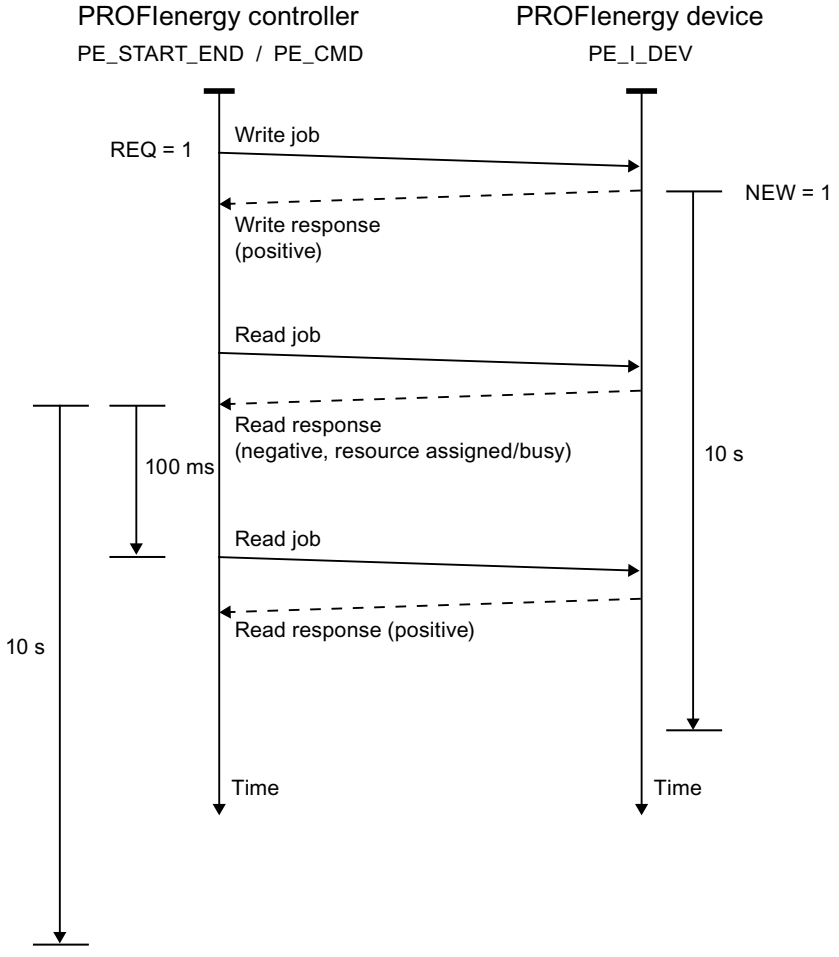
The instruction "PE_START_END" is used in the PE controller, preferably when only field devices from which energy data does not need to be read out are connected to the corresponding PE devices. Alternatively, the instruction "PE_CMD (Page 3159)" can be used to read energy data.

The energy-saving modes are configured in the user program of the PE controller. On completion of the "PE_START_END" instruction, the PE entity reports its current energy-saving mode and outputs this data at parameter PE_MODE_ID.

Write and read jobs of the "PE_START_END" instruction.

The instruction "PE_START_END" sends a PROFIenergy command internally as a write job to the PE entity using "WRREC (Page 3071)". "PE_START_END" then waits for acknowledgment from the PE entity. The acknowledgment data record is read with the instruction "RDREC (Page 3069)" every 100 milliseconds. Until acknowledgment is received from the PE entity, the function repeats the read job for 10 seconds at intervals of 100 milliseconds. The response data of the PE entity is also read with the instruction "RDREC (Page 3069)".

Below is a flowchart of the write and read jobs:



Parameter

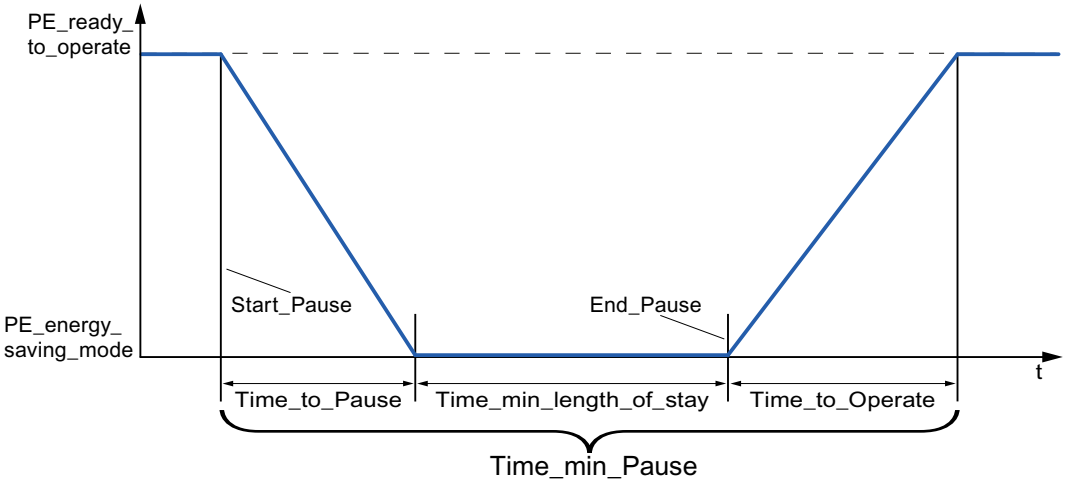
The following table shows the parameters of the instruction "PE_START_END":

Parameter	Declaration	Data type	Memory area	Description
START	Input	BOOL	I, Q, M, D, L or constant	Transmitting the PE command "Start_Pause" to the PE entity with the address set at parameter ID.
END	Input	BOOL	I, Q, M, D, L or constant	Transmitting the PE command "End_Pause" to the PE entity with the address set at parameter ID.
ID	Input	HW_SUBMODULE	I, Q, M, D, L or constant	Address of the PE entity Use the hardware ID of the head module for a PROFINET IO device. Refer to the system constants of the assigned IO controller for the hardware ID. The name of the head module is composed of the name of the IO device and the suffix [Head] (example: "IO_Device_1[Head]"). If the PE entity is an I-device, use the hardware identifier of a transfer area instead.
PAUSE_TIME	Input	TIME	I, Q, M, D, L, P or constant	Planned pause duration. • Range: T#1MS to T#24D20H31M23S647MS • Start value: T#0MS
VALID	Output	BOOL	I, Q, M, D, L	PE command successfully sent.
BUSY	Output	BOOL	I, Q, M, D, L	PE command still being processed.
ERROR	Output	BOOL	I, Q, M, D, L	Error occurred during processing. The error message is output at the STATUS parameter.
STATUS	Output	DWORD	I, Q, M, D, L, P	Block status / error number (see "STATUS parameter")
PE_MODE_ID	Output	BYTE	I, Q, M, D, L, P	Identification number of energy-saving mode (energy-saving level for the duration of the pause).

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

PAUSE_TIME parameter

The parameter PAUSE_TIME is used to set the default duration of the energy-saving period at the PE entity. The PE entity checks whether the pause period is of sufficient length and whether it can be implemented. The minimum pause duration (Time_min_Pause) must be greater than the sum of the times the device needs to switch to energy-saving mode (Time_to_Pause) and to switch back to operating mode (Time_to_Operate).



ET 200S checks whether the scheduled pause duration is greater than or equal to the minimum pause duration (PM-E_Pause_Min) saved on the ET 200S. This is fixed at 10 seconds. If a shorter pause is used, the power modules (PM-E) of the ET 200S will remain on.

The module does not switch back on automatically at the end of the pause; it remains in OFF mode until the "END" command is sent. This prevents uncoordinated switch-on, which can cause undesired peak loads.

STATUS parameter

Error information is output at the STATUS output parameter. If it is interpreted as ARRAY[1...4] of BYTE, the error information has the following structure:

Field element	Name	Meaning
STATUS[1]	Function_Num	Cause of the error • B#16#**00**: No error • B#16#**DE**: Error during reading of data record • B#16#**DF**: Error during writing of data record • B#16#**C0**: Error message from the instruction or from the communication instructions "RDREC (Page 3069)" and "WRREC (Page 3071)" used internally.
STATUS[2]	Error_Decode	Location of the error ID • **80**: DPV1 error as defined in IEC 61158-6 or application-specific • **FE**: DP/PNIO profiles - PROFIenergy-specific error

Field element	Name	Meaning
STATUS[3]	Error_Code_1	Error ID • When Error_Decode = **80**: – **80**: Simultaneous positive edge at the input parameters START and END. – **81**: Length conflict at the CMD_PARAM and CMD_PARAM_LEN parameters. – **82-8F**: Other error messages (reserved) • When Error_Decode = **FE**: – **01**: "Service Request ID" invalid – **02**: Incorrect "Request_Reference" – **03**: "Modifier" invalid – **04**: "Data Structure Identifier RQ" invalid – **05**: "Data Structure Identifier RS" invalid – **06**: "PE energy-saving modes" are not supported – **07**: "Response" is too long (maximum transmissible length exceeded) – **08**: "Count" invalid – **50**: No suitable "energy mode" is available. – **51**: Time value specified is not supported. – **52**: "PE_Mode_ID" invalid – **53**: Cannot switch to "PE energy-saving mode" because the device is in operation – **54**: Function cannot be used at this time. Wrong device configured or incorrect setup. – **55** to **FF**: Reserved
STATUS[4]	Error_Code_2	Manufacturer-specific error ID extension

Note

Error messages of the instructions RDREC and WRREC

The instruction "PE_START_END" uses the instructions "WRREC (Page 3071)" and "RDREC (Page 3069)" for communication. Error messages for these instructions are output in the field elements STATUS[1] to STATUS[4].

Please see the description of the corresponding STATUS (Page 3078) parameter for an explanation of the error codes of the "WRREC (Page 3071)" and "RDREC (Page 3069)" instructions.

Description of PROFIenergy (Page 3152)

PE_CMD: Start and exit energy-saving mode / Read out status information

Description

The instruction "PE_CMD" is used in the PE controller to start or terminate a pause in the energy-saving mode in the PE entity. Additional information and energy measurements can also be read out from a PE entity using "PE_CMD".

The instruction is best used with PE controllers to which assigned PE devices are connected from which energy measurements are to be read out. If this is not the case, the instruction "PE_START_END (Page 3154)" can also be used to start and end the pauses.

Transfer of the PROFIenergy commands (PE commands)

The instruction "PE_CMD" transfers a PROFIenergy command to a PE entity.

The instruction can also be used if additional commands are to be added to the PROFIenergy profile in future. The commands which can be used with the current PROFIenergy profile are listed in the description of the CMD and CMD_MODIFIER parameters (see the "CMD and CMD_MODIFIER parameters" table).

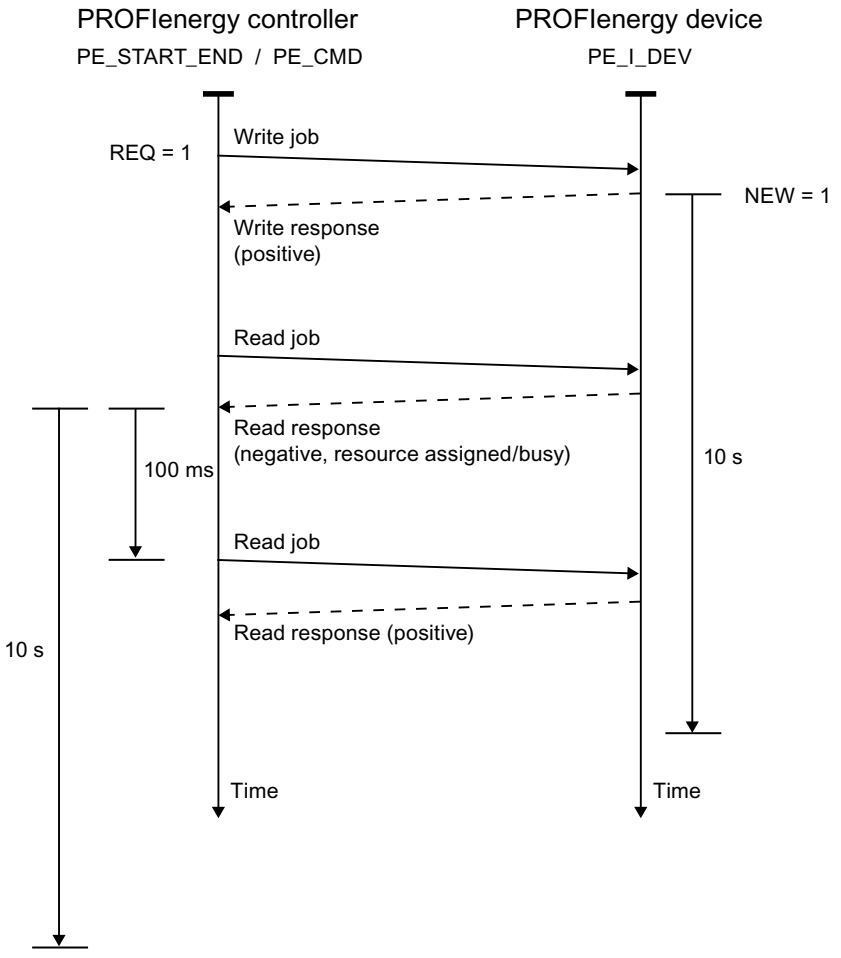
- The individual PE commands which are transferred to the PE entity using the instruction are assigned defined "Service_Request_IDs". The Service_Request_IDs 01 to 05 and 16 are assigned at the CMD parameter.
- The two PE commands 04 (Query_Modes) and 16 (Query_Measurement) are defined in more detail with the CMD_MODIFIER parameter.
- Additional values are transferred at the CMD_PARA parameter for individual PE commands (see the description of the individual PE commands). The parameter CMD_PARA_LEN defines the length of the data at the parameter CMD_PARA.

The commands are transferred without plausibility test. The response data of the PE entity is saved to the RESPONSE_DATA data area that is addressed by VARIANT pointer (for information about the response frame contents, refer to the description of the respective PE command).

Write and read jobs of the "PE_CMD" instruction.

The instruction "PE_CMD" uses "WRREC (Page 3071)" internally to transmit a PROFIenergy command as a write job to the PE entity. "PE_CMD" then waits for the acknowledgment from the PE entity. The acknowledgment data record is read with the instruction "RDREC (Page 3069)" every 100 milliseconds. Until acknowledgment is received from the PE entity, the function repeats the read job for 10 seconds at intervals of 100 milliseconds. The response data of the PE entity is also read with the instruction "RDREC (Page 3069)".

Below is a flowchart of the write and read jobs:



Parameter

The following table shows the parameters of the instruction "PE_CMD":

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Starts transferring the PE command upon a positive edge.
ID	Input	HW_ SUBMODULE	I, Q, M, D, L or constant	Address of the PE entity Use the hardware ID of the head module for a PROFINET IO device. Refer to the system constants of the assigned IO controller for the hardware ID. The name of the head module is composed of the name of the IO device and the suffix [Head] (example: "IO_Device_1[Head]"). If the PE entity is an I-device, use the hardware identifier of a transfer area instead.

Parameter	Declaration	Data type	Memory area	Description
CMD	Input	BYTE	I, Q, M, D, L, P or constant	Service-Request-ID of the PROFIenergy command in accordance with the PROFIenergy profile (see "CMD and CMD_MODIFIER parameters"). Further service request IDs are possible following extensions of the PROFIenergy profile.
CMD_MODIFIER	Input	BYTE	I, Q, M, D, L, P or constant	PROFIenergy sub-command (only when CMD=3 or CMD=16, see "CMD and CMD_MODIFIER parameters") Further sub-commands are possible following extensions of the PROFIenergy profile.
CMD_PARA	Input	VARIANT	I, Q, M, D, L	Parameters for the PE commands: • Get mode: PE_mode_ID • Get measurement values: List of Measurement_Ids The complete Service Data Request is entered.
CMD_PARA_LEN	Input	INT	I, Q, M, D, L, P or constant	The actual length of the command parameters (<= length defined in CMD_PARA; is verified by the instruction).
RESPONSE_DATA	InOut	VARIANT	I, Q, M, D, L	PROFIenergy information May be complete response frame including block header, depending on the command. Note: If the buffer is too small, only the number of bytes which is specified in the VARIANT pointer will be entered.
VALID	Output	BOOL	I, Q, M, D, L	Command successfully sent.
BUSY	Output	BOOL	I, Q, M, D, L	Command still being processed.
ERROR	Output	BOOL	I, Q, M, D, L	Error occurred during processing.
STATUS	Output	DWORD	I, Q, M, D, L	Block status / error number (see "STATUS parameter"):

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameters CMD and CMD_MODIFIER

CMD	CMD_ MODIFIER	PROFIenergy command	Description
01	0	Start_Pause (Page 3179)	Start energy-saving mode or switch to a different energy-saving mode.
02	0	End_Pause (Page 3179)	End energy-saving mode.

CMD	CMD_ MODIFIER	PROFIenergy command	Description
03	1	Query_Modes - List of energy-saving modes (Page 3180)	Output the energy-saving modes supported.
	2	Query_Modes - Get mode (Page 3181)	Output attributes of the energy-saving mode currently enabled.
04	0	PEM_Status (Page 3183)	Query status of energy-saving mode.
05	0	PE_Identify (Page 3185)	Read out the number and description of PE commands supported.
16	1	Query_Measurement - Get_Measurement_List (Page 3185)	List of measured values supported by the PE entity.
	2	Query_Measurement - Get_Measurement_Values (Page 3188)	Output the measured values of the PE entity.

STATUS parameter

Error information is output at the STATUS output parameter. If it is interpreted as ARRAY[1...4] of BYTE, the error information has the following structure:

Field element	Name	Meaning
STATUS[1]	Function_Num	Cause of the error • B#16#**00**: No error • B#16#**DE**: Error during reading of data record • B#16#**DF**: Error during writing of data record • B#16#**C0**: Error message from the internal communication instructions "RDREC (Page 3069)" and "WRREC (Page 3071)".
STATUS[2]	Error_Decode	Location of the error ID • **80**: DPV1 error as defined in IEC 61158-6 or application-specific • **FE**: DP/PNIO profiles - PROFIenergy-specific error

Field element	Name	Meaning
STATUS[3]	Error_Code_1	Error ID • When Error_Decode = **80**: – **81**: Length conflict at the CMD_PARA and CMD_PARA_LEN parameters, or maximum data record length (4095 bytes) exceeded. – **82-8F**: Other error messages (reserved) • When Error_Decode = **FE**: – **01**: "Service Request ID" invalid – **02**: Incorrect "Request_Reference" – **03**: "Modifier" invalid – **04**: "Data Structure Identifier RQ" invalid – **05**: "Data Structure Identifier RS" invalid – **06**: "PE energy-saving modes" are not supported – **07**: "Response" is too long (maximum transmissible length exceeded) – **08**: "Count" invalid – **50**: No suitable energy-saving mode (energy mode) is available. – **51**: Time value specified is not supported. – **52**: "PE_Mode_ID" invalid
STATUS[4]	Error_Code_2	Manufacturer-specific error ID extension

Note

Error messages of the instructions RDREC and WRREC

The instruction "PE_CMD" uses the instructions "WRREC (Page 3071)" and "RDREC (Page 3069)" for communication. Error messages for these instructions are output in the field elements STATUS[1] to STATUS[4].

Please see the description of the corresponding STATUS (Page 3078) parameter for an explanation of the error codes of the "WRREC (Page 3071)" and "RDREC (Page 3069)" instructions.

PE_DS3_Write_ET200S: Set power module switching behavior

Description

The instruction "PE_DS3_Write_ET200S" sends basic settings for power module switching behavior to the ET 200S. The switching behavior of up to 8 slots in the ET 200S (e.g. for power modules) can be defined with the instruction "PE_DS3_Write_ET200S".

Note

This instruction is not part of the PROIenergy profile but instead supplements SIMATIC-specific functions.

Parameter

The following table shows the parameters of the instruction "PE_DS3_Write_ET200S":

Parameter	Declaration	Data type	Memory area	Description
ENABLE	Input	BOOL	I, Q, M, D, L or constant	A positive edge triggers the transfer of the data record. The data record must be transferred again after voltage OFF/ON.
ID	Input	HW_SUBMODULE	I, Q, M, D, L or constant	Address of the ET 200S The address may be taken from the hardware configuration.
SLOT_NO_X	Input	INT	I, Q, M, D, L, P or constant	Slot number of switchable power module X.
FUNC_X	Input	INT	I, Q, M, D, L, P or constant	Function of the module in this slot. Use the parameter FUNC_X to define the switching behavior of the PM-E (power module of the ET 200S): • FALSE: – With "PAUSE_START": -No effect on PM-E -PM-E remains on – With "PAUSE_STOP": -Switches PM_E back on • TRUE: – With "PAUSE_START": -Switches PM_E off – With "PAUSE_STOP": -Switches PM-E back on
BUSY	Output	BOOL	I, Q, M, D, L	Transfer not yet complete.
DONE	Output	BOOL	I, Q, M, D, L	Transfer completed without errors.
ERROR	Output	BOOL	I, Q, M, D, L	Transfer completed with error.
STATUS	Output	DWORD	I, Q, M, D, L, P	Error number (see STATUS parameter of the instruction "PE_Start_End (Page 3154)")

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Description of PROFIenergy (Page 3152)

PE_WOL: Starting and stopping energy-saving mode via WakeOnLan

Description PE_WOL

Description

The "PE_WOL" instruction sends the PROFIenergy commands "Start_Pause" and "End_Pause" to multiple PROFIenergy-enabled devices in the PROFINET I/O systems.

Multiple PE devices can be coordinated via the instruction provided that the PE devices support the "Wake on LAN" function over a UDP connection.

The "PE_WOL" instruction can only be executed on a CPU with and integrated Ethernet interface. This CPU should be able to load blocks with a size of about 400 KB. You cannot use the block with PROFINET I/O systems that are connected via an Ethernet CP.

The instruction "PE_WOL" is executed asynchronously.

Definition: Wake on LAN

The Wake on LAN function allows data processing equipment to resume working from a state near total shutdown when a special Ethernet packet is received.

For this procedure to work, the data processing equipment must have a network controller that is capable of receiving such a packet.

This packet (Magic Packet™) has a special format. It contains the MAC address of the network adapter 15 times.

Selection of devices

The devices are selected using the user data block at the parameter PENERGY (Type: "PE_PLUS"). The user DB represents the database for processing multiple devices.

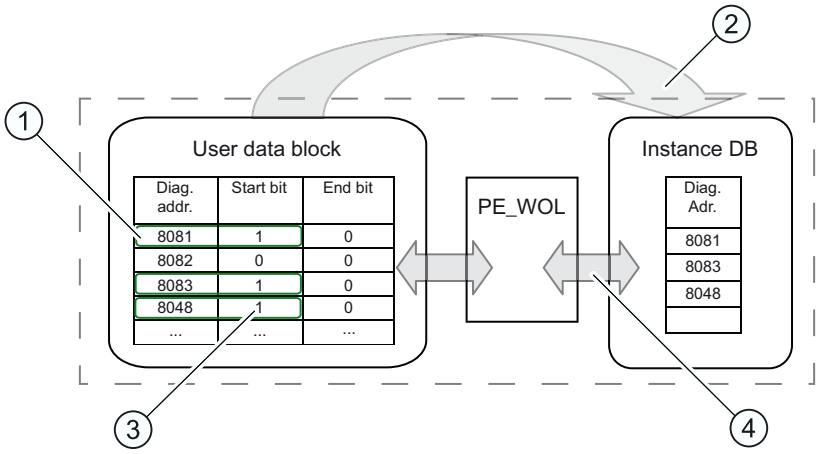
Prior to initialization of "PE_WOL", you must store at least the following information in the user DB:

- ID of the PROFINET I/O system
- Data of the connection which is used for "Wake On LAN".

- Port number which is used for "Wake On LAN".
- For each device
  - Pause time (PauseTime)
  - Switching of the device to the PE_SLEEP_MODE (EnableSleep)

You initialize the "PE_WOL" instruction with the COM_RST parameter. The jobs stored in the user DB are processed one after the other after initialization.

The graphic below illustrates how the PE command "Start_Pause" is transmitted to several devices:



(1) Step 1: The bit "CmdStartPause" of the devices to be shut down is set to "1" by the user.

(2) Step 2: The diagnostic addresses of the devices to be shut down (CmdStartPause = "1") are linked to the queue.

(3) Step 3: The bit "CmdStartPause" is reset automatically once the jobs have been linked.

(4) Step 4: The instruction "PE_WOL" processes the jobs as soon as they are linked.

A PROFIenergy command "CmdStartPause" or "CmdEndPause" can be sent for all recognized devices in the PROFINET IO system via the START and END parameters.

The status of the job processing as well as possible errors during processing are output by the STATUS parameter.

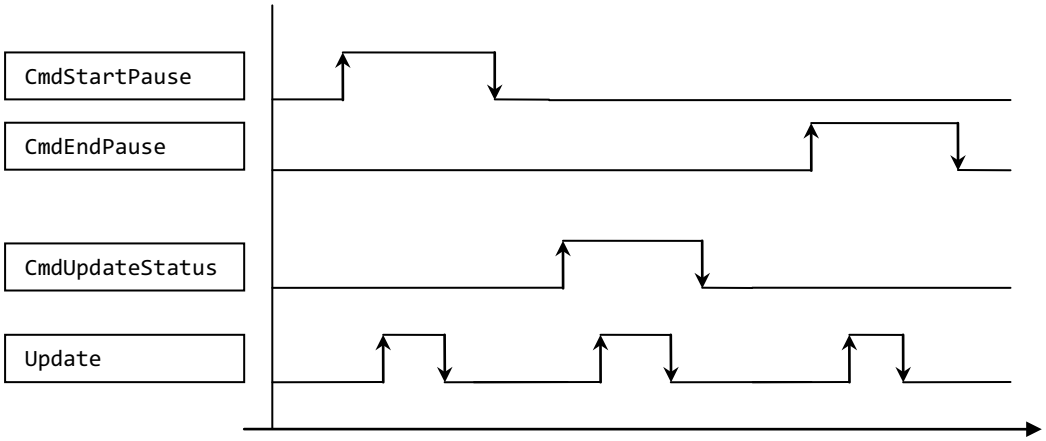
Operation of the instruction using the user DB

The operation of the instruction "PE_WOL" can only take place via the user DB. A basic procedure applies in this case:

1. Selection of the command to be executed for a device:
   - START_PAUSE ("CmdStartPause" in user DB)
   - ENDE_PAUSE ("CmdEndPause" in user DB)
   - UPDATE_STATUS ("CmdUpdateStatus" in user DB)
2. Setting the bit for updating ("Update" in the header of the user DB)
   At least one CPU cycle should pass with an "Update" = False between two updates; otherwise, edge detection cannot be guaranteed.

Prioritizing the PE commands

The graphic below shows the chronological sequence of three possible commands.



These are processed one after the other, regardless of whether the previous command call was successful or completed with an error.

Only one command is executed if you set two commands, such as "CmdEndPause" and "CmdUpdateStatus" simultaneously. A prioritization is present within the block:

- The command "CmdStartPause" has the highest priority and is therefore always executed if selected.
- The command "CmdEndPause" has the second highest priority.
- The command "CmdUpdateStatus" has the lowest priority.

If all three commands are set at the same time, the commands that are not executed remain preselected. In this case, the next rising edge executes the next command.

Parameters

The following table shows the parameters of the "PE_WOL" instruction:

Parameter	Declaration	Data type	Memory area	Description
COM_RST (Page 3168)	Input	BOOL	I, Q, M, D, L	Resets the block and performs a re-initialization. As long as True is set here, the initialization is started but not yet fully completed. Only the falling edge continues the initialization and switches to the normal operating mode after initialization.
START (Page 3169)	Input	BOOL	I, Q, M, D, L	A rising edge performs a "CmdStartPause" PROFIenergy command for all detected devices that support this function.
END (Page 3170)	Input	BOOL	I, Q, M, D, L	A rising edge performs a "CmdEndPause" PROFIenergy command for all detected devices that support this function.

Parameter	Declaration	Data type	Memory area	Description
PENERGY (Page 3170)	InOut	PE_PLUS	D	Pointer to the user DB that contains the database for processing multiple devices.
STATUS (Page 3175)	Output	DWORD	I, Q, M, D, L	Status/error number for the current status of the instruction (see "STATUS parameter").

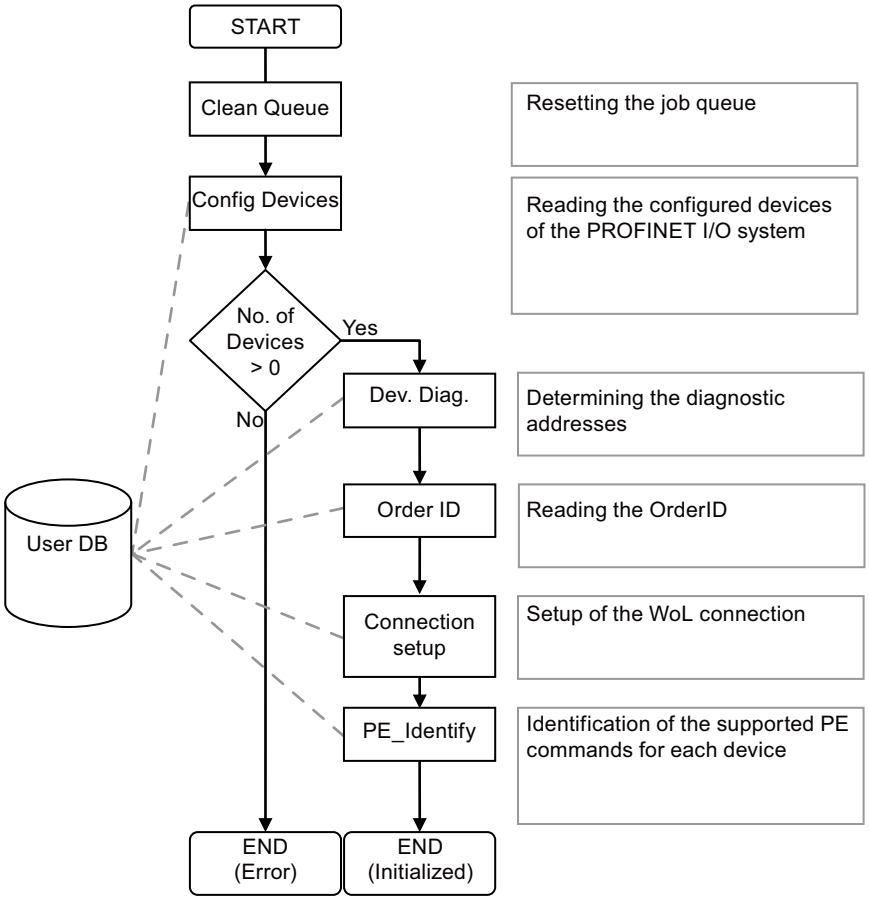
For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameter COM_RST

Sequence of the initialization routine

You start the initialization of the "PE_WOL" instruction with the COM_RST parameter.

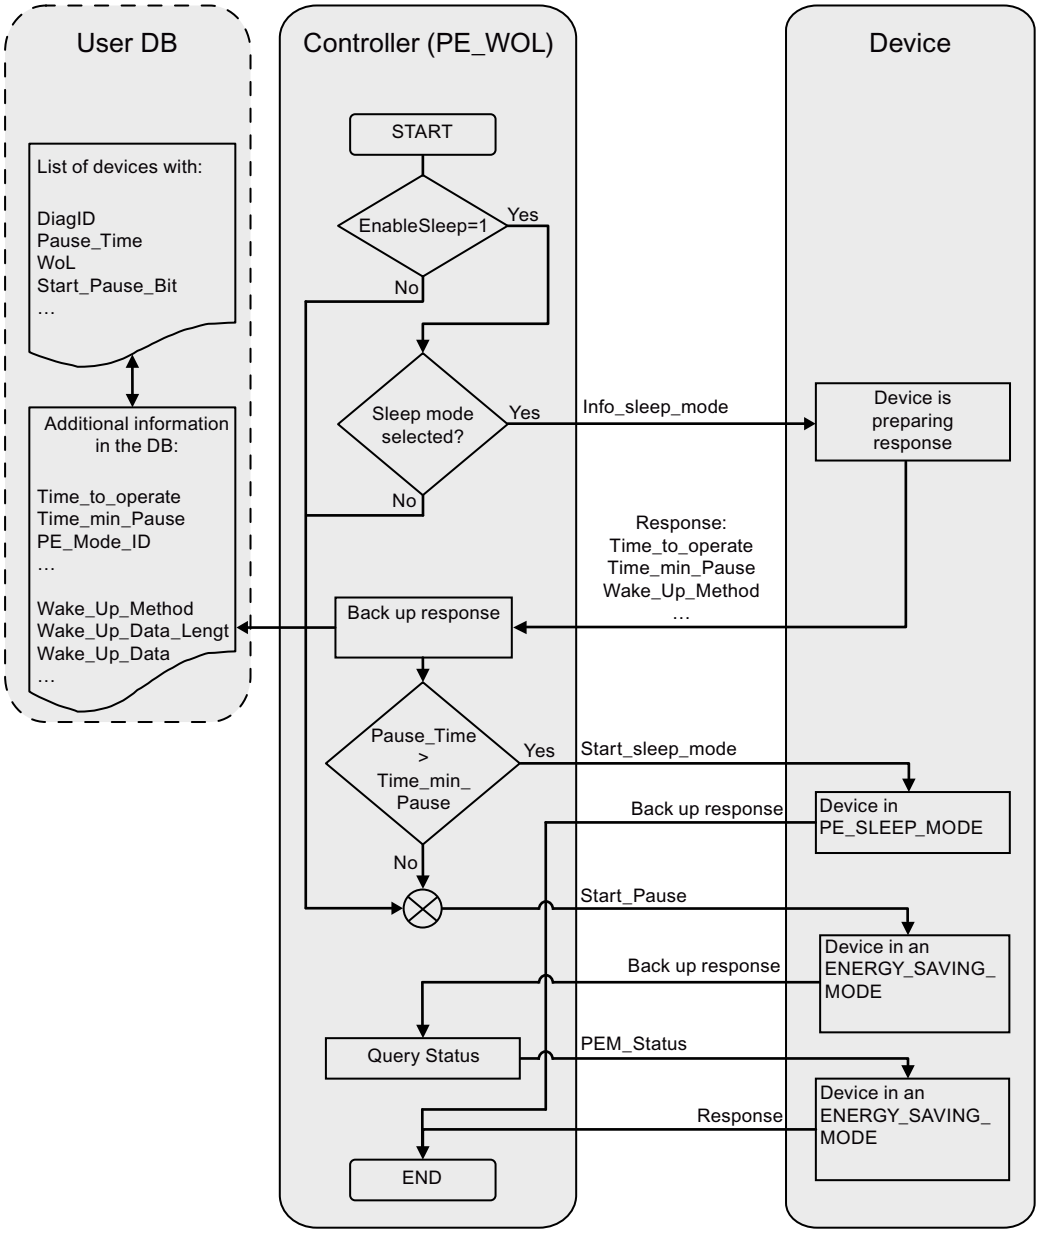
The following flow diagram shows the initialization routine.



Parameter START

Sequence of the CmdStartPause command

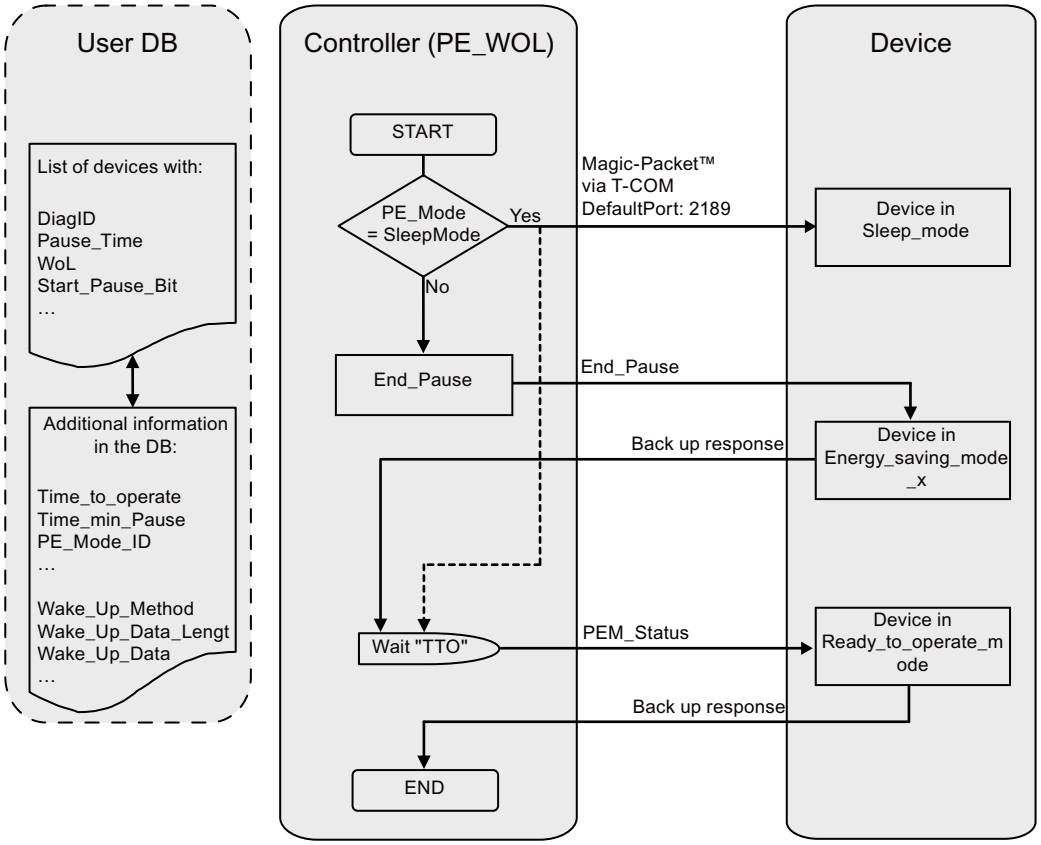
The flow diagram shows the internally used functions and interaction with a device when executing the CmdStartPause command.



Parameter END

Sequence of the CmdEndPause command

The flow diagram shows the internally used functions and interaction with a device when executing the CmdEndPause command.



PENERGY parameter

Data block at the PENERGY parameter

The user DB for the "PE_WOL" PROFIenergy instruction represents a data base for processing multiple devices.

The data block is usually divided into two parts. These are:

- Header 110 bytes
- Device section for a maximum of 256 devices each with 100 bytes (Device). These include:
  - Device-specific data (Device)
  - PROFIenergy-specific data (PE)
  - Data for the job processing (Task)
  - User data (UserData)

The data block operates with optimized access.

Connection parameter "Connection"

The "PE_WOL" instruction reserves a connection resource in the area of "Open User Communication". This is used as a UDP connection. The following parameters must be defined in the data block for this:

- Connection ID ("Connection.id" parameter)
  The connection ID is an integer within the range of 1 to 4095. It is used to identify the communication resources allocated by the firmware, for example the send and receive buffers.
  The connection ID must be unique throughout the CPU.
- Port number that is used for the "Wake on LAN" function ("Header.PortNo" parameter)
  Number of the UDP port via which a "Wake On LAN" packet is sent. These port numbers are part of the communication resources, which are identified and provided by the firmware through the connection ID. The default setting for port 2189 used here is currently not assigned by IANA. The port number is transferred to the connection configuration and applied to parameter "Connection.local_tsap_id[1]". The port number and the length of the remote port are defined using parameters "Connection.rem_tsap_id[1]" and "Connection.rem_tsap_id_LEN" and must be assigned manually.
- Interface ID ("Connection.local_device_id" parameter)
  The interface ID is also part of the connection description. This ID identifies the CPU interface to use for this connection. There are several possible valid values.
  However, these need to be adapted to the employed CPU and interface:
  - B#16#01 for S7-1500 CPUs, ET 200S CPU, or WinAC RTX with Ethernet interface in subslot IF1
  - B#16#02 for CPU 315(F)-2PN/DP or CPU 317(F)-2PN/DP
  - B#16#03 for CPU 319(F)-2PN/DP
  - B#16#05 for CPU 41x(F)-3PN/DP
  - B#16#06 for WinAC RTX with Ethernet interface in subslot IF2
  - B#16#0B for WinAC RTX with Ethernet interface in subslot IF3
  - B#16#0F for WinAC RTX with Ethernet interface in subslot IF4

Structure of the data block

The data block has the following structure:

Name	Data type	Offset	Comment
Header	PE_HEADER	-	Header information
Update (1)	BOOL	-	Signal for indicating a change in the data area. • True= indicates a change by the user. • False = indicates the application of changes.
Initialized	BOOL	-	Signal indicating the completed initialization. • True=Initialization finished. • False= indicates that the block is not initialized.
LinkUp	BOOL	-	Indicates successful configuration of the Ethernet interface. • True=interface ready for use. • False=interface not yet configured.
LinkDown	BOOL	-	Indicates an unconfigured interface. • True=interface is not yet configured. • False=interface is currently being configured or is now configured.
PROFINET_ID (1)	INT	-	ID of the PROFINET I/O system
Reserved	ARRAY [1..37] OF BYTE	-	Reserved
LastDeviceID	INT	-	Contains the highest Device-ID in this PROFINET I/O system.
PortNo (1)	WORD	-	Port number that is used for the "Wake on LAN" function (default= 2189).
Connection	TCON_Param	-	Contains the connection configuration of the "Wake on LAN" connection.

Name	Data type	Offset	Comment
BLOCK_LENGTH	UInt	-	Length of the structure (always B#16#40).
ID (1)	CONN_OUC	-	Connection ID
CONNECTION_TYPE (1)	USINT	-	Connection type (UDP = B#16#13)
ACTIVE_EST (1)	BOOL	-	Active connection establishment (always passive for UDP)
LOCAL_DEVICE_ID (1)	USINT	-	Contains the interface ID (CPU dependent)
LOCAL_TSAP_ID_LEN (1)	USINT	-	Contains the length in bytes of the own/local UDP port
REM_SUBNET_ID_LEN (1)	USINT	-	Unused (always B#16#00)
REM_STADDR_LEN (1)	USINT	-	Contains the length of the remote IP address or B#16#00.
REM_TSAP_ID_LEN (1)	USINT	-	Contains the length in bytes of the remote UDP port. The length specification must be entered manually.
NEXT_STADDR_LEN (1)	USINT	-	Contains the length of the default router address (not relevant).
LOCAL_TSAP_ID (1)	ARRAY[1..16] OF BYTE	-	Contains the own/local port number. The value is applied from parameter PortNo during initialization.
REM_SUBNET_ID (1)	ARRAY[1..6] OF USINT	-	Unused (always B#16#00)
REM_STADDR (1)	ARRAY[1..6] OF USINT	-	Contains the remote IP address.
REM_TSAP_ID (1)	ARRAY[1..16] OF BYTE	-	Contains the remote UDP port number. The port number must be entered manually.
NEXT_STADDR (1)	ARRAY[1..6] OF BYTE	-	irrelevant
SPARE (1)	WORD	-	
Device	ARRAY[1..256] OF PE_DEVICE	-	Array of devices
Device	PE_DEV	-	Contains data for each device
DeviceID	HW_DEVICE	-	Hardware identifier of the device. Assigned by the hardware configuration.
PE_EntityID	HW_IO	-	Hardware identifier of the PROFIenergy entity. Assigned by the hardware configuration.
MACAdr	ARRAY[1..6] OF BYTE	-	Contains the MAC address of the device.
IPAdr	ARRAY[1..4] OF BYTE	-	Contains the IP address of the device.
OrderID_MxLen	Byte	-	Contains the maximum length of the OrderID.
OrderId_ActLen	Byte		Contains the actual length of the OrderID.
OrderID_Data	ARRAY[1..20] OF CHAR		Contains the OrderID of the device.
PE	PE_PE	-	PROFIenergy-specific data.

Name	Data type	Offset	Comment
ModeID	BYTE	-	PE_MODE_ID according to PROFIenergy specification.
Result	BYTE	-	PE ErrorCode according to PROFIenergy specification.
PauseTime (1)	TIME	-	Contains the idle time in ms.
TimeToPause	TIME	-	Contains the time it takes for the device to go into Pause mode.
TimeToOperate	TIME	-	Contains the time it takes for the device to go into operating mode.
MinSleepTime	TIME	-	Contains the minimum time of the device in PE_SLEEP_MODE.
SleepToOperate	TIME	-	Contains the time it takes for the device to go from PE_SLEEP_MODE into operating mode.
StatusOperate	BOOL	-	Indicates the operating mode of the device.
StatusPause	BOOL	-	Indicates the device is in Pause mode.
StatusSleep	BOOL	-	Indicates the PE_SLEEP_MODE of the device.
StatusTransitOK	BOOL	-	Indicates the transition from one energy state to another.
StatusInTransit	BOOL	-	Indicates a current state transition.
StatusTransitNOK	BOOL	-	Indicates that the state change was not successful.
StatusError	BOOL	-	Indicates an error with the device.
StatusRetryEx	BOOL	-	Indicates an unsuccessful execution of a command. No more attempts will be made to execute this command.
CmdStartPause (1)	BOOL	-	Places a START_PAUSE command for this device in the queue.
CmdEndPause (1)	BOOL	-	Places a END_PAUSE command for this device in the queue.
CmdUpdateStatus (1)	BOOL	-	Places a PEM_STATUS command for this device in the queue.
EnableSleep (1)	BOOL	-	Allows PE_SLEEP_MODE for this device. • True= device should go to PE_SLEEP_MODE if idle time is sufficient • False=device may not go into PE_SLEEP_MODE.
Services	WORD	-	Shows all supported PROFIenergy services.
UserData (2)	ARRAY[1..24] OF BYTE	-	User-defined data
Task	PE_TASK	-	Job processing

Name		Data type	Offset	Comment
	Cmd	BYTE	-	Internal bits for job processing
	CmdJ	BYTE	-	Internal bits for job processing
	TimeStart	BOOL	-	Starts a delay time.
	TimeStarted	BOOL	-	The delay time has just started.
	TimeDone	BOOL	-	Shows the expiration of the delay time.
	Done	BOOL	-	Indicates that this job has been completed.
	DelayedCmd	BOOL	-	Indicates that a delayed command is still pending.
	IsV1_0	BOOL	-	Indicates that this device is a Spec. V1.0 device.
	IsWakeOnLAN	BOOL	-	Indicates that this device is woken up by "Wake On LAN".
	RetryCount	BYTE	-	Repetition counter for PE_COMMANDS
	Duration	TIME	-	Contains the value for the delay in ms.
	StartTime	TIME	-	Contains the start time for the delay time.
	MachineState	INT	-	Contains the internal status of the job.

(1) To be filled in by the user.

(2) Available for use by the user.

Parameter STATUS

Parameter STATUS

The output value at the STATUS parameter is divided into three areas:

- Bits 31 to 24: MESSAGE
- Bit 23 to 16: LOCATION
- Bit 15 to 0: INFORMATION

You can learn the meaning of each error code for the three areas in the following tables:

Table 11-55 Possible values for MESSAGE

Error code (W#16#...)	Description
00	No error.
50	Instruction initialized.
51	Determining configuration of the PROFINET I/O system.
52	The instruction could not determine any configured devices in the PROFINET I/O system.
53	Determining the logical addresses of configured devices.
54	Reading interface information out of the devices.
55	Determining I&M data (data record 0 only) of the configured devices.
56	Configuring PROFINET interface for sending the "Wake on LAN" MagicPaket™ via UDP.
57	Determining PROFIenergy capabilities of the connected devices.
62	Invalid PROFINET I/O system ID detected. The causative number is displayed in the INFORMATION field.

Error code (W#16#...)	Description
70	The instruction is initiated and processing jobs. The value in the INFORMATION field contains the number of currently active jobs.
80	The instruction has lost the initialization during processing of jobs. This generally occurs when either the instance DB or the user DB has been reloaded.
FF	Unknown error has occurred.

Table 11-56 Possible values for LOCATION

Error code (W#16#...)	Description
00	The instruction is either not initialized or it is idle.
70	The instruction is waiting for jobs.
71	The instruction has appended a job to the job list.
72	The instruction is preparing to send a job.
73	The instruction is sending a job to a device.
74	The instruction is waiting for a response from the device.
75	The instruction is evaluating the response of the device.
76	The instruction is removing the job from the job list.
FF	Unknown error has occurred.

Table 11-57 Possible values for INFORMATION

Error code (W#16#...)	Description
0000	No additional information available and no jobs active.
0001 -00FF	1 – 255 jobs are currently being processed.
7000	Re-initialization with COM_RST started but not yet completed.
8001	Error at parameter 1
8002	Error at parameter 2
8003	Error at parameter 3
8004	Error at parameter 4
8005	Error at parameter 5. This error is reported if there is no interconnection or an invalid interconnection to the user DB. Possible causes: • The user DB is too small. • The user DB is write-protected. • There is no user DB in the RAM. • The user DB is invalid for the employed CPU.

Error code (W#16#...)	Description
8085 to 80CE	Error when configuring the connection. The error messages of the internally used TCON instruction are output. The description of the error messages can be found in the table for the STATUS (Page 3664) parameter.
8100	An attempt has been made to place more than the maximum of 256 possible jobs. This is a temporary error, which is resolved by completing a few jobs. The placed jobs are not accepted and must be placed again.
8200	An attempt has been made to send an invalid or an unsupported PROFIenergy command (PE_COMMAND).
8400	Connection ID outside the permitted range. Initialization aborted. Check the ID of the connection configuration for "Wake on LAN". See data block at parameter PENERGY > Header > Connection > ID.
84xx	A communication error has occurred. The number of the device that generated the error is output to "xx".
85xx	An error has been returned from device xx. The number of the device that generated the error is output to "xx".
8600	The requested wake-up method is currently not supported.
FFFF	Unknown error has occurred.

PROFIenergy commands

Structure of the message frames

Structure of the response frame in accordance with the PROFIenergy profile

The table below shows the basic structure of the response frame in accordance with the PROFIenergy profile. The response frame consists of a general section (Header) and a specific section (Service Data Response). The contents of the specific section of the response frame can be found in the description of the relevant PROFIenergy command.

Block definition	Attributes	Value	Data type	Description
BlockHeader	BlockType	801_{hex}	WORD	
	BlockLength		WORD	Number of bytes without consideration of the fields BlockType and BlockLength.
	BlockVersionHigh	1_{hex}	BYTE	
	BlockVersionLow	0_{hex}	BYTE	

Block definition	Attributes	Value	Data type	Description
Response Header	Service_Request_ID	1_{hex} to FF $_{hex}$	BYTE	ID of the PI command executed. The ID of the PE command processed by the PE entity is returned in the response frame: • 01: Start_Pause • 02: End_Pause • 03: Query_Modes • 04: PEM_Status • 05: PE_Identify • 06 to 09: Reserved • 16: Query_Measurement • 11 to CF: Reserved • D0 to FF: Manufacturer-specific
	Request_Reference	1_{hex} to FF $_{hex}$	BYTE	Unique number to identify the query/response pair (returned by the server in the response).
Service Header Response	Status	1_{hex} to FF $_{hex}$	BYTE	Information whether or not the PI command was executed: • 00: Reserved • 01: Completed • 02: Completed with error • 03: Data incomplete • 04 to CF: Reserved • D0 to FF: Depends on the Service_Request_ID
	Data_Structure_ Identifier_RS	1_{hex} to FF $_{hex}$	BYTE	• 00: Reserved • 01 to FF: Data structure depends on the Service_Request_ID • 0xFF - Error
Service Data Response				Depends on the Service-Request-ID: • For the service request IDs, see the CMD and CMD_MODIFIER parameters of the instruction "PE_CMD (Page 3159)". • The specific contents of the response frame can be found in the description of the PE command (see for example the "Start_Pause (Page 3179)" command).

PI Command "Start_Pause"

Description

Use the PE command "Start_Pause" to start the energy-saving mode. The command Start_Pause can be used to:

- Switch the PE from "ready" state (PE_ready_to_operate) to an energy-saving mode (PE_energy_saving_mode).
- The PE entity can automatically switch between the energy-saving modes.
  Energy consumption can increase or decrease when you switch energy-saving mode.

Calling the PI command "Start_Pause"

The command "Start_Pause" is called with the instruction "PE_CMD (Page 3159)" with the following parameters:

Parameter	Value	Description
CMD	1	Call of PE command "Start_Pause".
CMD_MODIFIER	0	There are no additional specifications of the command call for command "Start_Pause".
CMD_PARA_LEN	4	Length of the CMD_PARA parameter of 4 bytes.
CMD_PARA	VARIANT	VARIANT pointer to the value for "Pause_Time" (TIME).

Response frame (Service Data Response)

The following response frame data of the PE entity is written to the data block that is referenced at parameter RESPONSE_DATA (see instruction "PE_CMD (Page 3159)"):

Attribute	Value	Data type	Description
PE_Mode_ID	1 to 255	BYTE	Identification number of the energy-saving mode
Reserved	0	BYTE	-

PI Command "End_Pause"

Description

The PE command "End_Pause" is used to end the energy-saving mode of the PE entity.

Calling the PE command "End_Pause"

The command "End_Pause" is called with the instruction "PE_CMD (Page 3159)" with the following parameters:

Parameter	Value	Description
CMD	2	Call of PE command "End_Pause".
CMD_MODIFIER	0	There are no additional specifications of the command call for command "End_Pause".
CMD_PARA_LEN	0	Length of the CMD_PARA parameter of 0 bytes.
CMD_PARA	irrelevant	-

Response frame (Service Data Response)

The following data of the PE entity response frame is written to the data block referenced at the RESPONSE_DATA parameter (see "PE_CMD (Page 3159)"):

Attribute	Value	Data type	Description
Time_to_operate	-	DWORD	Expected time it takes to switch to the "PE_ready_to_operate" mode.

PI command "Query_modes" - "List_Energy_Saving_Modes"

Description

Use PE command "Query_modes" and sub-command (modifier) "List_Energy_Saving_Modes" to output all energy-saving modes (PE_Mode_ID) supported by the PE entity.

The query result is written in the form of a response frame to the data block referenced by theRESPONSE_DATA parameter.

Calling the PE command "Query_modes" - "List_Energy_Saving_Modes"

The command "List_Energy_Saving_Modes" is called with the instruction "PE_CMD (Page 3159)" with the following parameters:

Parameter	Value	Description
CMD	3	Call of PE command "Query_modes".
CMD_MODIFIER	1	Specification of the command call: Select the sub-command "List_Energy_Saving_Modes" to output the number and types of energy-saving modes supported.
CMD_PARA_LEN	0	Length of the CMD_PARA parameter of 0 bytes.
CMD_PARA	irrelevant	-

Response frame (Service Data Response)

The following data of the PE entity response frame is written to the data block referenced at the RESPONSE_DATA parameter (see "PE_CMD (Page 3159)"):

Attribute	Value	Data type	Description
Number_of_PE_Mode_IDs	1	BYTE	The number of energy-saving modes.
PE_Mode_IDs	-	Array [...] of BYTE	Array with the IDs of the supported energy-saving modes. The meaning of the individual IDs depends on the PE entity.

PI command "Query_modes" - "Get_Mode"

Description

You use the PE command "Query_modes" and the sub-command (modifier) "Get_Mode" to output the attributes of the energy-saving mode which is currently enabled.

Calling the PE command "Query_modes" - "Get_Mode"

The call of the command with the instruction "PE_CMD" occurs with the following parameters:

Parameter	Value	Description
CMD	3	Call of the PE command "Query_modes"
CMD_MODIFIER	2	Specification of the command call: Select the sub-command "Get_Mode" to output the status of the mode which is currently enabled.
CMD_PARA_LEN	1	Length of the CMD_PARA parameter of 1 byte.
CMD_PARA	VARIANT	VARIANT pointer to the value for PE_MODE_ID.

Response frame (Service Data Response)

The following data of the PE entity response frame is written to the data block referenced at the RESPONSE_DATA parameter (see "PE_CMD (Page 3159)"):

Attribute	Value	Data type	Description
PE_Mode_ID	• 0 "PE_power_off" mode • 1...254 Energy-saving mode of the PE entity (manufacturer-specific) • 255 "PE_ready_to_operate" mode	BYTE	ID of the energy-saving mode currently enabled.
PE_Mode_Attributes	Bit 0: • = 0: Only static energy consumer and time values are available. • = 1: Dynamic energy consumer and time values are available. Bit 1 to 7: • Reserved	BYTE	
Time_min_Pause [1]	Time difference without date	DWORD	Minimum pause time for the PI mode. The minimum pause time is the sum of the values of the following attributes: • Time_to_Pause • Time_to_operate • Time_min_length_of_stay See the description "PAUSE_TIME parameter" of the instruction "PE_START_END: Start and exit energy-saving mode (Page 3154)".
Time_to_Pause [1]	Time difference without date	DWORD	Switch off time: Duration from call of energy-saving mode to start of energy-saving mode (transition duration of PE_ready_to_operate to PE_energy_saving_mode). The switch-off time depends on the PE entity.
Time_to_operate [1]	Time difference without date	DWORD	Switch-on time: Duration of the transition from energy-saving mode (PE_energy_saving_mode) to ready to operate mode (PE_ready_to_operate). The PE entity calculates the duration dynamically in the output operation.
Time_min_length_of_stay [1]		DWORD	Minimum active period of the energy-saving mode on the PE entity.
Time_max_length_of_stay [1]		DWORD	Maximum active period of the energy-saving mode on the PE entity.
Mode_Power_Consumption [2]		REAL	Power consumption of the PE entity in active energy-saving mode. Unit: kW

Attribute	Value	Data type	Description
Energy_ Consumption_ to_pause [2]		REAL	Energy consumption of the PE entity during transition from ready-to-operate mode (PE_ready_to_operate) to energy-saving mode (PE_energy_saving_mode) Unit: kWh
Energy_ Consumption_ to_operate [2]		REAL	Energy consumption of the PE entity during transition from energy-saving mode (PE_energy_saving_mode) to ready-to-operate mode (PE_ready_to_operate) Unit: kWh
[1] If the duration is infinite, 0xFFFFFFFF will be output. If the duration is zero, "0" will be output. [2] If the data for energy and power consumption is not defined by the PE entity, "0.0" will be output as the value.			

PI command "PEM_Status"

Description

The PE command "PEM_Status" is used to query the status of a PE entity energy-saving mode that is currently enabled.

Calling the PE command "PEM_Status"

The command "PEM_Status" is called with the instruction "PE_CMD" with the following parameters:

Parameter	Value	Description
CMD	4	Call of PE command "PEM_Status".
CMD_MODIFIER	0	There are no other specifications of the command call for command "PEM_Status".
CMD_PARA_LEN	0	Length of the CMD_PARA parameter of 0 bytes.
CMD_PARA	irrelevant	-

Response frame (Service Data Response)

The following data of the PE entity response frame is written to the data block referenced at the RESPONSE_DATA parameter (see "PE_CMD (Page 3159)"):

Attribute	Value	Data type	Description
PE_Mode_ID_ Source	• 0 "PE_power_off" mode • 1 to 254 Energy-saving mode of the PE entity (manufacturer-specific) • 255 "PE_ready_to_operate" mode	BYTE	Mode of the PE entity before a PE command is sent.
PE_Mode_ID_ Destination	• 0 "PE_power_off" mode • 1 to 254 Energy-saving mode of the PE entity (manufacturer-specific) • 255 "PE_ready_to_operate" mode	BYTE	Mode of the PE entity after a PE command is executed.
Time_to_operate	Time difference without date	DWORD	Switch-on time: Duration of the transition from energy-saving mode (PE_energy_saving_mode) to ready to operate mode (PE_ready_to_operate). The PE entity calculates the duration dynamically during output.
Remaining_time_to_ destination	Time difference without date	DWORD	Remaining time to switch to another mode.
Mode_Power_ Consumption		REAL	Power consumption of the PE entity in active energy-saving mode. Unit: kW
Energy_ Consumption_ to_Destination		REAL	Energy consumption for the current PI transition Unit: kWh
Energy_ Consumption_ to_operate		REAL	Energy consumption of the PE entity during transition from energy-saving mode (PE_energy-saving mode) to ready-to-operate mode (PE_ready_to_operate) Unit: kWh

PI command "PE_Identify"

Description

The PE command "PE_Identify" is used to read out the number and description of PE commands supported by the PE entity. The number of specific commands supported depends on the PE entity. As PE_Identify is itself a PE command, at least three supported PE commands will be output upon a positive response: Start_Pause, End_Pause and PE_Identify.

Calling the PE command "PE_Identify"

The command "PE_Identify" is called with the instruction "PE_CMD (Page 3159)" with the following parameters:

Parameter	Value	Description
CMD	5	Call of the command "PE_Identify".
CMD_MODIFIER	0	There are no other specifications of the command call for command "PE_Identify".
CMD_PARA_LEN	0	Length of the CMD_PARA parameter of 0 bytes.
CMD_PARA	irrelevant	-

Response frame (Service Data Response)

The following data of the PE entity response frame is written to the data block referenced at the RESPONSE_DATA parameter (see "PE_CMD (Page 3159)"):

Attribute	Value	Data type	Description
Count [1]	6	BYTE	Number of supported PROFIenergy commands
Start_Pause	1	BYTE	First PE command supported (Service_Request_ID)
End_Pause	2	BYTE	...
Query_Modes	3	BYTE	...
PEM_Status	4	BYTE	...
PE_Identify	5	BYTE	...
Query_Measurement	16	BYTE	Last PE command supported (Service_Request_ID)

[1] The number of commands supported is manufacturer-specific and depends on the PE entity used. The values given are an example of a response frame where all 6 PE commands are supported.

PI Command "Query_Measurement" - "Get_Measurement_list"

Description

Use the PE command "Query_Measurement" and sub-command (modifier) "Get_measurement_list" to query the specific measured values supported by the PE entity. The supported measured values are output as a list in the data block referenced by the RESPONSE_DATA parameter.

Calling the PE command "Query_Measurement" - "Get_Measurement_list"

The command is called with the instruction "PE_CMD (Page 3159)" with the following parameters:

Parameter	Value	Description
CMD	16	Call of the command "Query_Measurement".
CMD_MODIFIER	1	Specification of the command call: Select the sub-command "Get_Measurement_List" to output a list of supported measured values.
CMD_PARA_LEN	0	Length of the CMD_PARA parameter of 0 bytes.
CMD_PARA	irrelevant	-

Response frame (Service Data Response)

The following data of the PE entity response frame is written to the data block referenced at the RESPONSE_DATA parameter (see "PE_CMD (Page 3159)"):

Attribute	Value	Data type	Description
Count	-	BYTE	Number of measurement IDs
reserved	-	BYTE	
...			
Measurement_ID	-	WORD	First supported Measurement_ID The Measurement_ID is manufacturer-specific. For more information, refer to the manual of the respective PE entity.
Accuracy_Domain	-	BYTE	See "accuracy domain" table.
Accuracy_Class	-	BYTE	See "accuracy classes" table.
Range	-	REAL	Specifies the scale end value of the measured value (only for accuracy domain 1). The attribute range uses the same unit as defined using attribute Measurement_ID (only one unit is used for each Measurement_ID).
...			
Measurement_ID	-	WORD	Last supported Measurement_ID
Accuracy_Domain	-	BYTE	See "accuracy domain" table.
Accuracy_Class	-	BYTE	See "accuracy classes" table.
Range	-	REAL	Specifies the scale end value of the measurement value (only for accuracy domain 1). The attribute range uses the same unit as defined using attribute Measurement_ID (only one unit is used for each Measurement_ID).

Accuracy domains

Accuracy domain	Description
0	Reserved
1	The accuracy deviation is output in percentages of the scale end value. The percentage of the possible deviation is divided into accuracy classes (see table: Accuracy classes of the accuracy domains 1 and 2).

Accuracy domain	Description
2	The accuracy deviation is output in percentages of the current measurement value. The percentage of the possible deviation is divided into accuracy classes (see table: Accuracy classes of the accuracy domains 1 and 2).
3	The measuring accuracy adheres to the standard IEC 61557-12. The function performance classes for performance measurement and monitoring devices (PMD) without external sensors, and the system performance classes for PMD with external sensors, are coded as set out in the "Accuracy classes of accuracy domain 3" table.
4	The entry of the accuracy adheres to the standard EN 50470-3, chapter 8 (see also table: Accuracy classes of accuracy domain 4).

Accuracy classes

Table 11-58 Accuracy classes of the accuracy domains 1 and 2

Accuracy class	0	1	2	3	4	5	6	7	8
Meaning	Reserved	0.01%	0.02%	0.05%	0.1%	0.2%	0.5%	1%	1.5%

Accuracy class	9	10	11	12	13	14	15	>15
Meaning	2%	2.5%	3%	5%	10%	20%	>20%	Not defined

Table 11-59 Accuracy classes of accuracy domain 3

Accuracy class	0	1	2	3	4	5	6	7	8
Meaning	Reserved	0,02	0,05	0,1	0,2	0,5	1	1,5	2

Accuracy class	9	10	11	12	13	14	>13
Meaning	2,5	3	5	10	20	20%	Not defined

Table 11-60 Accuracy classes of accuracy domain 4

Accuracy class	0	1	2	3	4	5	6	>7
Meaning	Reserved	0,5	1,0	1,5	2,0	2,5	3,0	Not defined

PI Command "Query_Measurement" - "Get_Measurement_values"

Description

Use the PE command "Query_Measurement" and sub-command (modifier) "Get_measurement_values" to output a list of measured values supported by the PE entity. The measured values are output as a list in the data block referenced by the RESPONSE_DATA parameter.

Calling the PE command "Query_Measurement" - "Get_Measurement_values"

The command is called with the instruction "PE_CMD (Page 3159)" with the following parameters:

Parameter	Value	Description
CMD	16	Call of the command "Query_Measurement".
CMD_MODIFIER	2	Specification of the command call: Select the command "Get_Measurement_Values" to output a list of supported measurement values.
CMD_PARA_LEN	0	Depends on the number of measurement values. The length of the parameters results from the attribute count and the sum of the lengths of the attributes for the transferred measurement values.
CMD_PARA	VARIANT	VARIANT pointer to data structure with list of measured values to be queried (see "CMD_PARA parameter").

Parameter CMD_PARA

The structure specified with the VARIANT pointer at the CMD_PARA parameter must have the following setup:

Attribute	Value	Data type	Description
Count	-	BYTE	Number of measured values (Measurement-IDs)
reserved	0	BYTE	Not used
Measurement_ID	-	WORD	First measured value queried
...			
Measurement_ID	-	WORD	Last measured value queried

Response frame (Service Data Response)

The following response frame data of the PE entity is written to the data block that is referenced at parameter RESPONSE_DATA (see "PE_CMD (Page 3159)"):

Attribute	Value	Data type	Description
Count [1]	-	BYTE	Number of measured values (Measurement-IDs)
reserved	0	BYTE	Not used
Length_of_Structure	2 to 65535	WORD	Length of the structure in bytes

Attribute	Value	Data type	Description
Measurement_Data_Structure_ID	1 = simple value	BYTE	Defines the following structure.
Measurement_ID	0 to 65535	WORD	ID of the supported measurement value.
Status_of_ Measurement_Value	1 to 3	BYTE	Status of the measurement value: • 1: Valid • 2: Not supported • 3: Invalid
Transmission_Data_Type	-	REAL	
End_of_demand	-	TOD	Optional time stamping with data type TimeOfDay.
...			
Length_of_Structure	-	WORD	Length of the structure in bytes
Measurement_Data_Structure_ID	-	BYTE	Defines the following structure.
Measurement_ID	-	WORD	ID of the supported measurement value.
Status_of_Measurement_Value	-	BYTE	Status of the measurement value: • 1: Valid • 2: Not supported • 3: Invalid
Transmission_Data_Type	-	REAL	
End_of_demand	-	TOD	Optional time stamping with data type TimeOfDay.

[1] If the data length of the measurement values queried exceeds the size of the PDU (Protocol Data Unit) of the protocol layer, the data will not be completely transferred and only the supported measurement values will be output.

iDevice / iSlave

PE_I_DEV: Control PROFIenergy commands in the I-Device

Description

The instruction "PE_I_DEV" is used to process the PROFIenergy profile in the intelligent IO device (iDevice). The functions which are executed by the firmware in standard PROFIenergy-compatible IO devices, such as the ET 200S, are implemented in the iDevice by the instruction "PE_I_DEV" and the corresponding auxiliary blocks:

- The instruction "PE_I_DEV" is called cyclically by the user program of the iDevice and receives all PROFIenergy commands.
- The PROFIenergy response is generated by configuring an auxiliary block. The response in the pause is fully programmable. The response data must be provided within 10 seconds; otherwise, "State conflict 0x80B5" will occur at the STATUS parameter of the instruction in the IO controller.

No specific knowledge of the PROFIenergy standard is required to use the instruction.

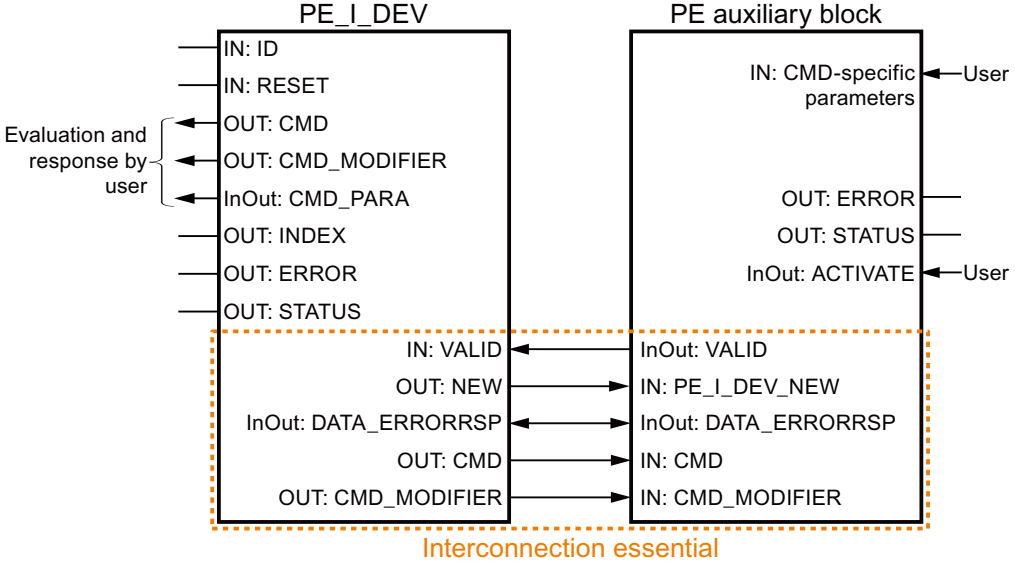
PROFIenergy auxiliary blocks (PE auxiliary blocks)

The PE auxiliary blocks are used to generate the response frame. Enter the response data (in plain text) at the input parameters of the relevant block.

- For each PROFIenergy command, there is a corresponding auxiliary block for a positive response:
  - PE command "Start_Pause": PE_Start_RSP (Page 3194)
  - PE command "End_Pause": PE_End_RSP (Page 3196)
  - PE command "Query_modes" - "List_Energy_Saving_Modes": PE_List_Modes_RSP (Page 3197)
  - PE command "Query_modes" - "Get_Mode": PE_Get_Mode_RSP (Page 3198)
  - PE command "PEM_Status": PE_PEM_Status_RSP (Page 3200)
  - PE command "PE_Identify": PE_Identify_RSP (Page 3202)
  - PE command "Query_Measurement" - "Get_Measurement_list": PE_Measurement_List_RSP (Page 3204)
  - PE command "Query_Measurement" - "Get_Measurement_values": PE_Measurement_Value_RSP (Page 3205)
- Irrespective of the PROFIenergy command, there is an additional shared auxiliary block for a negative response (see PE_Error_RSP (Page 3193)).

Interconnection of the auxiliary blocks

The instruction "PE_I_DEV" and the auxiliary blocks are coordinated. Some of the parameters are simply interconnected. The diagram below shows which of the parameters need to be interconnected.



Parameters

The following table shows the parameters of the instruction "PE_I_DEV":

Parameter	Declaration	Data type	Memory area	Description
RESET	Input	BOOL	I, Q, M, D, L or constant	Resets the instruction.
ID	Input	HW_SUBMODULE	I, Q, M, D, L or constant	Address of the transfer area, which is supplied in the IO controller with the data for PROFIenergy. The hardware identifier can be found in the system constants.
VALID	Input	BOOL	I, Q, M, D, L or constant	The response data for the PROFIenergy controller is ready and can be sent.
CMD_PARA	Output	VARIANT	I, Q, M, D, L	Parameters for: • Get mode: PE_mode_ID • Get measurement values: List of Measurement_IDs (list of IDs of the tags to be read; either one tag or multiple tags may be read at any given time). Maximum length: 234 bytes
DATA_ERRORRSP	InOut	VARIANT	I, Q, M, D, L	Pointer to the data area containing the acknowledgment data for the PROFIenergy controller. This must correspond to the pointer which is also used with the auxiliary blocks.
INDEX	Output	INT	I, Q, M, D, L	Data record number of the PROFIenergy record (set at 0x80A0)
CMD	Output	INT	I, Q, M, D, L	Service-Request-ID of the PROFIenergy command in accordance with the PROFIenergy profile (see "CMD and CMD_MODIFIER parameters"). Further PE commands (Service-Request-IDs) are possible following extensions of the PROFIenergy profile.
CMD_ MODIFIER	Output	INT	I, Q, M, D, L	PROFIenergy sub-command: • Only when CMD=3 or CMD=16; see "CMD and CMD_MODIFIER parameters". • For all other commands: "0". Further sub-commands are possible following extensions of the PROFIenergy profile.
NEW	Output	BOOL	I, Q, M, D, L	New data available from the PROFIenergy controller.
ERROR	Output	BOOL	I, Q, M, D, L	Command completed with error.
STATUS	Output	DWORD	I, Q, M, D, L	Error information (see "STATUS parameter").

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameters CMD and CMD_MODIFIER

CMD	CMD_ MODIFIER	PROFIenergy command	Description
01	0	Start_Pause	Start energy-saving mode or switch to a different energy-saving mode.
02	0	End_Pause	End energy-saving mode.
03	1	Query_Modes - List energy saving Modes	Output the energy-saving modes supported.
	2	Query_Modes - Get Mode	Output attributes of the energy-saving mode currently enabled.
04	0	PEM_Status	Query status of energy-saving mode.
05	0	PE_Identify	Read out the number and description of PE commands supported.
16	1	Query_Measurement - Get_Measurement_List	List of measured values supported by the PE entity.
	2	Query_Measurement - Get_Measurement_Values	Output of the measured values of the PE entity.

Parameter STATUS

Error information is output at the STATUS output parameter. If it is interpreted as ARRAY[1...4] of BYTE, the error information has the following structure:

Field element	Name	Meaning
STATUS[1]	Function_Num	Cause of the error • B#16#**00**: No error • B#16#**DE**: Error during reading of data record • B#16#**DF**: Error during writing of data record • B#16#**C0**: Error message from the "PE_I_DEV" instruction or the internally used "PRVREC (Page 3130)" and "RCVREC (Page 3128)" communication instructions.
STATUS[2]	Error_Decode	Location of the error ID • **80**: DPV1 error as defined in IEC 61158-6 or application-specific
STATUS[3]	Error_Code_1	Error ID (when Error_Decode = **80**): • **B1**: Write length error (error in write length or insufficient length information with the data type VARIANT).
STATUS[4]	Error_Code_2	For PROFINET errors: Output of IO controller error message If no PROFINET error has occurred, the value in STATUS[4] = "0".

Note

Error messages of the "PRVREC" and "RCVREC" instructions

The "PE_I_DEV" instruction uses the "PRVREC (Page 3130)" and "RCVREC (Page 3128)" instructions for communication. Error messages for these instructions are output in the field elements STATUS[1] to STATUS[4].

For the meaning of the error codes of the "PRVREC" and "RCVREC" instructions, see the description of the corresponding STATUS (Page 3078) parameter.

Description of PROFIenergy (Page 3152)

Auxiliary blocks of the instruction PE_I_DEV

PE_Error_RSP: Generate negative answer to command

Description

The auxiliary block "PE_Error_RSP" (Response with failure) generates a negative response if the command requested is not supported (either in general or temporarily). Response generation does not depend on the command requested.

Parameter

The following table shows the parameters of the "PE_Error_RSP" auxiliary block:

Parameter	Declaration	Data type	Memory area	Description
PE_I_DEV_NEW	Input	BOOL	I, Q, M, D, L or constant	The parameter must be interconnected with the NEW output parameter of the "PE_I_DEV (Page 3189)" instruction. The auxiliary block is only processed if the parameter value is set to "1".
ERROR_CODE	Input	BYTE	I, Q, M, D, L or constant	Error number
ACTIVATE	InOut	BOOL	I, Q, M, D, L	The instruction copies the input parameters to the DATA_ERROR_RSP data area at a rising edge at input ACTIVATE. The parameter is then reset by the instruction. The parameter must be set within 10 seconds after a rising edge is detected at parameter NEW of the "PE_I_DEV (Page 3189)" instruction.

Parameter	Declaration	Data type	Memory area	Description
VALID	InOut	BOOL	I, Q, M, D, L	The parameter must be interconnected with the VALID input of the "PE_I_DEV (Page 3189)" instruction. The auxiliary block sets the parameter as soon as the response data for the PROFIenergy controller is available and ready for transmission.
DATA_ ERRORRSP	InOut	VARIANT	D	Pointer on the data area in which the response data is stored. The parameter is identical to the pointer for DATA_ERRORRSP of the "PE_I_DEV (Page 3189)" instruction. The addressed data area contains the complete PROFIenergy frame. Minimum length: 244 bytes
ERROR	Output	BOOL	I, Q, M, D, L	• "0": No error • "1": Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	• "0": No error • "0x80B1": Error in VARIANT setting, e.g. incorrect range

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

PE_Start_RSP: Generate answer to command at start of pause

Description

The auxiliary block "PE_Start_RSP" (Start Pause) generates the response to the PE command Start_Pause (Page 3179). The instruction returns the energy-saving mode to which the device has switched (PE_MODE_ID parameter).

If the response differs depending on the length of the pause, you can return this fact in the feedback on the energy-saving mode (PE_Mode_ID = 1 for a brief pause, PE_Mode_ID = 2 for a longer pause, etc.).

Parameter

The following table shows the parameters of the "PE_Start_RSP" auxiliary block:

Parameter	Declaration	Data type	Memory area	Description
PE_I_DEV_NEW	Input	BOOL	I, Q, M, D, L or constant	The parameter must be interconnected with the NEW output parameter of the "PE_I_DEV (Page 3189)" instruction. The auxiliary block is only processed if the parameter value is set to "1".
CMD	Input	INT	I, Q, M, D, L or constant	Service-Request-ID of the PROFIenergy command The parameter must be interconnected with the CMD output parameter of the "PE_I_DEV (Page 3189)" instruction.
PE_MODE_ID	Input	BYTE	I, Q, M, D, L or constant	PE mode that the process assumes
ACTIVATE	InOut	BOOL	I, Q, M, D, L	The instruction copies the input parameters to the DATA_ERROR_RSP data area at a rising edge at input ACTIVATE. The parameter is then reset by the instruction. The parameter must be set within 10 seconds after a rising edge is detected at parameter NEW of the "PE_I_DEV (Page 3189)" instruction.
VALID	InOut	BOOL	I, Q, M, D, L	The parameter must be interconnected with the VALID input of the "PE_I_DEV (Page 3189)" instruction. The auxiliary block sets the parameter as soon as the response data for the PROFIenergy controller is available and ready for transmission.
DATA_ERRORRSP	InOut	VARIANT	D	Pointer on the data area in which the response data is stored. The parameter is identical to the pointer for DATA_ERRORRSP of the "PE_I_DEV (Page 3189)" instruction. The addressed data area contains the complete PROFIenergy frame. Minimum length: 244 bytes
ERROR	Output	BOOL	I, Q, M, D, L	• "0": No error • "1": Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	• "0": No error • "0x80B1": Error in VARIANT setting, e.g. incorrect range

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

PE_End_RSP: Generate answer to command at end of pause

Description

The auxiliary block "PE_End_RSP" generates the response to the PE command End_Pause (Page 3179). The response returned is the time required to switch from the current mode to "Ready_To_Operate" mode.

Parameter

The following table shows the parameters of the "PE_End_RSP" auxiliary block:

Parameter	Declaration	Data type	Memory area	Description
PE_I_DEV_NEW	Input	BOOL	I, Q, M, D, L or constant	The parameter must be interconnected with the NEW output parameter of the "PE_I_DEV (Page 3189)" instruction. The auxiliary block is only processed if the parameter value is set to "1".
CMD	Input	INT	I, Q, M, D, L or constant	Service-Request-ID of the PROFIenergy command The parameter must be interconnected with the CMD output parameter of the "PE_I_DEV (Page 3189)" instruction.
Time_to_Operate	Input	DWORD	I, Q, M, D, L or constant	Time required to switch from the current mode to "Ready_To_Operate".
ACTIVATE	InOut	BOOL	I, Q, M, D, L	The instruction copies the input parameters to the DATA_ERROR_RSP data area at a rising edge at input ACTIVATE. The parameter is then reset by the instruction. The parameter must be set within 10 seconds after a rising edge is detected at parameter NEW of the "PE_I_DEV (Page 3189)" instruction.
VALID	InOut	BOOL	I, Q, M, D, L	The parameter must be interconnected with the VALID input of the "PE_I_DEV (Page 3189)" instruction. The auxiliary block sets the parameter as soon as the response data for the PROFIenergy controller is available and ready for transmission.
DATA_ ERRORRSP	InOut	VARIANT	D	Pointer on the data area in which the response data is stored. The parameter is identical to the pointer for DATA_ERRORRSP of the "PE_I_DEV (Page 3189)" instruction. The addressed data area contains the complete PROFIenergy frame. Minimum length: 244 bytes

Parameter	Declaration	Data type	Memory area	Description
ERROR	Output	BOOL	I, Q, M, D, L	• "0": No error • "1": Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	• "0": No error • "0x80B1": Error in VARIANT setting, e.g. incorrect range

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

PE_List_Modes_RSP: Generate queried energy savings modes as answer

Description

The auxiliary block "PE_List_Modes_RSP" generates the response to the PE command List_Energy_Saving_Modes (Page 3180). The response generated includes the number and the IDs of energy-saving modes supported.

Parameter

The following table shows the parameters of the "PE_List_Modes_RSP" auxiliary block:

Parameter	Declaration	Data type	Memory area	Description
PE_I_DEV_NEW	Input	BOOL	I, Q, M, D, L or constant	The parameter must be interconnected with the NEW output parameter of the "PE_I_DEV (Page 3189)" instruction. The auxiliary block is only processed if the parameter value is set to "1".
CMD	Input	INT	I, Q, M, D, L or constant	Service-Request-ID of the PROFIenergy command The parameter must be interconnected with the CMD output parameter of the "PE_I_DEV (Page 3189)" instruction.
CMD_MODIFIER	Input	INT	I, Q, M, D, L or constant	PROFIenergy sub-command (evaluated only if CMD=3, or CMD=16). The parameter must be interconnected with the CMD_MODIFIER output parameter of the "PE_I_DEV" instruction.
Number_of_PE_Mode_IDs	Input	BYTE	I, Q, M, D, L or constant	Number of energy-saving modes supported. Permitted values: 1 to 254
PE_MODE_ID	Input	VARIANT	I, Q, M, D, L	Points to the area in which the IDs of the energy-saving modes supported (PE_Mode_ID) are stored. Valid range: 1 to 254.

Parameter	Declaration	Data type	Memory area	Description
ACTIVATE	InOut	BOOL	I, Q, M, D, L	The instruction copies the input parameters to the DATA_ERROR_RSP data area at a rising edge at input ACTIVATE. The parameter is then reset by the instruction. The parameter must be set within 10 seconds after a rising edge is detected at parameter NEW of the "PE_I_DEV (Page 3189)" instruction.
VALID	InOut	BOOL	I, Q, M, D, L	The parameter must be interconnected with the VALID input of the "PE_I_DEV (Page 3189)" instruction. The auxiliary block sets the parameter as soon as the response data for the PROFIenergy controller is available and ready for transmission.
DATA_ ERRORRSP	InOut	VARIANT	D	Pointer on the data area in which the response data is stored. The parameter is identical to the pointer for DATA_ERRORRSP of the "PE_I_DEV (Page 3189)" instruction. The addressed data area contains the complete PROFIenergy frame. Minimum length: 244 bytes
ERROR	Output	BOOL	I, Q, M, D, L	• "0": No error • "1": Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	• "0": No error • "0x80B1": Error in VARIANT setting, e.g. incorrect range

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

PE_Get_Mode_RSP: Generate queried energy data as answer

Description

The auxiliary block "PE_Get_Mode_RSP" generates the response to the command Get_Mode (Page 3181). The response frame contains the time, performance, or energy data of an energy-saving mode.

Parameter

The following table shows the parameters of the "PE_Get_Mode_RSP" auxiliary block:

Parameter	Declaration	Data type	Memory area	Description
PE_I_DEV_NEW	Input	BOOL	I, Q, M, D, L or constant	The parameter must be interconnected with the NEW output parameter of the "PE_I_DEV (Page 3189)" instruction. The auxiliary block is only processed if the parameter value is set to "1".
CMD	Input	INT	I, Q, M, D, L or constant	Service-Request-ID of the PROFIenergy command The parameter must be interconnected with the CMD output parameter of the "PE_I_DEV (Page 3189)" instruction.
CMD_MODIFIER	Input	INT	I, Q, M, D, L or constant	PROFIenergy sub-command (evaluated only if CMD=3, or CMD=16). The parameter must be interconnected with the CMD_MODIFIER output parameter of the "PE_I_DEV" instruction.
PE_Mode_ID	Input	BYTE	I, Q, M, D, L or constant	ID of the energy-saving mode currently enabled.
Time_min_Pause	Input	DWORD	I, Q, M, D, L or constant	Minimum pause duration for this PE energy-saving mode. This is the sum of the following three parameters: • Time_to_Pause • Time_to_operate • Time_min_length_of_stay
Time_to_Pause	Input	DWORD	I, Q, M, D, L or constant	Time between the edge at the START parameter (see "PE_I_DEV (Page 3189)") and the requested PE energy-saving mode being reached.
Time_to_Operate	Input	DWORD	I, Q, M, D, L or constant	Maximum switch-on time to "PE_ready_to_operate". The "Time_to_operate" parameter can be used directly for the relevant calculations. The value may be a static maximum, or be calculated dynamically by the PE entity.
Time_min_Lenght_of_stay	Input	DWORD	I, Q, M, D, L or constant	Minimum dwell time of the PE entity in this PE mode.
Time_max_Lenght_of_stay	Input	DWORD	I, Q, M, D, L or constant	Maximum dwell time of the PE entity in this PE mode.
Mode_Power_Consumption	Input	DWORD	I, Q, M, D, L or constant	Energy consumption in the current PE mode in [kW].
Energy_Consum_to_Pause	Input	DWORD	I, Q, M, D, L or constant	Energy consumption from "PE_ready_to_operate" to the current PE mode in [kWh].
Energy_Consum_to_operate	Input	DWORD	I, Q, M, D, L or constant	Energy consumption from the current PE mode to "PE_ready_to_operate" in [kWh].

Parameter	Declaration	Data type	Memory area	Description
ACTIVATE	InOut	BOOL	I, Q, M, D, L	The instruction copies the input parameters to the DATA_ERROR_RSP data area at a rising edge at input ACTIVATE. The parameter is then reset by the instruction. The parameter must be set within 10 seconds after a rising edge is detected at parameter NEW of the "PE_I_DEV (Page 3189)" instruction.
VALID	InOut	BOOL	I, Q, M, D, L	The parameter must be interconnected with the VALID input of the "PE_I_DEV (Page 3189)" instruction. The auxiliary block sets the parameter as soon as the response data for the PROFIenergy controller is available and ready for transmission.
DATA_ ERRORRSP	InOut	VARIANT	D	Pointer on the data area in which the response data is stored. The parameter is identical to the pointer for DATA_ERRORRSP of the "PE_I_DEV (Page 3189)" instruction. The addressed data area contains the complete PROFIenergy frame. Minimum length: 244 bytes
ERROR	Output	BOOL	I, Q, M, D, L	• "0": No error • "1": Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	• "0": No error • "0x80B1": Error in VARIANT setting, e.g. incorrect range

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

PE_PEM_Status_RSP: Generate PEM status as answer

Description

The auxiliary block "PE_PEM_Status_RSP" generates the response to the command PEM_Status (Page 3183).

Parameter

The following table shows the parameters of the "PE_PEM_Status_RSP" auxiliary block:

Parameter	Declaration	Data type	Memory area	Description
PE_I_DEV_NEW	Input	BOOL	I, Q, M, D, L or constant	The parameter must be interconnected with the NEW output parameter of the "PE_I_DEV (Page 3189)" instruction. The auxiliary block is only processed if the parameter value is set to "1".
CMD	Input	INT	I, Q, M, D, L or constant	Service-Request-ID of the PROFIenergy command The parameter must be interconnected with the CMD output parameter of the "PE_I_DEV (Page 3189)" instruction.
PE_MODE_ID_ Source	Input	BYTE	I, Q, M, D, L or constant	Source and Destination for PEM_STATUS. Values: • 0x00: PE_POWER_OFF • 0x01 – 0xFE: manufacturer-specific • 0xFF: PE_READY_TO_OPERATE
PE_MODE_ID_ Destination	Input	BYTE	I, Q, M, D, L or constant	
Time_to_Operate[1]	Input	DWORD	I, Q, M, D, L or constant	Maximum switch-on time to "PE_ready_to_operate". "Time_to_operate" can be used directly for the relevant calculations. The value may be a static maximum, or be calculated dynamically by the PE entity.
Remaining_time_ to_destination[1]	Input	DWORD	I, Q, M, D, L or constant	Optional: Time remaining until the requested PE mode. Dynamic value or static maximum value
Mode_Power_ Consumption[2]	Input	DWORD	I, Q, M, D, L or constant	Energy consumption in the current PE mode in [kW].
Energy_ Consumption_ to_Destination[2]	Input	DWORD	I, Q, M, D, L or constant	Energy consumption in the time until the requested PE mode in [kW].
Energy_ Consumption_ to_operate[2]	Input	DWORD	I, Q, M, D, L or constant	Energy consumption from the current PE mode to "PE_ready_to_operate" in [kWh].
ACTIVATE	InOut	BOOL	I, Q, M, D, L	The instruction copies the input parameters to the DATA_ERROR_RSP data area at a rising edge at input ACTIVATE. The parameter is then reset by the instruction. The parameter must be set within 10 seconds after a rising edge is detected at parameter NEW of the "PE_I_DEV (Page 3189)" instruction.
VALID	InOut	BOOL	I, Q, M, D, L	The parameter must be interconnected with the VALID input of the "PE_I_DEV (Page 3189)" instruction. The auxiliary block sets the parameter as soon as the response data for the PROFIenergy controller is available and ready for transmission.

Parameter	Declaration	Data type	Memory area	Description
DATA_ ERRORRSP	InOut	VARIANT	D	Pointer on the data area in which the response data is stored. The parameter is identical to the pointer for DATA_ERRORRSP of the "PE_I_DEV (Page 3189)" instruction. The addressed data area contains the complete PROFIenergy frame. Minimum length: 244 bytes
ERROR	Output	BOOL	I, Q, M, D, L	• "0": No error • "1": Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	• "0": No error • "0x80B1": Error in VARIANT setting, e.g. incorrect range
[1] If the time period is unlimited, the maximum value "0xFFFFFFFF" can be specified. If the time period is "Zero", "0x00" can be used. [2] If no energy consumption value has been defined, "0.0" can be specified.				

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

PE_Identify_RSP: Generate supported PROFIenergy commands as answer

Description

The auxiliary block "PE_Identify_RSP" generates the response to the command PE_Identify (Page 3185). In the response to the command, specify which PROFIenergy commands are supported. Please note that PE_IDENTIFY is itself a PE command and has to be included in the response.

Parameter

The following table shows the parameters of the "PE_Identify_RSP" auxiliary block:

Parameter	Declaration	Data type	Memory area	Description
PE_I_DEV_NEW	Input	BOOL	I, Q, M, D, L or constant	The parameter must be interconnected with the NEW output parameter of the "PE_I_DEV (Page 3189)" instruction. The auxiliary block is only processed if the parameter value is set to "1".
CMD	Input	INT	I, Q, M, D, L or constant	Service-Request-ID of the PROFIenergy command The parameter must be interconnected with the CMD output parameter of the "PE_I_DEV (Page 3189)" instruction.

Parameter	Declaration	Data type	Memory area	Description
Start_Pause	Input	BOOL	I, Q, M, D, L or constant	One parameter for each of the relevant PROFIenergy commands: • 0: PE command is not supported • 1: PE command is supported
End_Pause	Input	BOOL	I, Q, M, D, L or constant	
Query_Modes	Input	BOOL	I, Q, M, D, L or constant	
PEM_Status	Input	BOOL	I, Q, M, D, L or constant	
PE_Identify	Input	BOOL	I, Q, M, D, L or constant	
Query_ Measurement	Input	BOOL	I, Q, M, D, L or constant	
ACTIVATE	InOut	BOOL	I, Q, M, D, L	The instruction copies the input parameters to the DATA_ERROR_RSP data area at a rising edge at input ACTIVATE. The parameter is then reset by the instruction. The parameter must be set within 10 seconds after a rising edge is detected at parameter NEW of the "PE_I_DEV (Page 3189)" instruction.
VALID	InOut	BOOL	I, Q, M, D, L	The parameter must be interconnected with the VALID input of the "PE_I_DEV (Page 3189)" instruction. The auxiliary block sets the parameter as soon as the response data for the PROFIenergy controller is available and ready for transmission.
DATA_ ERRORRSP	InOut	VARIANT	D	Pointer on the data area in which the response data is stored. The parameter is identical to the pointer for DATA_ERRORRSP of the "PE_I_DEV (Page 3189)" instruction. The addressed data area contains the complete PROFIenergy frame. Minimum length: 244 bytes
ERROR	Output	BOOL	I, Q, M, D, L	• "0": No error • "1": Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	• "0": No error • "0x80B1": Error in VARIANT setting, e.g. incorrect range

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

PE_Measurement_List_RSP: Generate list of supported measured values as answer

Description

The auxiliary block "PE_Measurement_List_RSP" generates the response to the command Get_measurement_list (Page 3185). In the response, specify which measured values (Measurement-IDs) are supported.

Parameter

The following table shows the parameters of the "PE_Measurement_List_RSP" auxiliary block:

Parameter	Declaration	Data type	Memory area	Description
PE_I_DEV_NEW	Input	BOOL	I, Q, M, D, L or constant	The parameter must be interconnected with the NEW output parameter of the "PE_I_DEV (Page 3189)" instruction. The auxiliary block is only processed if the parameter value is set to "1".
CMD	Input	INT	I, Q, M, D, L or constant	Service-Request-ID of the PROFIenergy command The parameter must be interconnected with the CMD output parameter of the "PE_I_DEV (Page 3189)" instruction.
CMD_MODIFIER	Input	INT	I, Q, M, D, L or constant	PROFIenergy sub-command (evaluated only if CMD=3, or CMD=16). The parameter must be interconnected with the CMD_MODIFIER output parameter of the "PE_I_DEV" instruction.
Count	Input	BYTE	I, Q, M, D, L or constant	Number of measured values supported (measurement IDs)
Measurement_List	Input	VARIANT	D	Pointer to the array with the Measurement_IDs supported. For information on the structure of the array in accordance with the PROFIenergy profile, see: PI Command "Query_Measurement" - "Get_Measurement_list" (Page 3185)
ACTIVATE	InOut	BOOL	I, Q, M, D, L	The instruction copies the input parameters to the DATA_ERROR_RSP data area at a rising edge at input ACTIVATE. The parameter is then reset by the instruction. The parameter must be set within 10 seconds after a rising edge is detected at parameter NEW of the "PE_I_DEV (Page 3189)" instruction.
VALID	InOut	BOOL	I, Q, M, D, L	The parameter must be interconnected with the VALID input of the "PE_I_DEV (Page 3189)" instruction. The auxiliary block sets the parameter as soon as the response data for the PROFIenergy controller is available and ready for transmission.

Parameter	Declaration	Data type	Memory area	Description
DATA_ ERRORRSP	InOut	VARIANT	D	Pointer on the data area in which the response data is stored. The parameter is identical to the pointer for DATA_ERRORRSP of the "PE_I_DEV (Page 3189)" instruction. The addressed data area contains the complete PROFIenergy frame. Minimum length: 244 bytes
ERROR	Output	BOOL	I, Q, M, D, L	• "0": No error • "1": Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	• "0": No error • "0x80B1": Error in VARIANT setting, e.g. incorrect range

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

PE_Measurement_Value_RSP: Generate queried measured values as answer

Description

The auxiliary block "PE_Measurement_Value_RSP" generates the response to the command Get_measurement_values (Page 3188). In the response, return the values of the requested measurements.

Parameter

The following table shows the parameters of the "PE_Measurement_Value_RSP" auxiliary block:

Parameter	Declaration	Data type	Memory area	Description
PE_I_DEV_NEW	Input	BOOL	I, Q, M, D, L or constant	The parameter must be interconnected with the NEW output parameter of the "PE_I_DEV (Page 3189)" instruction. The auxiliary block is only processed if the parameter value is set to "1".
CMD	Input	INT	I, Q, M, D, L or constant	Service-Request-ID of the PROFIenergy command The parameter must be interconnected with the CMD output parameter of the "PE_I_DEV (Page 3189)" instruction.
CMD_MODIFIER	Input	INT	I, Q, M, D, L or constant	PROFIenergy sub-command (evaluated only if CMD=3, or CMD=16). The parameter must be interconnected with the CMD_MODIFIER output parameter of the "PE_I_DEV" instruction.
Count	Input	BYTE	I, Q, M, D, L or constant	Number of measured values (Measurement_Values).

Parameter	Declaration	Data type	Memory area	Description
Measure-ment_Values	Input	VARIANT	D	Pointer to the array with the measured values (Measurement_IDs). For information on the structure of the array in accordance with the PROFIenergy profile, see PI Command "Query_Measurement" - "Get_Measurement_values" (Page 3188)
ACTIVATE	InOut	BOOL	I, Q, M, D, L	The instruction copies the input parameters to the DATA_ERROR_RSP data area at a rising edge at input ACTIVATE. The parameter is then reset by the instruction. The parameter must be set within 10 seconds after a rising edge is detected at parameter NEW of the "PE_I_DEV (Page 3189)" instruction.
VALID	InOut	BOOL	I, Q, M, D, L	The parameter must be interconnected with the VALID input of the "PE_I_DEV (Page 3189)" instruction. The auxiliary block sets the parameter as soon as the response data for the PROFIenergy controller is available and ready for transmission.
DATA_ ERRORRSP	InOut	VARIANT	D	Pointer on the data area in which the response data is stored. The parameter is identical to the pointer for DATA_ERRORRSP of the "PE_I_DEV (Page 3189)" instruction. The addressed data area contains the complete PROFIenergy frame. Minimum length: 244 bytes
ERROR	Output	BOOL	I, Q, M, D, L	• "0": No error • "1": Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	• "0": No error • "0x80B1": Error in VARIANT setting, e.g. incorrect range

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

11.6.3.6 Module parameter assignment

Writing and reading data records

Principle

Some modules have a write-only system data area to which your program can transfer data records. This area contains data records with numbers from 0 to a maximum of 240. Not every module contains all of the data records (see following table).

Modules can also have a read-only system data area in which your program can read data records. This area contains data records with numbers from 0 to a maximum of 240. Not every module contains all of the data records (see following table).

Note

There are modules that have both system data areas. These are physically separate areas and the only thing they have in common is their logical structure.

Write-only system data area

The following table shows the structure of the write-only system data area. This table also shows how the permitted size of the individual data records and which instructions can be used to write them.

Data record number	Contents	Size	Can be written with instruction
0	Parameter	-	WR_DPARM (Page 3214)
1	Parameter	-	WR_DPARM (Page 3214)
2 to 127	User data	Each ≤ 240 bytes	WR_DPARM (Page 3214) WR_REC (Page 3123)
128 to 240	Parameter	Each ≤ 240 bytes	WR_DPARM (Page 3214) WR_REC (Page 3123)

Read-only system data area

The following table shows the structure of the read-only system data area. This table also shows the permitted size of the individual data records and which instructions can be used to read them.

Data record number	Contents	Size	Can be read with instruction
0	Module-specific diagnostics data (set as standard for the entire system)	4 bytes	RD_REC (Page 3118)
1	Channel-specific diagnostics data (incl. data record 0)	4 to 220 Bytes	RD_REC (Page 3118)
2 to 127	User data	Each ≤ 240 bytes	RD_REC (Page 3118)
128 to 240	Diagnostics data	Each ≤ 240 bytes	RD_REC (Page 3118)

System resources

If you start several asynchronous data record transfers one after the other with only short intervals between them, the allocation of system resources by the operating system ensures that all the jobs are executed and that they do not interfere with each other.

If the limits of the system resources are reached, this is indicated in RET_VAL. You can remedy this temporary error situation by simply repeating the job.

The maximum number of "simultaneously" active jobs of a single instruction type depends on the CPU.

RD_DPAR: Read module data record

Description

You use the instruction to read the data record with the number INDEX of the addressed component from the configured system data. This may be a module in a central rack or a distributed component (PROFIBUS DP or PROFINET IO).

The value TRUE for the output parameter VALID indicates that the data record was successfully transferred to the target range RECORD. In this case, the LEN output parameter contains the length of the read data in bytes.

If an error has occurred during transfer of the data record, this is indicated by the output parameter ERROR . In this case, the output parameter STATUS contains the error information.

Functional description

The "RD_DPAR" instruction works asynchronously, that is, its execution extends over multiple calls. You start the data record transfer by calling "RD_DPAR" with REQ = 1.

The output parameter BUSY and bytes 2 and 3 of the output parameter STATUS show the status of the job. Bytes 2 and 3 of STATUS match the output parameter RET_VAL of the instructions that operate asynchronously.

See also: Meaning of the parameters REQ, RET_VAL and BUSY with asynchronous instructions (Page 2193).

The transfer of the data record is complete when the output parameter BUSY has the value FALSE.

Parameter

The following table shows the parameters of the instruction "RD_DPAR":

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = 1: Read request
LADDR	Input	HW_IO	I, Q, M, D, L or constant	Identification number of the CPU or the interface. The number is assigned automatically and is stored in the properties of the CPU or of the interface of the hardware configuration.
INDEX	Input	INT	I, Q, M, D, L or constant	Data record number
RECORD	InOut	VARIANT	I, Q, M, D, L	Target range for the read data record
VALID	Output	BOOL	I, Q, M, D, L	New data record was received and is valid

Parameter	Declaration	Data type	Memory area	Description
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = 1: The job is not yet completed.
ERROR	Output	BOOL	I, Q, M, D, L	ERROR = 1: An error occurred during the reading process.
STATUS	Output	DWORD	I, Q, M, D, L	• Call ID (bytes 2 and 3) or error code • Byte 1: B#16#00, if no error. Otherwise function ID from DPV1-PDU: In the case of error for data record reading B#16#DE, in the case of error for data record writing B#16#DF. If no DPV1 protocol element is used: B#16#C0. • Byte 4: Manufacturer-specific error ID extension
LEN	Output	INT	I, Q, M, D, L	Length of the read data record information

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

STATUS parameter

Error code* (W#16#...)	Explanation	Restriction
0000	No error	-
7000	First call with REQ=0: No data transfer active; BUSY has the value "0".	-
7001	First call with REQ=1: Data transfer triggered; BUSY has the value "1".	Distributed I/O
7002	Intermediate call (REQ irrelevant): Data transfer already active; BUSY has the value "1".	Distributed I/O
8090	Address specified at parameter LADDR is invalid.	-
8092	A data type other than (Array of) bit string or integer was specified at the RECORD parameter.	-
8093	This instruction is not valid for the module selected with LADDR.	-
80A1	Negative acknowledgment during sending of data record to module (module defective or unplugged during sending).	-
80A2	DP protocol error at layer 2, possible hardware/interface error in DP slave.	Distributed I/O
80A3	DP protocol error at user interface/user.	Distributed I/O
80A4	Communication problem on com bus.	Error occurs between CPU and external DP interface module
80B0	Instruction for module type not possible, or module does not recognize the data record.	-
80B1	The length of the data record to be sent is incorrect.	-
80B2	The configured slot is not assigned.	-

Error code* (W#16#...)	Explanation	Restriction
80B3	Actual module type does not correspond to specified module type.	-
80C1	The data of the previous write job on the module for the same data record have not yet been processed by the module.	-
80C2	The module is currently processing the maximum possible number of jobs for a CPU.	-
80C3	The required resources (memory, etc.) are currently occupied.	
80C4	Internal temporary error. Job could not be executed. Repeat the job. If this error occurs often, check your installation for sources of electrical interference.	-
80C5	Distributed I/O not available or deactivated.	Distributed I/O
80C6	Data record transfer cancelled due to priority class abort (restart or background).	Distributed I/O
80D0	There is no entry for the module.	-
80D1	The data record number is not configured for the module (data record numbers > 241 are rejected).	-
80D2	The module cannot be assigned parameters according to its type identifier.	-
80D5	The data record is static.	-
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)	-
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".

RD_DPARA: Read module data record asynchronously

Description

You use the instruction to read the data record with the number RECNUM of a selected module from the configured system data. The read data record is entered in the target range defined by the parameter RECORD .

Functional description

The "RD_DPARA" instruction works asynchronously, that is, its execution extends over multiple calls. You start the reading process by calling the instruction with REQ = 1.

The output parameters RET_VAL and BUSY indicate the status of the job.

See also: Meaning of the parameters REQ, RET_VAL and BUSY with asynchronous instructions (Page 2193).

Parameters

The following table shows the parameters of the instruction "RD_DPARA":

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = 1: Read request
LADDR	Input	HW_IO	I, Q, M, D, L or constant	Identification number of the CPU or the interface. The number is assigned automatically and is stored in the properties of the CPU or of the interface of the hardware configuration.
RECNUM	Input	BYTE	I, Q, M, D, L or constant	Data record number (permitted values: 0 to 240)
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code. If no error occurred during the transmission, the following cases are distinguished: • RET_VAL contains the length of the actually read data record in bytes if the target range is larger than the read data record. • RET_VAL contains "0" if the length of the read data record is equal to the length of the target range.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = 1: The job is not yet completed.
RECORD	Output	VARIANT	I, Q, M, D, L	Target range for the data record read.

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

RET_VAL parameter

Error code* (W#16#...)	Explanation	Restriction
0000	No error	-
7000	First call with REQ=0: No data transfer active; BUSY has the value 0.	-
7001	First call with REQ=1: Data transfer triggered; BUSY has the value "1".	Distributed I/O
7002	Intermediate call (REQ irrelevant): Data transfer already active; BUSY has the value "1".	Distributed I/O
8090	Specified logical base address invalid.	-
8092	A data type other than (Array of) bit string or integer was specified at the RECORD parameter.	-
8093	This instruction is not valid for the module selected with LADDR.	-

Error code* (W#16#...)	Explanation	Restriction
80A1	Negative acknowledgment during sending of data record to module (module defective or unplugged during sending).	-
80A2	DP protocol error at layer 2, possible hardware/interface error in DP slave.	Distributed I/O
80A3	DP protocol error at user interface/user.	Distributed I/O
80A4	Communication on PBUS+ disrupted	-
80B0	Instruction for module type not possible, or module does not recognize the data record.	-
80B1	The length of the data record to be sent is incorrect. With RD_DPARM (Page 3213): The target range spanned by RECORD is too short.	-
80B2	The configured slot is not assigned.	-
80B3	Actual module type does not correspond to specified module type.	-
80C1	The data of the previous write job on the module for the same data record have not yet been processed by the module.	-
80C2	The module is currently processing the maximum possible number of jobs for a CPU.	-
80C3	The required resources (memory, etc.) are currently occupied.	
80C4	Internal temporary error. Job could not be executed. Repeat the job. If this error occurs often, check your installation for sources of electrical interference.	-
80C5	Distributed I/O not available or deactivated.	Distributed I/O
80C6	Data record transfer cancelled due to priority class abort (restart or background).	Distributed I/O
80D0	There is no entry for the module.	-
80D1	The data record number is not configured for the module (data record numbers > 241 are rejected).	-
80D2	The module cannot be assigned parameters according to its type identifier.	-
80D5	The data record is static.	-
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)	-
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".		

RD_DPARM: Read data record from configured system data

Description

You use instruction to read the data record with the number RECNUM of the addressed module from the configured system data. The read data record is entered into the target range spanned by the RECORD parameter.

Parameters

The following table shows the parameters of the instruction "RD_DPARM":

Parameter	Declaration	Data type	Memory area	Description
IOID	Input	BYTE	I, Q, M, D, L or constant	Address area identifier: • B#16#54 = Peripheral input (PI) • B#16#55 = Peripheral output (PQ) If the module is a mixed module, the area identifier of the lower address must be specified. If the addresses are identical, specify B#16#54.
LADDR	Input	HW_IO	I, Q, M, D, L or constant	Hardware ID of the CPU or the interface. The number is assigned automatically and is stored in the properties of the CPU or of the interface in the hardware configuration.
RECNUM	Input	BYTE	I, Q, M, D, L or constant	Data record number (permitted values: 0 to 240)
RET_VAL	Return	INT	I, Q, M, D, L	Length of the data record read in bytes if the read data record fits in the target range and no error occurred in the transfer. If an error occurs while the instruction is being executed, the return value contains an error code.
RECORD	Output	VARIANT	I, Q, M, D, L	Target range for the data record read.

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

RET_VAL parameter

Error code* (W#16#...)	Explanation	Restriction
0000	No error	-
7000	First call with REQ=0: No data transfer active; BUSY has the value "0".	-
7001	First call with REQ=1: Data transfer triggered; BUSY has the value "1".	Distributed I/O
7002	Intermediate call (REQ irrelevant): Data transfer already active; BUSY has the value "1".	Distributed I/O
8090	Specified logical base address invalid.	-

Error code* (W#16#...)	Explanation	Restriction
8092	A type other than BYTE is specified in the VARIANT reference at the RECORD parameter.	-
8093	This instruction is not valid for the module selected with LADDR.	-
80B1	The target range spanned by RECORD is too short.	-
80C3	The required resources (memory, etc.) are currently occupied.	-
80D0	There is no entry for the module.	-
80D1	The data record number is not configured for the module (data record numbers > 241 are rejected).	-
80D2	The module cannot be assigned parameters according to its type identifier.	-
80D5	The data record is static.	-
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)	-
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".		

WR_DPARM: Transfer data record

Description

You use the instruction "WR_DPARM" to transfer the data record with the number RECNUM from the configuration data to the addressed module. With this instruction, it is irrelevant whether the data record is static or dynamic.

Parameters

The following table shows the parameters of the instruction "WR_DPARM":

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L	REQ = 1: Write request
LADDR	Input	HW_IO	I, Q, M, D, L or constant	Hardware ID of the CPU or of the interface. The number is assigned automatically and is stored in the properties of the CPU or of the interface in the hardware configuration.
RECNUM	Input	BYTE	I, Q, M, D, L or constant	Data record number
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = 1: The writing process is not yet completed.

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

RET_VAL parameter

Error code* (W#16#...)	Explanation	Restriction
0000	No error	-
7000	First call with REQ=0: No data transfer active; BUSY has the value 0.	-
7001	First call with REQ=1: Data transfer triggered; BUSY has the value "1".	Distributed I/O
7002	Intermediate call (REQ irrelevant): Data transfer already active; BUSY has the value "1".	Distributed I/O
8090	Address specified at parameter LADDR is invalid.	-
8093	This instruction is not valid for the module selected with LADDR.	-
80A1	Negative acknowledgment during sending of data record to module (module defective or unplugged during sending).	-
80A2	DP protocol error at layer 2, possible hardware/interface error in DP slave.	Distributed I/O
80A3	DP protocol error at user interface/user.	Distributed I/O
80A4	Communication on PBUS+ disrupted	-
80B0	Instruction for module type not possible, or module does not recognize the data record.	-
80B1	The length of the data record to be sent is incorrect.	-
80B2	The configured slot is not assigned.	-
80B3	Actual module type does not correspond to specified module type.	-
80C1	The data of the previous write job on the module for the same data record have not yet been processed by the module.	-
80C2	The module is currently processing the maximum possible number of jobs for a CPU.	-
80C3	The required resources (memory, etc.) are currently occupied.	
80C4	Internal temporary error. Job could not be executed. Repeat the job. If this error occurs often, check your installation for sources of electrical interference.	-
80C5	Distributed I/O not available or deactivated.	Distributed I/O
80C6	Data record transfer cancelled due to priority class abort (restart or background).	Distributed I/O
80D0	There is no entry for the module.	-
80D1	The data record number is not configured for the module (data record numbers > 241 are rejected).	-
80D2	The module cannot be assigned parameters according to its type identifier.	-

Error code* (W#16#...)	Explanation	Restriction
80D5	The data record is static.	-
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)	-
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".		

11.6.3.7 Interrupts

ATTACH: Attach an OB to an interrupt event

Description

You use the instruction "ATTACH" to assign an organization block (OB) to a hardware interrupt event.

- You enter the symbolic or numeric name of the organization block in the OB_NR parameter. This will then be assigned to the event specified in the EVENT parameter.
- You select the hardware interrupt event at the EVENT parameter. Hardware interrupt events already generated are listed in the PLC tags under "System constants".

If the event in the EVENT parameter occurs following error-free execution of the "ATTACH" instruction, the organization block in the OB_NR parameter will be called and its program executed.

With the ADD parameter, you specify whether previous assignments of the organization block to other events should be canceled or retained. If the ADD parameter has the value "0", the existing assignments will be replaced by the current assignment.

Hardware interrupt events

Hardware interrupts can be used if events are not pending long enough to respond to them during runtime. Each hardware interrupt can be assigned to hardware interrupt OBs. These OBs contain the reaction to a particular event.

Hardware interrupts can be created for different events. Examples for this are:

- The detection of rising or falling edges for digital inputs.
- Violation of defined low and high limits for analog inputs.
- External reset, overflow/underflow, direction reversal etc. for high-speed counters.

Functional principle

Each hardware interrupt can be assigned to a hardware interrupt OB, which is placed in the queue for processing when the hardware interrupt event occurs. The assignment of OB and event can occur during configuration or at runtime:

- To assign an event to an OB during configuration, select a hardware interrupt OB for an event in the hardware configuration under "Hardware interrupts".
- Use the ATTACH instruction to make the assignment during runtime. The assignment of event and hardware interrupt OB is made via the EVENT and OB_NR parameters.

Parameters

The following table shows the parameters of the "ATTACH" instruction:

Parameter	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_ATT	I, Q, M, D, L or constant	Organization block (numbers up to 32767 are supported.)
EVENT	Input	EVENT_ATT	D, L or constant	Hardware interrupt event to be assigned to the OB. The hardware interrupt event must first be enabled in the hardware device configuration for inputs or high-speed counters.
ADD	Input	BOOL	I, Q, M, D, L or constant	Effects on previous assignments: • ADD=0 (default): This event replaces all previous event assignments for this OB. • ADD=1: This event is added to the previous event assignments for this OB.
RET_VAL	Return	INT	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

RET_VAL parameter

Error code* (W#16#....)	Description
0	No error
8090	OB does not exist
8091	OB is incorrect type
8093	Event does not exist
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

DETACH: Detach an OB from an interrupt event

Description

You use this instruction to cancel the existing assignment of an organization block to one or more hardware interrupt events during runtime.

You enter the symbolic or numeric name of the organization block in the OB_NR parameter. The assignment of this organization block to the event specified in the EVENT parameter will then be canceled.

- If you have selected an individual hardware interrupt event at the EVENT parameter, the assignment of the OB to this hardware interrupt event is cancelled. All other currently existing assignments remain active. You can select an individual hardware interrupt event using the drop-down list of the operand placeholder.
- If you have not selected a hardware interrupt event, all the events currently assigned to this OB_NR organization block are separated.

Parameters

The following table shows the parameters of the "DETACH" instruction:

Parameters	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_ATT	I, Q, M, D, L or constant	Organization block (numbers up to 32767 are supported.)
EVENT	Input	EVENT_ATT	D, L or constant	Hardware interrupt event
RET_VAL	Return	INT	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

RET_VAL parameter

Error code* (W#16#....)	Description
0	No error
1	No assignment exists (warning)
8090	OB does not exist
8091	OB has incorrect type
8093	Event does not exist
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

Cyclic interrupt

SET_CINT: Set cyclic interrupt parameters

Description

You use this instruction to set the parameters for a cyclic interrupt OB. The start time for a cyclic interrupt OB is generated from the respective time interval of the OB and the phase offset.

- The time interval of an OB is the interval at which the OB is periodically called. For example, if the time interval is 100 µs, the OB will be called every 100 µs during program execution.
- The phase offset is a time interval by which the call of a cyclic interrupt OB is offset. You can use the phase offset to process low priority organization blocks in a precise time base.

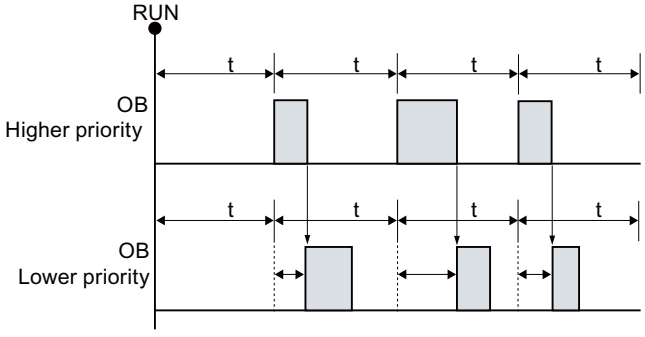
If the OB does not exist or if the time interval used is not supported, a corresponding error alarm is output in the RET_VAL parameter.

A time interval in the CYCLE parameter of "0" means that the OB will not be called.

Functional description

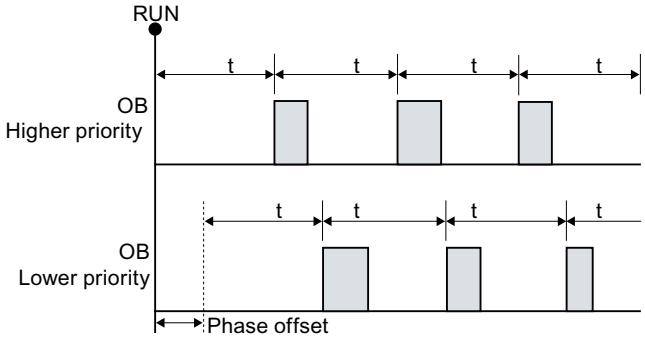
If a lower priority OB and a higher priority OB are called in the same time interval, the lower priority OB will only be called once the higher priority OB has been executed. The call time for the lower priority OB can be offset according to the length of time to execute the higher-priority OB.

OB call without phase offset



If a phase offset is configured for the lower priority OB and the phase offset is greater than the current execution time of the respective higher priority OB, then the block will be called in a fixed time base.

OB call with phase offset



Parameters

The following table shows the parameters of the "SET_CINT" instruction:

Parameter	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_CYCLIC	I, Q, M, D, L or constant	OB number (<32768)
CYCLE	Input	UDINT	I, Q, M, D, L or constant	Time interval in microseconds
PHASE	Input	UDINT	I, Q, M, D, L or constant	Phase offset
RET_VAL	Return	INT	I, Q, M, D, L	Status of the instruction

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#....)	Description
0	No error
8090	OB does not exist or is of the wrong type
8091	Incorrect time interval
8092	Incorrect phase offset
80B2	No event assigned to OB
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

QRY_CINT: Query cyclic interrupt parameters

Description

You can use this instruction to query the current parameters of a cyclic interrupt OB. The cyclic interrupt OB is identified using the OB_NR parameter.

The values of the queried cyclic interrupt parameters correspond to those at the time the "QRY_CINT" instruction is executed.

Parameters

The following table shows the parameters of the "QRY_CINT" instruction:

Parameter	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_CYCLIC (INT)	I, Q, M, D, L or constant	OB number (<32768) or symbolic addressing via the name of the OB (e.g. OB_MyOB)
CYCLE	Output	UDINT	I, Q, M, D, L	Time interval in microseconds
PHASE	Output	UDINT	I, Q, M, D, L	Phase offset
STATUS	Output	WORD	I, Q, M, D, L	Status of the cyclic interrupt: • Bit 0 to bit 4: see parameter STATUS • Other bits: Always "0"
RET_VAL	Return	INT	I, Q, M, D, L	Status of the instruction

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameter STATUS

Bit	Value	Meaning
0	0	Not used (always "0").
1	0	The cyclic interrupt is enabled.
	1	The cyclic interrupt is delayed.
2	0	The cyclic interrupt is not enabled or has expired.
	1	The cyclic interrupt is enabled.
3	0	Not used (always "0").
4	0	An OB with the specified number does not exist.
	1	An OB with the specified number exists.
Other bits		Not used (always "0").

Parameter RET_VAL

If an error occurs, the relevant error code will be displayed in the RET_VAL parameter and the STATUS parameter is set to "0".

Error code* (W#16#....)	Description
0	No error.
8090	OB does not exist or is of the wrong type
80B2	No result assigned to OB.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

Time-of-day interrupt

SET_TINT: Set time-of-day interrupt

Description

The instruction "SET_TINT" is used to set the start data and time of the time-of-day interrupt organization blocks from the user program, without having to make settings in the hardware configuration.

- Enter the number of the time-of-day interrupt-OBs at the parameter OB_NR for which you would like to set the start date and the time-of-day.
- Use the parameter SDT and PERIOD to specify when and how often the time-of-day interrupt OB should be called:
  - One-time call: Enter at the parameter SDT the date and the time-of-day and use the value "0" at the parameter PERIOD.
  - Repeated call: Enter the date and the time-of-day of the first call at the parameter SDT. Use the parameter PERIOD to define the time interval in which subsequent calls of the OBs should take place.

Observe the following when setting the start date and start time:

- The date and the time-of-day specification at the parameter SDT refers to the system time.
- The seconds and milliseconds specification is ignored and set to "0" at the start time.
- Only the starting date days 1, 2, ... 28 are possible if you want to specify a monthly time-of-day interrupt OBs. This restriction prevents skipping the monthly call (e.g. 30-day months or in February).
  The setting "end of the month" (W#16#2001) can be used at the parameter PERIOD as an alternative to the 29th 30th and the 31st of the month.

After setting the time-of-day interrupt with "SET_TINT" it still must be activated with the instruction "ACT_TINT".

Note

Additional information about time-of-day interrupt OBs

Other special features for the use of time-of-day interrupt OBs can be found in the descriptions of the organization blocks of the respective CPU:

For the S7-1200: Auto-Hotspot

For the S7-1500: Auto-Hotspot

The settings at the parameters SDT and PERIOD coincide with the settings for time-of-day interrupt in the properties of the time-of-day interrupt OBs.

Parameters

The following table shows the parameters of the "SET_TINT" instruction:

Parameters	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_TOD	I, Q, M, D, L or constant	Number of the time-of-day interrupt OBs • The numbers 10 to 17 are available for the time-of-day interrupt OBs. • An OB number starting with 123 can also be assigned as an alternative. The OB number is displayed in the program block folder and in the system constants.
SDT	Input	DT	D, L or constant	Start date and start time
PERIOD	Input	WORD	I, Q, M, D, L or constant	Execution intervals from the starting point SDT to: • W#16#0000 = single execution • W#16#0201 = once every minute • W#16#0401 = once hourly • W#16#1001 = once daily • W#16#1201 = once weekly • W#16#1401 = once monthly • W#16#1801 = once yearly • W#16#2001 = at month's end
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs during execution of the instruction, the actual parameter of RET_VAL contains an error code.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

RET_VAL parameter

Error code* (W#16#...)	Description
0000	No error occurred.
8090	Error at the parameter OB_NR (no time-of-day interrupt OB addressed).
8091	Error at the parameter SDT (invalid date and time-of-day specification).
8092	Incorrect input at the parameter PERIOD.
80A1	The set start time is in the past. This error code only occurs at PERIOD = W#16#0000.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

See also

ACT_TINT: Enable time-of-day interrupt (Page 3227)

SET_TINTL: Set time-of-day interrupt

Description

The instruction "SET_TINTL" is used to set the start data and time of the time-of-day interrupt organization blocks from the user program, without having to make settings in the hardware configuration.

- Enter the number of the time-of-day interrupt-OBs at the parameter OB_NR for which you would like to set the start date and the time-of-day.
- Use the parameter SDT and PERIOD to specify when and how often the time-of-day interrupt OB should be called:
  - One-time call: Enter at the parameter SDT the date and the time-of-day and use the value "0" at the parameter PERIOD.
  - Repeated call: Enter the date and the time-of-day of the first call at the parameter SDT. Use the parameter PERIOD to define the time interval in which subsequent calls of the OBs should take place.
- Use the parameter LOCAL to select whether the time specified at the parameter SDT refers to the local time or the system time.
- With the ACTIVATE parameter, you specify whether the settings made for the organization block are to be applied directly (ACTIVATE = true) or only after "ACT_TINT (Page 3227)" for the time-of-day interrupt organization block is called (ACTIVATE = false).

Observe the following when setting the start date and start time:

- The seconds and milliseconds specification is ignored and set to "0" at the start time.
- Only the starting date days 1, 2, ... 28 are possible if you want to specify a monthly time-of-day interrupt OBs. This restriction prevents skipping the monthly call (e.g. 30-day months or in February).
  The setting "end of the month" (W#16#2001) can be used at the parameter PERIOD as an alternative to the 29th 30th and the 31st of the month.

Please observe the following during the use of local time:

- Changeover from daylight saving to standard time: When calling time-of-day interrupt organization blocks with a start time within the second hour during changeover from daylight saving time to standard time, also use a time-delay interrupt during the first hour of the time changeover.
- Changeover from standard to daylight saving time: If you specify the skipped hour as the time-of-day for the daylight saving time changeover day, the error code 16#8091 will be output at a single execution (PERIOD = W#16#0000).

Note

Additional information about time-of-day interrupt OBs

Other special features for the use of time-of-day interrupt OBs can be found in the descriptions of the organization blocks of the respective CPU:

For the S7-1200: Auto-Hotspot

For the S7-1500: Auto-Hotspot

The settings at the parameters SDT and PERIOD coincide with the settings for time-of-day interrupt in the properties of the time-of-day interrupt OBs.

Parameters

The following table shows the parameters of the "SET_TINTL" instruction:

Parameters	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_TOD	I, Q, M, D, L or constant	Number of the time-of-day interrupt OBs • The numbers 10 to 17 are available for the time-of-day interrupt OBs. • An OB number starting with 123 can also be assigned as an alternative. The OB number is displayed in the program block folder and in the system constants.
SDT	Input	DTL	D, L or constant	Start date and start time
LOCAL	Input	BOOL	I, Q, M, D, L or constant	• true: Use local time • false: Use system time
PERIOD	Input	WORD	I, Q, M, D, L or constant	Execution intervals from the starting point SDT to: • W#16#0000 = single execution • W#16#0201 = Once every minute • W#16#0401 = once hourly • W#16#1001 = once daily • W#16#1201 = once weekly • W#16#1401 = once monthly • W#16#1801 = once yearly • W#16#2001 = at month's end
ACTIVATE	Input	BOOL	I, Q, M, D, L or constant	• true: set and activate the time-of-day interrupt • false: set the time-of-day interrupt and only activate at call of "ACT_TINT (Page 3227)"
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs during execution of the instruction, the actual parameter of RET_VAL contains an error code.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

RET_VAL parameter

Error code* (W#16#...)	Description
0000	No error occurred.
8090	Error at the parameter OB_NR (no time-of-day interrupt OB addressed).
8091	Error at the parameter SDT (invalid date and time-of-day specification).
8092	Incorrect input at the parameter PERIOD.
80A1	The set start time is in the past. This error code only occurs at PERIOD = W#16#0000.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

CAN_TINT: Cancel time-of-day interrupt

Description

The instruction "CAN_TINT" is used to delete the start data and start time of a specified time-of-day interrupt organization block. This deactivates the time-of-day interrupt, and the organization block is no longer called.

If you want to reuse the time-of-day interrupt, the start time must be reset (instruction "SET_TINTL (Page 3224)" or "SET_TINT (Page 3222)").

Thereafter, you must reactivate the time-of-day interrupt:

- If you use the instruction "SET_TINT (Page 3222)" or "SET_TINTL (Page 3224)" with parameter ACTIVE=false to set the time-of-day interrupt, call "ACT_TINT (Page 3227)".
- By using the instruction "SET_TINTL (Page 3224)" you can also activate the time-of-day interrupt directly with the parameter ACTIVE=true.

Parameters

The following table shows the parameters of the instruction "CAN_TINT":

Parameters	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_TOD	I, Q, M, D, L or constant	Number of the time-of-day interrupt OB, whose starting date and time-of-day are to be deleted.
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs during execution of the instruction, the actual parameter of RET_VAL contains an error code.

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error occurred.
8090	Error at the parameter OB_NR.
80A0	No starting date/time-of-day defined for the affected time-of-day interrupt OB.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

ACT_TINT: Enable time-of-day interrupt

Description

With the instruction "ACT_TINT" you can activate a time-of-day interrupt organization block from the user program. A prerequisite for the execution of the instruction is that the starting date and time-of-day are already set for the time-of-day interrupt OB.

Parameters

The following table shows the parameters of the instruction "ACT_TINT":

Parameters	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_TOD	I, Q, M, D, L or constant	Number of the time-of-day interrupt OBs • The numbers 10 to 17 are available for the time-of-day interrupt OBs. • An OB number starting with 123 can also be assigned as an alternative. The OB number is displayed in the program block folder and in the system constants.
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs during execution of the instruction, the actual parameter of RET_VAL contains an error code.

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error occurred.
8090	Error at the parameter OB_NR (no time-of-day interrupt OB addressed).
80A0	Start date and time-of day not set for the relevant time-of-day interrupt OB.

Error code* (W#16#...)	Description
80A1	The activated time is in the past. The error only occurs if the time-of-day interrupt is only to be executed once.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

QRY_TINT: Query status of time-of-day interrupt

Description

You can use this instruction to display the status of a time-of-day interrupt organization block in the STATUS output parameter.

Parameters

The following table shows the parameters of the "QRY_TINT" instruction:

Parameters	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_TOD	I, Q, M, D, L or constant	Number of the time-of-day interrupt OB whose status is queried The OB number is displayed in the program block folder and in the system constants.
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs during execution of the instruction, the actual parameter of RET_VAL contains an error code.
STATUS	Output	WORD	I, Q, M, D, L	Status of the time-of-day interrupt (see below)

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error occurred. Exception: Status message "0" on bit 4 (no OB with this number created).
8090	Error at the parameter OB_NR. Possible causes: • The value at the parameter OB_NR is not an OB number (<1 or > 32767) supported by the CPU. • The OB number does not address a time-of-day interrupt OB.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

Parameter STATUS

If an error occurs (see RET_VAL parameter), "0" is output in the STATUS parameter.

Bit	Value	Meaning
0	0	In Run.
	1	During startup.
1	0	The time-of-day interrupt is enabled.
	1	The time-of-day interrupt is disabled.
2	0	Time-of-day interrupt is not activated or has elapsed.
	1	The time-of-day interrupt is activated.
4	0	An OB with an OB number as specified at OB_NR parameter does not exist.
	1	An OB with an OB number as specified at OB_NR parameter does exist.
6	0	The time-of-day interrupt is based on the system time
	1	The time-of-day interrupt is based on the local time
Other		Always "0"

Time-delay interrupt

Using time-delay interrupts

Definition

After you have called the "SRT_DINT (Page 3230)" instruction, the operating system generates an interrupt after the specified delay time has elapsed, in other words, the assigned time-delay interrupt OB is called.

Prerequisites for the call

Before a time-delay interrupt can be called by the operating system, the following conditions must be met:

- The time-delay interrupt OB must be started by the "SRT_DINT (Page 3230)" instruction.
- The time-delay interrupt OB must not be deselected during configuration.
- The time-delay interrupt OB must exist in the CPU.

Purpose of the instructions "SRT_DINT", "CAN_DINT" and "QRY_DINT"

You use the instructions to

- Start time-delay interrupts ("SRT_DINT (Page 3230)")
- Cancel time-delay interrupts ("CAN_DINT (Page 3231)")
- Query time-delay interrupts ("QRY_DINT (Page 3232)")

Effects on the time-delay interrupt

The following table lists a number of different situations and explains the effect they have on a time-delay interrupt.

If ...	and ...	Then ...
A time-delay interrupt is started (by calling "SRT_DINT (Page 3230)")	The time-delay interrupt has already started,	The delay time is overwritten; the time-delay interrupt is started again.
	The time-delay interrupt OB does not exist at the time of the call,	The operating system generates a priority class error (calls OB 85). If OB 85 does not exist, the CPU changes to STOP.
	The interrupt is started in a startup OB and the delay time elapses before the CPU changes to RUN,	The call of the time-delay interrupt OB is delayed until the CPU is in RUN mode.
The delay time has elapsed,	A previously started time-delay interrupt OB is still being executed,	The operating system generates a time error (calls OB 80). If OB 80 does not exist, the CPU changes to STOP.

Response to warm restart and cold restart

During a warm restart or a cold restart, all the time-delay interrupt settings made in the user program by means of instructions are cleared.

Starting in a startup OB

A time-delay interrupt can be started in a startup OB. Two conditions must be satisfied to call the time-delay OB:

- The delay time must have elapsed.
- The CPU must be in the RUN mode.

If the delay time has elapsed and the CPU is not yet in the RUN mode, the time-delay interrupt OB call is delayed until the CPU is in RUN mode. The time-delay interrupt OB is then called before the first instruction in OB Main [OB 1] is executed.

SRT_DINT: Start time-delay interrupt

Description

The instruction "SRT_DINT" is used to start a time-delay interrupt, which calls a time-delay interrupt OB after the expiry of the delay time specified at the parameter DTIME. The delay time is started when a negative edge is generated in the EN enable input. The signal state of enable input EN must be "0" during delay time countdown. If the delay time countdown is interrupted, the OB configured in the OB_NR parameter is not executed.

Accuracy

The maximum time between the call of the "SRT_DINT" instruction and the start of the time-delay interrupt OB is one millisecond longer than the configured delay time, provided that no interruption events delay the call.

Parameters

The following table shows the parameters of the instruction "SRT_DINT":

Parameter	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_DELAY (INT)	I, Q, M, D, L or constant	Number of the OB to be executed after a delay time
DTIME	Input	TIME	I, Q, M, D, L or constant	Delay time (1 to 60000 ms) You can realize longer times, for example, by using a counter in a time-delay interrupt OB.
SIGN	Input	WORD	I, Q, M, D, L or constant	Identifier that appears when the time-delay interrupt OB is called in the start event information of the OB.
RET_VAL	Return	INT	I, Q, M, D, L	Status of the instruction

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error
8090	Incorrect parameter OB_NR
8091	Incorrect parameter DTIME
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

CAN_DINT: Cancel time-delay interrupt

Description

You use this instruction to cancel a started time-delay interrupt and, thus, also cancel the call of the time delay interrupt OB that is to be executed after the configured delay time. You specify the number of the organization block whose call is to be canceled in the OB_NR parameter.

Parameters

The following table shows the parameters of the "CAN_DINT" instruction:

Parameter	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_DELAY (INT)	I, Q, M, D, L or constant	Number of the OB whose call will be canceled
RET_VAL	Return	INT	I, Q, M, D, L	Status of the instruction

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error
8090	Incorrect parameter OB_NR
80A0	Time-delay interrupt has not started.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

QRY_DINT: Query time-delay interrupt status

Description

The instruction "QRY_DINT" is used to query the status of the time-delay interrupt.

Parameters

The following table shows the parameters of the instruction "QRY_DINT":

Parameter	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_DELAY (INT)	I, Q, M, D, L or constant	Number of the OB whose status is being queried.
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs during execution of the instruction, the actual parameter of RET_VAL contains an error code. The value "0" is displayed in the STATUS parameter.
STATUS	Output	WORD	I, Q, M, D, L	Status of the time-delay interrupt, see following table.

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameter STATUS

Bit	Value	Meaning
0	0	Operating system in RUN
	1	Operating system in startup
1	0	Time-delay interrupt is enabled by the operating system.
	1	Time-delay interrupt is disabled.
2	0	Time-delay interrupt is not activated or has elapsed.
	1	Time-delay interrupt is activated.
3	-	-
4	0	Time-delay interrupt OB with the specified number does not exist.
	1	Time-delay interrupt OB with the specified number exists.
Other bits		Always "0"

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error occurred.
8090	Incorrect information in the OB_NR parameter
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

Synchronous errors

Mask synchronous error events

Introduction

Synchronous errors are programming and access errors. Such errors occur as a result of programming with incorrect operand areas or numbers, or incorrect addresses. **Masking** these synchronous errors means the following:

- Masked synchronous errors do not trigger an error OB call and do not lead to a programmed alternative reaction.
- The CPU "records" the masked errors that have occurred in an error status register.

Masking is carried out by calling the "MSK_FLT (Page 3239)" instruction.

Unmasking errors means canceling a previously set mask and clearing the corresponding bit in the event status register of the current priority class. Masking is canceled as follows:

- By calling the "DMSK_FLT (Page 3240)" instruction.
- Once the current priority class has been completed.

If an error event occurs after it has been unmasked, then the operating system will start the associated error OB.

You can use the "READ_ERR (Page 3240)" instruction to read the masked errors that have occurred.

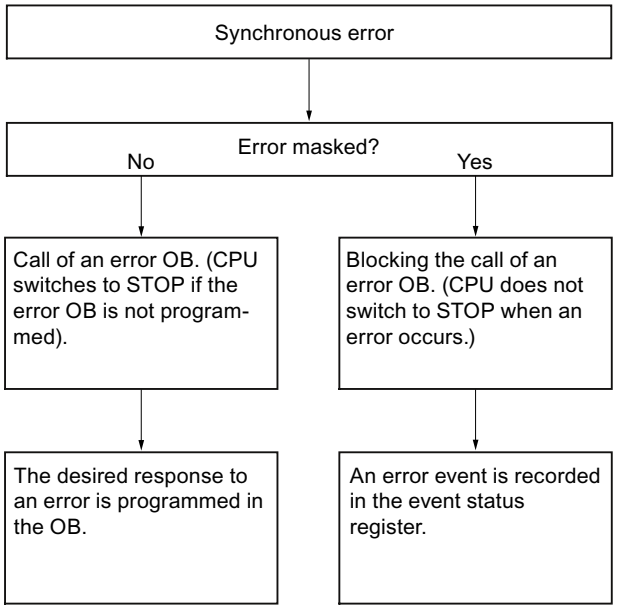
Note

Regardless of masking or unmasking of the error events for the S7-1500, the error event is entered in the diagnostic buffer and the group error LED of the CPU lights up.

Handling errors in general

Different actions are possible if programming and I/O area access errors occur in a user program:

- You can program an error OB that is called by the operating system when the corresponding error occurs.
- You can disable the error OB call individually for each priority class. In this case, the CPU does not change to STOP when an error of this type occurs in the particular priority class. The CPU enters the error in an error register. From this entry, however, you cannot recognize when or how often the error occurred.

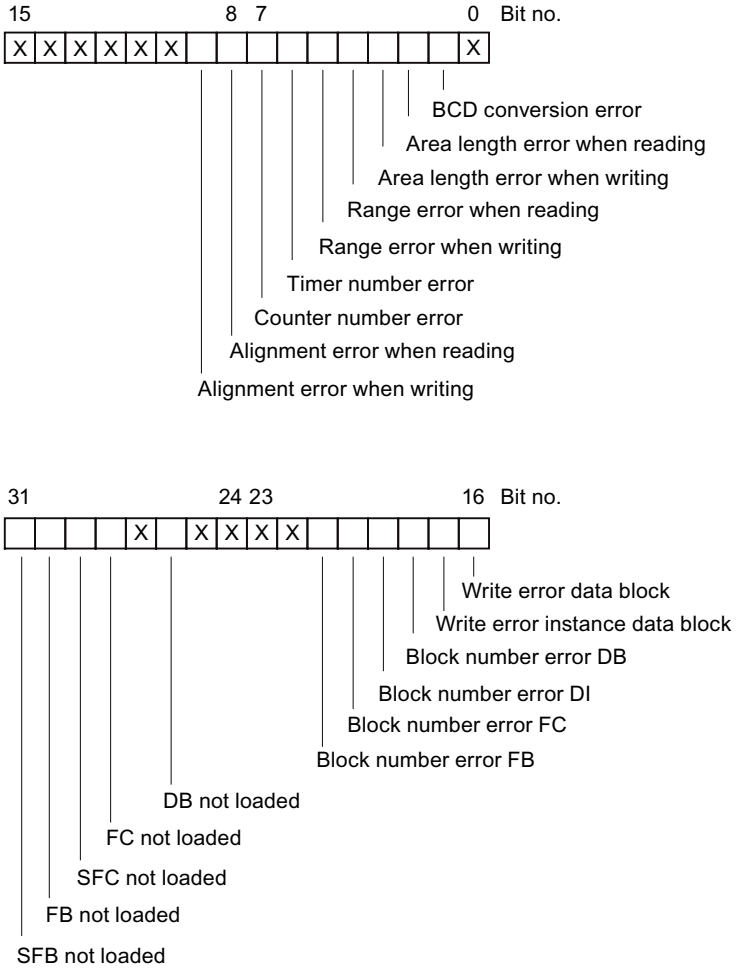


Synchronous errors are assigned to a particular bit pattern known as the **error filter**. You can find this error filter in the input and output parameters of the "MSK_FLT (Page 3239)", "DMSK_FLT (Page 3240)", and "READ_ERR (Page 3240)" instructions.

Synchronous errors are divided into **programming and access errors** which you can mask in two error masks. The error filters are illustrated in the following figures.

Programming error filter

The following figure shows the bit pattern of the error filter for programming errors. The error filter for the programming errors is available in the "PRGFLT_..." parameters (see below "Programming errors, Low-Word" or "Programming errors, High-Word").

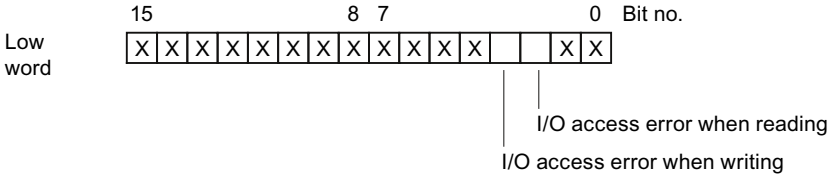


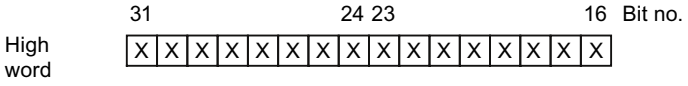
Legend: X Not relevant

The non-relevant bits "x" are set to "0" for the input and output parameters of the instructions "MSK_FLT (Page 3239)", "DMSK_FLT (Page 3240)", "READ_ERR (Page 3240)".

Access error mask

The following figure shows the bit pattern of the error mask for access errors. The error mask for access errors is located in the parameters ACCFLT_...

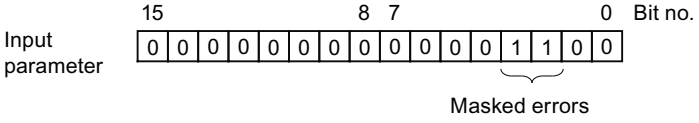


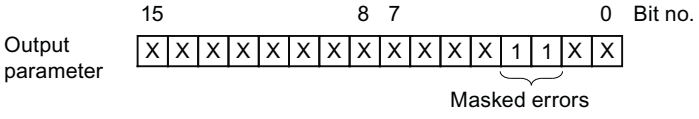


Legend: X Not relevant

Example: The following figure shows how the low word of the error mask for access errors appears with all masked errors.

- As input parameters for "MSK_FLT (Page 3239)"
- As output parameters for "MSK_FLT (Page 3239)"





Legend:
X Not relevant
0 Not masked
1 Masked

Programming error low word

The following table lists the errors assigned to the low word of the error filter for programming errors. The possible causes of the errors are also listed.

Error	Event ID (W#16#...)	Possible cause of error
BCD conversion error	2521	The value to be converted is not a BCD number (e.g. 5E8).
Area length error when reading	2522	An addressed operand is not located entirely within the possible operand range. Example: MW 320 should be read although the memory area is only 256 bytes long.
Area length error when writing	2523	An addressed operand is not located entirely within the possible operand range. Example: A value should be written to MW 320 although the memory area is only 256 bytes long.
Range error when reading	2524	An incorrect range identifier for the operand was specified during indirect, overlapping range addressing. Example: • Correct: LAR1 P#E 12.0 L W[AR1, P#0.0] • Incorrect: LAR1 P#12.0 L W[AR1, P#0.0] The range error is reported during this operation.
Range error when writing	2525	An incorrect range identifier for the operand was specified during indirect, overlapping range addressing. Example: • Correct: LAR1 P#E 12.0 T W[AR1, P#0.0] • Incorrect: LAR1 P#12.0 T W[AR1, P#0.0] The range error is reported during this operation.
Timer number error	2526	A non-existent timer is accessed. Example: • SI T [MW 0] with MW 0 = 129; the timer 129 should be started although there are only 128 timers available.
Counter number error	2527	A non-existent counter is accessed. • Example: ZV Z [MW 0] with MW 0 = 600; the counter 600 is accessed although only 512 counters are available.

Error	Event ID (W#16#...)	Possible cause of error
Alignment error when reading	2528	A byte, word or double word operand with a bit address ≠ 0 is addressed. Example: • Correct: LAR1 P#M12.0 L B[AR1, P#0.0] • Incorrect: LAR1 P#M12.4 L B[AR1, P#0.0]
Alignment error when writing	2529	A byte, word or double word operand with a bit address ≠ 0 is addressed. Example: • Correct: LAR1 P#M12.0 T B[AR1, P#0.0] • Incorrect: LAR1 P#M12.4 T B[AR1, P#0.0]

Programming error high word

The following table lists the errors assigned to the high word of the error filter for programming errors. The possible causes of the errors are also listed.

Error	Event ID (W#16#...)	Possible cause of error
Write error data block	2530	The data block to be written to is write-protected.
Write error instance data block	2531	The instance data block to be written to is write-protected.
Block number error DB	2532	The number of the data block is greater than the highest permissible number.
Block number error DI	2533	The number of the instance data block is greater than the highest permissible number.
Block number error FC	2534	The number of a called function (FC) is greater than the highest permissible number.
Block number error FB	2535	The number of a called function block (FB) is greater than the highest permissible number.
DB not loaded	253A	The data block is not loaded.
Instruction not loaded	253C to 253F	The instruction to be called is not loaded.

Access error

The following table contains the errors that are assigned to the error mask for access errors. The possible causes of the errors are also listed.

Error	Event ID (W#16#...)	Possible cause of error
I/O access error when reading	2942	• The address in the I/O area has no assigned signal module. • Access to this I/O area was not acknowledged within the specified module monitoring time (timeout).
I/O access error when writing	2943	

MSK_FLT: Mask synchronous error events

Description

You use the instruction to control the reaction of the CPU to synchronous errors. This is done by masking the respective synchronous errors (for error filters, see Mask synchronous error events (Page 3233)). When you call "MSK_FLT", you mask the synchronous errors in the current priority class.

If you set individual bits of the synchronous error filter to "1" in the input parameters, other bits that were set previously retain their value of "1". You obtain new error filters that you can read out using the output parameters. The synchronous errors you have masked do not call an OB but are simply entered in an error register. You can read the error register with the "READ_ERR (Page 3240)" instruction.

Parameters

The following table shows the parameters of the instruction "MSK_FLT":

Parameter	Declaration	Data type	Memory area	Description
PRGFLT_SET_MASK	Input	DWORD	I, Q, M, D, L or constant	Programming error to be masked
ACCFLT_SET_MASK	Input	DWORD	I, Q, M, D, L or constant	Access error to be masked
RET_VAL	Return	INT	I, Q, M, D, L	Error information
PRGFLT_MASKED	Output	DWORD	I, Q, M, D, L	Masked programming errors
ACCFLT_MASKED	Output	DWORD	I, Q, M, D, L	Masked access errors

You will find more detailed information on valid data types in "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	None of the errors were already masked.
0001	At least one of the errors was already masked. Nevertheless the other errors will be masked.
-	General error information See also: Getting error ID locally with GetErrorID (Page 2922)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

See also

Evaluating errors with output parameter RET_VAL (Page 2195)

DMSK_FLT: Unmask synchronous error events

Description

You use the instruction to unmask the errors masked with "MSK_FLT (Page 3239)". To do this, you must set the corresponding bits of the error filter to "1" in the input parameters. With the "DMSK_FLT" call, you unmask the corresponding synchronous errors of the current priority class. At the same time, the queried entries are cleared in the error register. You can read out the new error filters using the output parameters.

Parameters

The following table shows the parameters of the instruction "DMSK_FLT":

Parameter	Declaration	Data type	Memory area	Description
PRGFLT_RESET_MASK	Input	DWORD	I, Q, M, D, L or constant	Programming errors to be unmasked
ACCFLT_RESET_MASK	Input	DWORD	I, Q, M, D, L or constant	Access errors to be unmasked
RET_VAL	Return	INT	I, Q, M, D, L	Error information
PRGFLT_MASKED	Output	DWORD	I, Q, M, D, L	Still masked programming errors
ACCFLT_MASKED	Output	DWORD	I, Q, M, D, L	Still masked access errors

You will find more detailed information on valid data types in "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	All specified errors were unmasked.
0001	At least one of the errors was not masked. Nevertheless the other errors will be unmasked.
-	General error information See also: GET_ERR_ID: Get error ID locally (Page 2922)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

READ_ERR: Read out event status register

Description

You use the instruction to read the error register. The structure of the error register corresponds to that of the programming and access error filters, which you can program as input parameters with "MSK_FLT (Page 3239)" and "DMSK_FLT (Page 3240)".

In the input parameters, you enter the synchronous errors you want to read from the error register. When you call "READ_ERR", you read the required entries from the error register and at the same time clear these entries.

The error register contains information that tells you which of the masked synchronous errors in the current priority class occurred at least once. If a bit is set, this means that the corresponding masked synchronous error occurred at least once.

Parameters

The following table shows the parameters of the instruction "READ_ERR":

Parameter	Declaration	Data type	Memory area	Description
PRGFLT_QUERY	Input	DWORD	I, Q, M, D, L or constant	Query programming error
ACCFLT_QUERY	Input	DWORD	I, Q, M, D, L or constant	Query access error
RET_VAL	Return	INT	I, Q, M, D, L	Error information
PRGFLT_CLR	Output	DWORD	I, Q, M, D, L	Programming errors that occurred
ACCFLT_CLR	Output	DWORD	I, Q, M, D, L	Access errors that occurred

You will find more detailed information on valid data types in "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	All queried errors are masked.
0001	At least one of the queried errors is not masked.
-	General error information See also: Getting error ID locally with GetErrorID (Page 2922)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".

Evaluating errors with output parameter RET_VAL (Page 2195)

Asynchronous error event

DIS_IRT: Disable interrupt event

Description

The instruction "DIS_IRT" is used to disable the processing of new interrupts and asynchronous error events. Disabling means that if an interrupting event occurs, the operating system of the CPU reacts as follows:

- It **neither** calls an interrupt OB nor an asynchronous error OB,
- **nor** does it trigger the normal reaction if an interrupt OB or asynchronous error OB is not programmed.

If you disable interrupts and asynchronous error events, this remains in effect for all priority classes. The disable can only be canceled with the "EN_IRT (Page 3243)" instruction or by a warm or a cold restart.

Whether the operating system writes interrupts and asynchronous error events to the diagnostics buffer when they occur depends on the input parameter setting you select for MODE.

Note

Remember that when you program the "DIS_IRT" instruction, all interrupts that occur will be discarded.

Parameters

The following table shows the parameters of the instruction "DIS_IRT":

Parameter	Declaration	Data type	Memory area	Description
MODE	Input	BYTE	I, Q, M, D, L or constant	Specifies which interrupts and asynchronous errors are disabled.
OB_NR	Input	INT	I, Q, M, D, L or constant	OB number
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code.

You will find more detailed information on valid data types in "Overview of the valid data types (Page 1908)".

Parameter MODE

MODE (B#16#...)	Meaning
00	All newly occurring interrupts and asynchronous error events are disabled. (Synchronous errors are not disabled.) Assign the value "0" to the OB_NR parameter. Entries continue to be made in the diagnostics buffer.
01	All newly occurring events belonging to a specified interrupt class are disabled. Identify the interrupt class by specifying it as follows: • Time-of-day interrupts: 10 • Time-delay interrupts: 20 • Cyclic interrupts: 30 • Process interrupts: 40 • Interrupts for DPV1: 50 • Multicomputing interrupt: 60 • Redundancy error interrupts: 70 • Asynchronous error interrupts: 80 Entries continue to be made in the diagnostics buffer.
02	All new occurrences of a specified interrupt are disabled. You designate the interrupt using the OB number. Entries continue to be made in the diagnostics buffer.

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error occurred.
8090	The OB_NR input parameter contains an invalid value.
8091	The MODE input parameter contains an invalid value.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

EN_IRT: Enable interrupt event

Description

You use the instruction to enable the processing of new interrupts and asynchronous error events that you have previously disabled with the "DIS_IRT (Page 3242)" instruction. This means that if an interrupting event occurs, the operating system of the CPU reacts in one of the following ways:

- It calls an interrupt OB or asynchronous error OB.
  or
- It triggers the standard reaction if the interrupt OB or asynchronous error OB is not programmed.

Parameters

The following table shows the parameters of the instruction "EN_IRT":

Parameter	Declaration	Data type	Memory area	Description
MODE	Input	BYTE	I, Q, M, D, L or constant	Specifies which interrupts and asynchronous error events will be enabled.
OB_NR	Input	INT	I, Q, M, D, L or constant	OB number
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code.

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameter MODE

MODE	Meaning
0	All newly occurring interrupts and asynchronous error events are enabled.
1	All newly occurring events belonging to a specified interrupt class are enabled. Identify the interrupt class by specifying it as follows: • Time-of-day interrupts: 10 • Time-delay interrupts: 20 • Cyclic interrupts: 30 • Process interrupts: 40 • Interrupts for DPV1: 50 • Multicomputing interrupt: 60 • Redundancy error interrupts: 70 • Asynchronous error interrupts: 80
2	All newly occurring events of a specified interrupt are enabled. You designate the interrupt using the OB number.

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error occurred.
8090	The OB_NR input parameter contains an invalid value.
8091	The MODE input parameter contains an invalid value.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

DIS_AIRT: Delay execution of higher priority interrupts and asynchronous error events

Description

You use "DIS_AIRT" to delay the processing of interrupt OBs whose priority are higher than the priority of the current organization block.

You can call "DIS_AIRT" multiple times in an organization block. The "DIS_AIRT" calls are counted by the operating system. Processing is delayed more and more each time "DIS_AIRT" is executed. To cancel a delay, you must execute the "EN_AIRT (Page 3245)" instruction. To cancel all delays, the number of "EN_AIRT (Page 3245)" executions must be equal to the number of "DIS_AIRT" calls.

You can query the number of delays in the RET_VAL parameter of the "DIS_AIRT" instruction. If the value in the RET_VAL parameter is "0", there are no delays.

Parameters

The following table shows the parameters of the "DIS_AIRT" instruction:

Parameter	Declaration	Data type	Memory area	Description
RET_VAL	Return	INT	I, Q, M, D, L	Number of delays

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

RET_VAL parameter

Return value	Description
n	"n" shows the number of processing delays, i.e., the number of DIS_AIRT calls, after the instruction is complete (interrupt processing is only enabled again when n = 0; see EN_AIRT (Page 3245)).

EN_AIRT: Enable execution of higher priority interrupts and asynchronous error events

Description

You use "EN_AIRT" to enable processing of organization blocks when interrupts occur that have been delayed by the "DIS_AIRT (Page 3245)" instruction.

When "EN_AIRT" is executed, you cancel a processing delay that was registered by the operating system when "DIS_AIRT (Page 3245)" was called. To cancel all delays, the number of "EN_AIRT" executions must be equal to the number of "DIS_AIRT (Page 3245)" calls. If, for example, you have called "DIS_AIRT (Page 3245)" five times and thereby also delayed the processing five times, you must call the "EN_AIRT" instruction five times in order to cancel all five delays.

You can query the number of interrupt delays that have not yet been enabled after the execution of "EN_AIRT" in the RET_VAL parameter of the "EN_AIRT" instruction. The value "0" in the RET_VAL parameter means that all delays enabled by "DIS_AIRT (Page 3245)" have been cancelled.

Parameters

The following table shows the parameters of the "EN_AIRT" instruction:

Parameter	Declaration	Data type	Memory area	Description
RET_VAL	Return	INT	I, Q, M, D, L	Number of configured delays

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

RET_VAL parameter

Return value/ Error code* (W#16#...)	Description
n	"n" shows the number of processing delays that are not yet enabled after the instruction is complete (interrupt processing is only enabled again when n = 0).
8080	Although the interrupt processing was already enabled, the function was called again.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

11.6.3.8 Alarms

Program_Alarm: Generate program alarm with associated values

Description

The instruction "Generate program alarm with associated values" monitors a signal and generates a signal change at parameter SIG of a program alarm (for definition, see also: Auto-Hotspot). An incoming program alarm is generated with a signal change from 0 to 1 and an outgoing program alarm is generated with a signal change from 1 to 0. The program alarm is triggered synchronously to program execution.

You can append up to ten associated values to the program alarm at the parametersSD_i (0 ≤ i ≤10). The associated values are detected at the time of signal change at parameter SIG and assigned to the program alarm. For more information on configuring associated values, refer to the following sections: Auto-Hotspot, Auto-Hotspot.

Each incoming or outgoing alarm is assigned a time stamp:

- The current system time of the PLC when the signal change occurs is used by default (default value at the TIMESTAMP parameter).
- If you wish to specify a different time stamp, you can create one at the TIMESTAMP parameter.
  The time value must always be specified in system time (i.e. UTC) as this is the time used for time synchronization throughout the plant.
- If an alarm is to be time-stamped with a local time, a conversion module, which converts the local time to system time, must be connected in series. This is the only way to make sure that the time stamp is shown properly in the alarm display.

To use the current system time of the CPU, set the TIMESTAMP parameter to its default value (LDT#1970-01-01-00:00:00.0).

Call of the instruction "Generate program alarm with associated values"

The instruction can only be called in a function block (FB). The block is processed synchronously. This means that an alarm is triggered as soon as the block is exited. If there is an error during processing, an error code is output.

Once the instruction has been inserted in the FB, a multi-instance of the data type "Program_Alarm" is created in the "Static" section of the block interface. You can choose any name for this multi-instance in the dialog which appears. It is also the name of the program alarm.

Finally, add the parameters of the instruction in line with your requirements (see the "Parameters" table).

Configuring the program alarm

The program alarm settings are displayed in the "Properties" window when you select the name of the program alarm in the "Static" section or in the network of the FB. In this window, you can select the alarm class, priority, etc. and edit the alarm text.

The settings that are made here can be edited in the project tree. Go to "PLC alarms" and open the "Program alarms" tab. All existing program alarms are then displayed in the "Alarm types" table.

Parameters

The following table shows the parameters of the instruction "Generate program alarm with associated values":

Parameter	Declaration	Data type	Memory area	Description
SIG	Input	BOOL	I, Q, M, D, L, T, C or constant	The signal to be monitored. • Positive signal edge: An incoming program alarm is generated • Negative signal edge: An outgoing program alarm is generated
TIMESTAMP	Input	LDT	M, D, L or constant	This parameter is used to assign an alarm a time stamp, for example, from an input signal with a distributed stamp. The time value must always be specified in system time (i.e. UTC), as this is the time used for time synchronization throughout the plant. • "Not assigned" means that the system time of the CPU will be used as the interrupt time stamp when a signal change occurs (default). • Any system time input will be used as the interrupt time stamp when a signal change occurs. Note: If an interrupt is to be time-stamped with a local time, a conversion module must be connected in series to convert the local time to system time. This is the only way to make sure that the time stamp is shown correctly in the interrupt display.
SD_i	Input	VARIANT	I, Q, M, D, L	i-th associated value (1 ≤ i ≤ 10) You can use binary numbers, integers, floating-point numbers, or character strings as associated values.

Parameter	Declaration	Data type	Memory area	Description
Error	Output	BOOL	I, Q, M, D, L	Status parameter Error Error = TRUE indicates that an error has occurred during processing. The possible error cause is displayed at the Status parameter.
Status	Output	WORD	I, Q, M, D, L	Status parameter Status Display of error information (see "Error and Status parameters").

You can find additional information on valid data types under "See also".

Parameters Error and Status

The following table contains all specific error information that can be output via the Error and Status parameters.

Error	Status*	Explanation
0	0000	No error, or the instruction was not processed because there was no signal edge at the parameter SIG.
1	0085	"Only information" alarm type
1	8001	Invalid static alarm information
1	8002	No valid static alarm information
1	8004	Maximum size of 512 bytes reached for the associated values of the alarm.
1	8005	A positive signal edge is pending at parameter SIG and there is still an alarm pending which has not yet been acknowledged.
1	8007	Outgoing alarm which was not preceded by an incoming alarm.
1	8087	Static alarms are deactivated.
1	8089	Alarm is too long.
1	80Ax	The SD_i parameter has an invalid value.
1	80C1	The CPU cannot generate any alarms at this time because initialization routines are running (this is the case after download in RUN, for example). Try again later.
1	80C2	The maximum number of alarms per time unit has been sent. Try again later.
1	80C3	All dynamic alarm instances are being used. Try again later.
1	80C4	Alarm is being output and cannot be overwritten. Try again later.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".		

Example

In the following example, you generate a program alarm with associated value for a signal change.

Create one tag in a global data block for storing the signal value to be monitored.

Program_Alarm_Tags

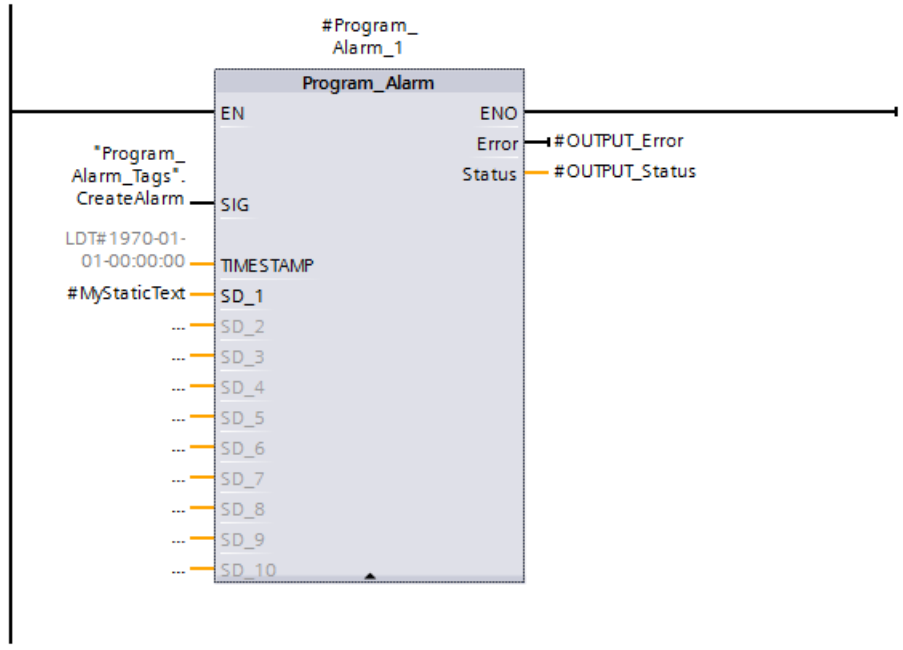
		Name	Data type	Start value
1		Static		
2		CreateAlarm	Bool	false

The instruction is called in a function block. Create four parameters for the function block for interconnection of the instruction.

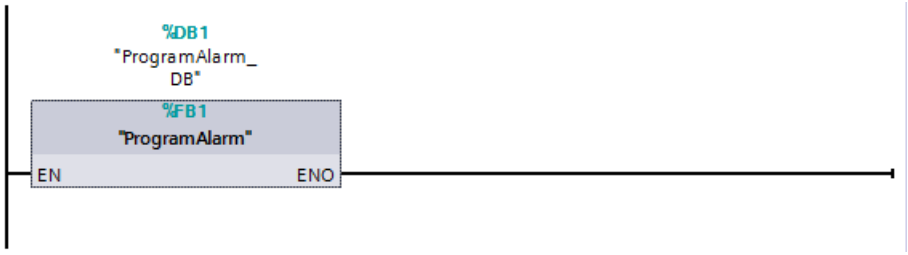
ProgramAlarm

		Name	Data type	Default value
1		Input		
2		<Add new>		
3		Output		
4		<Add new>		
5		InOut		
6		<Add new>		
7		Static		
8		MyStaticText	String	'MyStaticText'
9		Program_Alarm_1	Program_Alarm	
10		Temp		
11		OUTPUT_Error	Bool	
12		OUTPUT_Status	Word	

Interconnect the parameters of the instruction as follows.



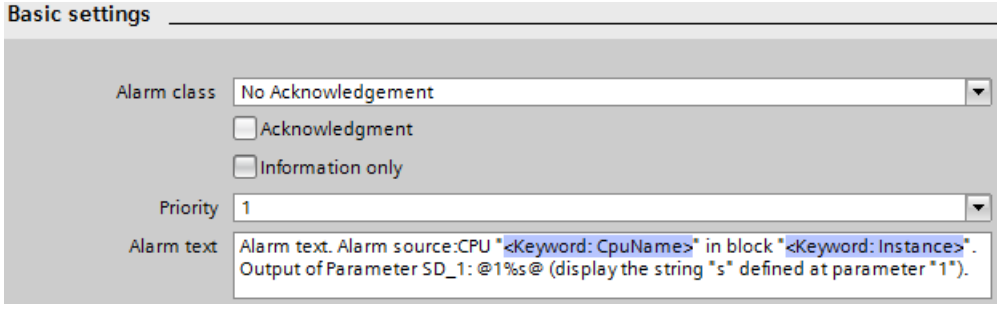
Call the function block in an OB.



A PLC alarm is generated automatically when the instruction is created. Open the PLC alarms dialog and select the alarm to be processed on the Program alarms tab. Create the alarm text, including two key words.

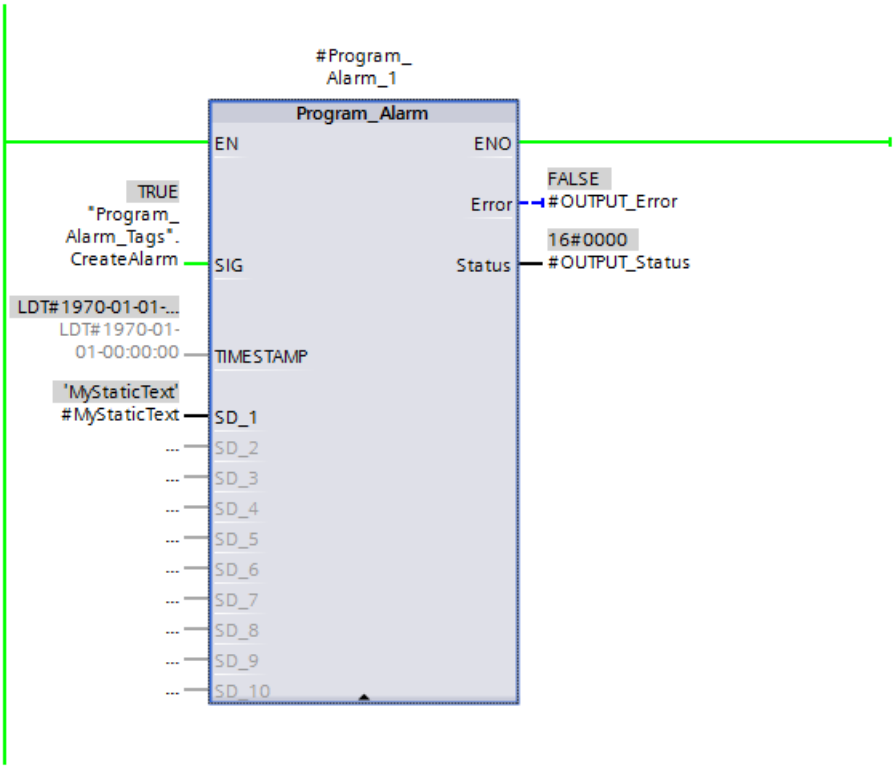
Note: If you right-click in the text box, you can insert a key word, tag, or text list.

As a result of the character sequence "@1%s@", the value of parameter SD_1 ("#MyStaticText") is read out and output as a character string.



If parameter SIG ("CreateAlarm") has the signal state "TRUE", the PLC alarm is output. At output parameter STATUS ("OUTPUT_Status"), the value "0001" indicates that a signal change has occurred. Then, it is indicated that no further processing is taking place (the value is "0000"). At parameter SD_1 ("#MyStaticText"), the associated value of the PLC alarm is output.

A time stamp can be transferred to parameter TIMESTAMP. If not interconnected, parameter TIMESTAMP outputs the local time of the CPU clock. At output parameter ERROR ("OUTPUT_Error"), it is indicated that the processing of the instruction is proceeding error-free.



For the output of the PLC alarm, use the web server of the CPU. In order to use the web server, the following is necessary:

- The web server must be activated in the CPU settings.

Use the Internet browser to open the web server (via the IP address of the CPU) and log on in the web server menu. The CPU outputs the alarm text as long as the signal being monitored ("CreateAlarm") supplies the value "TRUE".

Time	Message text
02:32:09.226 pm	Alarm text. Alarm source:CPU "PLC_2" in block "ProgramAlarm_DB". Output of Par

Example

You can find a detailed application example in the Siemens Industry Online Support (http://support.automation.siemens.com/WW/llisapi.dll?aktprim=99&lang=en&referer=%2fWW%2f&func=cslib.csinfo2&siteid=csius&extranet=standard&viewreg=WW&groupid=4000002) under the following FAQ ID: 98210758.

Overview of the valid data types (Page 1908)

Get_AlarmState: Output alarm status

Description

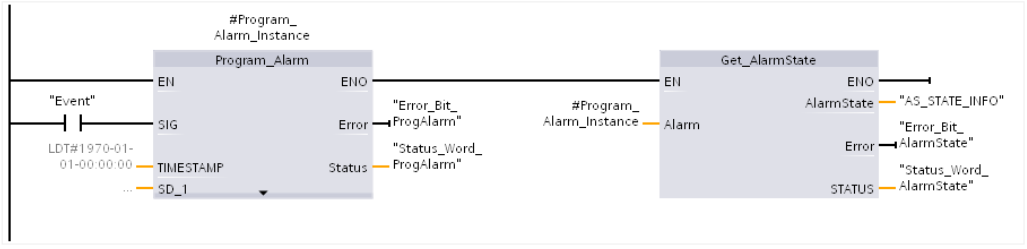
Use the instruction "Output alarm status" to output the alarm status of a program alarm.

There are three possible alarm statuses:

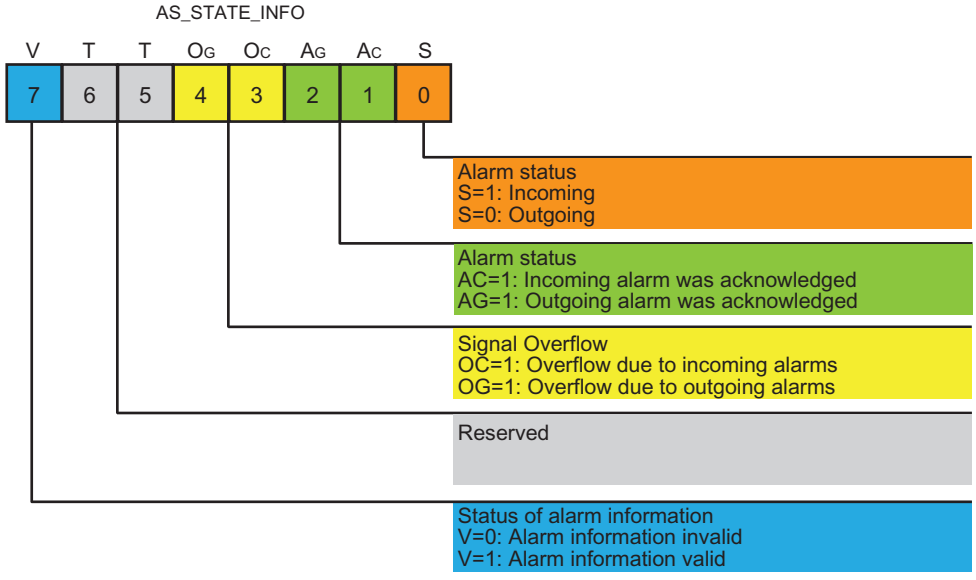
- Incoming
- Outgoing
- Acknowledged

The output of the alarm status always refers to a program alarm that was created using the instruction "Generate program alarm with associated values".

The program alarm is selected with the Alarm input parameter. Specify the instance DB of the instruction "Generate program alarm with associated values" at the parameter Alarm.



The alarm status is returned in a byte via the AlarmState output parameter. The meaning of the individual bits is shown in the following figure:



The execution status of the instruction is shown with the output parameters Error and STATUS.

Parameters

The following table lists the parameters of the instruction "Output alarm status":

Parameter	Declaration	Data type	Memory area	Description
Alarm	Input	ALARM_BASE	D	Instance of the instruction "Generate program alarm with associated values" • Alarm.Messagetype = Alarm_AP, the the bit Ac has either the signal status 0 or 1 and the bit Ag has the signal status 1 – not active: 0x86 (1000 0110) – active/not acknowledged: 0x85 (1000 0101) – active/acknowledged: 0x87 (1000 0111) – outgoing/not acknowledged: 0x84 (1000 0100) • Alarm.Messagetype = Notify_AP, the the bit Ac has either the signal status 0 or 1 and the bit Ag has the signal status 1 – not active: 0x86 (1000 0110) – active: 0x85 (1000 0101) • Alarm.Messagetype = Inforeport_AP, the bits Ac and Ag both have the signal status 1 – Static: 0x86 (1000 0110) • If the alarm is not active or it is an Inforeport, bit S has the signal status 0.
AlarmState	Output	BYTE	I, Q, M, D, L	Status of the alarm as a bit array

Parameter	Declaration	Data type	Memory area	Description
Error	Output	BOOL	I, Q, M, D, L	Status parameter • 0: No error • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy STATUS to a free data area.

You can find additional information on valid data types under "See also".

Parameter STATUS

Error code* (W#16#...)	Explanation
8001	Invalid static alarm instance
8002	ID of the alarm is invalid
8003	No active alarms within the alarm class • Alarm_AP: The alarm is outgoing and acknowledged. • Notify_AP: The alarm is outgoing. • Inforeport Bit V is set to signal status 0.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Example

In the following example, you output the alarm status of a program alarm.

Create four tags in a global data block for storing the data.

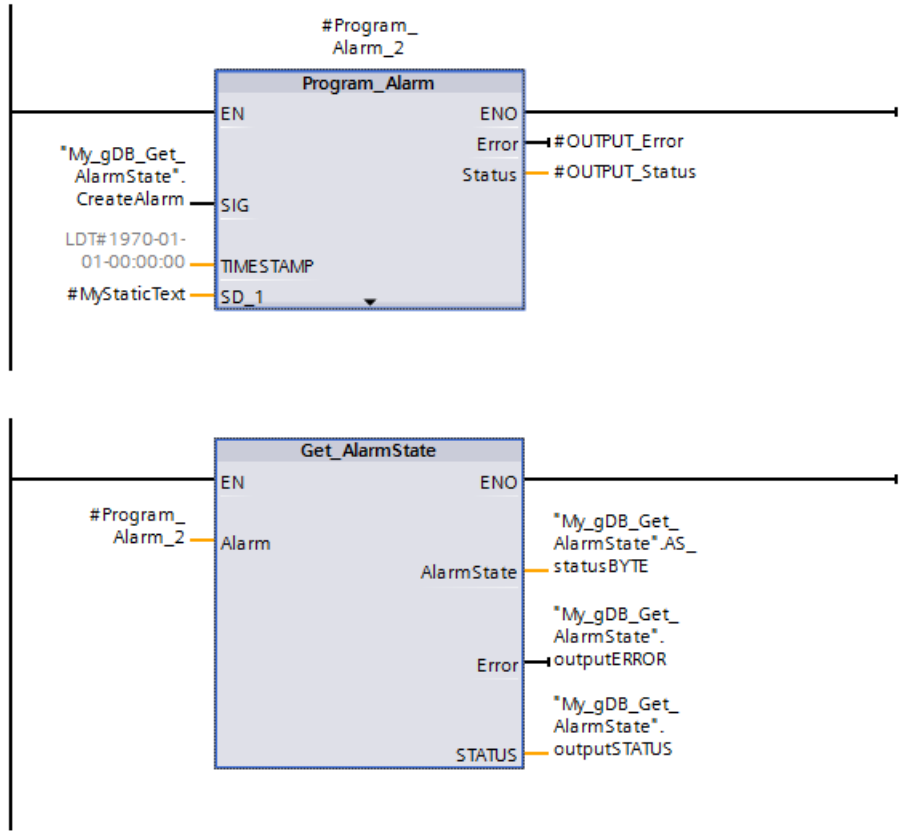
My_gDB_Get_AlarmState

	Name	Data type	Start value
1	Static		
2	AS_statusBYTE	Byte	16#0
3	outputERROR	Bool	false
4	outputSTATUS	Word	16#0
5	CreateAlarm	Bool	false

The "Get_AlarmState" instruction is called together with the "Program_Alarm" instruction in a function block. Create four parameters for the function block for interconnection of the instructions.

7		Static		
8		MyStaticText	String	'MyStaticText'
9		Program_Alarm_2	Program_Alarm	
10		Temp		
11		OUTPUT_Error	Bool	
12		OUTPUT_Status	Word	

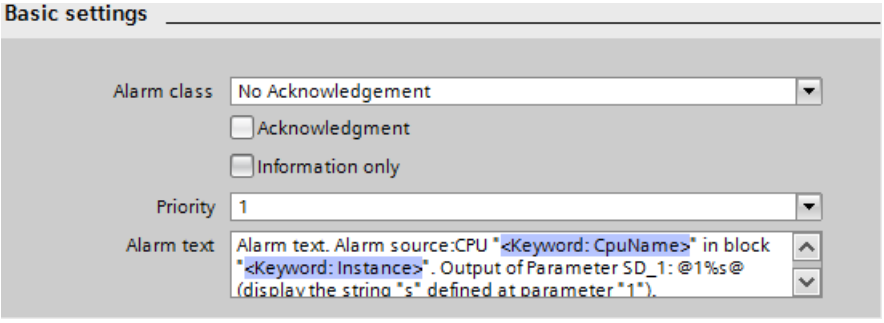
Interconnect the parameters of the instructions as follows.



Call the function block in an OB.

A PLC alarm is generated automatically when the "Program_Alarm" instruction is created. Open the PLC alarms dialog and select the alarm to be processed on the Program alarms tab. Create the alarm text, including two key words.

Select the following settings for the alarm. The alarm belongs to the alarm class "Notify_AP".



If input parameter SIG ("CreateAlarm") of the "Program_Alarm" instruction has the signal state "TRUE", the PLC alarm is output.

In the case of the "Get_AlarmState" instruction, the following occurs: The PLC alarm is communicated to the "Get_AlarmState" instruction using input parameter ALARM. At output parameter AlarmState ("AS_statusBYTE"), it is indicated that the alarm corresponding to the alarm class "Notify_AP" is active.

At output parameters ERROR ("outputERROR") and STATUS ("outputSTATUS"), it is indicated that the processing of the instruction is proceeding error-free.

My_gDB_Get_AlarmState

	Name	Data type	Start value	Monitor value
1	Static			
2	AS_statusBYTE	Byte	16#0	16#85
3	outputERROR	Bool	false	FALSE
4	outputSTATUS	Word	16#0	16#0000
5	CreateAlarm	Bool	false	TRUE

For the output of the PLC alarm, use the web server of the CPU.

Example

You can find a detailed application example in the Siemens Industry Online Support (http://support.automation.siemens.com/WW/llisapi.dll?aktprim=99&lang=en&referer=%2fWW%2f&func=cslib.csinfo2&siteid=csius&extranet=standard&viewreg=WW&groupid=4000002) under the following FAQ ID: 98210758.

Overview of the valid data types (Page 1908)

Program_Alarm: Generate program alarm with associated values (Page 3246)

Gen_UsrMsg: Generate user diagnostic alarms

Description

You use the "Gen_UsrMsg" instruction to generate an alarm that is entered in the diagnostic buffer.

You use the Mode parameter to select whether an incoming or an outgoing alarm is to be generated:

- When Mode = 1: Create an incoming alarm.
- When Mode = 2: Create an outgoing alarm.
- Regardless of whether an incoming or outgoing alarm is generated, the alarm always has the attribute "Information only".

The entry in the diagnostic buffer is created synchronously. Alarm transmission is asynchronous.

If an error occurs during the execution of an instruction, it is output via the parameter RET_VAL.

Content of the alarm

The content of the alarm is defined with a text list:

- Specify the text list you want to use with the parameter TextListID. For this purpose open the dialog "Text lists" in the project navigation. Show the column "ID" in the dialog "Text lists". Apply the ID at the parameter TextListID.
- Use the parameter TextID to select the text list entry you want to write in the diagnostic buffer. For this purpose select an entry from the "Text lists entries" dialog by applying a number from the columns "Range from / range to" at the parameter TextID. The same number must be used from both the "Range from" and "Range to" columns for the text list entry.
- Additional information about text lists can be found here: Text lists (Page 463)

Defining associated values

New associated values can be defined in the text entry and then added to the alarm:

- Associated values are defined by adding the following information in the text list entry: @<No. of the associated value><Element type><Format specification>@
- Use the system data type AssocValues to specify which associated value is added when generating the alarm.
- Additional information on the structure of associated values can be found here: Auto-Hotspot

Parameters

The following table shows the parameters of the "Gen_UsrMsg" instruction:

Parameter	Declaration	Data type	Memory area	Description
Mode	Input	UInt	I, Q, M, D, L or constant	Parameters for selecting the status of the alarm: • 1: incoming alarm • 2: outgoing alarm
TextID	Input	UInt	I, Q, M, D, L or constant	ID of the text list entry that should be used for the alarm text.
TextListID	Input	UInt	I, Q, M, D, L or constant	ID of the text list that contains text list entry.
Ret_Val	Return	Int	I, Q, M, D, L	Error code of the instruction.
AssocValues	InOut	VARIANT	D, L	Pointer to the system data type AssocValues that allows you to define the associated values.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter AssocValues

Use the system data type AssocValues to define which associated values will be sent. A maximum of 8 associated values are possible. The structure of the system data type is created by entering the data type "AssocValues" as a data block.

The associated values are selected by entering the numbers of the associated values for the parameters Value[x]. Note the following:

- The values for TextID and TextListID are treated by the instruction as the associated values to be sent. As a result, "1" and "2" are already assigned as numbers for addressing associated values. Do not use the numbers "1" or "2" to address associated values.
- Address the associated value at parameter Value [1] as number "3", at parameter Value [2] as number "4", and so forth.

Byte	Parameter	Data type	Start value	Description	Number of the associated value
0..1	Value[1]	UINT	0	First associated value of the alarm.	3
2..3	Value[2]	UINT	0	Second associated value of the alarm.	4
4..5	Value[3]	UINT	0	...	5
6..7	Value[4]	UINT	0	...	6
8..9	Value[5]	UINT	0	...	7
10..11	Value[6]	UINT	0	...	8
12..13	Value[7]	UINT	0	...	9
14..15	Value[8]	UINT	0	Eighth associated value of the alarm.	10

Parameter RET_VAL

The following table contains all specific error information that can be output via the RET_VAL parameter.

Error code* (W#16#...)	Explanation
0000	No error
8080	Value in the Mode parameter is not supported.
80C1	Resource bottleneck due to too many parallel calls.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Example

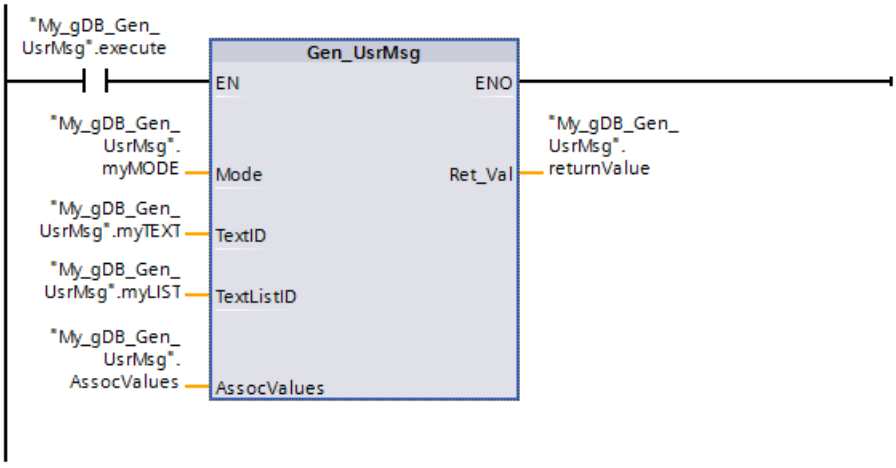
In the following example, you generate an alarm that is entered in the diagnostic buffer.

Create five tags and an "AssocValues" structure (with the AssocValues data type) in a global data block for storing the data.

My_gDB_Gen_UsrMsg

	Name	Data type	Start value
1	Static		
2	myMODE	UInt	1
3	myTEXT	UInt	3
4	myLIST	UInt	512
5	returnValue	Int	0
6	execute	Bool	false
7	AssocValues	AssocValues	
8	Value	Array[1..8] of UInt	
9	Value[1]	UInt	33
10	Value[2]	UInt	411
11	Value[3]	UInt	578
12	Value[4]	UInt	6122
13	Value[5]	UInt	722
14	Value[6]	UInt	8111
15	Value[7]	UInt	9829
16	Value[8]	UInt	10457

Interconnect the parameters of the instruction as follows.



Use the "Text lists" entry to create a Text list and a Text list entry for the alarm. Apply the ID of the text list at parameter TextListID ("myLIST"). Apply the ID (Range ...) of the text list entry at parameter TextID ("myTEXT"). Assign the alarm parameters as follows.

Text lists

Name	Id	Selection	Comment
USER_1	512	Decimal	

Text list entries of USER_1

Range from	Range to	Entry
3	3	This is a user generated message. Return Value[3]: @5I%6d@

If the normally open contact ("execute") supplies the signal state "TRUE", the "Gen_UsrMsg" instruction is executed. According to the value of parameter Mode ("myMODE"), an incoming

alarm is generated. The alarm to be output is made known to the instruction using parameters TextListID ("myLIST") and TextID ("myTEXT"). The associated values of the alarm are transferred using parameter AssocValues ("AssocValues").

When the alarm is generated, the character string "@5I%6d@" contained in the alarm text is interpreted as follows:

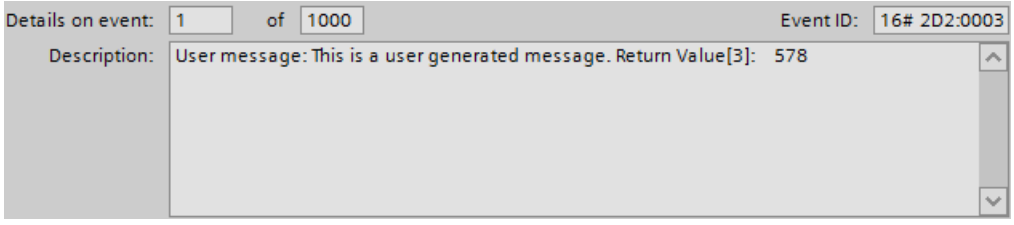
- The associated value with the number "5" is read out in the INT data type. The number corresponds to parameter Value[3] of the "AssocValues" structure.
- The associated value is output as a decimal number. The decimal number is limited to six places.

At output parameter Ret_Val ("returnValue"), it is indicated that the processing of the instruction is proceeding error-free.

My_gDB_Gen_UsrMsg

	Name	Data type	Start value	Monitor value
1	Static			
2	myMODE	UInt	1	1
3	myTEXT	UInt	3	3
4	myLIST	UInt	512	512
5	returnValue	Int	0	0
6	execute	Bool	false	FALSE
7	AssocValues	AssocValues		
8	Value	Array[1..8] of UInt		
9	Value[1]	UInt	33	33
10	Value[2]	UInt	411	411
11	Value[3]	UInt	578	578
12	Value[4]	UInt	6122	6122
13	Value[5]	UInt	722	722
14	Value[6]	UInt	8111	8111
15	Value[7]	UInt	9829	9829
16	Value[8]	UInt	10457	10457

For the output of the alarm, for a CPU of the S7-1500 series, open the entry "Online & Diagnostics > Diagnostic buffer".



Example

You can find a detailed application example in the Siemens Industry Online Support (http://support.automation.siemens.com/WW/llisapi.dll?aktprim=99&lang=en&referer=%2fWW%2f&func=cslib.csinfo2&siteid=csius&extranet=standard&viewreg=WW&groupid=4000002) under the following FAQ ID: 98210758.

11.6.3.9 Diagnostics

RD_SINFO: Read current OB start information

Description

You use the instruction "RD_SINFO" to read the start information

- of the last OB called that has not yet been completely executed, and
- of the last startup OB started.

There is no time stamp in either case. If the call is in OB 100, OB 101 or OB 102, two identical start information messages will be returned.

Parameter

The following table shows the parameters of the "RD_SINFO" instruction:

Parameter	Declaration	Data type	Memory area	Description
RET_VAL	Return	INT	I, Q, M, D, L	Error information
TOP_SI	Output	VARIANT	D, L	Start information of the current OB
START_UP_SI	Output	VARIANT	D, L	Start information of the startup OB last started

You will find more detailed information on valid data types in "Overview of the valid data types (Page 1908)".

SDTs of the TOP_SI parameter

The following table shows the possible SDTs for the TOP_SI parameter:

Organization blocks (OB)	System data types (SDT)	System data type numbers
Any	SI_classic	592
	SI_none	593

Note

The structure elements specified for the SI_classic structure are identical in content to the temporary tags of any OB created with the block property "Default".

Please note, however, that temporary tags of the individual OBs can have different names and different data types. Also note that the call interface of each OB includes additional information regarding the date and the time of the OB request.

Bits 4 to 7 of the EV_CLASS structure element contain the event class. The following values are possible here:

- 1: Start events from standard OBs
- 2: Start events from synchronous error OBs
- 3: Start events from asynchronous error OBs

The PRIORITY structure element supplies the priority class belonging to the current OB.

Apart from these two elements, NUM is also relevant. NUM contains the number of the current OB or the startup OB that was started last.

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
8080	Start information of the current OB does not correspond to the specified user-defined data type
8081	Start information of the current OB does not correspond to the specified system data type
8082	Start information of the last startup OB started does not correspond to the specified user-defined data type
8083	Start information of the last startup OB started does not correspond to the specified system data type

Example

OB 80 is the OB that was called last and that has not yet been completely processed and OB 100 is the start-up OB that was started last.

The following table shows the assignment between the structure elements of the TOP_SI parameter of the "RD_SINFO" instruction and the associated local tags of OB 80.

TOP_SI structure element	Data type	OB 80 - Associated local tag	Data type
EV_CLASS	BYTE	OB80_EV_CLASS	BYTE
EV_NUM	BYTE	OB80_FLT_ID	BYTE
PRIORITY	BYTE	OB80_PRIORITY	BYTE
NUM	BYTE	OB80_OB_NUMBR	BYTE
TYP2_3	BYTE	OB80_RESERVED_1	BYTE
TYP1	BYTE	OB80_RESERVED_2	BYTE
ZI1	WORD	OB80_ERROR_INFO	WORD
ZI2_3	DWORD	OB80_ERR_EV_CLASS	BYTE
		OB80_ERR_EV_NUM	BYTE
		OB80_OB_PRIORITY	BYTE
		OB80_OB_NUM	BYTE

The following table shows the assignment between the structure elements of the START_UP_SI parameter of the "RD_SINFO" instruction and the associated local tags of OB 100.

START_UP_SI structure element	Data type	OB 100 - Local tag	Data type
EV_CLASS	BYTE	OB100_EV_CLASS	BYTE
EV_NUM	BYTE	OB100_STRTUP	BYTE
PRIORITY	BYTE	OB100_PRIORITY	BYTE
NUM	BYTE	OB100_OB_NUMBR	BYTE
TYP2_3	BYTE	OB100_RESERVED_1	BYTE
TYP1	BYTE	OB100_RESERVED_2	BYTE
ZI1	WORD	OB100_STOP	WORD
ZI2_3	DWORD	OB100_STRT_INFO	DWORD

Evaluating errors with output parameter RET_VAL (Page 2195)

RT_INFO: Read out runtime statistics

Description

Use the instruction "RT_INFO" to generate statistics on the runtime of specific organization blocks, communication or the user program.

Use the MODE parameter to select which information is going to be output:

- MODE 1 to 3 return the data on the runtime of a specific organization block whose number was specified at the OB parameter.
- MODE 10 and 11 return the proportions of runtime used for communication and the user program.
- MODE 20 and 21 return the percentages of the runtime allotted to communication and the user program for the last program cycle.
- MODE 23 to 25 output the shortest, longest, and current cycle time of the user program.
- MODE 30 to 32 return data on configured settings of the user program.

All measurements are started once again when the CPU transitions from startup to RUN.

Parameters

The following table shows the parameters of the instruction "RT_INFO":

Parameter	Declaration	Data type	Memory area	Description
MODE	Input	UINT	I, Q, M, D, L or constant	Use the MODE parameter to select the information you want to read out (see table "MODE parameter").
OB	Input	OB_ANY	I, Q, M, D, L or constant	Use the OB parameter to select the OB for which you want to read out information.
RET_VAL	Return	INT	I, Q, M, D, L	Error information (see " RET_VAL parameter").
INFO	InOut	VARIANT	I, Q, M, D, L	Pointer to the area to which the read data is to be written. The data type required for INFO depends on the MODE parameter (see table "MODE parameter").

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter MODE

The following table shows which information is returned for the values at the MODE parameter.

MODE (decimal)	Description	Note	Value at OB parameter	Data type of INFO	Available as of CPU version
1	Runtime of a specific OB	The runtime information always refers to the specified OB. Processes, such as interruptions by OBs of a higher priority or communication, are not included. You can use the instruction "RUNTIME" to measure the runtime of the entire program.	OB number	LTIME	S7-1500 V1.5
2	Maximum runtime of a specific OB		OB number	LTIME	S7-1500 V1.5
3	Minimum runtime of a specific OB		OB number	LTIME	S7-1500 V1.5

MODE (decimal)	Description	Note	Value at OB parameter	Data type of INFO	Available as of CPU version
10	Percentage of total runtime used by higher-priority OBs The runtime of all OBs used in the user program with a higher priority than cyclical program OBs is output (ProgramCycle). These usually include all OB types except startup OBs. The CPU determines which OBs can be used and their priority. This information is included in the basic chapters on programming.	-	Not relevant	UINT	S7-1500 V1.5
11	Percentage of total runtime used by communication The percentage of communication processes in the total runtime of the user program is output.		Not relevant	UINT	S7-1500 V1.5
20	Identical to MODE 10 except that the evaluation is based on the last program cycle executed.	• If the cycle time is too high (> 1 second), the calculation cannot be performed. The instruction outputs the value 65535 (0xFFFF). • If the cycle time is too low (< 1 millisecond), the calculation cannot be performed. In this case, the last cycle with a duration of at least one millisecond is evaluated. By assigning a minimum cycle time in the CPU properties, you can prevent cycle times from falling below 1 ms.	Not relevant	UINT	S7-1500 V1.7
21	Identical to MODE 11 except that the evaluation is based on the last program cycle executed.		Not relevant	UINT	S7-1500 V1.7
23	Longest cycle time Duration of the longest cycle since the last transition from STOP to RUN.	The times correspond to the "Cycle times measured" values in the "Cycle time" dialog of the TIA Portal. You can open the dialog using Online & Diagnostics > Diagnostics > Cycle time.	Not relevant	LTIME	S7-1500 V1.7
24	Shortest cycle time Duration of the shortest cycle since the last transition from STOP to RUN.		Not relevant	LTIME	S7-1500 V1.7
25	Current/last cycle time Duration of the last cycle.		Not relevant	LTIME	S7-1500 V1.7

MODE (decimal)	Description	Note	Value at OB parameter	Data type of INFO	Available as of CPU version
30	Cycle monitoring time Maximum permitted duration of the CPU program. If the cycle time exceeds the cycle monitoring time, the CPU goes to STOP or calls a time error OB.	The times correspond to the "Cycle times assigned" values in the "Cycle time" dialog of the TIA Portal. You can open the dialog using Online & Diagnostics > Diagnostics > Cycle time.	Not relevant	LTIME	S7-1500 V1.5
31	Output of the configured minimum cycle time for the user program. If a minimum cycle time has been assigned in the CPU properties, the operating system delays the start of the new cycle until the minimum cycle time has been reached.		Not relevant	LTIME	S7-1500 V1.5
32	Output of the configured maximum communication load as a percentage	The specification of the percentage of the cycle load allotted to communication is made in the CPU properties under "Communication load".	Not relevant	UINT	S7-1500 V1.5

Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

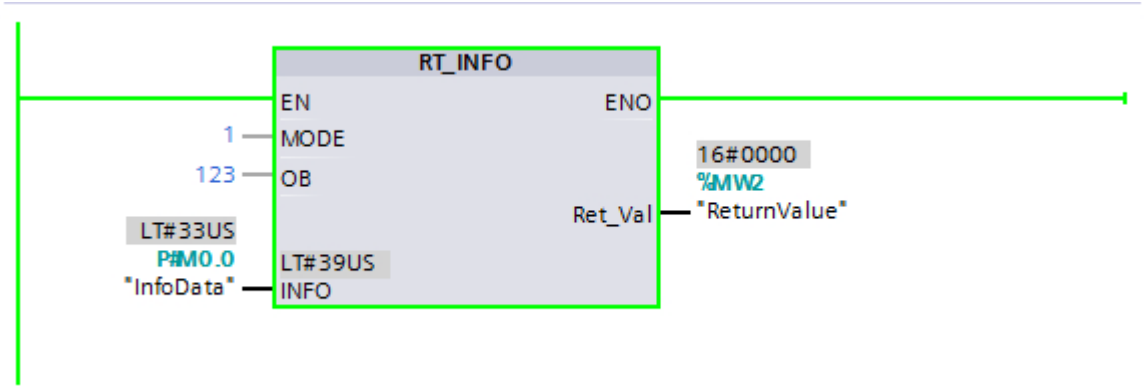
Error code* (W#16#...)	Explanation
0	No error
8080	Value at the MODE parameter is not supported.
8081	Organization block selected at OB parameter does not exist in the user program.
8092	Selected MODE parameter is not supported by this CPU version.
80C3	Insufficient resources. Try to call the instruction again at a later time.
8452	Data type at INFO parameter is incorrect. Check whether the correct data type was selected depending on the MODE parameter.

Example

In the following example, you read out the runtime of a cycle organization block.

- Create a new block of type "Program cycle". Specify the OB number at the OB parameter.
- Enter "1" (read out runtime of a particular OB) at the MODE parameter.
- Specify a tag with the data type LTIME at the INFO parameter ("InfoData" in this case).
- Specify a tag with the data type INT at the Ret_Val parameter to output the error messages of the instruction.

After calling the instruction, the actual measured runtime is written to the "InfoData" tag.



See also

Evaluating errors with output parameter RET_VAL (Page 2195)

LED: Read LED status

Description

You can use the "LED" instruction to read out the status (e.g., "On" or "Off") of a particular module LED.

- With the LADDR parameter, you address the CPU or the interface.
- With the LED parameter, you select the module LED whose current status is to be read out using the instruction.
- The RET_VAL parameter outputs the status of the selected LED when the instruction is called. Depending on the LED selected, only certain status information may be displayed. For example, some LEDs have only color information. Refer to the hardware documentation of the respective module for the available status information of a particular LED.

Parameters

The following table shows the parameters of the "LED" instruction:

Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_IO	I, Q, M, L or constant	Hardware identifier of the CPU or interface The number is assigned automatically and is stored in the properties of the CPU or interface in the hardware configuration (*CPU name* + *~Common*).
LED	Input	UINT	I, Q, M, D, L or constant	Identification number of the LED: • 1: STOP/RUN • 2: ERROR • 3: MAINT (maintenance) • 4: Redundant • 5: Link (green) • 6: Rx/Tx (yellow)
RET_VAL	Return	INT	I, Q, M, D, L	Status of LED

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

RET_VAL parameter

RET_VAL	Description
0 to 9	LED status: • 0 = LED does not exist • 1 = Permanently switched off • 2 = Color 1 (e.g., for LED STOP/RUN: green) permanently ON • 3 = Color 2 (e.g., for LED STOP/RUN: orange) permanently ON • 4 = Color 1 flashing at 2 Hz • 5 = Color 2 flashing at 2 Hz • 6 = Colors 1 and 2 flashing alternately at 2 Hz • 7 = LED is active, color 1 • 8 = LED is active, color 2 • 9 = LED exists, but status information not available
8091	Hardware component addressed using the LADDR parameter does not exist.
8092	A hardware component that does not support LEDs was addressed using the LADDR parameter.
8093	The hardware identifier specified at the LED parameter is not defined.
80Bx	The CPU specified in the LADDR parameter does not support the "LED" instruction.

Example

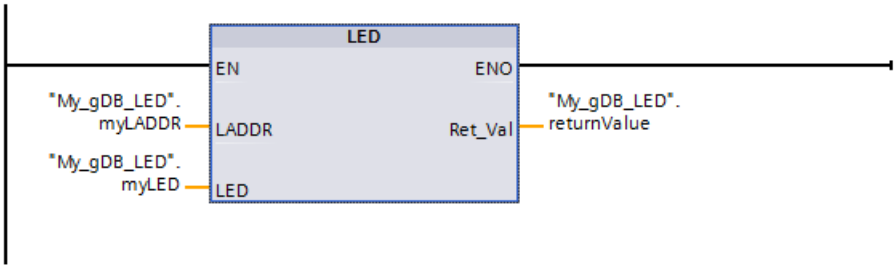
In the following example, you read out the status of the CPU LED.

Create three tags in a global data block for storing the data.

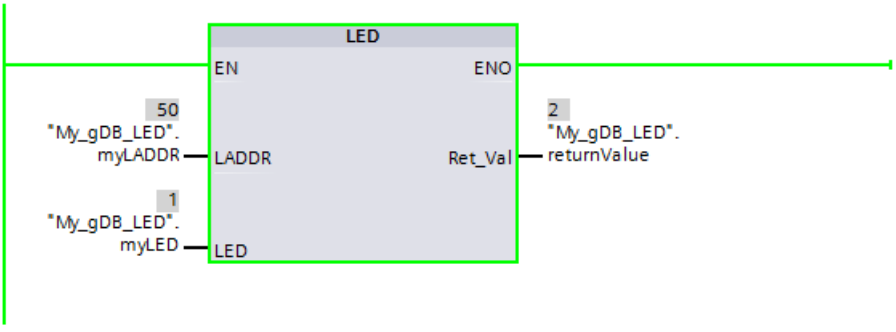
My_gDB_LED

		Name	Data type	Start value
1		Static		
2		myLADDR	HW_IO	50
3		myLED	UInt	1
4		returnValue	Int	0

Interconnect the parameters of the instruction as follows.



The HW identifier of the CPU is made known to the "LED" instruction through parameter LADDR ("myLADDR"). The CPU LED to be monitored is made known through parameter LED ("myLED"). The status of the CPU LED (STOP/RUN) is queried. If the CPU is placed in RUN mode from STOP, the value "6" (green and orange alternating) is indicated at output parameter RET_VAL ("returnValue"). Then, the value "2" (permanently green) is indicated as the LED status ("returnValue").



Note: The meaning of the colors for the STOP/RUN LED are as follows:

Color	Meaning
Red	STOP
Green	RUN
Alternating green and orange	The CPU is loading
Alternating red and green	Program processing is running

Additional information on the meaning of the LED colors can be found in the hardware description of the CPU.

Get_IM_Data: Reading identification and maintenance data

Description

The "Get_IM_Data" instruction reads the identification and maintenance data (I&M) data from a device. Use the LADDR parameter to select the device from which you want to read the I&M via the hardware identifier.

You select the data to be read via the instruction using the IM_TYPE parameter:

- IM_TYPE = 0: I&M 0 data
  The I&M 0 data are the device-specific basic information of a device and contain information such as the manufacturer ID, order number, serial number and the hardware and firmware version. Only read access is possible to the I&M 0 data. The information is also displayed in the TIA Portal with the "Online & Diagnostics" view of a device.
- IM_TYPE = 11: I&M 1 data from the parameter assignment data of the CPU
  The I&M 1 data contains a functional description of the device and the location ID, i.e. the information about how the device is designated within the plant.
- IM_TYPE = 12: I&M 2 data from the parameter assignment data of the CPU
  The I&M 2 data includes the date of installation, i.e. the information about when the device was installed in the plant.
- IM_TYPE = 13: I&M 3 data from the parameter assignment data of the CPU
  The I&M 3 data contains additional information about the installed device. The additional information is free text and can be assigned as desired.

The I&M data read is written to the addressed area defined at the DATA parameter.

The execution status of the read job is displayed via the BUSY, DONE, ERROR output parameters and the two middle bytes of the STATUS output parameter.

Definition: Identification and maintenance data (I&M)

Identification and maintenance (I&M) data refers to information stored in a module, which assists you in checking the plant configuration, locating hardware changes in a plant and eliminating errors.

- Identification data (I-data) is static information about a device that can only be read.
- Maintenance data (M-data) refers to plant-dependent information, such as the installation location or date. Maintenance data are created during configuration and written to the module.

Parameters

The following table shows the parameters of the "Get_IM_Data" instruction:

Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_IO	I, Q, M, D, L or constant	Hardware ID of the device The number is assigned automatically and is stored in the properties of the device or in the hardware configuration.
IM_TYPE	Input	UINT	I, Q, M, D, L or constant	Identification and maintenance data number Possible values: • 0: I&M 0 data • 11: I&M 1 data from the parameter assignment data of the CPU • 12: I&M 2 data from the parameter assignment data of the CPU • 13: I&M 3 data from the parameter assignment data of the CPU
DATA	InOut	VARIANT	I, Q, M, D, L	Area for storing the read identification and maintenance data (see below).
DONE	Output	BOOL	I, Q, M, D, L	The instruction was executed successfully. The I&M data were transferred to the DATA parameter.
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Execution of the instruction complete or not yet started. • 1: Execution of the instruction not yet complete.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter The parameter is only set for the duration of one call. To display it, you should therefore copy STATUS to a free data area.

You can find more information on the data types in "Overview of the valid data types (Page 1908)".

Parameter DATA for I&M 0 data

You can use an array (ARRAY of BYTE) or a special data structure to store the I&M 0 data:

- If you address an array (ARRAY of BYTE) at parameter DATA, the read I&M 0 data is copied as a byte sequence to DATA. If the addressed array is longer than the read data, the unneeded bytes are filled with zeros.
- The following "IM0_Data" structure can also be used at the DATA parameter for I&M 0 data:

Parameter		Data type	Bytes	Description
Manufacturer_ID		UINT	2	Manufacturer ID (e.g. "42" for SIEMENS)
Order_ID		CHAR[20]	20	Order number
Serial_Number		CHAR[16]	16	Serial number
Hardware_Revision		UNIT	2	Hardware revision
Software_Revision		STRUCT	4	Firmware revision
	Type	CHAR	1	-
	Functional	UNIT8	1	-
	Bugfix	UNIT8	1	-
	Internal	UINT8	1	-
Revision_Counter		UINT	2	Revision counter
Profile_ID		UNIT	2	Profile
Profile_Specific_Type		UNIT	2	Device class
IM_Version		UNIT	2	I&M version
I&M_Supported		UNIT	2	I&M data (I&M 0-I&M 4) supported at the device end

If a different data type is used at the DATA parameter, the STATUS parameter outputs error code 8093.

DATA parameter for I&M 1, I&M 2, and I&M 3 data

You can use a string (STRING), an array (ARRAY of CHAR/BYTE) or a data structure (STRUCT) to store the I&M data:

- If you address a string (STRING data type) at the the DATA parameter, the length of the string automatically adjusts the length of the read I&M data (up to 254 characters).
- If you address a data structure (ARRAY of CHAR/BYTE or STRUCT) a the DATA parameter, the I&M data read are written to the individual components of the data type used. If the addressed data structure is longer than the read data, the remaining components are filled with zeros.
- If you crate a data structure with a STRUCT data type at the DATA parameter, use a data block without optimized block access (see category "Attributes" of the block properties).

If a data type other than STRING, ARRAY of BYTE/CHAR or STRUCT is used at the DATA parameter, the STATUS parameter generates error code 8093.

Note

Additional information about I&M data

You can find more information about I & M data, for example, on the PROFIBUS & PROFINET International websites (link: http://www.profibus.com (http://www.profibus.com)).

Parameter STATUS

Error code* (W#16#...)	Description
0	No error
7000	No job in progress.
7001	First call of the asynchronous instruction "Get_IM_Data". Execution of the instruction not yet complete (BUSY = 1, DONE = 0).
7002	Additional call of the asynchronous instruction "Get_IM_Data". Execution of the instruction not yet complete (BUSY = 1, DONE = 0).
807F	Maximum of 10 parallel executions of the instances exceeded: • Avoid more than 10 parallel calls of the instruction. • Repeat the call at a later time, as this is a temporary error.
8091	The device addressed at the LADDR parameter does not exist.
8092	LADDR addresses a device that does not support the output of the I&M data.
8093	Data type at the DATA parameter is not supported.
80B1	The "Get_IM_Data" instruction is not supported by the CPU used.
80B2	Invalid value at the IM_TYPE parameter or the selected IM_TYPE is not supported by the CPU or the addressed device.
8752	The memory area specified at the DATA parameter is too small to store all the I&M data. The read I&M data are stored only up to the maximum length of the specified memory area.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Example

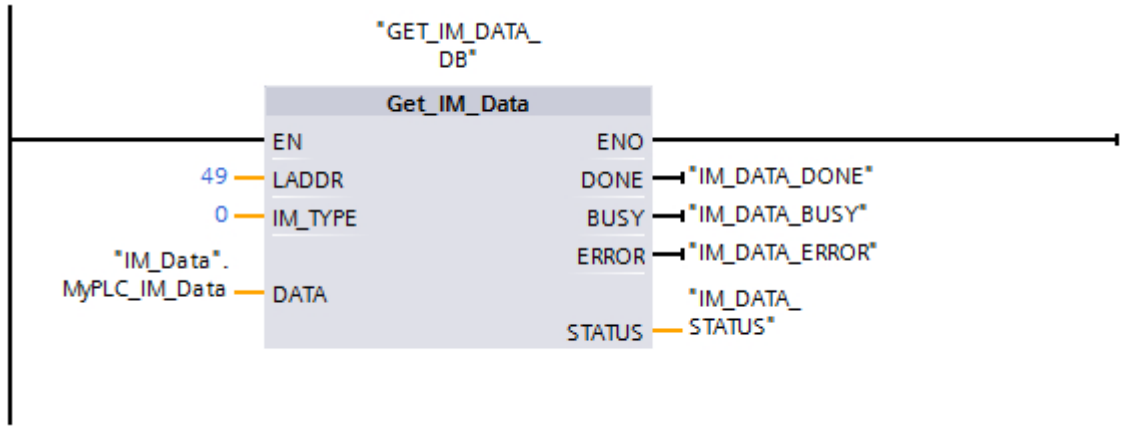
In the following example, you read out the IM0 data of an S7-1500 CPU. The IM0 data are the basic information of a device and contain information such as the manufacturer ID, order number, serial number and the hardware and firmware version.

To store the IM0 data, you create a structure with the IM0_Data data type in a global data block. You can assign any name to the structure ("MyPLC_IM_Data" in this case).

IM_Data

	Name	Datentyp	Startwert
1	Static		
2	MyPLC_IM_Data	IM0_Data	
3	Manufacturer_ID	UInt	0
4	Order_ID	String[20]	''
5	Serial_Number	String[16]	''
6	Hardware_Revision	UInt	0
7	Software_Revision	IM0_Version	
8	Type	Char	' '
9	Functional	USInt	0
10	Bugfix	USInt	0
11	Internal	USInt	0
12	Revision_Counter	UInt	0
13	Profile_ID	UInt	0
14	Profile_Specific_Type	UInt	0
15	IM_Version	Word	16#0
16	IM_Supported	Word	16#0

Enter the hardware identifier of the CPU at the LADDR parameter. The hardware identifier uniquely identifies the product. To determine the hardware identifier of your CPU, open the PLC tag table and the System constants tab. Then, search for the CPU in the Name column. The associated value is the hardware identifier that you enter at the LADDR parameter.



Once the instruction is successfully executed, the IM0 data is written to the data block.

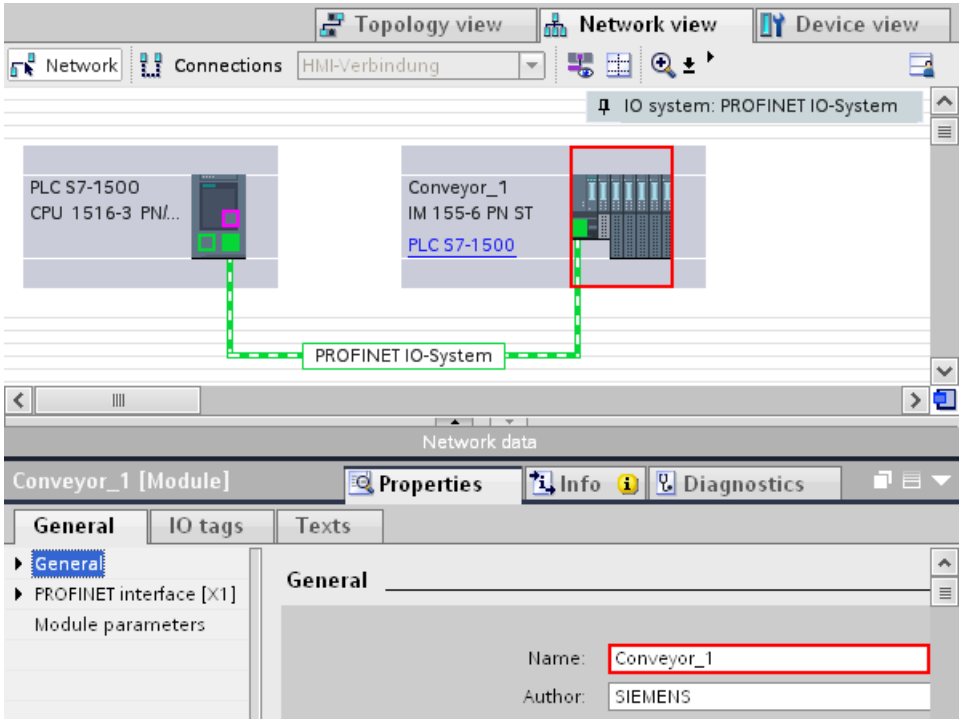
IM_Data

	Name	Datentyp	Startwert	Beobachtungswert
1	Static			
2	MyPLC_IM_Data	IM0_Data		
3	Manufacturer_ID	UInt	0	42
4	Order_ID	String[20]	''	'6ES7 511-1AK00-0AB0 '
5	Serial_Number	String[16]	''	'S C-DOS710132013'
6	Hardware_Revision	UInt	0	3
7	Software_Revision	IM0_Version		
8	Type	Char	' '	'V'
9	Functional	USInt	0	1
10	Bugfix	USInt	0	5
11	Internal	USInt	0	0
12	Revision_Counter	UInt	0	0
13	Profile_ID	UInt	0	0
14	Profile_Specific_Type	UInt	0	0
15	IM_Version	Word	16#0	16#0101
16	IM_Supported	Word	16#0	16#001E

GET_NAME: Reading the name of a module

Description

The instruction "GET_NAME" reads the name of an IO device. The name is displayed in the network view and in the properties of the IO device:



You select the IO device by using the hardware identifier of the PROFINET IO system (at the LADDR parameter) and the device number of the IO device (STATION_NR parameter).

Once the instruction has been executed, the name of the IO device is written to the area addressed with the DATA parameter.

The name that is read depends on the type of IO device:

- For a DP slave or IO device, the name of the head module is output.
- For an I-slave or I-device, the name of the interface module is output.
- The name of the interface is output for an HMI panel.
- The name of the interface module is output for a PC station.
- The name of the Device Access Point (DAP) is displayed (name of the interface or head module) for GSD devices.

The length of the name is output at the LEN parameter. If the name is longer than the area specified at the DATA parameter, only that section which corresponds to the maximum length of the addressed area will be written.

The maximum length for a name is 128 characters.

Note

Name of the CPU readout (Version 1.1)

If you assign a "0" at each of the parameters LADDR and STATION_NR the instruction will output the name of the CPU.

Parameters

The following table shows the parameters of the "GET_NAME" instruction:

Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_IOSYSTEM	I, Q, M, D, L or constant	Hardware identifier of the PROFINET IO system. The number can be taken from the system constants or the properties of the IO system.
STATION_NR	Input	UINT	I, Q, M, D, L or constant	Device number of the IO device. The device number can be applied in the Network view from the properties of the IO device under "Ethernet addresses".
DATA	InOut	VARIANT	I, Q, M, D, L	Pointer to the area to which the name of the module is written.
DONE	Output	BOOL	I, Q, M, D, L	The instruction was executed successfully. Name of the module transferred to the area at the DATA parameter.
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Execution of the instruction complete. • 1: Execution of the instruction not yet complete.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
LEN	Output	DINT	I, Q, M, D, L	Length of the name of the IO device (number of characters).
STATUS	Output	WORD	I, Q, M, D, L	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy STATUS to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter STATUS

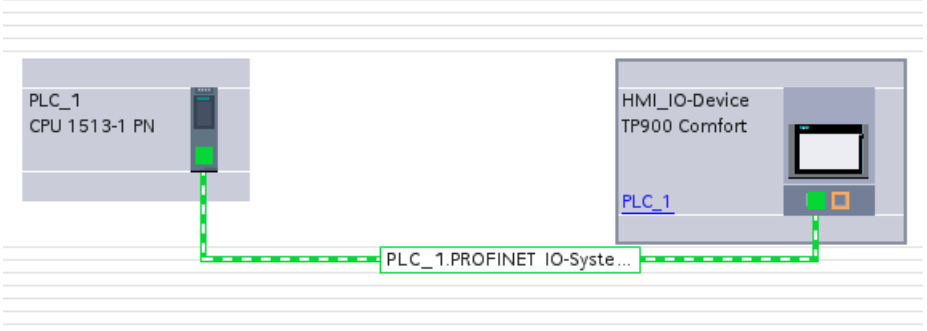
Error code* (W#16#...)	Explanation
0	No error
7000	No job in progress.
7001	First call of the asynchronous instruction "GET_NAME". Execution of the instruction not yet complete (BUSY = 1, DONE = 0).
7002	Additional call of the asynchronous instruction "GET_NAME". Execution of the instruction not yet complete (BUSY = 1, DONE = 0).
8090	• The LADDR input parameter contains an invalid value. • The hardware identifier specified at the LADDR parameter does not exist in the project.
8092	The value at the LADDR parameter does not address a PROFINET IO system.
8093	Instruction does not support data type at the DATA parameter.
8095	Device number (STATION_NR parameter) does not exist in the selected PROFINET IO system or does not address an IO device.
80B1	The CPU used does not support the instruction.
80C3	Temporary resource error: The CPU is currently processing the maximum possible number of simultaneous block calls. "GET_NAME" cannot be executed unless at least one of the block calls is finished.
8852	The area specified at the DATA parameter is too short for the full name of the IO device. The name will be written up to the maximum possible length. To read the full name, use a longer data area at the DATA parameter. The area must have at least as many characters as there are at the LEN parameter.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Example

The following example shows how you can read out the station name of a HMI panel.

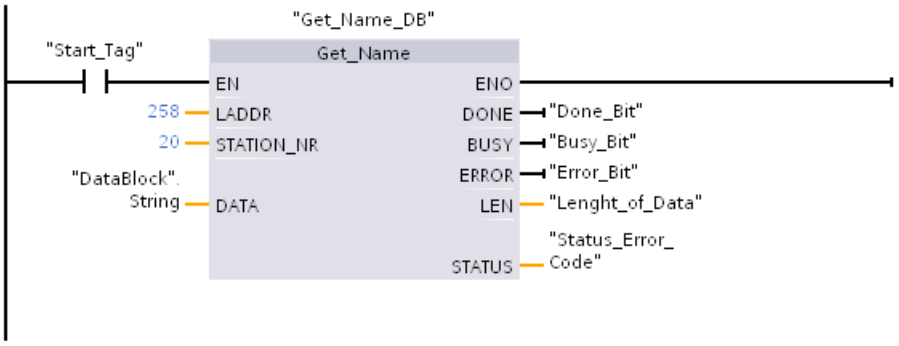
Configuration of the HMI panel:

- The HMI panel with the station name "HMI_IO-Device" is created in the network view and assigned to the same PROFINET IO system as the CPU.
- The operating mode "IO device" was activated in the properties of the hardware configuration for the HMI panel and the CPU was assigned as the IO controller.
- The device number "20" assigned in the properties under "Ethernet addresses".



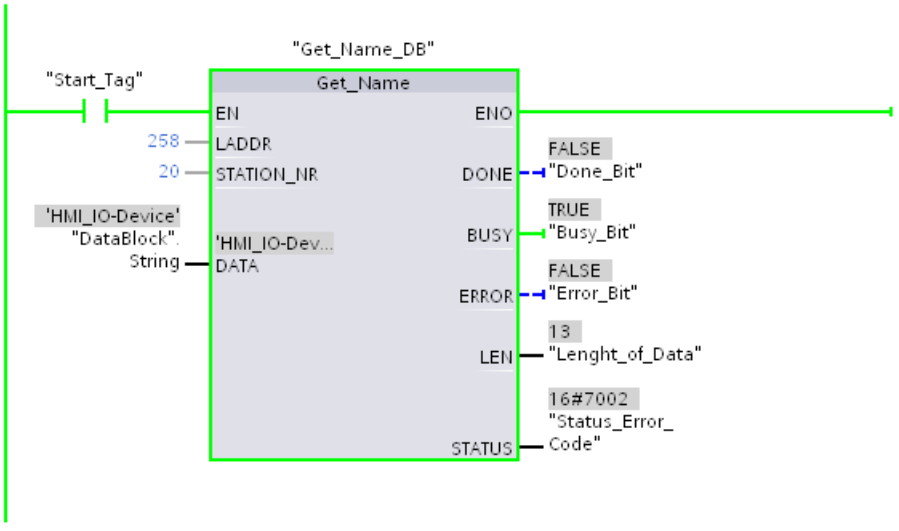
Assigning parameters to the instruction "GET_NAME":

- The hardware ID (258) of the IO system was specified at the parameter LADDR.
- The device number (20) of the HMI panel was specified at the parameter STATION_NR.
- A tag was connected with the data type STRING of a data block at the parameter DATA.
- PLC tags (memory area, flags) were defined for the output parameters of the instruction.



Execution of the instruction:

- After execution of the instruction, the name of the station of the HMI panels (HMI_IO-Device) is written into the data block at the parameter DATA.
- The number of characters of the name is output (13) at the parameter LEN.



GetStationInfo: Read information of an IO device

Description

You can use the "GetStationInfo" instruction to read information of a PROFINET IO device. The instruction also enables you to read the information of an IO device located in a lower-level IO system (connected via CP/CM).

The IO device is addressed via the hardware identifier of the station at the LADDR parameter. The hardware identifier is displayed in the "Devices & Networks" view in the station properties.

Use the MODE parameter to select the information to be read.

At the DATA parameter, specify the data area to which you want to write the read address data. For storing the IP address, use the "IF_CONF_v4" structure. For storing the MAC address, use the "IF_CONF_MAC" structure.

Enable reading of the address data using the REQ control parameter. This requires the IO device to be accessible.

The execution status of the read job is displayed via the BUSY, DONE, ERROR output parameters and the STATUS output parameter.

Note

Address the IO device using only the hardware identifier of the station

The station, the IO device and PROFINET interface have their own hardware identifier. Use only the hardware identifier of the station for the "GetStationInfo" instruction.

If a PROFINET is addressed via the LADDR parameter, for example, the address data is not read and the error code 8092 is generate.

To read the address data of an integrated PROFINET interface or a CM/CP in the central configuration, use the "RDREC" instruction.

Parameters

The following table shows the parameters of the "GetStationInfo" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L	Control parameter Request Activates the reading of the information with REQ = "1".
LADDR	Input	HW_DEVICE	I, Q, M, D, L or constant	Hardware identifier of the station of the IO device The number can be taken from the properties of the station in the Network view or from the "System constants" tab of the standard tag table.
DETAIL	Input	HW_SUB-MODULE	I, Q, M, D, L or constant	The DETAIL parameter is not used. Leave the parameter unconnected.
MODE	Input	UNIT	I, Q, M, D, L or constant	Selection of address data to be read: • MODE = 1: Address parameter according to IPv4 (S7-1500 CPUs as of firmware version V1.1) • MODE = 2: MAC address (S7-1500 CPUs as of firmware version V1.5)

Parameter	Declaration	Data type	Memory area	Description
DATA	InOut	VARIANT	D, L	Pointer to the area to which the address data of the IO device is written. Use the "IF_CONF_v4" structure for MODE = 1 and the "IF_CONF_MAC" structure for MODE = 2.
DONE	Output	BOOL	I, Q, M, D, L	The instruction was executed successfully. The address data was transferred to the DATA parameter.
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Execution of the instruction complete. • 1: Execution of the instruction not yet complete.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy STATUS to a free data area.

You can find more information on the data types in "Overview of the valid data types (Page 1908)".

Parameter DATA

- Use the "IF_CONF_v4" structure at the DATA parameter to store the address parameter according to IPv4.

Byte	Parameter	Data type	Start value	Description
0 … 1	Id	UINT	30	ID of the "IF_CONF_v4" structure.
2 … 3	Length	UNIT	18	Length of data read in BYTE.
4 ... 5	Mode	UNIT	0	Not relevant for the "GetStationInfo" instruction (left at "0").
6 ... 9	InterfaceAddress	ARRAY [1..4] of BYTE	-	IP address of the IO device in the format IP_V4, e.g. for 192.168.3.10: • addr[1] = 192 • addr[2] = 168 • addr[3] = 3 • addr[4] = 10

Byte	Parameter	Data type	Start value	Description
10 … 13	SubnetMask	ARRAY [1..4] of BYTE	-	Subnet mask of the IO device in the format IP_V4, e.g. for 255.255.255.0: • addr[1] = 255 • addr[2] = 255 • addr[3] = 255 • addr[4] = 0
14 ... 17	DefaultRouter	ARRAY [1..4] of BYTE	-	IP address of the router in the format IP_V4, e.g. for 192.168.3.1: • addr[1] = 192 • addr[2] = 168 • addr[3] = 3 • addr[4] = 1

- Use the "IF_CONF_MAC" structure at parameter DATA for storing the MAC address.

Byte	Parameter	Data type	Start value	Description
0 … 1	Id	UINT	3	ID of the "IF_CONF_MAC" structure.
2 … 3	Length	UNIT	12	Length of data read in BYTE.
4 ... 5	Mode	UNIT	0	Not relevant for the "GetStationInfo" instruction (left at "0").
6 ... 11	MACAddress	ARRAY [1..6] of BYTE	-	MAC address of the IO device, e.g. for 08-00-06-12-34-56 • Mac[1] = 8 • Mac[2] = 0 • Mac[3] = 6 • Mac[4] = 12 • Mac[5] = 34 • Mac[6] = 56

Parameter STATUS

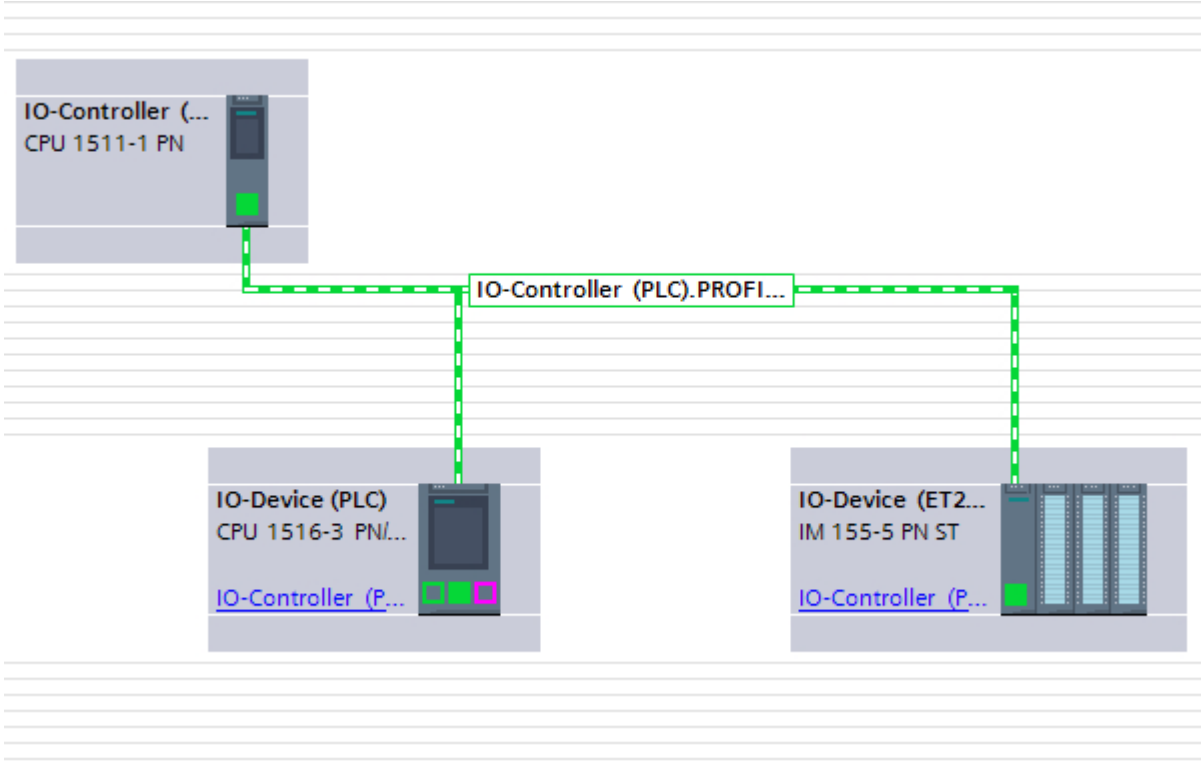
Error code* (W#16#...)	Explanation
0	No error
7000	No job in progress.
7001	First call of the asynchronous instruction "GetStationInfo". Execution of the instruction not yet complete (BUSY = 1, DONE = 0).
7002	Additional call of the asynchronous instruction "GetStationInfo". Execution of the instruction not yet complete (BUSY = 1, DONE = 0).
8080	Value at the MODE parameter is not supported.
8090	The hardware identifier specified at the LADDR parameter is not configured.
8092	The LADDR parameter does not address a PROFINET IO device.
8093	Invalid data type at the DATA parameter.
80A0	Cannot read requested information.

Error code* (W#16#...)	Explanation
80C0	Addressed IO device is not reachable.
80C3	The maximum number of simultaneous calls of the "GetStationInfo" instruction (10 instances) has been reached.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Example

Below, you use the „GetStationInfo“ instruction to read the IP address data of an IO device and write the information to a data block. The IP address data includes the IP address, subnet mask and (if used) the address data of the router.

The instruction is executed on the IO controller and reads the IP address information of a lower-level IO device (an ET200MP in this example).



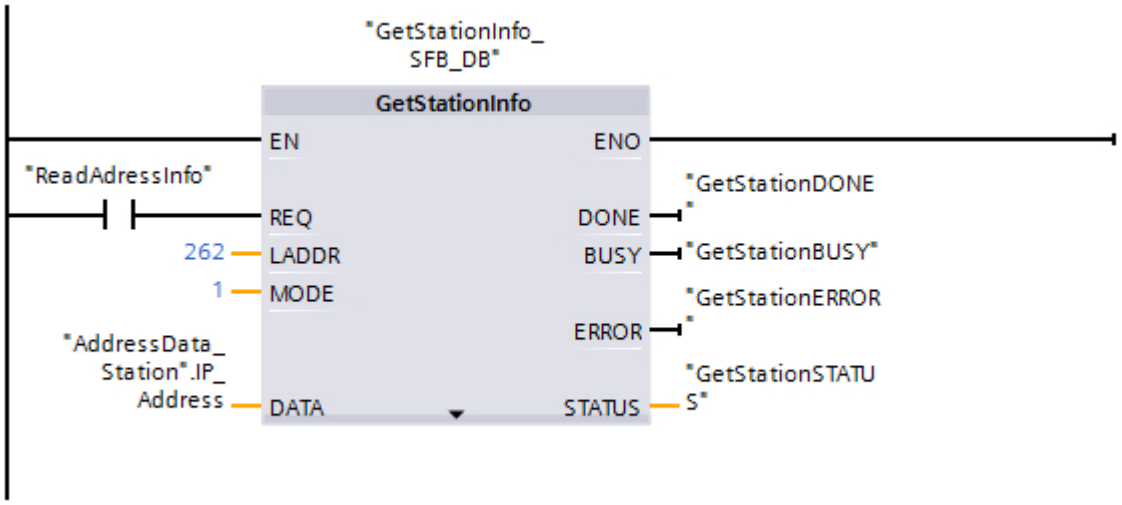
To store the address data, you create a structure with the IF_CONF_v4 data type in a global data block. You can assign any name to the structure ("IP_Address" in this case).

AddressData_Station

	Name	Datentyp	Startwert	Beobachtungswert	Kommentar
1	Static				
2	IP_Address	IF_CONF_v4			
3	Id	UInt	30		
4	Length	UInt	18		
5	Mode	UInt	0		
6	InterfaceAddress	IP_V4			
7	ADDR	Array[1..4] of Byte			IPv4 address
8	ADDR[1]	Byte	0		
9	ADDR[2]	Byte	0		
10	ADDR[3]	Byte	0		
11	ADDR[4]	Byte	0		
12	SubnetMask	IP_V4			
13	ADDR	Array[1..4] of Byte			IPv4 address
14	ADDR[1]	Byte	0		
15	ADDR[2]	Byte	0		
16	ADDR[3]	Byte	0		
17	ADDR[4]	Byte	0		
18	DefaultRouter	IP_V4			
19	ADDR	Array[1..4] of Byte			IPv4 address
20	ADDR[1]	Byte	0		
21	ADDR[2]	Byte	0		
22	ADDR[3]	Byte	0		
23	ADDR[4]	Byte	0		

Then call the "GetStationInfo" instruction:

- You use the IF_CONF_v4 structure at the DATA parameter.
- Enter the hardware identifier of the IO device at the LADDR parameter. The hardware identifier uniquely identifies the product. To determine the hardware identifier of your IO device, open the PLC tag table and the System constants tab. Then, search for the device in the Name column and for the „Hw_Device“ in the Data type column. The associated value is the hardware identifier that you enter at the LADDR parameter.
- Select "1" (read address parameters according to IPv4) for the MODE parameter.



You start reading the address data with REQ= 1 (TRUE). Once the instruction is successfully executed, the IP address data is written to the data block.

DeviceStates: Read module status information in an IO system

Description

You use the instruction "DeviceStates" to query specific status information for all modules in an IO system, which means:

- Either for all IO devices in a PROFINET IO system
- Or for all DP slaves in a DP master system

The Boolean value that is output indicates the modules to which the selected status applies. You can, for example, read which IO devices are currently disabled in a PROFINET IO system.

Information is also displayed as to whether the status information to be read applies to at least one of the IO devices or DP slaves.

The instruction can be called in a cyclic OB as well as in an interrupt OB (e.g. OB82 - diagnostic interrupt).

Parameters

The following table shows the parameters of the "DeviceStates" instruction:

Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_IOSYSTEM	I, Q, M, L or constant	Hardware identifier of the PROFINET IO or DP master system (see description below)
MODE	Input	UINT	I, Q, M, D, L or constant	Selection of status information to be read (see description below)
RET_VAL	Return	INT	I, Q, M, D, L	Status of instruction (see description below)
STATE	InOut	VARIANT	I, Q, M, D, L	Buffer for status of the IO devices or the DP slaves (see description below)

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter LADDR

You select the PROFINET IO or DP master system at the LADDR parameter by means of the hardware identifier.

The hardware identifier is available:

- Either in the Network view of the properties of the PROFINET IO or DP master system.
- Or in the PLC tag table in the listed system constants with the data type HW_IOSYSTEM.

Parameter MODE

You use the MODE parameter to read out status information. You can read out one of the following status information items for the entire PROFINET IO or DP master system:

- 1: IO devices/DP slaves are configured
- 2: IO devices/DP slaves are faulty
- 3: IO devices/DP slaves are disabled
- 4: IO devices/DP slaves exist
- 5: IO devices/DP slaves for which a problem has occurred. For example:
  - Maintenance demanded or recommended
  - Not accessible
  - Not available
  - Error occurred

Parameter STATE

With the STATE parameter, the status of the IO devices/DP slaves that was selected with the MODE parameter is output.

If the status selected using MODE applies to an IO device/DP slave, the following bits are set to "1" at the STATE parameter:

- Bit 0 = 1: Group display. The bit n of at least one IO device/DP slave was set to "1".
- Bit n = 1: The status selected with MODE applies to the IO device/DP slave.
  - With a PROFINET IO system, bit n corresponds to the device number of the respective IO device (see properties of the PROFINET interface in the device view and network view)
  - With a PROFIBUS DP system, bit n corresponds to the PROFIBUS address of the DP slave (see properties of the DP slave in the device view and network view)

Use "BOOL" or "Array of BOOL" as data type:

- To only output the bit for group display of the status information, you can use the data type BOOL at the STATE parameter.
- To output the status information for all IO devices/DP slaves, use Array of BOOL with the following length:
  - With PROFINET IO system: 1024 bits
  - With DP master system: 128 bits

Parameter RET_VAL

Error code* (W#16#...)	Description
0	No error
8091	Hardware identifier of the LADDR parameter does not exist. Check (for example, in the system constants) whether the value for LADDR exists in the project.
8092	LADDR does not address a PROFINET IO or DP master system.
8093	Invalid data type at the STATE parameter.
80B1	Instruction "DeviceStates" is not supported by the CPU.
80B2	The selected MODE parameter is not supported by the used CPU for the IO system specified in the LADDR parameter.
8452	The complete status information does not fit in the tag configured in the STATE parameter.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Example - Reading out the presence of IO devices in the PROFINET IO master system

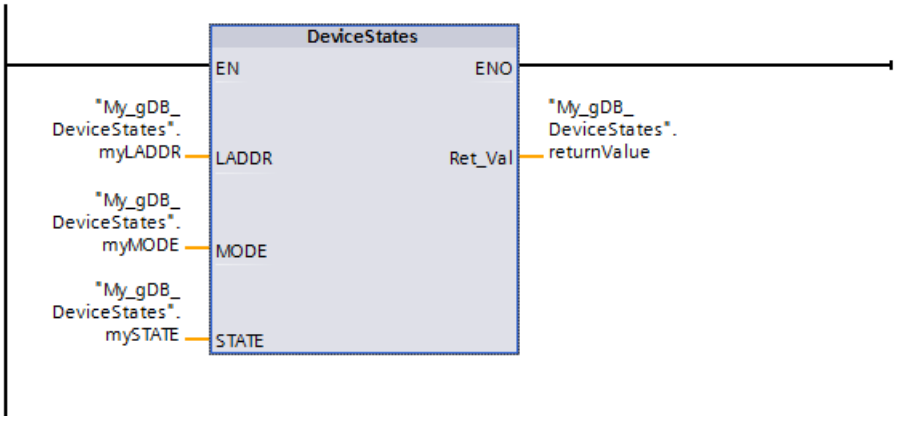
In the following example, you query the existence of IO devices in an IO system. The IO system will consist of two CPUs of the S7-1500 series. The "PLC_14" CPU will contain the program, including the "DeviceStates" instruction. The "PLC_13" CPU will be configured as an IO device.

In the "PLC_14" CPU: Create three tags and a "mySTATE" structure (with the Array of BOOL data type) in a global data block for storing the data.

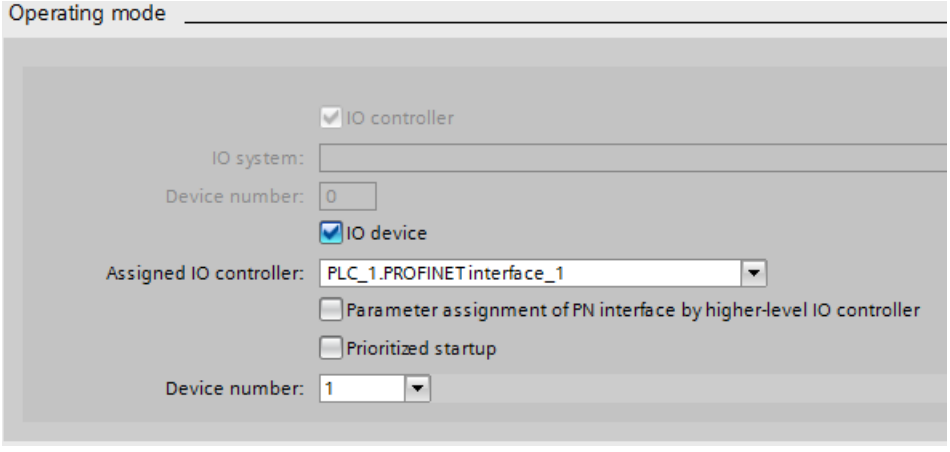
My_gDB_DeviceStates

	Name	Data type	Start value
1	Static		
2	myLADDR	HW_IOSYSTEM	258
3	myMODE	UInt	4
4	returnValue	Int	0
5	mySTATE	Array[0..1023] ...	
6	mySTATE[0]	Bool	false
7	mySTATE[1]	Bool	false
8	mySTATE[2]	Bool	false
9	mySTATE[3]	Bool	false
10	mySTATE[4]	Bool	false
11	mySTATE[5]	Bool	false
12	mySTATE[6]	Bool	false

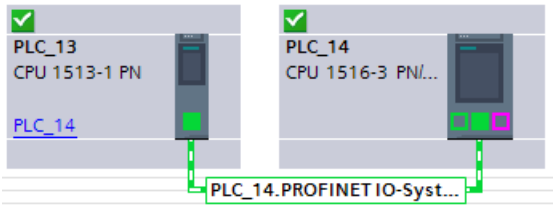
In the "PLC_14" CPU: The instruction is called in a cyclic OB. Interconnect the parameters of the instruction as follows.



In the "PLC_13" CPU: Set up this CPU "PLC_13" as an IO device using the CPU properties. The IO device receives the device number 1.



An IO system is displayed in the Network view.



In the "PLC_14" CPU: The HW identifier of the IO system is made known to the "DeviceStates" instruction through parameter LADDR ("myLADDR"). According to the value "4" of parameter MODE ("myMODE"), the IO system is searched for IO devices.

At parameter STATE ("mySTATE"), the presence is output for the IO devices (based on the value of parameter MODE). Bit 0 serves as a group value and indicates that IO devices are present. Bit 1 indicates that the IO device with the device number 1 is present.

The output parameter RET_VAL ("returnValue") indicates that processing took place without errors.

My_gDB_DeviceStates

	Name	Data type	Start value	Monitor value
1	Static			
2	myLADDR	HW_IOSYSTEM	258	16#0102
3	myMODE	UInt	4	4
4	returnValue	Int	0	0
5	mySTATE	Array[0..1023] ...		
6	mySTATE[0]	Bool	false	TRUE
7	mySTATE[1]	Bool	false	TRUE
8	mySTATE[2]	Bool	false	FALSE
9	mySTATE[3]	Bool	false	FALSE
10	mySTATE[4]	Bool	false	FALSE
11	mySTATE[5]	Bool	false	FALSE
12	mySTATE[6]	Bool	false	FALSE

Example - Reading the faulty stations of a PROFINET IO master system

A PROFINET IO system consists of 4 IO devices with the device numbers 1, 2, 3 and 4. The IO device with number 2 is faulty.

The instruction "DeviceStates" is executed for the PROFINET IO system with MODE = 2 (faulty/not faulty).

The following bits are set in the STATE parameter:

- Bit 0 = 1: A fault exists for at least one of the IO devices.
- Bit 1 = 0: IO device with device number 1 is not faulty.
- Bit 2 = 1: IO device with device number 2 is faulty.
- Bit 3 = 0: IO device with device number 3 is not faulty.
- Bit 4 = 0: IO device with device number 4 is not faulty.
- Bit 5 = 0: irrelevant
- Bit 6 = 0: irrelevant
- ...

Example - Reading the faulty stations of a PROFIBUS DP master system

A DP master system consists of 4 DP slaves with the PROFIBUS addresses 3, 4, 5 and 6. The DP slave with address 4 is faulty.

The instruction "DeviceStates" is executed for the DP master system with MODE = 2 (faulty/ not faulty).

The following bits are set in the STATE parameter:

- Bit 0 = 1: A fault exists for at least one of the DP slaves.
- Bit 1 = 0: irrelevant
- Bit 2 = 0: irrelevant
- Bit 3 = 0: DP slave with address 3 is not faulty.
- Bit 4 = 1: DP slave with address 4 is faulty.
- Bit 5 = 0: DP slave with address 5 is not faulty.
- Bit 6 = 0: DP slave with address 6 is not faulty.
- Bit 7 = 0: irrelevant
- Bit 8 = 0: irrelevant
- ...

ModuleStates: Read module status information of a module

Description

You can use the "ModuleStates" instruction to read the status information of the modules of a PROFINET IO device or PROFIBUS DP slave.

The Boolean value that is output indicates the modules to which the selected status applies. You can, for example, read which modules are currently disabled in a PROFINET IO device.

Information is also displayed as to whether the status information to be read applies to at least one of the modules.

The instruction can be called in a cyclic OB as well as in an interrupt OB (e.g. OB82 - diagnostic interrupt).

Parameters

The following table shows the parameters of the "ModuleStates" instruction:

Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_DEVICE	I, Q, M, D, L or constant	Hardware identifier of the station (see description below)
MODE	Input	UINT	I, Q, M, D, L or constant	Selection of module status information to be read (see description below)
RET_VAL	Return	INT	I, Q, M, D, L	Status of instruction (see description below)
STATE	InOut	VARIANT	I, Q, M, D, L	Buffer for the module status (see description below)

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter LADDR

You select the IO device or the DP slave at the LADDR parameter by means of the hardware identifier of the station.

The hardware identifier is available:

- Either in the network view of the properties of the IO device station or DP slave station.
- Or in the PLC tag table for the listed system constants with the data type HW_DEVICE (for an IO device) or with the data type HW_DPSLAVE (for a DP slave).

Parameter MODE

You use the MODE parameter to read out status information. One of the following status information items can be read for the modules:

- 1: Modules are configured
- 2: Modules are faulty
- 3: Modules are disabled
- 4: Modules exist
- 5: There is a problem in the modules. For example:
  - Maintenance demanded or recommended
  - Not accessible
  - Not available
  - Error occurred

Parameter STATE

The STATE parameter outputs the status of the modules selected with the MODE parameter.

If the status selected using MODE applies to a module, the following bits are set to "1":

- Bit 0 = 1: Group display. The bit n of at least one module was set to "1".
- Bit n = 1: The status selected with MODE applies to the module in slot n-1 (example: bit 3 = slot 2).

Use "BOOL" or "Array of BOOL" as data type:

- To only output the bit for group display of the status information, you can use the data type BOOL at the STATE parameter.
- To output the status information for all modules, use Array of BOOL with a length of 128 bits.

Parameter RET_VAL

Error code* (W#16#...)	Description
0	No error
8091	Hardware identifier of the LADDR parameter does not exist. Check (for example, in the system constants) whether the value for LADDR exists in the project.
8092	LADDR does not address an IO device or DP slave.
8093	Invalid data type at the STATE parameter.
80B1	The instruction "ModuleStates" is not supported by the CPU.
80B2	The selected MODE parameter is not supported by the used CPU for the IO device/the DP slave in the LADDR parameter.
8452	The complete status information does not fit in the tag configured in the STATE parameter.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Example

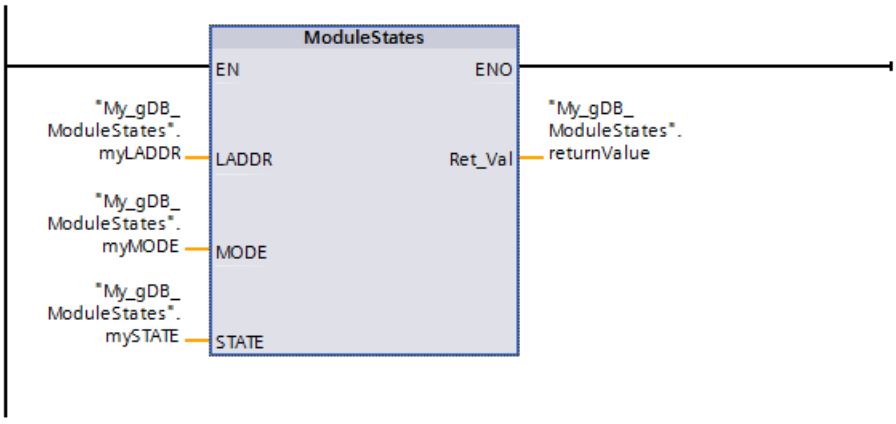
In the following example, you query the existence of modules of a PROFINET IO device. The IO system will consist of two CPUs of the S7-1500 series. The "PLC_14" CPU will contain the program, including the "ModuleStates" instruction. The "PLC_13" CPU will be configured as an IO device.

In the "PLC_14" CPU: Create three tags and a "mySTATE" structure (with the Array of BOOL data type) in a global data block for storing the data.

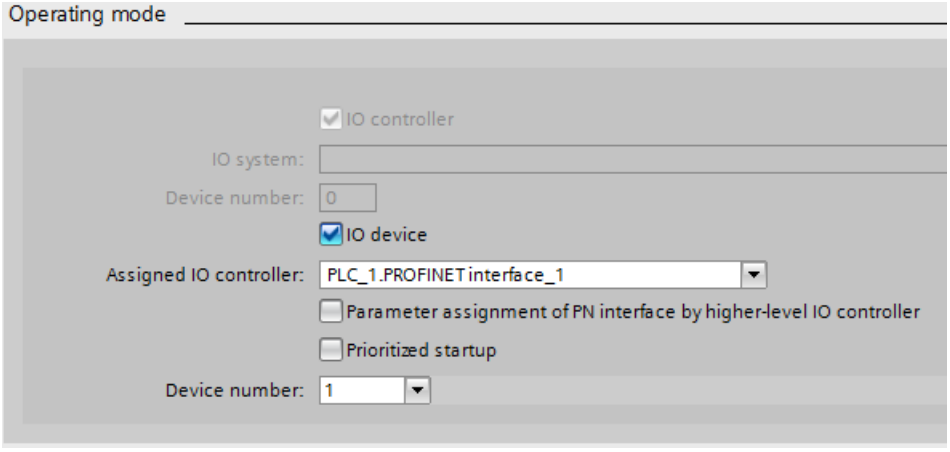
My_gDB_ModuleStates

	Name	Data type	Start value
1	Static		
2	myLADDR	HW_DEVICE	260
3	myMODE	UInt	4
4	returnValue	Int	0
5	mySTATE	Array[0..127] of Bool	
6	mySTATE[0]	Bool	false
7	mySTATE[1]	Bool	false
8	mySTATE[2]	Bool	false
9	mySTATE[3]	Bool	false
10	mySTATE[4]	Bool	false
11	mySTATE[5]	Bool	false
12	mySTATE[6]	Bool	false

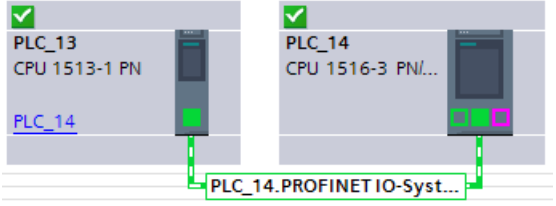
In the "PLC_14" CPU: The instruction is called in a cyclic OB. Interconnect the parameters of the instruction as follows.



In the "PLC_13" CPU: Set up this CPU "PLC_13" as an IO device using the CPU properties.



An IO system is displayed in the Network view.



In the "PLC_14" CPU: A module is located in slot 1 of the IO device.

In the "PLC_14" CPU: The HW identifier of the IO device is made known to the "ModuleStates" instruction through parameter LADDR ("myLADDR"). According to the value "4" of parameter MODE ("myMODE"), the IO device is searched for modules.

At parameter STATE ("mySTATE"), the presence is output for the modules (based on the value of parameter MODE). Bit 0 serves as a group value and indicates that modules are present. Bit 2 indicates that a module is present in slot 1.

The output parameter RET_VAL ("returnValue") indicates that processing took place without errors.

My_gDB_ModuleStates

	Name	Data type	Start value	Monitor value
1	Static			
2	myLADDR	HW_DEVICE	260	16#0104
3	myMODE	UInt	4	4
4	returnValue	Int	0	0
5	mySTATE	Array[0..127] of Bool		
6	mySTATE[0]	Bool	false	TRUE
7	mySTATE[1]	Bool	false	FALSE
8	mySTATE[2]	Bool	false	TRUE
9	mySTATE[3]	Bool	false	FALSE
10	mySTATE[4]	Bool	false	FALSE
11	mySTATE[5]	Bool	false	FALSE
12	mySTATE[6]	Bool	false	FALSE

Example

An IO device includes 4 modules in slots 1 to 4. The module in slot 2 is faulty.

The instruction "ModuleStates" is executed for the IO device with MODE = 2 (faulty/not faulty).

The following bits are set in the STATE parameter:

- Bit 0 = 1: A fault exists for at least one module.
- Bit 1 = 0: Slot number 0 (used by IO device)
- Bit 2 = 0: Module in slot number 1 is not faulty.
- Bit 3 = 1: Module in slot number 2 is faulty.
- Bit 4 = 0: Module in slot number 3 is not faulty.
- Bit 5 = 0: Module in slot number 4 is not faulty.
- Bit 6 = 0: irrelevant
- Bit 7 = 0: irrelevant

GEN_DIAG: Generate diagnostics information

Description

The "GEN_DIAG" instruction generates diagnostics information for hardware components from other manufacturers for use in TIA Portal diagnostics. The GSD(GSDL/GSDML) file supplied by the manufacturer must first be installed before the instruction can be used.

The instruction generates all diagnostic events (including those for maintenance).

- Use the LADDR parameter to select the hardware component for which you want to generate a diagnostic event.
- Use the MODE parameter to specify whether the event is to be outgoing or incoming.
- Use the DiagEvent parameter to define the diagnostic event in the DiagnosticDetail structure. The structure is created automatically in the local interface of the block when you define a tag at the DiagEvent parameter.

The diagnostics information is provided synchronously. Diagnostics information transfer and alarm output are asynchronous.

Notice

Failsafe-specific errors messages are not valid

If you define failsafe-specific diagnostics information at the DiagEvent parameter, the instruction will check this information and output the error code 80A1.

Parameters

The following table shows the parameters of the "GEN_DIAG" instruction:

Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_ANY	I, Q, M, D, L or constant	Identification number of the hardware component
MODE	Input	UINT	I, Q, M, D, L or constant	Selection of incoming/outgoing information: • 1: The diagnostic event specified is an incoming event • 2: The diagnostic event specified is an outgoing event • 3: All diagnostic events are outgoing. There are therefore no hardware component faults (green diagnostics symbol). The DiagEvent parameter is not evaluated when MODE = 3.

Parameter	Declaration	Data type	Memory area	Description
DiagEvent	InOut	DiagnosticDetail	L	Specifies the diagnostic event (see "DiagEvent parameter").
RET_VAL	Return	INT	I, Q, M, D, L	Status of instruction / error message (see "RET_VAL parameter")

You will find more detailed information on valid data types in "Overview of the valid data types (Page 1908)".

DiagEvent parameter

The structure DiagnosticDetail is a system data type for specifying the diagnostic event. Its structure is as follows:

Parameter		Data type	Description
DiagnosticDetail		Struct	
	ChannelInfo	WORD	Channel properties (0...7)
	ALID	UINT	Local ID of the alarm. The ID uniquely identifies the alarm.
	TextID	UINT	ID of an alarm text in a text list.
	ChannelNumber	UINT	Manufacturer-specific channel number (0x0000 — 0x7FFF)
	Addval_0	DWORD	Placeholder for additional information The value / list of values depends on the connection error.
	TextID2	UINT	Texts for CPU response (mode, OB calls, etc.).
	LADDR	HW_ANY	Identical to the LADDR parameter.
	TextListId	UINT	• 0: No text list • ≠0: ID of the text list
	ChannelDirection	UINT	• 0000: irrelevant • FFF1: Input • FFF2: Output • FFF3: Input/Output
	Addval_1	DWORD	Placeholder for additional information on the channel error (depends on the GSD file). For channel error types, see also: IEC 61158 (PROFINET IO Type 10 and PROFIBUS DP Type 3).

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0	No error
8080	Value in the MODE parameter is not supported.
8090	Identification for hardware component not available at the LADDR parameter.

Error code* (W#16#...)	Explanation
8091	Diagnostics information cannot be generated for the hardware component addressed at the LADDR parameter.
80A1	• Content of the DiagnosticsDetail structure at the DiagEvent parameter is invalid or inconsistent. • Failsafe-specific diagnostics information defined at the DiagEvent parameter (not valid).
80A4	Hardware component addressed cannot be accessed.
80C1	Insufficient resources for parallel execution.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

GET_DIAG: Read diagnostic information

Description

You can use the "GET_DIAG" instruction to read the diagnostic information of a hardware object. The hardware object is selected using the parameter LADDR. With the MODE parameter, you select which diagnostic information is to be read.

Parameters

The following table shows the parameters of the "GET_DIAG" instruction:

Parameter	Declaration	Data type	Memory area	Description
MODE	Input	UINT	I, Q, M, D, L or constant	Use the MODE parameter to select which diagnostic data is to be output.
LADDR	Input	HW_ANY (WORD)	I, Q, M, L or constant	Hardware identifier of the device.
RET_VAL	Return	INT	I, Q, M, D, L	Status of the instruction
CNT_DIAG	Output	UINT	I, Q, M, D, L	Reserved (always "0").
DIAG	InOut	VARIANT	I, Q, M, D, L	Diagnostic information corresponds to the selected mode, see table below
DETAIL	InOut	VARIANT	I, Q, M, D, L	Parameter is hidden. Do not use this parameter!

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter MODE

Depending on the value at the MODE parameter, different diagnostic data is output at the DIAG, CNT_DIAG and DETAIL output parameters.

MODE	Description	DIAG	CNT_DIAG
0	Output of all supported diagnostic information for a module as DWORD, where Bit X=1 indicates that mode X is supported.	Bits of the DWORD data type: • Bit 0 = 1: MODE 0 is supported • Bit 1 = 1: MODE 1 is supported • Bit 2 = 1: MODE 2 is supported • Bit 3 = 1: Not relevant	0
1	Output of the diagnostic status of the addressed hardware object.	Structure DIS (see below for description): • MaintenanceState • ComponentStateDetail • OwnState • IOState • OperatingState	0
2	Output of the status of all subordinate modules of the addressed hardware object.	Structure DNN (see below for description): • SubordinateState • SubordinateIOState • DNNmode	0

DIS structure

With parameter MODE = 1, the diagnostic information is output in accordance with the DIS structure. In this case, enter the system data type "DIS" as data type for the tag declaration.

The following table shows the meaning of the individual parameter values.

Parameter	Data type	Value	Description
MaintenanceState	DWORD	Enum	
		0	No maintenance required
		1	The module or device is disabled.
		2	-
		3	-
		4	-
		5	Maintenance required
		6	Maintenance demanded
		7	Error
		8	Status unknown / error in subordinate module
		9	-
		10	Inputs/outputs are not available.

Parameter	Data type	Value	Description
ComponentState-Detail	DWORD	Bit array	Status of the module sub-modules: • Bit 0 to 15: Status message of the module • Bit 16 to 31: Status message of the CPU
		0 to 2 (enum)	Additional information: • Bit 0: No additional information • Bit 1: Transfer not permitted
		3	Bit 3 = 1: At least one channel supports qualifiers for diagnostics
		4	Bit 4 = 1: Maintenance required for at least one channel or one component.
		5	Bit 5 = 1: Maintenance demanded for at least one channel or one component.
		6	Bit 6 = 1: Error in at least one channel or one component.
		7 to 10	Reserved (always = 0)
		11 to 14	• Bit 11 = 1: PNIO - sub-module correct • Bit 12 = 1: PNIO - replacement module • Bit 13 = 1: PNIO - incorrect module • Bit 14 = 1: PNIO - module disconnected
		15	Reserved (always = 0)
		16 to 31	Status information for modules generated by the CPU: • Bit 16 = 1: Module disabled • Bit 17 = 1: CiR operation active • Bit 18 = 1: Input not available • Bit 19 = 1: Output not available bit • 20 = 1: Overflow diagnostics buffer bit • 21 = 1: Diagnostics not available bit • 22 - 31: Reserved (always 0)
OwnState	UINT	Enum	The value of the parameter Ownstate describes the maintenance status of the module.
		0	No fault
		1	The module or device is disabled.
		2	Maintenance required
		3	Maintenance demanded
		4	Error
		5	The module or the device cannot be reached from the CPU (valid for modules and devices below a CPU).
		6	Inputs/outputs are not available.
		7	-

Parameter	Data type	Value	Description
IOState	WORD	Bit array	I/O status of the module
		0	Bit 0 = 1: No maintenance required
		1	Bit 1 = 1: The module or device is disabled.
		2	Bit 2 = 1: Maintenance required
		3	Bit 3 = 1: Maintenance demanded
		4	Bit 4 = 1: Error
		5	Bit 5 = 1: The module or the device cannot be reached from the CPU (valid for modules and devices below a CPU).
		6	Inputs/outputs are not available.
		7	Qualifier; bit 7 = 1, if bit 0, 2, or 3 are set
		8 to 15	Reserved (always = 0)
OperatingState	UINT	Enum	
		0	-
		1	In STOP / Firmware update
		2	In STOP / reset memory
		3	In STOP / self start
		4	In STOP
		5	Memory reset
		6	In START
		7	In RUN
		8	-
		9	In HOLD
		10	-
		11	-
		12	Module defective
		13	-
		14	No power
		15	CiR
		16	In STOP / without ODIS
		17	In
		18	
		19	
		20	

DNN structure

With parameter MODE = 2, the diagnostic information details are output in accordance with the DNN structure. In this case, enter the system data type "DNN" as data type for the tag declaration.

The following table shows the meaning of the individual parameter values.

Parameter	Data type	Value	Description
SubordinateState	UINT	Enum	Status of the subordinate module (see parameter OwnState of the DIS structure)
SubordinateIOState	WORD	Bitarray	Status of the inputs and outputs of the subordinate module (see parameter IO State of the DIS structure)
DNNmode	WORD	Bitarray	• Bit 0 = 0: Diagnostics enabled • Bit 0 = 1: Diagnostics disabled • Bit 1 to 15: Reserved

Parameter RET_VAL

Error code* (W#16#...)	Description
0	No error
n	The data area at the DETAIL parameter is too small. Not all details of the diagnostic data can be output.
8080	Value in the MODE parameter is not supported.
8081	Type at the DIAG parameter is not supported with the selected mode (parameter MODE).
8082	Type at the DETAIL parameter is not supported by the selected mode (parameter MODE).
8090	LADDR does not exist
80C1	Insufficient resources for parallel execution.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Example

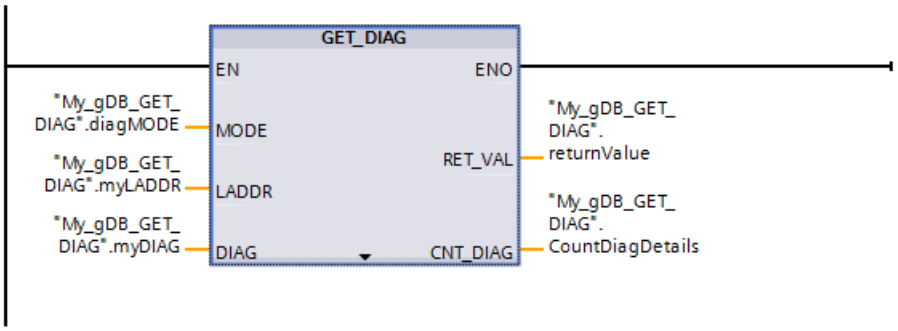
In the following example, you read out the diagnostic information of a CPU.

Create four tags and a "myDIAG" structure (with the DIS data type) in a global data block for storing the data.

My_gDB_GET_DIAG

	Name	Data type	Start value
1	Static		
2	diagMODE	UInt	1
3	myLADDR	HW_ANY	50
4	returnValue	Int	0
5	CountDiagDetails	UInt	0
6	myDIAG	DIS	
7	MaintainanceState	DWord	16#0
8	ComponentStateDetail	DWord	16#0
9	OwnState	UInt	0
10	IOState	Word	16#0
11	OperatingState	UInt	0

Interconnect the parameters of the instruction as follows.



The HW identifier of the CPU is made known to the "GET_DIAG" instruction through parameter LADDR ("myLADDR"). According to the value "1" of parameter MODE ("diagMODE"), the following applies:

- The instruction reads the status of the addressed hardware object (of the CPU).
- At parameter DIAG ("myDIAG"), the diagnostic information is output in a structure (DIS data type).

To understand the diagnostic information, the hex values must be converted to binary code. At parameter DIAG ("myDIAG"), the following is indicated:

- MaintenanceState: According to the value "0", the CPU requires no maintenance.
- ComponentStateDetail: According to the hex value "0000_8000", bit 15 is active.
- OwnState: According to the value "0", no fault has occurred.
- IOState: According to the hex value "0001", there is no maintenance required.
- OperatingState: Outputs "0".

The output parameter RET_VAL ("returnValue") indicates that processing took place without errors. At output parameter CNT_DIAG ("CountDiagDetails"), it is indicated that "0" diagnostic details of parameter DETAIL have been output.

My_gDB_GET_DIAG

	Name	Data type	Start value	Monitor value
1	Static			
2	diagMODE	UInt	1	1
3	myLADDR	HW_ANY	50	16#0032
4	returnValue	Int	0	0
5	CountDiagDetails	UInt	0	0
6	myDIAG	DIS		
7	MaintainanceState	DWord	16#0	16#0000_0000
8	ComponentStateDetail	DWord	16#0	16#0000_8000
9	OwnState	UInt	0	0
10	IOState	Word	16#0	16#0001
11	OperatingState	UInt	0	0

Note: For example, you could individually read out bit 3 (channel diagnostics yes/no) from the ComponentStateDetail tag.

- Address the bit as follows: ComponentStateDetail.%X3.

11.6.3.10 Pulse

CTRL_PWM: Pulse-width modulation

Description

You can use the "CTRL_PWM" instruction to enable and disable a pulse output supported by the CPU using the software.

- Enter the hardware ID of the pulse generator that you want to control with the instruction at the input PWM.
- The pulse output is enabled when the bit in the ENABLE input of the instruction is set.
  - If ENABLE has a value of TRUE the pulse generator will generate a pulse with the properties defined in the device configuration.
  - When the bit in the ENABLE input is reset or the CPU changes to STOP, the pulse output is disabled and no more pulses are generated.

BUSY always has the value of FALSE for S7-1200 since S7-1200 activates the pulse generator if the instruction "CTRL_PWM" is executed.

The ENO enable output is set only when the EN enable input has signal state "1" and no errors have occurred during execution of the instruction.

Note

Use of the force table for PWM and PTO

Digital inputs and outputs that are used for PWM and PTO cannot be forced. Digital inputs and outputs that were assigned via device configuration cannot be controlled by either the force table or the monitoring table.

Requirement

A prerequisite for the correct execution of the instruction is that the specified pulse generator is activated in the hardware configuration.

Open the properties of the module in the device view. Go to "Pulse generators (PTO/PWM)", open the desired PTO/PWM and activate the function the "Activate this pulse generator" under "General".

Go to "Assigning parameters" and set the Pulse options.

Note

Pulse output parameters are assigned exclusively in the device configuration and not using the "CTRL_PWM" instruction. Any change of parameters that is intended to have an effect on the CPU must therefore be made while the CPU is in STOP mode. Changing the duration of the pulse is an exception.

Changing the pulse duration from the user program

The pulse duration setting made in the dialog "Pulse options" can be changed from the user program.

The value set for "Initial pulse duration" is written in the output bytes of the pulse generator. The start address and the end address are displayed in the properties of the pulse generator under "I/O-addresses".

To change the pulse duration, write the desired values in the output word address specified in the device configuration.

Example:

- A value of 500 (decimal) is used for the "Initial pulse duration". The start address of the PTO/PWM is "1000" and the end address is "1001".
- The binary value of "0000000111110100" (=500 decimal) is written in both of the output bytes.
  - Start address (AB1000): 0000_0001 (BIN)
  - End address (AB1001): 1111_0100 (BIN)

Please note that the pulse duration always depends on the parameters set for the Pulse duration format (hundredths, thousandths, ...).

Parameters

The following table shows the parameters of the "CTRL_PWM" instruction:

Parameter	Declaration	Data type	Memory area	Description
PWM	Input	HW_PWM	I, Q, M, D, L or constant	Hardware ID of the pulse generator The hardware ID can be found in the properties of the pulse generator in the Device view. The hardware IDs of the pulse generators are also listed in the system constants.
ENABLE	Input	BOOL	I, Q, M, D, L or constant	The pulse output is enabled when ENABLE = TRUE and disabled when ENABLE = FALSE.
BUSY	Output	BOOL	I, Q, M, D, L	Processing status
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction (see below).

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter STATUS

Error code* (W#16#...)	Description
0	No errors
80A1	Hardware ID of the pulse generator is invalid.

Error code* (W#16#...)	Description
80D0	Pulse generator with the specified hardware ID is not activated. Activate the pulse generator in the CPU properties under "Pulse generators (PTO/PWM)".
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

11.6.3.11 Recipes and data logging

Recipe functions

RecipeExport: Exporting recipes

Description

The "RecipeExport" instruction exports the recipe data from a data block to a CSV file on the memory card of the CPU.

The export is triggered by the "REQ" parameter. The BUSY parameter is set to "1" during the export. During the export, the CSV file is created in the "Recipes" folder in the main directory of the memory card. The name of the data block is used as file name of the created CSV file. If a CSV file with an identical name already exists, it is overwritten during the export.

After the execution of the instruction, BUSY is reset to "0" and the completion of the operation is indicated with "1" at the DONE parameter. If an error occurs during execution, this is signaled by the parameters ERROR and STATUS.

Parameters

The following table shows the parameters of the "RecipeExport" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L, T, C or constant (T and C are only available in LAD and FBD with S7-1500)	Control parameter REQUEST: Activates the export on a rising edge.
RECIPE_DB	InOut	VARIANT	D	Pointer to the recipe data block. For information on the structure of the data block, refer to: Structure of a recipe DB (Page 3315)
DONE	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Job not yet started or still executing. • 1: Job executed without errors.
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter • 0: The instruction is not executed. • 1: The instruction is executed.

Parameter	Declaration	Data type	Memory area	Description
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Neither warning nor error. • 1: An error has occurred. STATUS supplies detailed information on the type of error.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter See the "STATUS" parameter table.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter STATUS

Error code* (W#16#...)	Explanation
0	No error occurred
7000	No job processing active
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8090	File name of the CSV file contains invalid characters. The file name of the CSV file is identical to the name of the data block.
8091	The data structure referenced with RECIPE_DB cannot be processed.
8092	Data structure at RECIPE_DB parameter exceeds 5000 bytes.
80B3	Insufficient memory space on the memory card or the internal load memory.
80B4	The memory card is write-protected.
80C0	CSV files is temporarily locked.
80C1	Data block temporarily locked.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

RecipeImport: Importing recipes

Description

The "RecipeImport" instruction imports the recipe data from a CSV file on the memory card into the data block at the RECIPE_DB parameter. The values in the data block are overwritten in the process.

Note the following when importing the CSV file:

- The CSV file must be located in the "Recipes" directory of the memory card.
- The name of the CSV file must match the name of the data block at the RECIPE_DB parameter.

- The first line (header) of the CSV file contains the name of the recipe components (see also: Structure of a recipe DB (Page 3315)). The first line is ignored during import. The names of the recipe components in the CSV file and the data block are not reconciled during import.
- In each case the first value in each line of the CSV file is the index number of the recipe. The individual recipes are imported in the order of the index. For this, the index in the CSV file has to be in ascending order and may contain no gaps (if this is not the case, the error message 80B0 is output at the STATUS parameter.
- The CSV file may not contain more recipe data records than provided for in the data block. The maximum number of data records is indicated by the array limits in the data block.

The import is triggered by the "REQ" parameter. The BUSY parameter is set to "1" during the import. After the execution of the instruction, BUSY is reset to "0" and the completion of the operation is indicated with "1" at the DONE parameter. If an error occurs during execution, this is signaled by the parameters ERROR and STATUS.

Parameters

The following table shows the parameters of the "RecipeImport" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L, T, C or constant (T and C are only available in LAD and FBD with S7-1500)	Control parameter REQUEST: Activates the import on a positive edge.
RECIPE_DB	InOut	VARIANT	D	Pointer to the recipe data block. For information on the structure of the data block, refer to: Structure of a recipe DB (Page 3315)
DONE	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Job not yet started or still executing. • 1: Job executed without errors.
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter • 0: The instruction is not executed. • 1: The instruction is executed.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Neither warning nor error. • 1: An error has occurred. STATUS supplies detailed information on the type of error.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter See the "STATUS" parameter table.

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameter STATUS

Error code* (W#16#...)	Explanation
0	No error occurred
7000	No job processing active
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8090	The file name contains invalid characters.
8092	No matching CSV file found for the import. Possible cause: The name of the CSV file does not match the name of the recipe DB.
80C0	CSV file is temporarily locked.
80C1	Data block is temporarily locked.
80B0	Numbering in the index of the CSV file is not continuous, not ascending or exceeds the maximum number (array limit) in the data block.
80B1	Structure of the recipe data block and the CSV file do not match: The CSV file contains too many fields.
80B2	Structure of the recipe data block and the CSV file do not match: The CSV file contains too few fields.
80D0 +n	Structure of the recipe data block and the CSV file do not match: Data type in field n does not match (n<=46).
80FF	Structure of the recipe data block and the CSV file do not match: Data type in field n does not match (n>46).
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

Structure of a recipe DB

Introduction

The following sections describes the structure of a recipe DB based on a simple example. The recipe DB consists of five data records, three of which are used. The fourth and fifth data records are left free for later expansions. Each data record contains one recipe, which is made up of the recipe name and eight ingredients.

product-name	water	barley	wheat	hops	yeast	wa-terTmp	mashTmp	mash-Time	QTest
Pils	10	9	3	280	39	40	30	100	0
Lager	10	9	3	150	33	50	30	120	0
BlackB-eer	10	9	3	410	47	60	30	90	1
Not_used	0	0	0	0	0	0	0	0	0
Not_used	0	0	0	0	0	0	0	0	0

Structure of the recipe data block

The recipe data are implemented as follows in a global data block:

- The template for all recipes is the PLC data type "Beer_Recipe" with the recipe components "procutname", "water", etc. with the corresponding data types.
- In a global data block, the PLC data type is used as Array [1.. 5] of "Beer_Recipe". The array limits (1 to 5 in this case) indicate the maximum number of recipes that the DB may contain.
- The values for the recipe components are added as start value in the data block.
- The global DB is interconnected with the instruction via the InOut parameter RECIPE_DB.

Recipe_DB

	Name	Data type	Offset	Start value
1	Static			
2	Products	Array [1 .. 5] of "Beer_Recipe"	...	
3	Products[1]	"Beer_Recipe"	...	
4	Products[2]	"Beer_Recipe"	...	
5	Products[3]	"Beer_Recipe"	...	
6	productname	String[20]	...	'BlackBeer'
7	water	UInt	...	10
8	barley	UInt	...	9
9	wheat	UInt	...	3
10	hops	UInt	...	410
11	yeast	UInt	...	47
12	waterTmp	UInt	...	60
13	mashTmp	UInt	...	30
14	mashTime	UInt	...	90
15	QTest	UInt	...	1
16	Products[4]	"Beer_Recipe"	...	
17	Products[5]	"Beer_Recipe"	...	

Exporting to CSV file

After the execution of the "RecipeExport (Page 3312)" instruction the data of the DB are written to a CSV file with the following structure:

Recipe_DB.csv

```
index,productname,water,barley,wheat,hops,yeast,waterTmp,mashTmp,mashTime,QTest
1,”Pils”,10,9,3,280,39,40,30,100,0
2,”Lager”,10,9,3,150,33,50,30,120,0
3,”BlackBeer”,10,9,3,410,47,60,30,90,1
4,”Not_used”,0,0,0,0,0,0,0,0,0
5,”Not_used”,0,0,0,0,0,0,0,0,0
```

Display in Excel

The CSV file can be opened in Excel to make reading and editing easier. If the commas are not recognized as separators when you open the file, use the Excel import function to output the data in structured form:

	A	B	C	D	E	F	G	H	I	J	K
1	index	product	water	barley	wheat	hops	yeast	waterTmp	mashTmp	mashTime	QTest
2	1	"Pils"	10	9	3	280	39	40	30	100	0
3	2	"Lager"	10	9	3	150	33	50	30	120	0
4	3	"BlackBeer"	10	9	3	410	47	60	30	90	1
5	4	"Not_used"	0	0	0	0	0	0	0	0	0
6	5	"Not_used"	0	0	0	0	0	0	0	0	0

Editing the CSV file

The CSV file can be uploaded to the PC/programming device by means of the Web server and edited. After editing, the modified file can be reloaded in the CPU. You must delete the existing CSV file for this.

You can use the "RecipeImport (Page 3313)" instruction to re-import the modified data from the CSV file into the data block.

Note that the modified data must still be compatible with the data block. In other words:

- No changes may be made to the structure in the table (for example, by adding ingredients in a new column).
- If you add data records to the file, make sure when importing into the data block that the array limits through which you specify the maximum number of data records correspond to at least the number of data records.
- An index is automatically generated during export to the CSV file. If you create additional data records, add consecutive index numbers accordingly.
- The values in the table cells must correspond to the data types used in the data block with respect to format as well as length.
  - Example 1: If data type INT was used in the data block, you can only use integers in the table.
  - Example 2: If data type SINT was used in the data block, you can only use integers with the values -128 to +127 in the table.

  Always keep in mind the permitted data types and data areas as listed in the table below when you make changes in the table.

Data type		Format	Note
Floating-point numbers	LReal	+9.9999999999999E+999	Always written exponentially
	Real	+9.9999999E+99	Always written exponentially
Signed integers	LInt	+9999999999999999999	Value range for signed integers: -9223372036854775808 .. +9223372036854775807
	DInt	+9999999999	Value range of integers: -2147483648 to +2147483647
	Int	+99999	Value range of integers: -32768 to +32767
	SInt	+999	Value range of integers: -128 to +127
Unsigned integers	ULInt	+99999999999999999999	Value range of integers: 0 to +18446744073709551615
	UDInt	+9999999999	Value range of integers: 0 to +4294967295
	UInt	+99999	Value range of integers: 0 to +65535
	USInt	+999	Value range of integers: 0 to +255
Binary numbers	LWord	+99999999999999999999	Value range of integers: 0 to +18446744073709551615
	DWord	+9999999999	Value range of integers: 0 to +4294967295
	Word	+99999	Value range of integers: 0 to + 65535
	Byte	+999	Value range of integers: 0 to +255
	Bool	9	Value range: 0 or 1

Data type		Format	Note
Date and time	LTIME	dddddd:hh:mm:ss.999_999_999	ISO format with milliseconds, microseconds and nanoseconds
	TIME	hhh:mm:ss.999	ISO format with milliseconds
	S5TIME	hhh:mm:ss.999	ISO format with milliseconds
	LDT	YYYY-MM-DD hh:mm:ss.999_999_999	ISO format with milliseconds, microseconds and nanoseconds
	DTL	YYYY-MM-DD hh:mm:ss.999_999_999	ISO format with milliseconds, microseconds and nanoseconds
	DT	YYYY-MM-DD hh:mm:ss.999	ISO format with milliseconds
	DATE	YYYY-MM-DD	ISO format
	LTime_Of_Day	hh:mm:ss.999_999_999	ISO format
	TOD	hh:mm:ss.999	ISO format
Characters	WString	"abcd"	• Character string inside double quotation marks. When a recipe DB is imported, the double quotation marks may be omitted. • Current length • A character string of data type WString consists of elements of the WChar data type. When a recipe DB is exported, the contents of characters of the WChar data type are limited to 16#FF (example: 16#1255 is changed to 16#55).
	String	"abcd"	• Character string inside double quotation marks. When a recipe DB is imported, the double quotation marks may be omitted. • Current length
	WChar	"a"	Individual character inside double quotation marks. When a recipe DB is imported, the double quotation marks may be omitted. When a recipe DB is exported, the contents of characters of the WChar data type are limited to 16#FF (example: 16#1255 is changed to 16#55).
	Char	"a"	Individual character inside double quotation marks. When a recipe DB is imported, the double quotation marks may be omitted.

Data logging

Data logging - Overview

Saving process values

The data logging instructions are used in the user program to save process values to data logs. Data logs can be saved on the Memory Card (MC) or in the internal load memory. The data logs are saved in CSV format (Comma Separated Value).

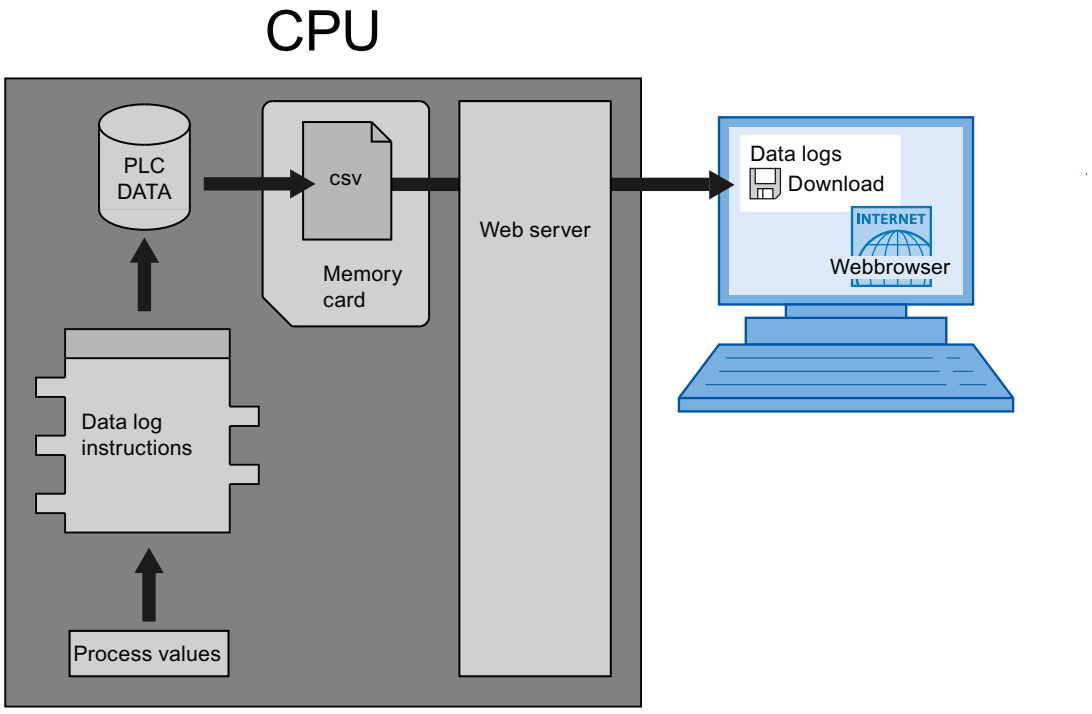
The data types are converted into a character string according to the following rules:

Data type		Format	Note
Floating-point numbers	LReal	+9.9999999999999E+999	Always written exponentially
	Real	+9.9999999E+99	Always written exponentially
Signed integers	LInt	+9999999999999999999	Value range for signed integers: -9223372036854775808 .. +9223372036854775807
	DInt	+9999999999	Value range of integers: -2147483648 to +2147483647
	Int	+99999	Value range of integers: -32768 to +32767
	SInt	+999	Value range of integers: -128 to +127
Unsigned integers	ULInt	+99999999999999999999	Value range of integers: 0 to +18446744073709551615
	UDInt	+9999999999	Value range of integers: 0 to +4294967295
	UInt	+99999	Value range of integers: 0 to + 65535
	USInt	+999	Value range of integers: 0 to +255
Binary numbers	LWord	+99999999999999999999	Value range of integers: +00000000000000000000 to +18446744073709551615
	DWord	+9999999999	Value range of integers: +0000000000 to +4294967295
	Word	+99999	Value range of integers: +00000 to + 65535
	Byte	+999	Value range of integers: +000 to +255
	Bool	9	Value range: 0 or 1
Date and time	LTIME	dddddd:hh:mm:ss. 999_999_999	ISO format with milliseconds, microseconds and nanoseconds
	TIME	hhh:mm:ss.999	ISO format with milliseconds
	S5TIME	hhh:mm:ss.999	ISO format with milliseconds
	LDT	YYYY-MM-DD hh:mm:ss. 999_999_999	ISO format with milliseconds, microseconds and nanoseconds
	DTL	YYYY-MM-DD hh:mm:ss. 999_999_999	ISO format with milliseconds, microseconds and nanoseconds
	DT	YYYY-MM-DD hh:mm:ss.999	ISO format with milliseconds
	DATE	YYYY-MM-DD	ISO format
	LTime_Of_Day	hh:mm:ss.999_999_999	ISO format
	TOD	hh:mm:ss.999	ISO format

Data type		Format	Note
Characters	WString	"abcd"	• Character string inside double quotation marks • The current length is padded with spaces up to the maximum length. • A character string of data type WString consists of elements of the WChar data type. When a data log is saved, the contents of characters of the WChar data type are limited to 16#FF (example: 16#1255 is changed to 16#55).
	String	"abcd"	• Character string inside double quotation marks • The current length is padded with spaces up to the maximum length.
	WChar	"a"	Individual character inside double quotation marks. When a data log is saved, the contents of characters of the WChar data type are limited to 16#FF (example: 16#1255 is changed to 16#55).
	Char	"a"	Individual character inside double quotation marks

The data logging instructions are used in your program to create or open a data log, to write an entry and to close the data log file.

You decide by the creation of the data buffer which program values are stored in the data log during the creation of the data buffer. The data buffer is used as a memory for new data log entries. New values have to be written to the buffer before "DataLogWrite (Page 3334)" is called. During execution of the "DataLogWrite (Page 3334)" instruction, data is written from the buffer to a data log record.



Data log files can be copied to the PC as follows:

- If the PROFINET interface is connected to the PC, you use a Web browser to access the data logs via the Web server. The CPU can be in RUN or STOP mode for this. If the CPU is in "RUN" mode, the program continues running while the Web server is transferring data.
- If there is a memory card in the CPU, you can remove this card and insert it into a standard slot for SD (Secure Digital) cards or MMC (MultiMediaCard) cards on a PC or programming device. Use File Manager to transfer the data log files from the memory card to the PC. The CPU goes to "STOP" when you remove the memory card.

Properties of the data log

Writing of the data records of a data log is carried out in accordance with the principle of a ring buffer. New data records are added until the maximum number of data records is reached (RECORD parameter). The next data record then overwrites the "oldest" data record of the data log.

If you want to prevent data records from being overwritten, use the "DataLogNewFile (Page 3340)" instruction to create a new data log file based on the current data log. New data records are then written into the new data log.

Creating data logs

With the "DataLogCreate (Page 3323)" instruction, you can create a new data log file in the ""\DataLogs" directory of the load memory.

- The name assigned at the NAME parameter is the designation for the data log and is also used the file name for the CSV file. The file is stored in the directory "DataLogs".
- The block parameter DATA specifies the data buffer for the new data log object and the columns and data types in the data log. The columns and data types of a data record in the data log are generated by the elements in the structure declaration or the array declaration of this data buffer. Each element of a structure or of an array corresponds to a column in a line in the data log.
- You can use the HEADER block parameter to assign a header text in the header to each column.
- The "DataLogCreate (Page 3323)" instruction returns an ID. This ID is used by the other data logging instructions as a reference for the created data log.

Opening data logs

You use the instruction "DataLogOpen" (S7-1200 and S7-1500) to open an existing data log on the memory card. A data log must be open before you can write new data records to it.

Data log opens automatically when you execute the instructions "DataLogCreate (Page 3323)" and "DataLogNewFile (Page 3340)".

Up to 10 data logs can be open simultaneously. You can select the data log to be opened using the ID or name of the data log.

- If you specify the ID and the name of the data log in the ID and NAME parameters, respectively, the data log will be identified based on the ID. The data log name will not be compared.
- If you select the data log using the NAME parameter and no ID is specified, the ID will be displayed in the ID parameter when the data log is opened.
- If you select the data log using the ID parameter and no name is specified, the name will be displayed in the NAME parameter when the data log is opened.

You use the MODE parameter to specify whether the data records of the data log are to be deleted upon opening.

Writing to data logs

A data log must be open ("DataLogOpen (Page 3329)" instruction) before a data record can be written to a data log. The "DataLogWrite (Page 3334)" instruction writes a data record to the data log.

Closing data logs

You use the "DataLogClose (Page 3337)" instruction to close an open data log. You select the data log using the ID parameter.

The data log is closed automatically when the CPU switches to STOP and upon restart.

Deleting data logs

You use the instruction "DataLogDelete (Page 3338)" (S7-1500) to delete a data log file from the memory card. The data log and the data records it contains can only be deleted if the log was created with the instruction "DataLogCreate (Page 3323)".

Select the data log to be deleted using the NAME and ID parameters. The ID parameter is evaluated first. If there is a data log with the relevant ID, the NAME parameter will not be evaluated. If the value "0" is used at the ID parameter, a value with the data type STRING must be used at the NAME parameter.

Clearing data logs

You use the instruction "DataLogClear (Page 3333)" (S7-1500) to delete all the data records in an existing data log. The instruction does not delete the optional header of the CSV file (see the description of the HEADER parameter of the instruction "DataLogCreate (Page 3323)").

You use the ID parameter to select the data log whose data records are to be deleted. Before you can delete data records, the data log must be open.

New file for data logs

You use the instruction "DataLogNewFile (Page 3340)" (S7-1200) or "DataLogTypedNewFile (Page 3341)" (S7-1500) to create a new data log with the same properties as an existing data log. This allows you to retain the contents of an existing data log.

When called, the instruction creates a new data log on the memory card or in the internal load memory with the name defined at the NAME parameter. You use the ID parameter to specify the ID of the old data log whose properties you want to apply to the new data log. The ID of the new data log is then output via the ID parameter.

You specify the file size of the new data log with the RECORDS parameter of the instruction.

You can run a consistency check for "DataLogTypedNewFile (Page 3341)" (S7-1500).

DataLogCreate: Create data log

Description

With the "DataLogCreate" instruction you create a data log.

The data log is saved on the memory card or in the internal load memory in the directory "\DataLogs". The amount of data that can be stored in a data log is dependent on the available space on the memory card or the storage space in the internal load memory of the CPU.

You specify the maximum number of data records that can be stored in a data log in the RECORDS parameter. If the specified maximum number of data records in the data log is reached, the oldest data record will be overwritten. To avoid overwriting of existing data records, use the "DataLogNewFile (Page 3340)" instruction. The instruction can be used to create a new data log with the same structure when the number specified at the RECORDS parameter is reached (return value 1 at the STATUS parameter of the "DataLogWrite (Page 3334)" instruction). The data records are then saved in the new data log.

You can specify the name for the data log in the NAME parameter. The data log is created in CSV (Comma Separated Value) format. With the HEADER parameter, you can create an (optional) header for the data log.

Once the data log is created, it is opened automatically. This means that data can be written.

Parameters

The following table shows the parameters of the "DataLogCreate" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, L, D, T, C or constant (T and C are only available in LAD and FBD with S7-1500)	Execution of the instruction The data log is created with a rising edge at the parameter REQ.
RECORDS	Input	UDInt	I, Q, M, L, D or constant	Maximum number of data records in the data log If the instruction "DataLogWrite (Page 3334)" writes more records than specified in this parameter, the oldest record is overwritten.

Parameter	Declaration	Data type	Memory area	Description
FORMAT	Input	UInt	I, Q, M, L, D or constant	Data format: • 0: Internal (not supported) • 1: CSV (Comma separated values)
TIMESTAMP	Input	UInt	I, Q, M, L, D or constant	Time stamp: • 0: No time stamp • 1: Date and time The extra columns in the header are automatically added if time-stamping is activated.
NAME	Input	VARIANT	L, D	Name of the data log The specified name is also used as a file name for the csv file. The restrictions for Windows file names apply when assigning the name. The following characters must not be used: "\", "/", ":", "*", "?", "<", ">", "|", "space"
ID	InOut	DWORD	I, Q, M, L, D	Object ID of the data log (only output) The ID of the data log is required for further data logging instructions to address the created data log.
HEADER	InOut	VARIANT	L, D	Header of the data log (optional) The parameter is hidden after the instruction is added. The header is written as the first line in the CSV file.
DATA	InOut	VARIANT	L, D	Pointer to the data structure that is to be written as data record when executing the instruction "DataLogWrite (Page 3334)".
DONE	Output	BOOL	I, Q, M, L, D	Status parameter: • 0: Processing not yet complete. • 1: Processing of instruction finished successfully.
BUSY	Output	BOOL	I, Q, M, L, D	Status parameter: • 0: Processing of the instruction has not started, completed, or canceled. • 1: Processing of the instruction is in progress.
ERROR	Output	BOOL	I, Q, M, L, D	Status parameter: • 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, L, D	Detailed status information: Detailed error and status information is output at the parameter STATUS. The parameter is only set for the duration of one call. To display the status, you should therefore copy the STATUS parameter to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

HEADER parameter

The HEADER parameter is a VARIANT pointer to a data block that defines a header for the CSV file (header). The header is always the first line in the CSV file representation.

- When creating a header, remember that the individual columns must be separated by a comma (S7-1200) or a semicolon (S7-1500).
- A STRING, Array of BYTE, or Array of CHAR data type can be used for the individual column names. A longer character string is possible with the Array [...] of type data type than with the STRING data type. When the STRING data type is used, the length is limited to 254 bytes.

If no header is to be created, do not specify a value in the HEADER parameter.

Parameter DATA

The DATA parameter is a VARIANT pointer to a structure or an array in a data block. An element of a structure or an array corresponds to a column in the data log with a specific data type.

Note the following when creating the data block:

- The number of columns must correspond to the number of columns defined in the HEADER parameter.
- Each element of the structure or the array corresponds to a column entry in the CSV file. Therefore, no nesting structures (STRUCT in STRUCT) may be used when using the data type STRUCT.
- The data structure can contain up to 256 elements. If there are more than 256 elements, error code 8C52 is output at the STATUS parameter.
- The tags of the data block can be set as retentive or non-retentive tags. However, the retentivity setting must be the same for all tags of the data block.

Parameter STATUS (S7-1200)

Error code* (W#16#...)	Description
0	No errors.
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8070	Complete internal instance memory is assigned.
8090	Invalid file name (see description of the NAME parameter).
8093	Data log already exists.
8097	File length exceeds the file system limit.

Error code* (W#16#...)	Description
80A2	Write error returned from file system.
80B3	Insufficient memory space on the memory card.
80B4	The memory card is write-protected.
80C1	Too many data logs are open.
80C3	Resources are not sufficient. Possible causes: • Multiple calling of instructions with different parameters. • More than 10 data logs open simultaneously. At least one data log must be closed in order to continue because the instruction "DataLogCreate" automatically opens the the log that is being created.
8253	The RECORDS parameter has an invalid value.
8453	Invalid format selection.
8553	Invalid time stamp.
8B51	Impermissible data type at parameter HEADER or length exceeds the maximum size.
8C20	String with length specification other than 254 used.
8C24	Invalid assignment at parameter DATA (for example, bit memory used as memory area).
8C51	Impermissible data type at parameter DATA / data structure cannot be used.
8C52	Structure at the parameter DATA contains more than 256 elements.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Parameter STATUS (S7-1500)

Error code* (W#16#...)	Description
0	No errors.
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
8070	Complete internal instance memory is assigned.
8090	Invalid file name (see description of the NAME parameter).
8091	"NAME" parameter is not a string.
8093	Data log already exists.
8097	File length exceeds the file system limit.
80A2	Write error returned from file system.
80B3	Insufficient memory space on the memory card.
80B4	The memory card is write-protected.
80C0	Access currently not possible.
80C1	Too many data logs are open.
80C3	Resources are not sufficient. Possible causes: • Multiple calling of instructions with different parameters. • More than 10 data logs open simultaneously. At least one data log must be closed in order to continue because the instruction "DataLogCreate" automatically opens the the log that is being created.
8253	The RECORDS parameter has an invalid value.
8353	Invalid format selection.

Error code* (W#16#...)	Description
8453	Invalid time stamp.
8B24	Invalid assignment at parameter HEADER (for example, bit memory used as memory area).
8B51	Impermissible data type at parameter HEADER or length exceeds the maximum size.
8C24	Invalid assignment at parameter DATA (for example, bit memory used as memory area).
8C51	Impermissible data type at parameter DATA / data structure cannot be used.
8C52	Structure at the parameter DATA contains more than 256 elements.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Example

In the following example, a simple data log is created with a time stamp and three process values.

Tags in the global data block

The values for the input parameters of the data log are stored in the global data block "DataLogDB":

- DataLogName (String): The tag contains the name of the data log which is also used as the file name for the CSV file.
- DataLogID (DInt): The ID of the data log is written in this tag when the instruction is called.
  - The ID is automatically assigned by the instruction.
  - Use the tag "DataLogID" in other DataLog instructions in order to address this data log.
- MyHeader (String): This tag contains the header of the DataLog, i.e. the column headings for the process values. A semicolon is used as a delimiter for the columns when using a S7-1500.
- MyData (Struct): This tag contains the three process values that are written in the data log. Each time a record is written (instruction "DataLogWrite (Page 3334)") the current values are written in a new record.

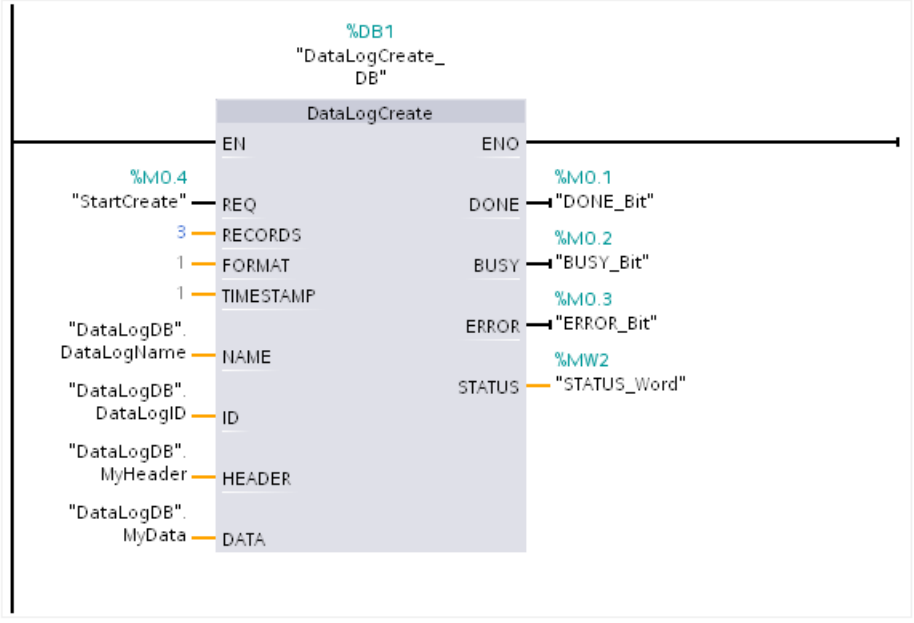
DataLogDB

	Name	Data type	Start value	Retain
1	Static			
2	DataLogName	String	'MyDataLog'	
3	DataLogID	DInt	0	
4	MyHeader	String	'Value1;Value2;Value3'	
5	MyData	Struct		
6	ProcessValue1	Int	2	
7	ProcessValue2	Int	3	
8	ProcessValue3	Int	4	

Calling the "DataLogCreate" instruction

The instruction is called with the following input parameters:

- REQ (BOOL): With REQ = "1" the data log is created.
- RECORD (3): A maximum of three data records can be written in the data log. Thereafter, the oldest data record is overwritten.
- FORMAT (1): The data log is created as a CSV file.
- TIMESTAMP (1): Activated. Two additional columns are automatically created (date and time) for the data log. The current time stamp is written in the data record each time "DataLogWrite (Page 3334)" is executed.
- NAME (VARIANT): Pointer to the tag "DataLogName" in the data block "DataLogDB".
- ID (VARIANT): Pointer to the tag "DataLogID" in the data block "DataLogDB".
- HEADER (VARIANT): Pointer to the tag "MyHeader" in the data block "DataLogDB".
- DATA (VARIANT): Pointer to the tag "MyData" in the data block "DataLogDB".



Readout of the data log via the web server

You can readout the created data log with the web server:

- Activate the web server in the properties of the CPU. The authorization "...to read files" must be activated for the web server in order to readout the data log.
- You can access the web server via the Internet browser by entering the IP address of the CPU as a URL.
- Under "Filebrowser" the directory "\DataLogs" was automatically created which contains the data log.
- The DataLog only contains one entry "//END" if the instruction "DataLogWrite (Page 3334)" has still not been executed. The first data record is written after the initial execution of "DataLogWrite (Page 3334)".

	A	B	C	D	E	F
1	SeqNo	Date	Time	ProcessValue1	ProcessValue2	ProcessValue3
2	1	01.07.2013	12:33:42.917	2	3	4
3						
4						
5

Data logging - Overview (Page 3318)

DataLogOpen: Open data log

DataLogOpen: Open data log

Description

You use the "DataLogOpen" instruction to open an existing data log on the memory card. A data log must be open before you can write new data records to it.

Data log opens automatically when you execute the instructions "DataLogCreate (Page 3323)" and "DataLogNewFile (Page 3340)".

Up to 10 data logs can be open simultaneously. You can select the data log to be opened using the ID or name of the data log.

- If you specify the ID and the name of the data log in the ID and NAME parameters, respectively, the data log will be identified based on the ID. The data log name will not be compared.
- If you select the data log using the NAME parameter and no ID is specified, the ID will be displayed in the ID parameter when the data log is opened.
- If you select the data log using the ID parameter and no name is specified, the name will be displayed in the NAME parameter when the data log is opened.

You use the MODE parameter to specify whether the data records of the data log are to be deleted upon opening.

Parameters

The following table shows the parameters of the "DataLogOpen" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, L, D or constant	Execution of the instruction upon a rising edge.
MODE	Input	UInt	I, Q, M, L, D or constant	Mode for opening the data log: • MODE= "0" Data records of the data log are retained • MODE= "1" Data records of the data log are deleted, but the header is retained
NAME	Input	VARIANT	L, D	(File) name of the data log.
ID	InOut	DWORD	I, Q, M, L, D	Object ID of the data log.
DONE	Output	BOOL	I, Q, M, L, D	Instruction was executed successfully.
BUSY	Output	BOOL	I, Q, M, L, D	Execution of instruction not yet complete.
ERROR	Output	BOOL	I, Q, M, L, D	• 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, L, D	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy the STATUS parameter to a free data area.

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameter STATUS

Error code* (W#16#...)	Description
0	No errors.
2	Warning: Data log file has already been opened by this application.
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8070	Complete internal instance memory is assigned.
8090	There are inconsistencies between the data log definition and existing data log data.
8091	A data type other than String was used at the NAME parameter.
8092	Data log does not exist.
80B4	The memory card is write-protected.

Error code* (W#16#...)	Description
80C0	The data log file is locked.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".

Data logging - Overview (Page 3318)

DataLogOpen: Open data log

Description

You use the "DataLogOpen" instruction to open an existing data log on the memory card. A data log must be open to write new data records to it.

Data log opens automatically when you execute the instructions "DataLogCreate (Page 3323)" and "DataLogNewFile (Page 3340)".

Up to 10 data logs can be open simultaneously. You can select the data log to be opened using the ID or name of the data log.

- If you specify the ID and the name of the data log in the ID and NAME parameters, respectively, the data log will be identified based on the ID. The data log name will not be compared.
- If you select the data log using the NAME parameter and no ID is specified, the ID will be displayed in the ID parameter when the data log is opened.
- If you select the data log using the ID parameter and no name is specified, the name will be displayed in the NAME parameter when the data log is opened.

You use the MODE parameter to specify whether the data records of the data log are to be deleted upon opening.

The parameter DATA enables a consistency check between the data log to be opened and the definition of the data log of the instruction "DataLogCreate (Page 3323)". The consistency check can only be executed if the data log was created with the instruction "DataLogCreate (Page 3323)":

- If you are using the same pointer at the DATA parameter as at the DATA parameter of the "DataLogCreate (Page 3323)" instruction, a check is performed to determine whether the data types match. If this is not the case, the error code W#16#8090 is output at the STATUS parameter.
- If the data log to be opened was not created with "DataLogCreate (Page 3323)", a consistency check is not possible. In this case, enter the value "NULL" in the DATA parameter.

Parameters

The following table shows the parameters of the "DataLogOpen" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, L, D, T, C or constant (T and C are only available in LAD and FBD with S7-1500)	Execution of the instruction upon a rising edge.
MODE	Input	UInt	I, Q, M, L, D or constant	Mode for opening the data log: • MODE= "0" Data records of the data log are retained • MODE= "1" Data records of the data log are deleted, but the header is retained
NAME	Input	VARIANT	L, D	(File) name of the data log.
ID	InOut	DWORD	I, Q, M, L, D	Object ID of the data log.
DATA	InOut	VARIANT	L, D	With consistency check: Pointer to the data area at the DATA parameter of the "DataLogCreate (Page 3323)" instruction.
DONE	Output	BOOL	I, Q, M, L, D	Instruction was executed successfully.
BUSY	Output	BOOL	I, Q, M, L, D	Execution of instruction not yet complete.
ERROR	Output	BOOL	I, Q, M, L, D	• 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, L, D	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy the STATUS parameter to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter STATUS

Error code* (W#16#...)	Description
0	No errors.
2	Warning: Data log file has already been opened by this application.
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8070	Complete internal instance memory is assigned.

Error code* (W#16#...)	Description
8090	Data types inconsistent. The data log at parameter ID uses different data types than specified at parameter DATA.
8091	A data type other than String was used at the NAME parameter.
8092	Data log does not exist.
80B4	The memory card is write-protected.
80C1	Too many files open.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".

DataLogClear: Empty data log

Description

The "DataLogClear" instruction deletes all data records in an existing data log. The instruction does not delete the optional header of the CSV file (see the description of the HEADER parameter of the instruction "DataLogCreate (Page 3323)").

You use the ID parameter to select the data log whose data records are to be deleted.

Requirement

Before you can delete data records, the data log must be open (see "DataLogOpen (Page 3329) instruction").

Parameters

The following table shows the parameters of the "DataLogClear" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, L, D, T, C or constant (T and C are only available in LAD and FBD with S7-1500)	Execution of the instruction upon a rising edge.
ID	InOut	DWORD	I, Q, M, D, L	Object ID of the data log
DONE	Output	BOOL	I, Q, M, D, L	Instruction was executed successfully.
BUSY	Output	BOOL	I, Q, M, D, L	Execution of the instruction not yet complete.

Parameter	Declaration	Data type	Memory area	Description
ERROR	Output	BOOL	I, Q, M, D, L	• 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output at the STATUS parameter.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy the STATUS parameter to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter STATUS

Error code* (W#16#...)	Explanation
0000	No error.
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8080	The data log file selected with the ID parameter cannot be processed with the "DataLogClear" instruction.
8092	Data log does not exist.
80A2	Write error signaled back by the file system.
80B0	Data log is not open.
80B4	The memory card is write-protected.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".

DataLogWrite: Write data log

Description

The instruction "DataLogWrite" is used to write a data record to an existing data log. The ID parameter is used to select the data log to which the data record is to be written. To create a new data record, the data log must be open. The instruction creates a new data record in the format that was specified in the DATA parameter when the data log was created.

Before calling the "DataLogWrite" instruction, transfer the data to the tag that you interconnected at the DATA parameter of the "DataLogCreate" instruction. When the "DataLogWrite" instruction is executed, the transferred data is copied to the data log.

Notice

Data log data loss when the power supply to the CPU is interrupted

If the power supply is interrupted during execution of the "DataLogWrite" instruction, the data record to be transferred is lost.

Parameters

The following table shows the parameters of the "DataLogWrite" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, L, D, T, C or constant (T and C are only available in LAD and FBD with S7-1500)	Execution of the instruction upon a rising edge.
ID	InOut	DWORD	I, Q, M, L, D	Object ID of the data log
DONE	Output	BOOL	I, Q, M, L, D	Instruction was executed successfully.
BUSY	Output	BOOL	I, Q, M, L, D	Execution of the instruction not yet complete.
ERROR	Output	BOOL	I, Q, M, L, D	• 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, L, D	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy the STATUS parameter to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter STATUS (S7-1200)

Error code* (W#16#...)	Description
0	No errors
0001	Last possible data record created at the end of the file. Creating another data record will overwrite an older data record.
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".

Error code* (W#16#...)	Description
8070	Complete internal instance memory is assigned.
8092	Data log does not exist.
80A2	Write error signaled back by the file system.
80B0	Data log is not open.
80B3	Insufficient memory space on the memory card.
80B4	The memory card is write-protected.
80C0	Data log is locked.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Parameter STATUS (S7-1500)

Error code* (W#16#...)	Description
0	No errors
0001	Last possible data record created at the end of the file. Creating another data record will overwrite an older data record.
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
8070	Complete internal instance memory is assigned.
8092	Data log does not exist.
80A2	Write error signaled back by the file system.
80B0	Data log is not open.
80B3	Insufficient memory space on the memory card.
80B4	The memory card is write-protected.
80C0	Data log is locked.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".

Data logging - Overview (Page 3318)

DataLogClose: Close data log

Description

You use the "DataLogClose" instruction to close an open data log. You select the data log using the ID parameter.

Note

Closing data logs automatically

The data log is closed automatically when the CPU goes to STOP or if there is a restart.

Parameters

The following table shows the parameters of the "DataLogClose" instruction:

Parameters	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, L, D, T, C or constant (T and C are only available in LAD and FBD with S7-1500)	Execute function on a rising edge.
ID	InOut	DWORD	I, Q, M, L, D	Object ID of the data log
DONE	Output	BOOL	I, Q, M, L, D	Instruction was executed successfully.
BUSY	Output	BOOL	I, Q, M, L, D	Execution of the instruction not yet complete.
ERROR	Output	BOOL	I, Q, M, L, D	• 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, L, D	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy the STATUS parameter to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

STATUS (S7-1200) parameter

Error code* (W#16#...)	Description
0	No errors
1	Data log is not open
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0

Error code* (W#16#...)	Description
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8092	Data log does not exist.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

STATUS (S7-1500) parameter

Error code* (W#16#...)	Description
0	No errors
1	Data log is not open
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
8070	Complete internal instance memory is assigned.
8092	Data log does not exist.
80B4	The memory card is write-protected.
80C0	Access currently not possible.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

DataLogDelete: Delete data log

Description

You use the "DataLogDelete" instruction to delete a data log file from the memory card. The data log and the data records it contains can only be deleted if it was created with the "DataLogCreate" or "DataLogNewFile" instruction.

Parameters

The following table shows the parameters of the "DataLogDelete" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, L, D, T, C or constant (T and C are only available in LAD and FBD with S7-1500)	Execution of the instruction upon a rising edge.
NAME	Input	VARIANT	L, D	File name of the data log
DELFILE	Input	BOOL	I, Q, M, D, L	• 0: Data log is retained. • 1: Data log is deleted.
ID	InOut	DWORD	I, Q, M, D, L	Object ID of the data log

Parameter	Declaration	Data type	Memory area	Description
DONE	Output	BOOL	I, Q, M, D, L	Instruction was executed successfully.
BUSY	Output	BOOL	I, Q, M, D, L	Deletion of the data log is not yet complete.
ERROR	Output	BOOL	I, Q, M, D, L	• 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output at the STATUS parameter.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy the STATUS parameter to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameters NAME and ID

Select the data log to be deleted using the NAME and ID parameters. The ID parameter is evaluated first. If there is a data log with the relevant ID, the NAME parameter will not be evaluated. If the value "0" is used at the ID parameter, a value with the data type STRING must be used at the NAME parameter.

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0	No error.
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8091	A data type other than STRING is being used at the NAME parameter.
8092	Data log does not exist.
80A2	Write error signaled back by the file system.
80B4	The memory card is write-protected.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".

DataLogCreate: Create data log (Page 3323)

DataLogNewFile: Data log in new file

DataLogNewFile: Data log in new file

Description

You use the "DataLogNewFile" instruction to create a new data log with the same properties as an existing data log. This allows the contents of an existing data log to be retained.

When called, the instruction creates a new data log on the memory card or in the internal load memory with the name defined at the NAME parameter. You use the ID parameter to specify the ID of the old data log whose properties you want to apply to the new data log. The ID of the new data log is then output via the ID parameter.

You specify the file size of the new data log with the RECORDS parameter of the instruction.

Once the new data log is created, it is opened automatically. This means that data can be written.

Parameters

The following table shows the parameters of the "DataLogNewFile" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, L, D or constant	Execution of the instruction upon a rising edge.
RECORDS	Input	UDInt	I, Q, M, L, D or constant	Number of data records in the data log.
NAME	Input	VARIANT	L, D	File name of the new data log.
ID	InOut	DWORD	I, Q, M, L, D	Object ID of the data log • In: ID of the existing data log • Out: ID of the new data log
DONE	Output	BOOL	I, Q, M, L, D	Instruction was executed successfully.
BUSY	Output	BOOL	I, Q, M, L, D	Execution of the instruction not yet complete.
ERROR	Output	BOOL	I, Q, M, L, D	• 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, L, D	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy the STATUS parameter to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter STATUS

Error code* (W#16#...)	Description
0	No errors.
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8070	Complete internal instance memory is assigned.
8090	Invalid file name.
8091	Data type at parameter NAME is not STRING.
8092	Source data log does not exist.
8093	New data log already exists.
8097	File length exceeds the file system limit.
80A0	Data types inconsistent. The data log at parameter ID uses different data types than specified at parameter DATA.
80A2	Write error signaled back by the file system.
80B3	Load memory not sufficient.
80B4	The memory card is write-protected.
80C1	Too many files open.
8253	The RECORDS parameter has an invalid value.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

DataLogNewFile: Data log in new file

Description

You use the "DataLogNewFile" instruction to create a new data log with the same properties as an existing data log. This allows the contents of an existing data log to be retained.

When called, the instruction creates a new data log on the memory card or in the internal load memory with the name defined at the NAME parameter. You use the ID parameter to specify the ID of the old data log whose properties you want to apply to the new data log. The ID of the new data log is then output via the ID parameter.

You specify the file size of the new data log with the RECORDS parameter of the instruction.

The parameter DATA enables a consistency check between the new data log to be created and the definition of the data log of the instruction "DataLogCreate (Page 3323)". The

consistency check can only be executed if the data log was created with the instruction "DataLogCreate (Page 3323)":

- If you are using the same pointer at the DATA parameter as at the DATA parameter of the "DataLogCreate (Page 3323)" instruction, a check is performed to determine whether the data types match. If the data types do not match, the error code W#16#80A0 is output at the STATUS parameter.
- If the data log to be opened was not created with "DataLogCreate (Page 3323)", a consistency check is not possible. In this case, enter the value "NULL" in the DATA parameter.

Once the new data log is created, it is opened automatically. This means that data can be written.

Parameters

The following table shows the parameters of the "DataLogNewFile" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, L, D, T, C or constant (T and C are only available in LAD and FBD with S7-1500)	Execution of the instruction upon a rising edge.
RECORDS	Input	UDInt	I, Q, M, L, D or constant	Number of data records in the data log.
NAME	Input	VARIANT	L, D	File name of the new data log.
ID	InOut	DWORD	I, Q, M, L, D	Object ID of the data log • In: ID of the existing data log • Out: ID of the new data log
DATA	InOut	VARIANT	L, D	Data type for consistency check
DONE	Output	BOOL	I, Q, M, L, D	Instruction was executed successfully.
BUSY	Output	BOOL	I, Q, M, L, D	Execution of the instruction not yet complete.
ERROR	Output	BOOL	I, Q, M, L, D	• 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, L, D	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy the STATUS parameter to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter STATUS

Error code* (W#16#...)	Description
0	No errors.
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8070	Complete internal instance memory is assigned.
8090	Invalid file name
8091	Data type at parameter NAME is not STRING.
8092	Source data log does not exist.
8093	New data log already exists.
8097	File length exceeds the file system limit.
80A0	Data types inconsistent. The data log at parameter ID uses different data types than specified at parameter DATA.
80A2	Write error signaled back by the file system.
80B3	Load memory not sufficient.
80B4	The memory card is write-protected.
80C0	Access currently not possible.
80C1	Too many files open.
8253	The RECORDS parameter has an invalid value.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Example program for working with data logs

Introduction

The following example program shows the essential functions of the data log instructions. For detailed information about individual instructions, open the corresponding help description using the corresponding links.

General notes on using data logs

- The data log created is automatically opened when the "DataLogCreate" and "DataLogNew" instructions are executed.
- Data logs are automatically closed after the CPU switches from RUN to STOP or after a restart of the CPU.
- For the "DataLogWrite" instruction to be executed, the data log must be open.
- For S7-1200 CPUs, a maximum of eight data logs can be open simultaneously. For S7-1500 CPUs, a maximum of ten data logs can be open simultaneously.

Example program

The contents of the data logs are defined in a data block (DB) in this example. The DB is used to create a data log (DataLogCreate (Page 3323)) and to provide process values for writing a data record (DataLogWrite (Page 3334)).

The three entries of the "MyData" structure are used as process values: MyCount, MyTemerature and MyPressure. In the data block, these three values are stored temporarily and then transferred with the "DataLogWrite (Page 3334)" instruction to a data log as a data record.

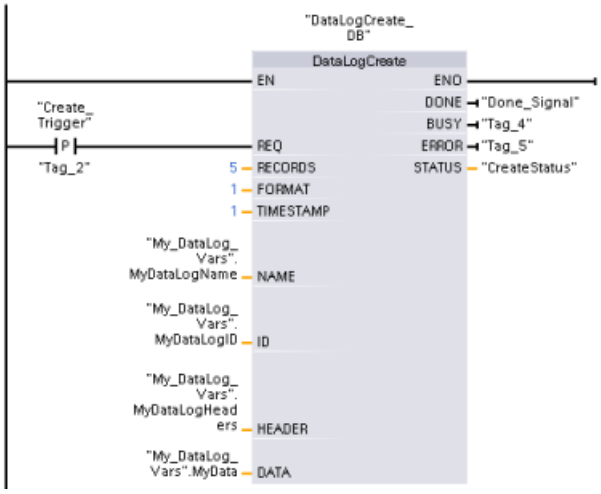
My_Datalog_Vars

	Name	Datentyp	Startwert
1	Static		
2	MyNewDataLogName	String	'MyNEWDataLog'
3	MyDataLogName	String	'MyDataLog'
4	MyDataLogID	DWord	0
5	MyDataLogHeaders	String	'Count,Temperature,Pressure'
6	MyData	Struct	
7	MyCount	Int	0
8	MyTemperature	Real	0.0
9	MyPressure	Real	0.0

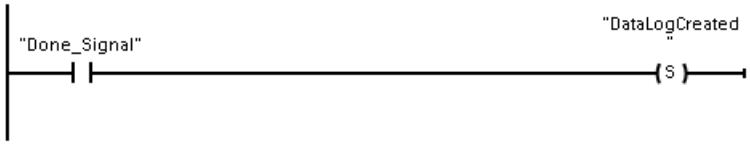
A data record is composed later from the following six entries:

1. The data record number (assigned automatically)
2. The date (assigned automatically when "1" is used for DataLogCreate at the TIMESTAMP parameter).
3. The time of day (assigned automatically when "1" is used for DataLogCreate at the TIMESTAMP parameter).
4. The current value of "MyCount" from the "MyData" structure.
5. The current value of "MyTemperature" from the "MyData" structure.
6. The current value of "MyPressure" from the "MyData" structure.

Network 1: A rising edge at REQ starts the creation of the data log with the DataLogCreate (Page 3323) instruction.

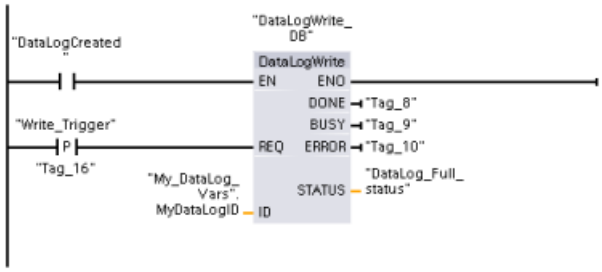


Network 2: Acquire the DONE output of DataLogCreate (Page 3323), because it is only valid for one cycle.

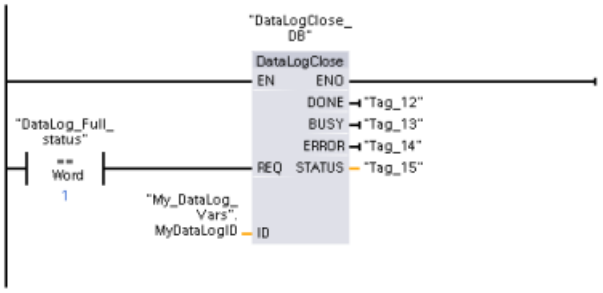


Network 3: A rising edge triggers the point in time at which new process values are stored in the MyData structure. This step is used to store the desired process values temporarily in the data block.

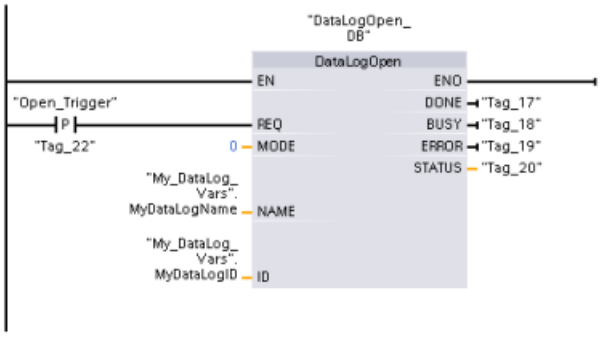
Network 4: Once the execution of DataLogCreate (Page 3323) is complete, (DONE parameter =1, see Network 1), the EN input of DataLogWrite (Page 3334) is set. The reason for this is that a generation process extends over several cycles and must be completed in order for a write operation to be performed. Writing is triggered for a data record by a rising edge at the REQ input.



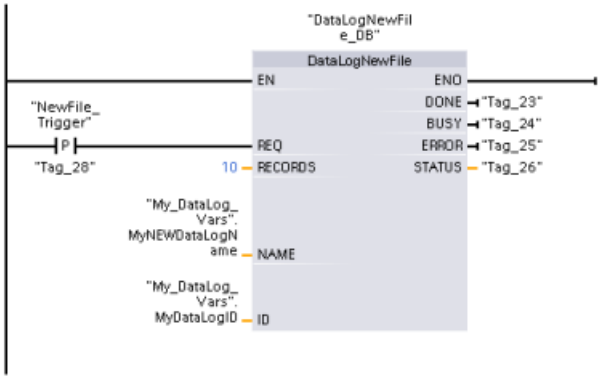
Network 5: Close the data log after the last data record has been written. The data log was created for 5 data records (see Network 1). That means, after 5 data records, 0001 is output on the DataLogWrite (Page 3334) instruction at the STATUS parameter (last possible data record created at the end of the file. Creating another data record overwrites an older data record). In this case, the REQ input is set and the DataLogClose (Page 3337) instruction is executed. When the data log is closed, no more data records can be written.



Network 6: The data log must be opened again with the DataLogOpen (Page 3331) instruction in order to write a data record again at a later time. If another data record is now written with DataLogWrite (Page 3334), the oldest data record is overwritten.



Network 7: If you do not want to overwrite the older data records, you can use the DataLogNewFile (Page 3341) instruction to create a new data log with the same structure. To do this, enter the ID of the existing data log whose structure you want to copy at the ID parameter of the instruction. Once the DataLogNewFile (Page 3341) instruction has been executed, a new and unique ID value for the new data log is assigned.

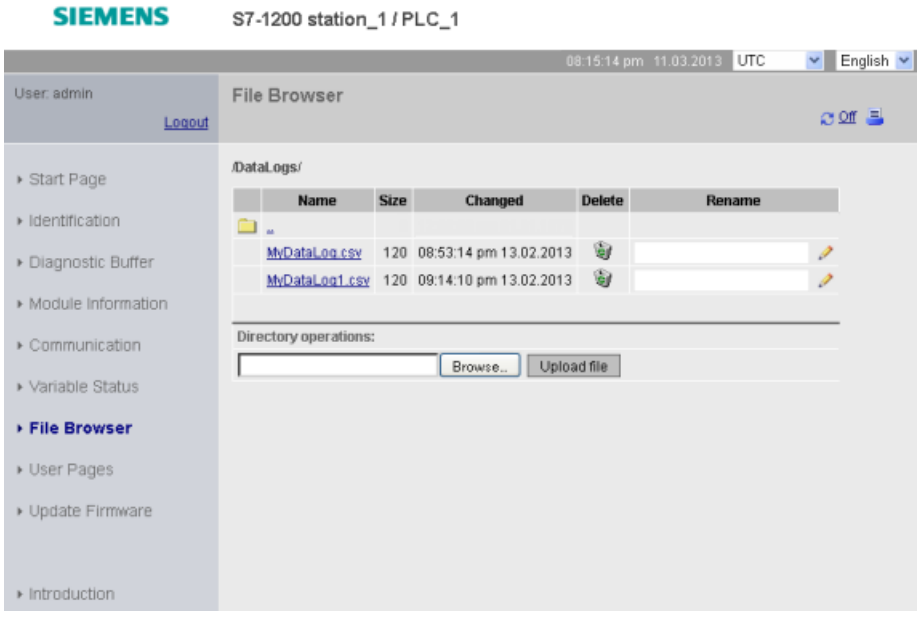


Note that the call for DataLogNewFile (Page 3341) also extends over several cycles. Therefore, similar to the DataLogCreate (Page 3323) instruction, you should also query the DONE bit to prevent premature execution of DataLogWrite (Page 3334) (see Networks 1, 2 and 4).

Result

Opening of written data via the web server

The data logs created with the example program can be displayed via the web server. To do this, open the web server using an Internet browser and open the "\DataLogs" directory.



Note

The "Delete" and "Rename" options are only available if you are logged on with editing rights. You assign the rights in the hardware configuration in the web server properties of the CPU.

Contents of the CSV files

- "5" is set as the maximum number of data records when creating the data log with the DataLogCreate instruction. If this number is not exceeded, all written data records are included in the data log.

	A	B	C	D	E	F
1	Record	Date	UTC Time	Count	Temperature	Pressure
2	1	9/30/2010	20:26:56	1	9.86E+01	3.52E+01
3	2	9/30/2010	20:28:43	2	1.00E+02	3.73E+01
4	3	9/30/2010	20:29:03	3	9.99E+01	3.68E+01
5	4	9/30/2010	20:29:21	4	9.95E+01	3.64E+01
6	5	9/30/2010	20:30:19	5	9.92E+01	3.74E+01
7						

- If another data record is added to this, the oldest data record (Record 1) is overwritten.

	A	B	C	D	E	F

11.6.3.12 Data block functions

CREATE_DB: Create data block

Description

The instruction "CREATE_DB" is used to create a new data block in the load and/or work memory.

The instruction "CREATE_DB" does not change the checksum of the user program.

Number of the data block

The data block created is assigned a number from the range defined at the LOW_LIMIT (low limit) and UP_LIMIT (high limit) parameters. "CREATE_DB" assigns the smallest possible number from the specified range to the DB. You cannot assign the numbers of the DBs already contained in the user program.

To create a DB with a specific number, enter the same number for the high and low limit of the range to be specified. If a DB with the same number already exists in the work memory and/

or load memory, or if the DB exists as a copied version, the instruction will be terminated and an error message will be generated at the RET_VAL parameter.

Start values of the data block

Using the SRCBLK parameter, you can define start values for the DB to be created. The SRCBLK parameter is a pointer to a DB or a DB area from which you apply the start values. The DB addressed at the SRCBLK parameter must have been generated with standard access ("Optimized block access" attribute disabled).

- If the area specified at the SRCBLK parameter is larger than the DB generated, the values up to the length of the DB generated will be applied as start values.
- If the area specified at the SRCBLK parameter is smaller than the DB generated, the remaining values will be filled with "0".

To ensure data consistency, you must not change this data area while "CREATE_DB" is being executed (which means as long as the BUSY parameter has the value TRUE).

Functional description

The "CREATE_DB" instruction works asynchronously, which means its execution extends over multiple calls. You start the job by calling "CREATE_DB" with REQ=1.

The output parameters RET_VAL and BUSY indicate the status of the job.

See also: Meaning of the parameters REQ, RET_VAL and BUSY with asynchronous instructions (Page 2193)

Parameters

The following table shows the parameters of the "CREATE_DB" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = 1: Request to create the data block
LOW_LIMIT	Input	UINT	I, Q, M, D, L or constant	Low limit of the area ### used by "CREATE_DB" to assign a number to your DB 60000)
UP_LIMIT	Input	UINT	I, Q, M, D, L or constant	High limit of the area ### used by "CREATE_DB" to assign a number to your DB (largest possible DB number: 60999)
COUNT	Input	UDINT	I, Q, M, D, L or constant	The count value specifies the number of bytes which you want to reserve for the DB generated. The number of bytes must be an even number. The maximum length is 65534 bytes.

<table>
<tr><th>Parameter</th><th>Declaration</th><th>Data type</th><th>Memory area</th><th>Description</th></tr>
<tr><td rowspan="9">ATTRIB</td><td rowspan="9">Input</td><td rowspan="9">BYTE</td><td rowspan="9">I, Q, M, D, L or constant</td><td>You use the first 4 bits of the byte at parameter ATTRIB to define the properties of the data block *:</td></tr>
<tr><td>• Bit 0 = 0: Attribute "Only store in load memory" is not set.
• Bit 0 = 1: Attribute "Only store in load memory" is set. With this setting, the DB takes up no space in the work memory and is not included in the program. The DB cannot be accessed with bit commands. When bit 0 = 1, the selection for bit 2 is irrelevant.</td></tr>
<tr><td>• Bit 1 = 0: Attribute "Data block write-protected in the device" is not set.
• Bit 1 = 1: Attribute "Data block write-protected in the device" is set.</td></tr>
<tr><td>• Bit 2 = 0: DB is retentive (only for DBs generated in the load memory). The DB is regarded as retentive if at least one value has been set as retentive.
• Bit 2 = 1: DB is not retentive</td></tr>
<tr><td>• Bit 3= 0: Creation of the DB either in the load memory or in the work memory (selection using bit 0, see above)
• Bit 3= 1: Creation of the DB both in the load memory and in the work memory (bit 0 irrelevant)
To ensure compatibility with STEP 7 V5.x, bits 0 and 3 must be used in combination:</td></tr>
<tr><td><table><tr><th>Bit 0</th><th>Bit 3</th><th>DB generation</th></tr><tr><td>0</td><td>0</td><td>In work memory only</td></tr><tr><td>1</td><td>0</td><td>In load memory only</td></tr><tr><td>0</td><td>1</td><td>Work and load memory</td></tr><tr><td>1</td><td>1</td><td>Work and load memory</td></tr></table></td></tr>
<tr><td>• Bit 4 = 0 - No start values specified (input values at the SRCBLK parameter will be ignored).
• Bit 4 = 1 - Specify start values (values correspond to the DB addressed by the SRCBLK parameter).</td></tr>
<tr><td>SRCBLK</td><td>Input</td><td>VARIANT</td><td>D</td><td>Pointer to the data block whose values will be used to initialize the data block to be generated.</td></tr>
<tr><td>RET_VAL</td><td>Return</td><td>INT</td><td>I, Q, M, D, L</td><td>Error information</td></tr>
<tr><td>BUSY</td><td>Output</td><td>BOOL</td><td>I, Q, M, D, L</td><td>BUSY= 1: The process is not yet complete.</td></tr>

<tr><td colspan="5">* The properties selected here correspond to the attributes in the properties of a data block.</td></tr>
</table>

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error
0081	The target range is greater than the source range. The complete source range is written to the target range. The remaining bytes of the target range are filled with 0.
7000	First call with REQ = 0: No data transfer active; BUSY has the value "0".
7001	First call with REQ = 1: Data transfer triggered; BUSY has the value "1".
7002	Intermediate call (REQ irrelevant): Data transfer already active; BUSY has the value "1".
8081	The source range is larger than the target range. The complete target range is written. The remaining bytes of the source range are ignored.
8092	The "Create data block" function is currently unavailable because • The "Compress user memory" function is currently active. • The maximum number of blocks on your CPU has already been reached.
8093	No data block or a data block that is not in the work memory is specified for the SRCBLK parameter.
8094	A not yet supported attribute was specified for the ATTRIBparameter.
80A1	DB number error: • The number is "0" • Low limit > high limit
80A2	DB length error: • The length is "0" • The length is an odd number • The length is greater than permitted by the CPU
80A3	The data block at the SRCBLK parameter was not created with standard access.
80B1	There is no DB number free.
80B2	Not enough work memory.
80B4	The memory card is write-protected.
80BB	Not enough load memory.
80C3	The maximum number of simultaneously active "CREATE_DB" instructions has already been reached.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

READ_DBL: Read from data block in the load memory

Description

With the instruction you copy a DB or an area of a DB in load memory (Micro Memory Card) to the data area of a destination DB. The destination DB must be relevant for execution; that is, it must not be created with the attribute UNLINKED. The content of the load memory is not changed during the copy process.

To ensure data consistency, you must not change the target range while "READ_DBL" is being executed (i.e., as long as the BUSY parameter has the value TRUE).

The following restrictions apply to the SRCBLK and DSTBLK parameters (source and destination blocks):

- You must be able to divide the length of the VARIANT pointer by eight.
- For a VARIANT pointer of type STRING, the length must be equal to 1.
- The source and destination block must have been created with the same block access, i.e. both must use either the access type "Optimized" or "Standard".

Note

""READ_DBL" is processed asynchronously. Therefore, it is not suitable for frequent (or cyclical) reading of tags in the load memory.

Once started, a job is always completed. If the maximum number of simultaneously active "READ_DBL" instructions is reached and you call "READ_DBL" once again at this time in a priority class having higher priority, error code W#16#80C3 will be returned. Consequently it does not make sense to restart the high-priority job right away.

Functional description

The "READ_DBL" instruction works asynchronously, that is, its execution extends over multiple calls. You start the job by calling "READ_DBL" with REQ = 1.

The output parameters RET_VAL and BUSY indicate the status of the job.

See also: Meaning of the parameters REQ, RET_VAL and BUSY with asynchronous instructions (Page 2193)

Parameters

The following table shows the parameters of the "READ_DBL" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = 1: Read request
SRCBLK	Input	VARIANT	D	Pointer to data block in the load memory that is to be read from
RET_VAL	Return	INT	I, Q, M, D, L	Error information
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = 1: The reading process is not yet complete.
DSTBLK	Output	VARIANT	D	Pointer to the data block in the work memory that is to be written to

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error
0081	The target range is greater than the source range. The source range is written completely to the target range; the remaining bytes of the target range will not be changed.
7000	First call with REQ = 0: No data transfer active; BUSY has the value "0".
7001	First call with REQ=1: Data transfer triggered; BUSY has the value "1".
7002	Intermediate call (REQ irrelevant): Data transfer already active; BUSY has the value "1".
8x51	Note: This error code is only for S7-1200 CPUs. Data type error in the data block.
8081	The source range is larger than the target range. The complete target range is written. The remaining bytes of the source range are ignored.
8082	Destination DB type different from source DB type (optimized/standard access).
8093	Note: This error code is only for S7-1500 CPUs. No data block or a data block that is not in the work memory is specified for the DSTBLK parameter.
80B1	Note: This error code is only for S7-1500 CPUs. At parameter DSTBLK, only data blocks that are located in the load memory are permitted.
8xB1	Note: This error code is only for S7-1200 CPUs. No data block is specified for the SRCBLK parameter, or the data block specified there is not a load memory object.
80B4	Memory card is write-protected or DSTBLK points to a DB with F-attribute (that must not be written)
8xC0	Note: This error code is only for S7-1200 CPUs. The destination DB is currently being processed by another instruction or a communication function.
80C3	The maximum number of simultaneously active "READ_DBL" instructions has already been reached.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".

GET_ERR_ID: Get error ID locally (Page 2922)

WRIT_DBL: Write to data block in the load memory

Description

The instruction "WRIT_DBL" is used to transfer the contents of a DB or a DB area from the work memory to a DB or a DB area in the load memory (Micro Memory Card). The source DB must be relevant for execution, which means it must not be created with the Only store in load memory attribute.

To ensure data consistency, it is not permitted to change the source range while "WRIT_DBL" is being executed (i.e., as long as the BUSY parameter has the value TRUE).

The following restrictions apply to the SRCBLK and DSTBLK parameters (source and destination blocks):

- For a VARIANT pointer of type BOOL, the length must be divisible by 8.
- For a VARIANT pointer of type STRING, the length must be equal to 1.
- The source and destination blocks must have been created with the same block access, i.e. both must use "Optimized block access" or optimized access must be disabled for both.

The "WRIT_DBL" instruction does not change the checksum of the user program if you write a DB that was created using an instruction. However, when a loaded DB is written, the first entry in this DB changes the checksum of the user program.

Note

"WRIT_DBL" is not suitable for frequent (or cyclical) writing of tags in the load memory. This is because the Micro Memory Card technology limits the number of write accesses that can be made to a Micro Memory Card.

Functional description

The "WRIT_DBL" instruction works asynchronously, that is, its execution extends over multiple calls. You start the job by calling "WRIT_DBL" with REQ=1.

The output parameters RET_VAL and BUSY indicate the status of the job.

See also: Meaning of the parameters REQ, RET_VAL and BUSY with asynchronous instructions (Page 2193).

Parameters

The following table shows the parameters of the instruction "WRIT_DBL":

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = 1: Write request
SRCBLK	Input	VARIANT	D	Pointer to the DB in the work memory that is to be read from
RET_VAL	Return	INT	I, Q, M, D, L	Error information
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = 1: The writing process is not yet complete.
DSTBLK	Output	VARIANT	D	Pointer to the data block in the load memory that is to be written to

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error
0081	The target range is greater than the source range. The source range is written completely to the target range; the remaining bytes of the target range will not be changed.
7000	First call with REQ = 0: No data transfer active; BUSY has the value "0".
7001	First call with REQ = 1: Data transfer triggered; BUSY has the value "1".
7002	Intermediate call (REQ irrelevant): Data transfer already active; BUSY has the value "1".
8x51	Note: This error code is only for S7-1200 CPUs. Data type error in the data block.
8081	The source range is larger than the target range. The complete target range is written. The remaining bytes of the source range are ignored.
8082	Destination DB type different from source DB type (optimized/non-optimized access).
8093	Note: This error code is only for S7-1500 CPUs. No data block or a data block that is not in the work memory is specified for the SRCBLK parameter.
80B1	Note: This error code is only for S7-1500 CPUs. At parameter DSTBLK, only data blocks that are located in the load memory are permitted.
8xB1	Note: This error code is only for S7-1200 CPUs. For parameter DSTBLK, no data block is specified or the data block specified there is not in the load memory.
80B4	• The memory card is write-protected. • DB with F-attribute must not be read.
80BB	Insufficient load memory available.
8xC0	Note: This error code is only for S7-1200 CPUs. The destination DB is currently being processed by another instruction or a communication instruction.
80C3	Note: This error code is only for S7-1500 CPUs. The maximum number of simultaneously active "WRIT_DBL" instructions has already been reached.
General error codes	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

ATTR_DB: Read data block attribute

Description

You use the instruction "ATTR_DB" to obtain information about a data block (DB) located in the work memory of the CPU. The instruction determines the attributes set at the ATTRIB parameter for the DB selected.

The length cannot be read for data blocks with optimized access, the DB_LENGH parameter contains the length "0" for DBs with optimized access.

Data blocks for Motion Control cannot be read with the "ATTR_DB" instruction. The error code 80B2 is output for this.

Parameters

The following table shows the parameters of the "ATTR_DB" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = 1: Read request for block attributes
DB_NUM-BER	Input	DB_ANY (UINT)	I, Q, M, D, L or constant	Number of the DB to be tested
RET_VAL	Output	INT	I, Q, M, D, L	Error information
DB_LENGTH	Output	UDINT	I, Q, M, D, L	Number of data bytes which the selected DB contains.
ATTRIB	Output	BYTE	I, Q, M, D, L	DB properties:
				• Bit 0*= 0: Attribute "Only store in load memory" is not set. • Bit 0*= 1: Attribute "Only store in load memory" is set.
				• Bit 1 = 0: Attribute "Data block write-protected in the device" is not set. • Bit 1 = 1: Attribute "Data block write-protected in the device" is set.
				If bit 0 = 1, then bit 2 is irrelevant and gets the value 1. • Bit 2 = 0: Retentive - The DB is regarded as retentive if at least one value has been set as retentive. • Bit 2 = 1: Not retentive - The complete DB is not retentive.
				• Bit 3*= 0: The DB is either in the load memory (bit 0 = 1) or in the work memory (bit 0 = 0). • Bit 3*= 1: The DB is generated in both the load and the work memory
* The relationship between bit 0 and bit 3 is explained in the parameters of the instruction "CREATE_DB: Create data block (Page 3348)".				

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error occurred.
80A1	Error in input parameter DB_NUMBER: the actual parameter selected • Is "0" • Is greater than the maximum permitted DB number for the CPU used.

Error code* (W#16#...)	Explanation
80B1	The DB with the specified number does not exist on the CPU.
80B2	Data blocks of Motion Control technology objects cannot be read with the "ATTR_DB" instruction.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

DELETE_DB: Delete data block

Description

You use the instruction "DELETE_DB" to delete a data block (DB) that was created from the user program by calling the instruction "CREATE_DB (Page 3348)".

If the data block was not created with "CREATE_DB", the error code W#16#80B5 is output at the RET_VAL parameter.

The selected data block is not deleted immediately, but rather at the cycle control point after execution of the cycle OB.

Functional description

The "DELETE_DB" instruction works asynchronously, that is, its execution extends over multiple calls. You start the interrupt transfer by calling the instruction with REQ = 1.

Output parameter BUSY and bytes 2 and 3 of output parameter RET_VAL show the status of the job.

The deletion of the data block is complete when output parameter BUSY has the value FALSE.

Parameters

The following table shows the parameters of the "DELETE_DB" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ =1: Request to delete the DB with the number in parameter DB_NUMBER
DB_NUMBER	Input	UINT	I, Q, M, D, L or constant	Number of the DB to be deleted
RET_VAL	Output	INT	I, Q, M, D, L	Error information (see "RET_VAL parameter")
BUSY	Output	BOOL	I, Q, M, D, L	BUSY= 1: The process is not yet complete.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error occurred.
7000	First call with REQ = 0: No data transfer active; BUSY has the value "0".
7001	First call with REQ = 1: Data transfer triggered; BUSY has the value "1".
7002	Intermediate call (REQ irrelevant): Data transfer already active; BUSY has the value "1".
80A1	Error in input parameter DB_NUMBER: • The value at the parameter is "0". • The value at the parameter is greater than the maximum permitted DB number for the CPU used.
80B1	The DB with the specified number does not exist on the CPU.
80B4	The DB cannot be deleted because the memory card of the CPU is write-protected.
80B5	The DB was not created using "CREATE_DB".
80BB	Not enough load memory.
80C3	The "Delete a DB" function cannot be executed at this time due to a temporary resource bottleneck.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

11.6.3.13 Addressing

Instructions for address conversion

Description

There are different options for addressing a module (IO address, hardware identifier, slot).

You can convert the address data with the following instructions:

- GEO2LOG: Determine hardware identifier from slot (Page 3359)
- LOG2GEO: Determine slot from hardware identifier (Page 3361)
- LOG2MOD: Determine the hardware identifier from addressing of STEP 7 V5.5 SPx (Page 3361)
- IO2MOD: Determine hardware identifier from an IO address (Page 3362)
- RD_ADDR: Determine IO addresses from the hardware identifier (Page 3364)

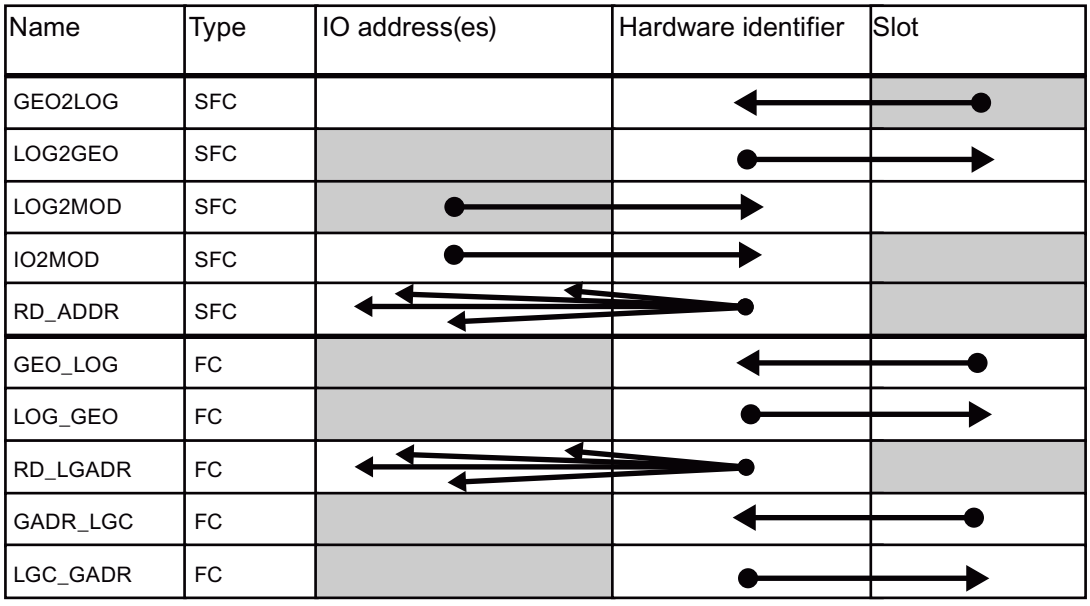
The following instructions are supported in addition for migrated projects:

- GEO_LOG: Determine hardware identifier from slot (Page 3366)
- LOG_GEO: Determine slot from hardware identifier (Page 3368)
- RD_LGADR: Determine IO addresses from the hardware identifier (Page 3369)

- GADR_LGC: Determine hardware identifier from slot and offset in the user data address area (Page 3370)
- LGC_GADR: Determine slot from hardware identifier (Page 3372)

Type of address conversion

The figure below shows which instruction runs which address conversion.



GEO2LOG: Determine hardware identifier from slot

Description

You use the "GEO2LOG" instruction to determine hardware identifier based on slot information that you define using the system data type GEOADDR.

Depending on the type of hardware you define at the parameter HWTYPE the following information is evaluated from the other parameters GEOADDR:

- When HWTYPE = 1 (IO system):
  - Only IOSYSTEM is evaluated. The other parameters of GEOADDR are not taken into consideration.
  - The hardware identifier of the IO system is output.
- When HWTYPE = 2 (IO device):
  - IOSYSTEM and STATION are evaluated. The other parameters of GEOADDR are not taken into consideration.
  - The hardware identifier of the IO device is output.

- With HWTYPE = 4 (module):
  - IOSYSTEM, STATION and SLOT are evaluated. The SUBSLOT parameter of GEOADDR is not taken into consideration.
  - The hardware identifier of the module is output.
- With HWTYPE = 5 (submodule):
  - All parameters of GEOADDR are evaluated.
  - The hardware identifier of the submodule is output.

The AREA parameter of the GEOADDR system data type is not evaluated.

Parameters

The following table shows the parameters of the "GEO2LOG" instruction:

Parameter	Declaration	Data type	Memory area	Description
GEOADDR	Input	VARIANT	D, L	Pointer to the structure of the GEOADDR system data type. The system data type contains the slot information from which the hardware ID is determined. See also: System data type GEOADDR (Page 3365)
RET_VAL	Return	INT	I, Q, M, D, L	Output of error information.
LADDR	Output	HW_ANY	I, Q, M, D, L	Hardware identifier of the assembly or the module. The number is automatically assigned and is stored in the properties in the hardware configuration.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0	No error occurred.
8091	Invalid value for in GEOADDR for HWTYPE.
8094	Invalid value for in GEOADDR for IOSYSTEM.
8095	Invalid value for in GEOADDR for STATION.
8096	Invalid value for in GEOADDR for SLOT.
8097	Invalid value for in GEOADDR for SUBSLOT.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

See also

Instructions for address conversion (Page 3358)

LOG2GEO: Determine slot from hardware identifier

Description

You use the "LOG2GEO" instruction to determine the module slot belonging to a hardware identifier.

Parameters

The following table shows the parameters of the "LOG2GEO" instruction:

Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_ANY	I, Q, M, D, L or constant	Hardware identifier of the module whose slot you want to find. The hardware ID is assigned automatically and is stored in the properties of the module in the hardware configuration and the system constants.
RET_VAL	Output	INT	I, Q, M, D, L	Output of error information.
GEOADDR	InOut	VARIANT	D	Pointer to the GEOADDR system data type. The slot information is written in the system data type GEOADDR. See also: System data type GEOADDR (Page 3365)

You will find more detailed information on valid data types in "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0	No error occurred.
8090	The address specified at the LADDR parameter is invalid.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

LOG2MOD: Determine the hardware identifier from addressing of STEP 7 V5.5 SPx

Description

You use the "LOG2MOD" instruction to determine the hardware identifier for an IO (sub)module from the addressing of STEP 7 5.5 SPx (IO data address or diagnostic address).

The hardware identifier is used at the LADDR input parameter for addressing of various instructions. You can convert the addressing parameters from STEP 7 5.5 SPx by calling "LOG2MOD" beforehand.

Parameter

The following table shows the parameters of the "LOG2MOD" instruction:

Parameter	Declaration	Data type	Memory area	Description
IOID	Input	BYTE	I, Q, M, D, L or constant	Identifier of the address area as in STEP 7 5.5 SPx: • B#16#00: Bit15 of ADDR specifies whether an input (Bit15=0) or output address (Bit15=1) exists. • B#16#54= Peripheral input (PI) • B#16#55= Peripheral output (PQ)
ADDR	Input	WORD	I, Q, M, D, L or constant	Logical address of the IO data of the module as offset (corresponding addressing in STEP 7 5.5 SPx) or diagnostic address.
RET_VAL	Return	INT	I, Q, M, D, L	Error code of the instruction.
HWID	Output	HW_IO	I, Q, M, D, L	Determined hardware identifier of the IO (sub)module.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

RET_VAL parameter

Error code* (W#16#...)	Explanation
0	No error occurred.
8093	• Specified address is not used by any hardware components. • Specified value at IOID parameter is invalid.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

IO2MOD: Determine hardware identifier from an IO address

Description

The "IO2MOD" instruction determines the hardware identifier of the module from an IO address (I, Q, PI, PQ) of a module.

Enter the IO address at the ADDR parameter. If a series of IO addresses is used at this parameter, only the first address is evaluated to determine the hardware identifier. If the first address is correctly specified, the length for the address specification at the ADDR is of no significance. If an address area is used that encompasses several modules or non-used addresses, the hardware identifier of the first module can also be determined.

If no IO address of a module is specified at parameter ADDR, the error code 8090 is output at parameter RET_VAL.

Note

Input of IO address in SCL

You cannot program using the IO access ID "%QWx:P" in SCL. In this case, use the symbolic tag name or the absolute address in the process image.

Parameters

The following table shows the parameters of the "IO2MOD" instruction:

Parameter	Declaration	Data type	Memory area	Description
ADDR	Input	VARIANT	I, Q, M, D, L	IO address (I, Q, PI, PQ) within a module. Make sure that slice access is not used for the parameter ADDR. If this is the case, incorrect values are output at the LADDR parameter.
RET_VAL	Return	INT	I, Q, M, D, L	Error code of the instruction.
LADDR	Output	HW_IO	I, Q, M, D, L	Determined hardware identifier (logical address) of the IO module.

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0	No error occurred.
8090	IO address specified at ADDR parameter is not used by any hardware component.
8092	Invalid data type used at parameter ADDR (for example, WCHAR or WSTRING).
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

RD_ADDR: Determine IO addresses from the hardware identifier

Description

The "RD_ADDR" instruction determines the length and the start address of the inputs or outputs based on the hardware identifier of a sub(module).

- Use the LADDR parameter to select the input or output module based on the hardware identifier.
- The following output parameters are used depending on whether it is an input module or output module:
  - In the case of an input module the determined values are output at the PIADDR and PICOUNT parameters.
  - In the case of an output module the determined values are output at the PQADDR and PQCOUNT parameters.
- The PIADDR and PQADDR parameters each contain the start address of the I/O addresses of the module.
- The PICOUNT and PQCOUNT parameters each contain the number of bytes of the inputs our outputs (1 byte for 8 inputs/outputs, 2 bytes for 16 inputs/outputs).

Note

Addressing packed modules

If packed modules (not the first module of the packed module group) are addressed, the displayed data deviates from the hardware configuration. "0" is returned for PIADDR or PQADDR and PICOUNT or PQCOUNT. RET_VAL does not indicate an error (16#0000).

Parameters

The following table shows the parameters of the "RD_ADDR" instruction:

Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_IO	I, Q, M, D, L or constant	Hardware identifier of the (sub)module.
RET_VAL	Return	INT	I, Q, M, D, L	Error code of the instruction.
PIADDR	Output	UDINT	I, Q, M, D, L	Start address of the input module.
PICOUNT	Output	UINT	I, Q, M, D, L	Number of bytes of the inputs.
PQADDR	Output	UDINT	I, Q, M, D, L	Start address of the output module.
PQCOUNT	Output	UINT	I, Q, M, D, L	Number of bytes of the outputs.

You will find more detailed information on valid data types in "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0	No error occurred.
8090	Hardware identifier of the module at the LADDR parameter is invalid.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

System data type GEOADDR

Geographical address

The system data type GEOADDR contains the geographical address of a module, i.e. the slot information.

- Geographical address for PROFINET IO
  For PROFINET IO the geographical address was composed of the ID of the PROFINET IO system, the device number, the slot number and the submodule (if a sub-module is used).
- Geographical address for PROFIBUS DP
  For PROFIBUS DP, the geographical address consists of the ID of the DP master system, the station number and the slot number.

The slot information of the modules can be found in the hardware configuration of each module.

System data type GEOADDR

The structure GEOADDR is automatically created if you enter "GEOADDR" as the data type in a data block.

The system data type GEOADDR has the following structure:

Parameter name	Data type	Description
GEOADDR	STRUCT	
HWTYPE	UINT	Hardware type: • 1: IO system (PROFINET/PROFIBUS) • 2: IO device/DP slave • 3: Rack • 4: Module • 5: Submodule If a hardware type is not supported by the instruction, a HWTYPE "0" is output.
AREA	UINT	Area ID: • 0 = CPU • 1 = PROFINET IO • 2 = PROFIBUS DP • 3 = AS-i
IOSYSTEM	UINT	PROFINET IO system (0=central unit in the rack)
STATION	UINT	• Number of the rack if area identifier AREA = 0 (central module). • Station number if area identifier AREA > 0.
SLOT	UINT	Slot number
SUBSLOT	UINT	Number of the submodule. This parameter has the value "0" if no submodule is available or can be plugged.

Legacy

GEO_LOG: Determine hardware identifier from slot

Description

The corresponding module slot of a signal module is known. Use the "GEO_LOG" instruction to determine the corresponding hardware identifier of the module from this.

Parameters

The following table shows the parameters of the instruction "GEO_LOG":

Parameter	Declaration	Data type	Memory area	Description
MASTER	Input	INT	I, Q, M, D, L or constant	Area ID: • 0, if the slot is located in a centralized configuration. • 1 to 32: DP master system ID of the associated field device if the slot is located in a field device on PROFIBUS • 100 to 115: PROFINET IO system ID of the associated field device if the slot is located in a field device on PROFINET
STATION	Input	INT	I, Q, M, D, L or constant	• If MASTER = 0: Number of the rack • If MASTER > 0: Station number of the field device
SLOT	Input	INT	I, Q, M, D, L or constant	Slot number
SUBSLOT	Input	INT	I, Q, M, D, L or constant	The parameter SUBSLOT is not evaluated by the instruction.
RET_VAL	Return	INT	I, Q, M, D, L	Error information
LADDR	Output	HW_IO	I, Q, M, D, L	Hardware identifier of the module

You will find more detailed information on valid data types in "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error occurred.
8094	No subnet was configured with the specified SUBNETID .
8095	Illegal value for STATION parameter
8096	Illegal value for SLOT parameter
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

See also

Instructions for address conversion (Page 3358)

LOG_GEO: Determine slot from hardware identifier

Description

You use the "LOG_GEO" instruction to determine the module slot belonging to a hardware identifier.

Parameters

The following table shows the parameters of the instruction "LOG_GEO":

Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_IO	I, Q, M, D, L or constant	Hardware identifier of the module for which the slot is to be determined.
RET_VAL	Return	INT	I, Q, M, D, L	Error information
AREA	Output	INT	I, Q, M, D, L	Area ID: indicates how the remaining output parameters are to be interpreted: • 0: central device • 2: PROFIBUS DP / PROFINET IO
MASTER	Output	INT	I, Q, M, D, L	With AREA = 0: • 0: If the slot is located in one of the racks (central device). With AREA = 2: • 1 to 32: DP master system ID of the associated field device if the slot is located in a field device on PROFIBUS • 100 to 115: PROFINET IO system ID of the associated field device if the slot is located in a field device on PROFINET
STATION	Output	INT	I, Q, M, D, L	• With MASTER = 0: Number of the rack • With MASTER > 0: Station number of the field device
SLOT	Output	INT	I, Q, M, D, L	Slot number
SUBSLOT	Output	INT	I, Q, M, D, L	The SUBSLOT parameter is not output by the instruction (always "0").
OFFSET	Output	INT	I, Q, M, D, L	The OFFSET parameter is not output by the instruction (always "0").

You will find more detailed information on valid data types in "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error occurred.
8090	Specified logical address invalid
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".

Instructions for address conversion (Page 3358)

RD_LGADR: Determine IO addresses from the hardware identifier

Description

Based on the hardware identifier, you can determine the logical addresses of a module, a central submodule or a submodule for PNIO with the "RD_LGADR" instruction.

- You can specify the hardware ID of the submodule at the LADDR parameter.
- The addresses are written to the PEADDR and PAADDR parameters is ascending order.
  - For an input module, only the PEADDR parameter is written. For an output module, the PAADDR parameter is written.
  - An Array of WORD is used to store the addresses in each case.
- The number of addresses is output at the PECOUNT parameter (for an input module) and PACOUNT parameter (for an output module).

Parameters

The following table shows the parameters of the instruction "RD_LGADR":

Parameter	Declaration	Data type	Memory area	Description
IOID	Input	BYTE	I, Q, M, D, L or constant	Address area identifier: • B#16#54 = Peripheral input (PI) • B#16#55 = Peripheral output (PQ)
LADDR	Input	HW_ANY	I, Q, M, D, L or constant	Hardware identifier of the module or the submodule.
RET_VAL	Return	INT	I, Q, M, D, L	Error information
PEADDR	Output	ANY	I, Q, M, D, L	Field for the PI addresses with the Array of WORD data type
PECOUNT	Output	INT	I, Q, M, D, L	Number of returned PI addresses

Parameter	Declaration	Data type	Memory area	Description
PAADDR	Output	ANY	I, Q, M, D, L	Field for the PQ addresses with the Array of WORD data type
PACOUNT	Output	INT	I, Q, M, D, L	Number of returned PQ addresses

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

RET_VAL parameter

Error code (W#16#...)	Explanation
0000	No error occurred.
8090	Specified logical address invalid or illegal value for the IOID parameter.
80A0	Error in the output parameter PEADDR: The data type of the array elements is not WORD.
80A1	Error in the output parameter PAADDR: The data type of the array elements is not WORD.
80A2	Error in the output parameter PEADDR: The specified array could not accommodate all the logical addresses.
80A3	Error in the output parameter PAADDR: The specified array could not accommodate all the logical addresses.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)

Instructions for address conversion (Page 3358)

GADR_LGC: Determine hardware identifier from slot and offset in the user data address area

Description

You use the "GADR_LGC" instruction to determine the hardware identifier of a signal module. The hardware identifier is determined from the module slot and the offset in the user data address area of the module.

Note

Output of the diagnostic address

If you use the "GADR_LGC" instruction on power modules or modules with packed addresses, then the diagnostic address will be returned.

Note

Restriction on use

The "GADR_LGC" instruction cannot be used for modules behind gateways (e.g., IE/PB link). Use the "GEO2LOG" instruction instead.

Parameters

The following table shows the parameters of the instruction "GADR_LGC":

Parameter	Declaration	Data type	Memory area	Description
SUBNETID	Input	BYTE	I, Q, M, D, L or constant	Area ID: • 0: If the slot is located in the central module • 1 to 32: DP master system ID of the corresponding distributed I/O system if the slot is in a distributed I/O device. • 100 to 115: PROFINET IO system ID of the associated field device if the slot is located in a field device on PROFINET
RACK	Input	WORD	I, Q, M, D, L or constant	• Number of the rack, if area identifier is 0 • Device number of the distributed I/O device if the area identifier > 0
SLOT	Input	WORD	I, Q, M, D, L or constant	Slot no.
SUBSLOT	Input	BYTE	I, Q, M, D, L or constant	Sub-module slot (if no sub-module can be inserted, 0 must be entered here)
SUBADDR	Input	WORD	I, Q, M, D, L or constant	Offset in the user data address area of the module
RET_VAL	Return	INT	I, Q, M, D, L	Error information
IOID	Output	BYTE	I, Q, M, D, L	The IOID output parameter is not written (always "0").
LADDR	Output	HW_MODULE	I, Q, M, D, L	Hardware identifier of the module

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error occurred.
8093	Illegal value for SUBNETID parameter
8094	No subnet was configured with the specified SUBNETID .
8095	Illegal value for RACK parameter.

Error code* (W#16#...)	Explanation
8096	Illegal value for SLOT parameter.
8097	Illegal value for SUBSLOT parameter.
8098	Illegal value for SUBADDR parameter.
8099	The slot is not configured.
809A	The sub-address of the selected slot is not configured (only possible with central I/O for CPU and IM).
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

See also

Instructions for address conversion (Page 3358)

LGC_GADR: Determine slot from hardware identifier

Description

You use the "LGC_GADR" instruction to determine the module slot belonging to a hardware identifier.

Note

The "LGC_GADR" instruction cannot be used on a module with packed addresses (ET 200S).

Note

Restriction on use

The "LGC_GADR" instruction cannot be used for modules behind gateways (e.g., IE/PB link). Use the "LOG2GEO" instruction instead.

Parameters

The following table shows the parameters of the instruction "LGC_GADR":

Parameter	Declaration	Data type	Memory area	Description
IOID	Input	BYTE	I, Q, M, D, L or constant	Is not evaluated.
LADDR	Input	HW_MODULE	I, Q, M, D, L or constant	Hardware identifier of the module
RET_VAL	Return	INT	I, Q, M, D, L	Error information
AREA	Output	BYTE	I, Q, M, D, L	Area ID: indicates how the remaining output parameters are to be interpreted: • 0: Central module • 2: PROFIBUS DP

Parameter	Declaration	Data type	Memory area	Description
RACK	Output	WORD	I, Q, M, D, L	Rack number: • With central module AREA= 0): – Rack number • For PROFIBUS DP (AREA=2): – Low byte: Station number – High byte: DP master system ID
SLOT	Output	WORD	I, Q, M, D, L	Slot number: • With central module AREA= 0): – Slot number • For PROFIBUS DP (AREA=2): – Slot no. in the station
SUBADDR	Output	WORD	I, Q, M, D, L	Is not output (always "0").

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error occurred.
8090	Specified logical address invalid or illegal value for the IOID parameter.
8093	This instruction is not permitted for the module selected by the parameters IOID and LADDR .
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".

11.6.4 Technology

11.6.4.1 S7-1200 Motion Control

S7-1200 Motion Control as of V4

MC_Power

MC_Power: Enable, disable axes as of V4

Description

The Motion Control instruction "MC_Power" enables or disables an axis.

Requirements

- The positioning axis technology object has been configured correctly.
- There is no pending enable-inhibiting error.

Override response

Execution of "MC_Power" cannot be aborted by a Motion Control command.

Disabling the axis (input parameter "Enable" = FALSE) aborts all Motion Control commands for the associated technology object in accordance with the selected "StopMode".

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis	-	Axis technology object	
Enable	INPUT	BOOL	FALSE	TRUE	The axis is enabled.
				FALSE	All current jobs are interrupted in accordance with the "StopMode" configured. The axis is stopped and disabled.

Parameter	Declaration	Data type	Default value	Description	
StopMode	INPUT	INT	0	0	Emergency stop If a request to disable the axis is pending, the axis brakes at the configured emergency deceleration. The axis is disabled after reaching standstill.
				1	Immediate stop If a request to disable the axis is pending, this set-point zero is output and the axis is disabled. The axis is braked depending on the configuration in the drive, and is brought to a standstill. With drive connection via PTO (Pulse Train Output): When you disable the axis, the pulse output is stopped with a frequency-dependent deceleration: • Output frequency ≥ 100 Hz Deceleration: max. 30 ms • Output frequency < 100 Hz Deceleration: 30 ms up to max. 1.5 s at 2 Hz
				2	Emergency stop with jerk control If a request to disable the axis is pending, the axis brakes at the configured emergency deceleration. If the jerk control is activated, the configured jerk is taken into account. The axis is disabled after reaching standstill.
Status	OUTPUT	BOOL	FALSE	Status of axis enable	
				FALSE	The axis is disabled. The axis does not execute Motion Control commands and does not accept any new commands (exception: MC_Reset command). For drive connection via PTO (Pulse Train Output): The axis is not homed. Upon disabling, the status does not change to FALSE until the axis reaches a standstill.
				TRUE	The axis is enabled. The axis is ready to execute Motion Control commands. Upon axis enabling, the status does not change to TRUE until the signal "Drive ready" is pending. If the "Drive ready" drive interface was not configured in the axis configuration, the status changes to TRUE immediately.
Busy	OUTPUT	BOOL	FALSE	TRUE	"MC_Power" is active.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred in Motion Control instruction "MC_Power" or in the associated technology object. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7477) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7477) for parameter "ErrorID"	

Note

If the axis is switched off due to an error, it will be enabled again automatically after the error has been eliminated and acknowledged. This requires that the input parameter "Enable" has retained the value TRUE during this process.

Enabling an axis with configured drive interface

To enable the axis, follow these steps:

1. Check the requirements indicated above.
2. Initialize input parameter "StopMode" with the desired value. Set the input parameter "Enable" to TRUE.
   The enable output for "Drive enabled" changes to TRUE to enable the power to the drive.
   The CPU waits for the "Drive ready" signal of the drive.
   When the "Drive ready" signal is available at the configured ready input of the CPU, the axis is enabled. The output parameter "Status" and the tag of the technology object <Axis name>.StatusBits.Enable indicate the value TRUE.

Enabling an axis without configured drive interface

To enable the axis, follow these steps:

1. Check the requirements indicated above.
2. Initialize input parameter "StopMode" with the desired value. Set the input parameter "Enable" to TRUE. The axis is enabled. The output parameter "Status" and the tag of the technology object <Axis name>.StatusBits.Enable indicate the value TRUE.

Disabling an axis

To disable an axis, you can follow the steps described below:

1. Bring the axis to a standstill.
   You can identify when the axis is at a standstill in the tag of the technology object <Axis name>.StatusBits.StandStill.
2. Set input parameter "Enable" to FALSE after standstill is reached.
3. If output parameters "Busy" and "Status" and tag of technology object <Axis name>.StatusBits.Enable indicate the value FALSE, disabling of the axis is complete.

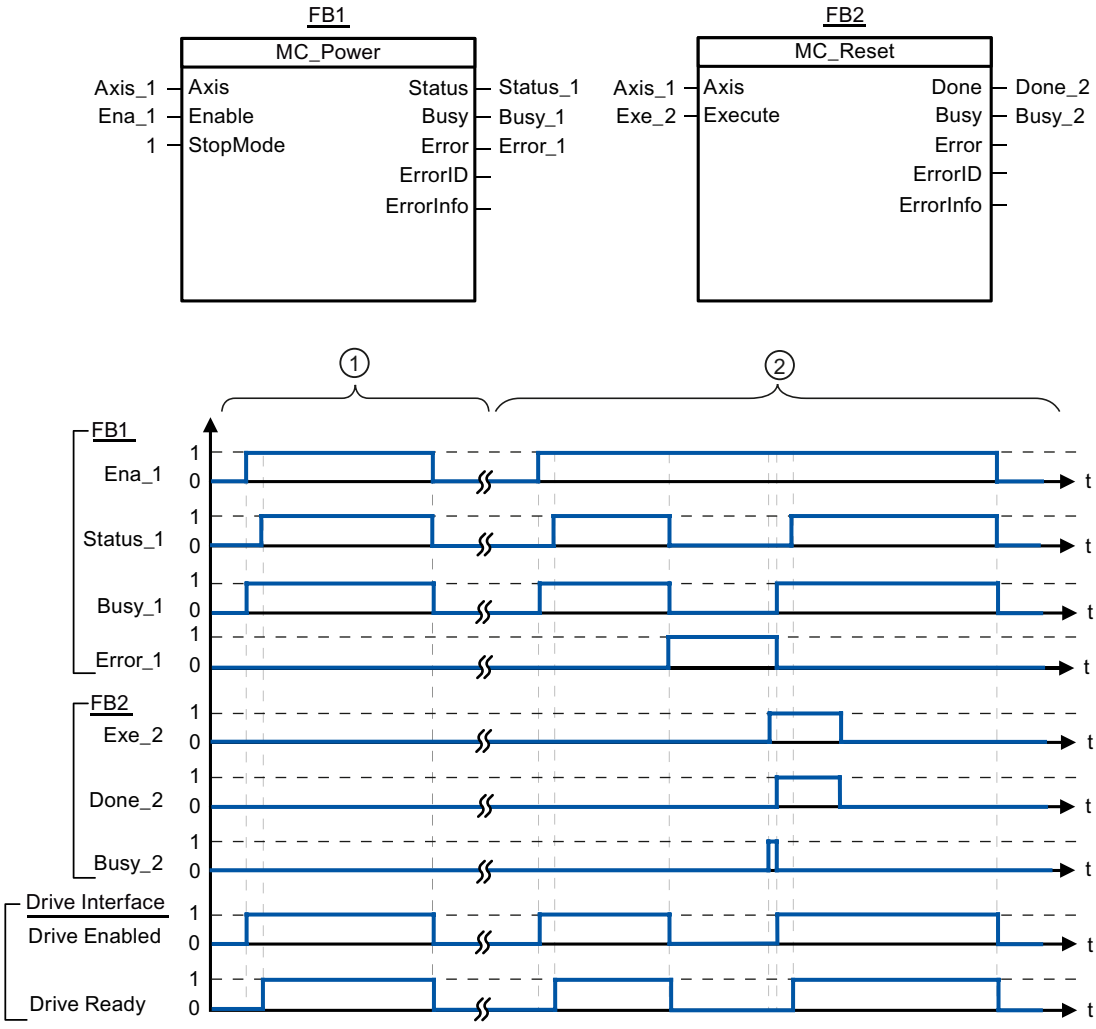
MC_Home: Home axes, set reference point as of V4 (Page 3381)

MC_Power: Function chart as of V4

Function chart



①	An axis is enabled and then disabled again. When the drive has signaled "Drive ready" back to the CPU, the successful enable can be read out via "Status_1".
②	Following an axis enable, an error has occurred that caused the axis to be disabled. The error is eliminated and acknowledged with "MC_Reset". The axis is then enabled again.

See also

MC_Power: Enable, disable axes as of V4 (Page 3374)

MC_Reset

MC_Reset: Acknowledge fault as of V4

Description

Motion Control instruction "MC_Reset" can be used to acknowledge "Operating error with axis stop" and "Configuration error". The errors that require acknowledgment can be found in the "List of ErrorIDs and ErrorInfos" under "Remedy".

The axis configuration can be downloaded to the work memory after a download in RUN mode.

Requirements

- The positioning axis technology object has been configured correctly.
- The cause of a pending configuration error requiring acknowledgment has been eliminated (for example, acceleration in positioning axis technology object has been changed to a valid value).

Override response

The MC_Reset command cannot be aborted by any other Motion Control command.

The new MC_Reset command does not abort any other active Motion Control commands.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Restart	INPUT	BOOL	FALSE	TRUE	Download the axis configuration from the load memory to the work memory. The command can only be executed when the axis is disabled. Refer to the notes on Download to the CPU (Page 7434).
				FALSE	Acknowledges pending errors
Done	OUTPUT	BOOL	FALSE	TRUE	Error has been acknowledged.
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7477) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7477) for parameter "ErrorID"	

Acknowledging an error requiring acknowledgment with MC_Reset

To acknowledge an error, follow these steps:

1. Check the requirements indicated above.
2. Start the acknowledgment of the error with a rising edge at input parameter "Execute".
3. If output parameter "Done" indicates the value TRUE and tag of technology object <Axis name>.StatusBits.Error the value FALSE, the error has been acknowledged.

S7-1200 Motion Control V1...3 (Page 3410)

MC_Home

MC_Home: Home axes, set reference point as of V4

Description

Motion Control instruction "MC_Home" is used to match the axis coordinates to the real, physical drive position. Homing is required for absolute positioning of the axis. The following types of homing can be executed:

- Active homing (Mode = 3)
  The homing procedure is executed automatically.
- Passive homing (Mode = 2)
  During passive homing, the "MC_Home" Motion Control instruction does not carry out any homing motion. The travel required for this step must be implemented by the user via other Motion Control instructions. When the homing switch is detected, the axis is homed.
- Direct homing absolute (Mode = 0)
  The current axis position is set to the value of parameter "Position".
- Direct homing relative (Mode = 1)
  The current axis position is offset by the value of parameter "Position".

Requirements

- The positioning axis technology object has been configured correctly.
- The axis is enabled.
- No MC_CommandTable command may be active upon start with Mode = 0, 1, or 2.

Override response

The override response depends on the selected mode:

Mode = 0, 1

The MC_Home command cannot be aborted by any other Motion Control command.

The MC_Home command does not abort any active Motion Control commands. Position-related motion commands are resumed after homing according to the new homing position (value at input parameter: "Position").

Mode = 2

The MC_Home command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 2, 3

The new MC_Home command aborts the following active Motion Control command:

- MC_Home command Mode = 2

Position-related motion commands are resumed after homing according to the new homing position (value at input parameter: "Position").

Mode = 3

The MC_Home command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_Home command aborts the following active Motion Control commands:

- MC_Home command Mode = 2, 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description
Axis	INPUT	TO_Axis	-	Axis technology object
Execute	INPUT	BOOL	FALSE	Start of the job with a positive edge
Position	INPUT	REAL	0.0	• Mode = 0, 2, and 3 Absolute position of axis after completion of the homing operation • Mode = 1 Correction value for the current axis position Limit values: $-1.0e^{12} \leq$ Position $\leq 1.0e^{12}$

Parameter	Declaration	Data type	Default value	Description	
Mode	INPUT	INT	0	Homing mode	
				0	Direct homing (absolute) New axis position is the position value of parameter "Position".
				1	Direct homing (relative) New axis position is the current axis position + position value of parameter "Position".
				2	Passive homing Homing according to the axis configuration. Following homing, the value of parameter "Position" is set as the new axis position.
				3	Active homing Homing procedure in accordance with the axis configuration. Following homing, the value of parameter "Position" is set as the new axis position.
Done	OUTPUT	BOOL	FALSE	TRUE	Command completed
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution the job was aborted by another job.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7477) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7477) for parameter "ErrorID"	

Resetting the "Homed" status

The "Homed" status of a technology object (<AxisName>.StatusBits.HomingDone) is reset under the following conditions:

- **Drive connection via PTO (Pulse Train Output):**
  - Start a "MC_Home" command for active homing
    (After successful completion of the homing operation, the "Homed" status is reset.)
  - Disabling of axis by the "MC_Power" Motion Control instruction
  - Changeover between automatic mode and manual control
  - After POWER OFF -> POWER ON of the CPU
  - After CPU restart (RUN-STOP -> STOP-RUN)
- **Technology objects with incremental actual values:**
  - Start a "MC_Home" command for active homing
    (After successful completion of the homing operation, the "Homed" status is reset.)
  - Error in the encoder system, or encoder failure
  - Restart of the technology object
  - After POWER OFF → POWER ON of the CPU
  - Memory reset

  - Modification of the encoder configuration
  - Replacement of the CPU

Homing an axis

To home the axis, follow these stops:

1. Check the requirements indicated above.
2. Provide the necessary input parameters with values and start the homing operation with a rising edge at input parameter "Execute".
3. If output parameter "Done" and technology object tag <Axis name>.StatusBits.HomingDone indicate the value TRUE, homing is complete.

MC_Halt: Stop axes as of V4 (Page 3385)

MC_Halt

MC_Halt: Stop axes as of V4

Description

The "MC_Halt" Motion Control instruction stops all movements and brings the axis to a standstill with the configured deceleration. The standstill position is not defined.

Requirements

- The positioning axis technology object has been configured correctly.
- The axis is enabled.

Override response

The MC_Halt command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_Halt command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command

- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Done	OUTPUT	BOOL	FALSE	TRUE	Zero velocity reached
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7477) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7477) for parameter "ErrorID"

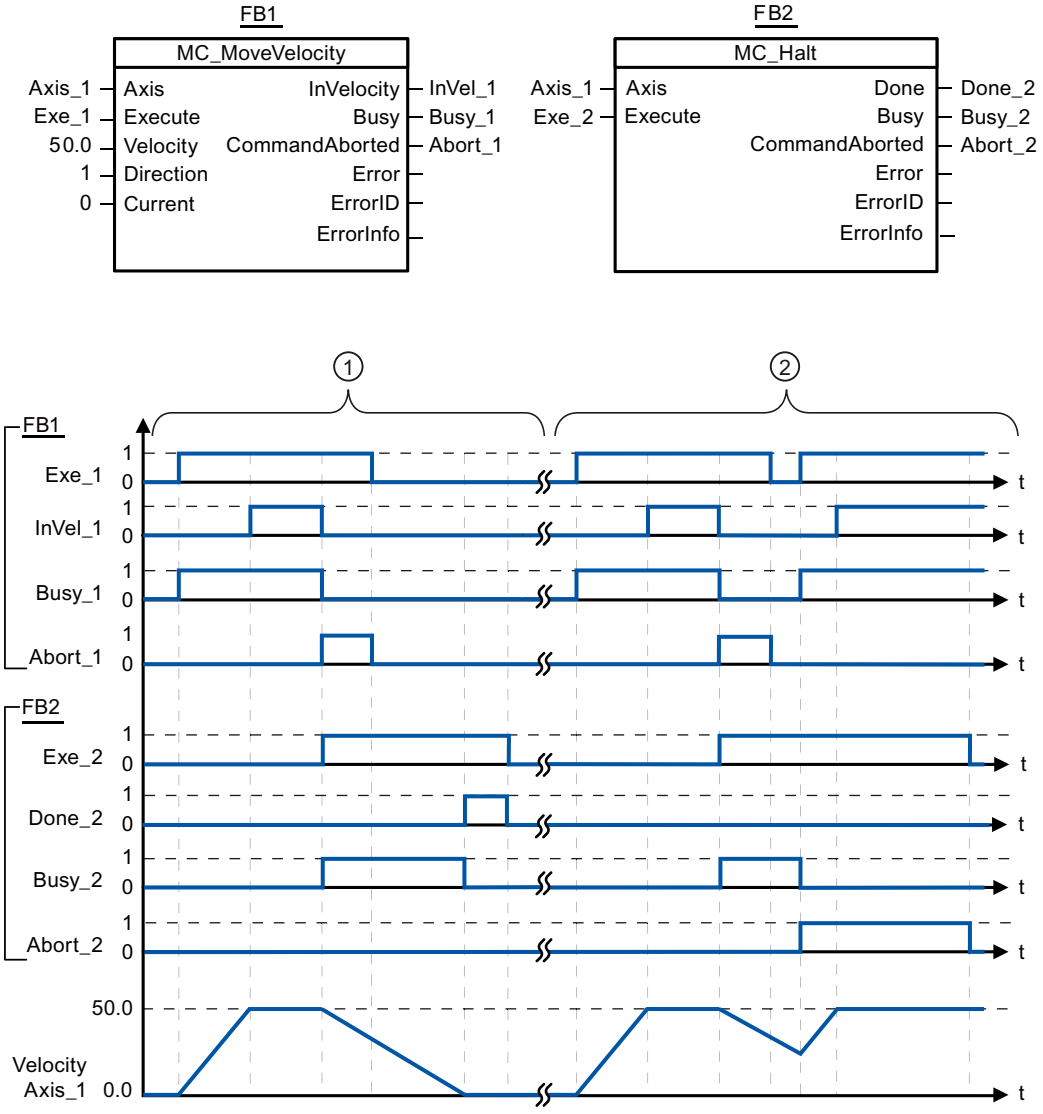
MC_Halt: Function chart as of V4

Function chart



The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 5.0

①	The axis is braked by an MC_Halt command until it comes to a standstill. The axis standstill is signaled via "Done_2".
②	While an MC_Halt command is braking the axis, this command is aborted by another motion command. The abort is signaled via "Abort_2".

MC_Halt: Stop axes as of V4 (Page 3385)

MC_MoveAbsolute

MC_MoveAbsolute: Absolute positioning of axes as of V4

Description

The "MC_MoveAbsolute" Motion Control instruction starts an axis positioning motion to move it to an absolute position.

Requirements

- The positioning axis technology object has been configured correctly.
- The axis is enabled.
- The axis is homed.

Override response

The MC_MoveAbsolute command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_MoveAbsolute command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Positioning-Axis	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Position	INPUT	REAL	0.0	Absolute target position Limit values: $-1.0e^{12} \leq$ Position $\leq 1.0e^{12}$	
Velocity	INPUT	REAL	10.0	Velocity of axis This velocity is not always reached on account of the configured acceleration and deceleration and the target position to be approached. Limit values: Start/stop velocity ≤ Velocity ≤ maximum velocity	
Done	OUTPUT	BOOL	FALSE	TRUE	Absolute target position reached
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7477) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7477) for parameter "ErrorID"

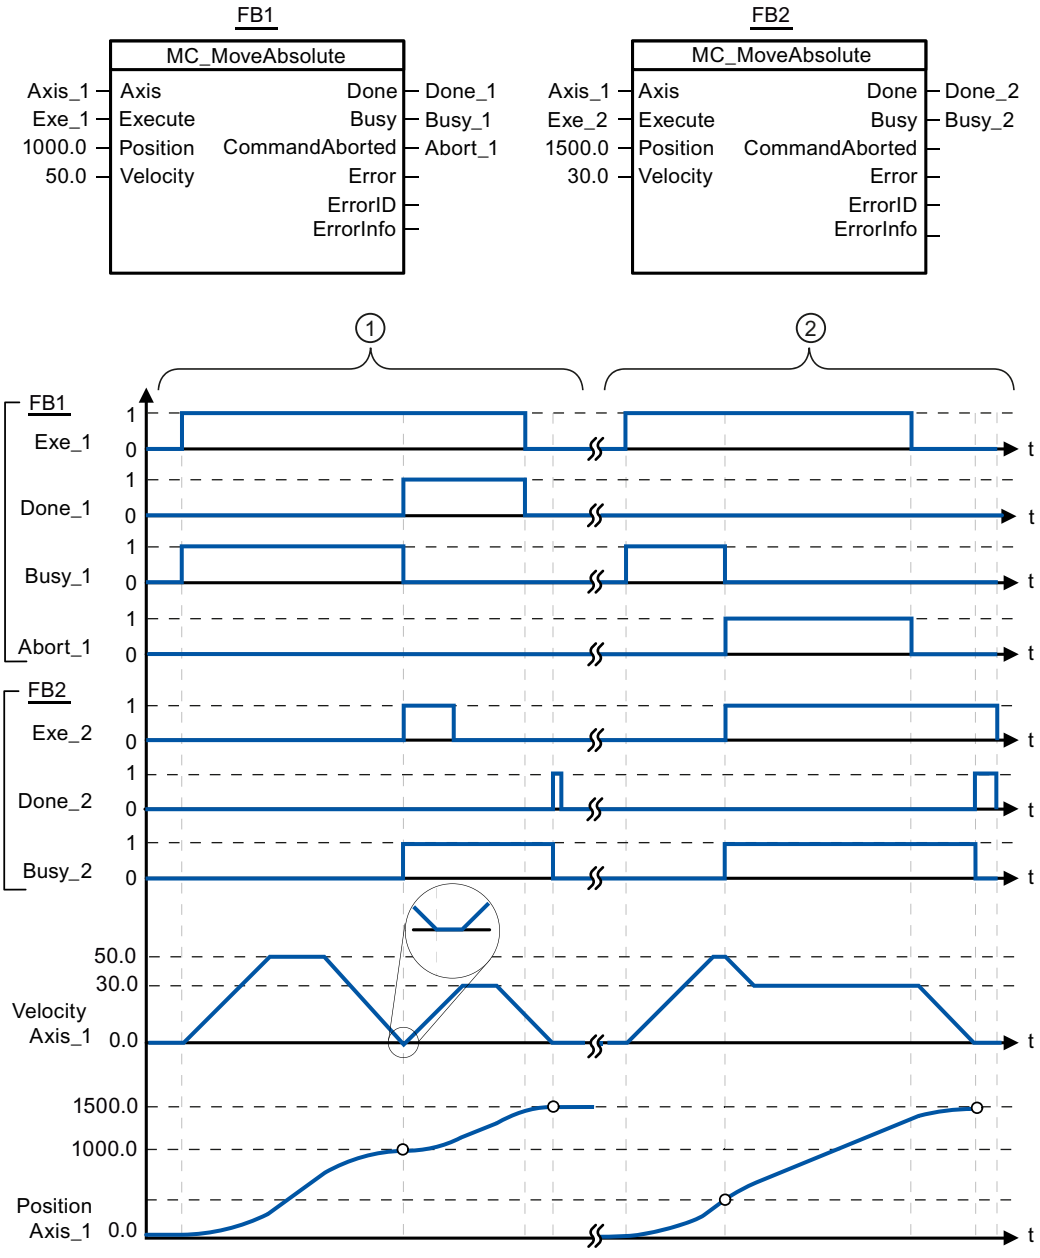
MC_MoveAbsolute: Function chart as of V4

Function chart



The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 10.0

①	An axis is moved to absolute position 1000.0 with an MC_MoveAbsolute command. When the axis reaches the target position, this is signaled via "Done_1". When "Done_1" = TRUE, another MC_MoveAbsolute command, with target position 1500.0, is started. Because of the response times (e.g., cycle time of user program, etc.), the axis comes to a standstill briefly (see zoomed-in detail). When the axis reaches the new target position, this is signaled via "Done_2".
②	An active MC_MoveAbsolute command is aborted by another MC_MoveAbsolute command. The abort is signaled via "Abort_1". The axis is then moved at the new velocity to the new target position 1500.0. When the new target position is reached, this is signaled via "Done_2".

MC_MoveAbsolute: Absolute positioning of axes as of V4 (Page 3388)

MC_MoveRelative

MC_MoveRelative: Relative positioning of axes as of V4

Description

The "MC_MoveRelative" Motion Control instruction starts a positioning motion relative to the start position.

Requirements

- The positioning axis technology object has been configured correctly.
- The axis is enabled.

Override response

The MC_MoveRelative command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_MoveRelative command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Positioning-Axis	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Distance	INPUT	REAL	0.0	Travel distance for the positioning operation Limit values: $-1.0e^{12} \leq$ Distance $\leq 1.0e^{12}$	
Velocity	INPUT	REAL	10.0	Velocity of axis This velocity is not always reached on account of the configured acceleration and deceleration and the distance to be traveled. Limit values: Start/stop velocity ≤ Velocity ≤ maximum velocity	
Done	OUTPUT	BOOL	FALSE	TRUE	Target position reached
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7477) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7477) for parameter "ErrorID"

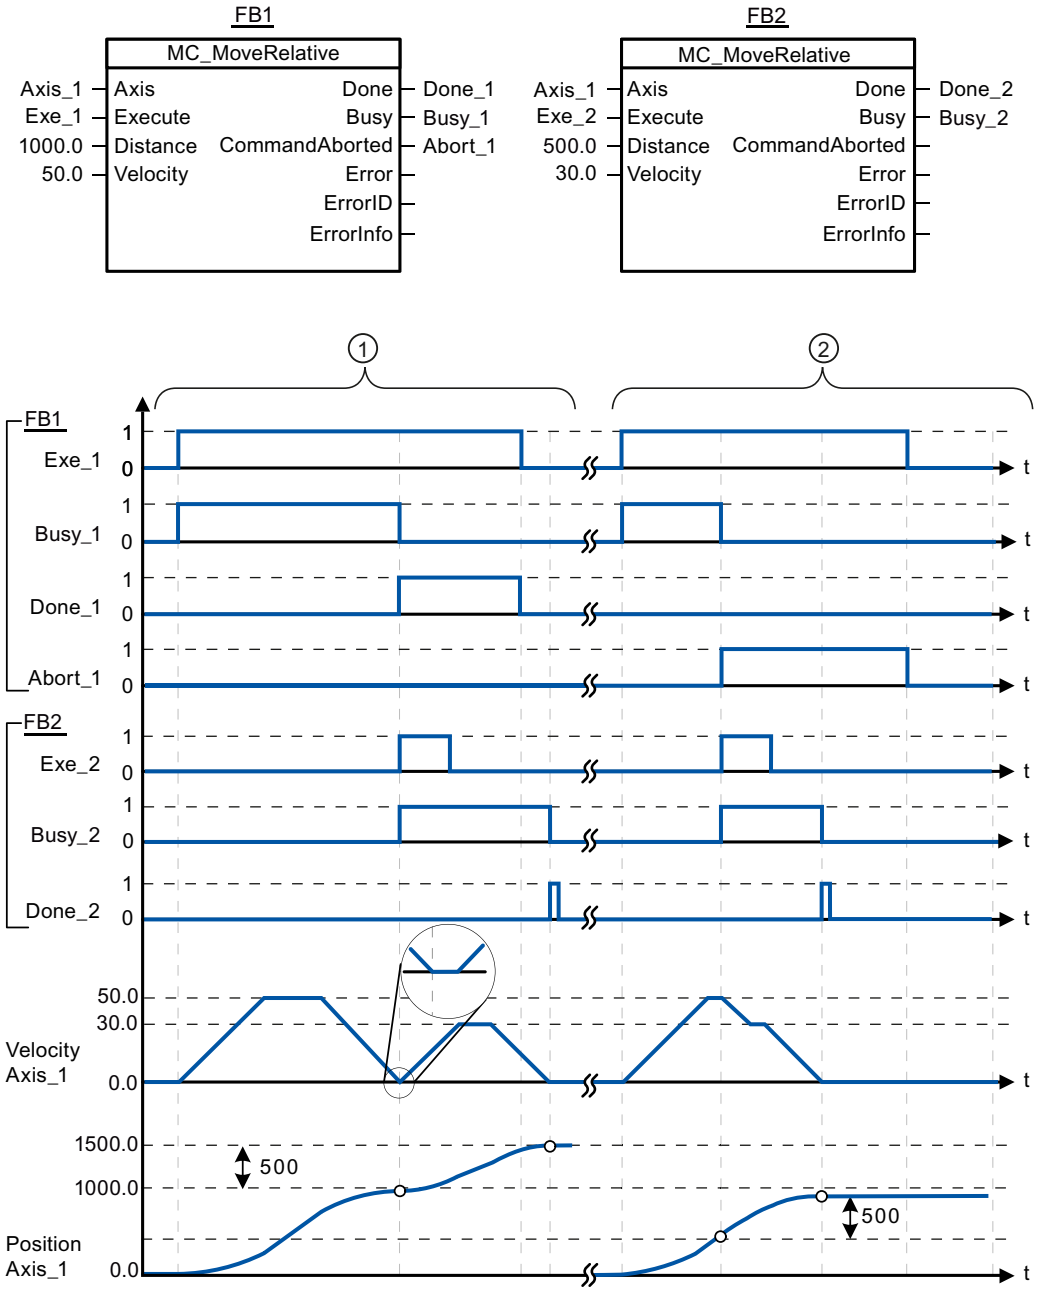
MC_Reset: Acknowledge fault as of V4 (Page 3379)

MC_MoveRelative: Function chart as of V4

Function chart



The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 10.0

①	The axis is moved by an MC_MoveRelative command by the distance ("Distance") 1000.0. When the axis reaches the target position, this is signaled via "Done_1". When "Done_1" = TRUE, another MC_MoveRelative command, with travel distance 500.0, is started. Because of the response times (e.g., cycle time of user program, etc.), the axis comes to a standstill briefly (see zoomed-in detail). When the axis reaches the new target position, this is signaled via "Done_2".
②	An active MC_MoveRelative command is aborted by another MC_MoveRelative command. The abort is signaled via "Abort_1". The axis is then moved at the new velocity by the new distance ("Distance") 500.0. When the new target position is reached, this is signaled via "Done_2".

See also

MC_MoveRelative: Relative positioning of axes as of V4 (Page 3391)

MC_MoveVelocity

MC_MoveVelocity: Move axes at preset rotational speed as of V4

Description

The Motion Control instruction "MC_MoveVelocity" moves the axis constantly at the specified velocity.

Requirements

- The positioning axis technology object has been configured correctly.
- The axis is enabled.

Override response

MC_MoveVelocity can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_MoveVelocity command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command

- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Velocity	INPUT	REAL	10.0	Velocity specification for axis motion Limit values: Start/stop velocity ≤ |Velocity ≤ maximum velocity (Velocity = 0.0 is permitted)	
Direction	INPUT	INT	0	Direction specification	
				0	Direction of rotation corresponds to the sign of the value in parameter "Velocity"
				1	Positive direction of rotation (The sign of the value in parameter "Velocity" is ignored)
				2	Negative direction of rotation (The sign of the value in parameter "Velocity" is ignored)
Current	INPUT	BOOL	FALSE	Maintain current velocity	
				FALSE	"Maintain current velocity" is deactivated. The values of parameters "Velocity" and "Direction" are used.
				TRUE	"Maintain current velocity" is activated. The values in parameters "Velocity" and "Direction" are not taken into account. When the axis resumes motion at the current velocity, the "InVelocity" parameter returns the value TRUE.
InVelocity	OUTPUT	BOOL	FALSE	TRUE	• "Current" = FALSE: The velocity specified in parameter "Velocity" was reached. • "Current" = TRUE: The axis travels at the current velocity at the start time.
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7477) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7477) for parameter "ErrorID"	

Note

PLCopen Version 2.0

The Motion Control instruction "MC_MoveVelocity" is compatible to PLCopen Version 2.0 as of V4.

The "InVelocity" and "Busy" parameters show their status regardless of the "Execute" parameter until the command is overridden or stopped by an error. For more information, refer to the section " Tracking active commands (Page 7450).

Behavior with zero setpoint velocity (Velocity = 0.0)

An MC_MoveVelocity command with "Velocity" = 0.0 (such as an MC_Halt command) aborts active motion commands and stops the axis with the configured deceleration.

When the axis comes to a standstill, output parameter "InVelocity" indicates TRUE for at least one program cycle.

"Busy" indicates the value TRUE during the deceleration process and changes to FALSE together with "InVelocity". If parameter "Execute" = TRUE is set, "InVelocity" and "Busy" are latched.

When the "MC_MoveVelocity" command is started, status bit "SpeedCommand" is set in the technology object. Status bit "ConstantVelocity" is set upon axis standstill. Both bits are adapted to the new situation when a new motion command is started.

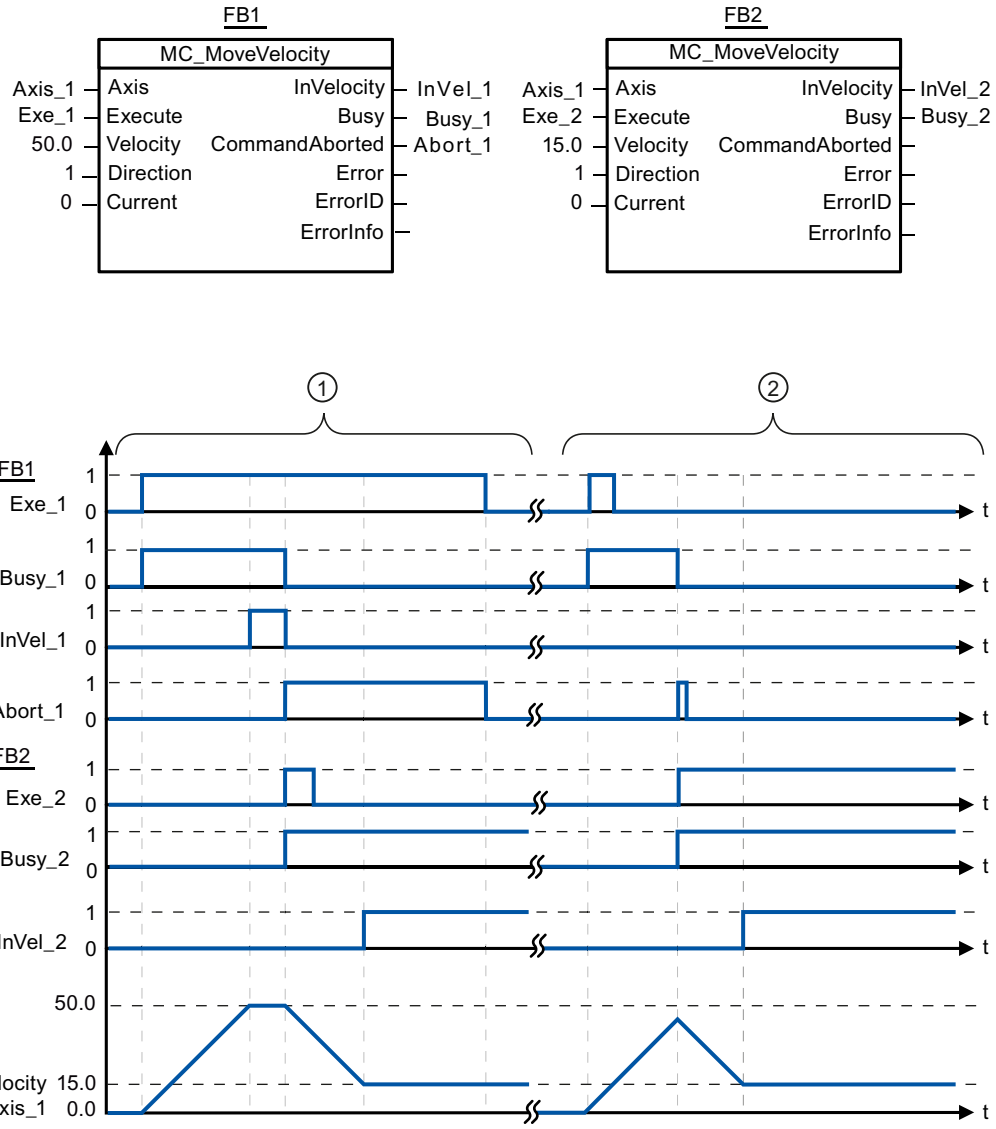
MC_MoveVelocity: Function chart as of V4

Function chart



The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 10.0

①	An active MC_MoveVelocity command signals via "InVel_1" that its target velocity has been reached. It is then aborted by another MC_MoveVelocity command. The abort is signaled via "Abort_1". When the new target velocity 15.0 is reached, this is signaled via "InVel_2". The axis then continues moving at the new constant velocity.
②	An active MC_MoveVelocity command is aborted by another MC_MoveVelocity command prior to reaching its target velocity. The abort is signaled via "Abort_1". When the new target velocity 15.0 is reached, this is signaled via "InVel_2". The axis then continues moving at the new constant velocity.

MC_MoveVelocity: Move axes at preset rotational speed as of V4 (Page 3395)

MC_MoveJog

MC_MoveJog: Move axes in jog mode as of V4

Description

Motion control instruction "MC_MoveJog" moves the axis constantly at the specified velocity in jog mode. You use this Motion Control instruction, for example, for testing and commissioning purposes.

Requirements

- The positioning axis technology object has been configured correctly.
- The axis is enabled.

Override response

The MC_MoveJog command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_MoveJog command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis	-	Axis technology object	
JogForward	INPUT	BOOL	FALSE	As long as the parameter is TRUE, the axis moves in the positive direction at the velocity specified in parameter "Velocity".	
JogBackward	INPUT	BOOL	FALSE	As long as the parameter is TRUE, the axis moves in the negative direction at the velocity specified in parameter "Velocity".	
If both parameters are simultaneously TRUE, the axis stops with the configured deceleration. An error is indicated in parameters "Error", "ErrorID", and "ErrorInfo".					
Velocity	INPUT	REAL	10.0	Preset velocity for jog mode Limit values: Start/stop velocity ≤ velocity ≤ maximum velocity	
InVelocity	OUTPUT	BOOL	FALSE	TRUE	The velocity specified in parameter "Velocity" was reached.
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7477) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7477) for parameter "ErrorID"

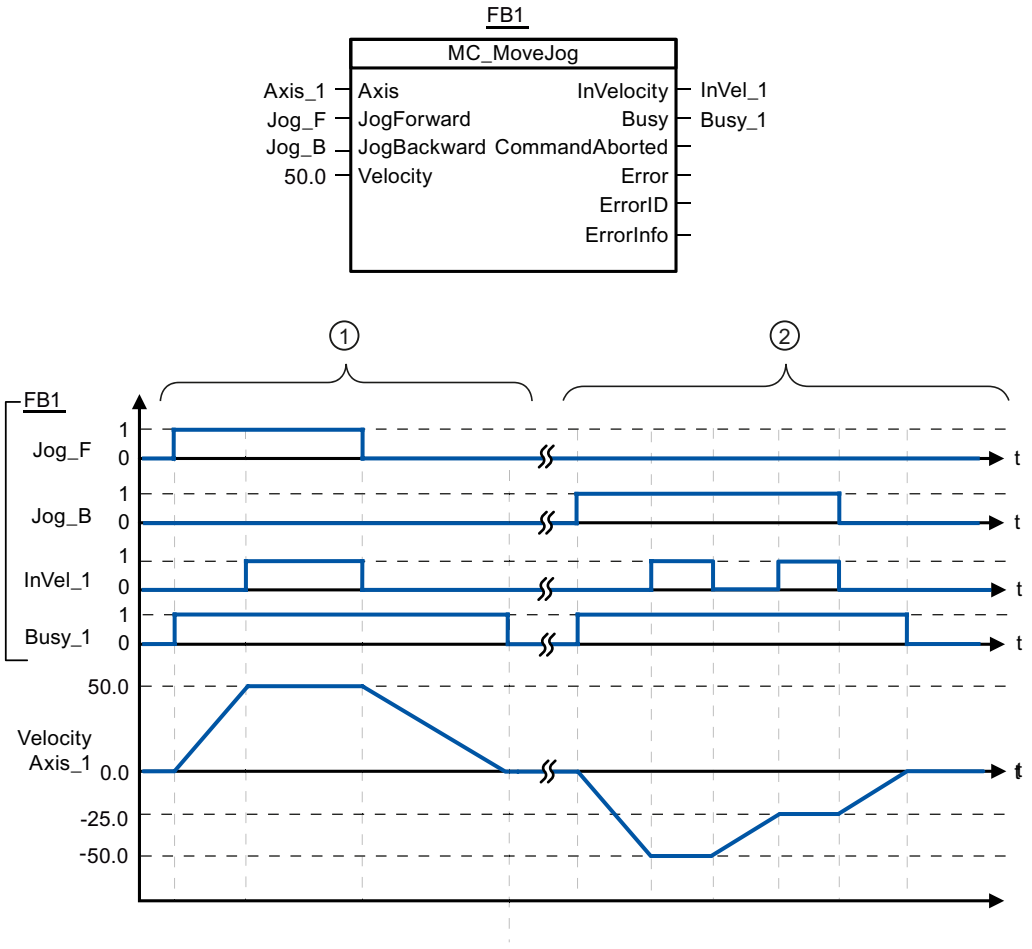
S7-1200 Motion Control V1...3 (Page 3410)

MC_MoveJog: Function chart as of V4

Function chart



The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 5.0

①	The axis is moved in the positive direction in jog mode via "Jog_F". When the target velocity 50.0 is reached, this is signaled via "InVel_1". After "Jog_F" is reset, the axis is braked to a standstill.
②	The axis is moved in the negative direction in jog mode via "Jog_B". When the target velocity -50.0 is reached, this is signaled via "InVel_1". When "Jog_B" is set, the value at parameter "Velocity" changes to 25.0. "InVel_1" is reset and the axis is braked. When the new target velocity -25.0 is reached, this is signaled via "InVel_1". After "Jog_B" is reset, the axis is braked to a standstill.

MC_MoveJog: Move axes in jog mode as of V4 (Page 3399)

MC_CommandTable

MC_CommandTable: Run axis commands as motion sequence as of V4

Description

The Motion Control instruction "MC_CommandTable" combines multiple individual axis control commands in one movement sequence. "MC_CommandTable" is available for axes with drive connection via PTO (Pulse Train Output).

Requirements

- The positioning axis technology object has been inserted and correctly configured.
- The drive is connected via PTO (Pulse Train Output).
- The command table technology object has been inserted and correctly configured.
- The axis is enabled.

Override response

The MC_CommandTable command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_CommandTable command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The active Motion Control command is canceled by the start of the first "Positioning Relative", "Positioning Absolute", "Velocity set point" or "Halt" command.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis	-	Axis technology object	
CommandTable	INPUT	TO_CommandTable	-	Command table technology object	
Execute	INPUT	BOOL	FALSE	Command table start with positive edge	
StartStep	INPUT	INT	1	Defines the step at which the execution of the command table should begin Limit values: 1 ≤ StartStep ≤ EndStep	
EndStep	INPUT	INT	32	Defines the step up to which the execution of command table should take place Limit values: StartStep ≤ EndStep ≤ 32	
Done	OUTPUT	BOOL	FALSE	TRUE	Command table has been successfully executed
Busy	OUTPU	BOOL	FALSE	TRUE	The command table is being executed
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The command table was canceled by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command table. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7477) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7477) for parameter "ErrorID"	
CurrentStep	OUTPUT	INT	0	Step in command table currently being executed	
StepCode	OUTPUT	WORD	16#0000	User-defined numerical value / bit pattern of the step currently being executed

MC_MoveJog: Move axes in jog mode as of V4 (Page 3399)

MC_ChangeDynamic

MC_ChangeDynamic: Change dynamic settings of axis as of V4

Description

Motion Control instruction "MC_ChangeDynamic" allows you to change the following settings of the axis:

- Change the ramp-up time (acceleration) value
- Change the ramp-down time (deceleration) value
- Change the emergency stop ramp-down time (emergency stop deceleration) value
- Change the smoothing time (jerk) value

For the effectiveness of the change, refer to the description of the tag (Page 7498).

Requirements

The positioning axis technology object has been configured correctly.

Override response

A MC_ChangeDynamic command cannot be aborted by any other Motion Control command.

A new MC_ChangeDynamic command does not abort any active Motion Control commands.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
ChangeRampUp	INPUT	BOOL	FALSE	TRUE	Change ramp-up time in line with input parameter "RampUpTime"
RampUpTime	INPUT	REAL	5.00	Time (in seconds) to accelerate axis from standstill to configured maximum velocity without jerk limit. The change will influence the tag <Axis name>. Config.DynamicDefaults.Acceleration. For the effectiveness of the change, refer to the description of this tag.	
ChangeRampDown	INPUT	BOOL	FALSE	TRUE	Change ramp-down time to correspond to input parameter "RampDownTime"

Parameter	Declaration	Data type	Default value	Description	
RampDownTime	INPUT	REAL	5.00	Time (in seconds) to decelerate axis from the configured maximum velocity to standstill without jerk limiter. The change will influence the tag <Axis name>. Config.DynamicDefaults.Deceleration . For the effectiveness of the change, refer to the description of this tag.	
ChangeEmergency	INPUT	BOOL	FALSE	TRUE	Change emergency stop ramp-down time in line with input parameter "EmergencyRampTime"
EmergencyRampTime	INPUT	REAL	2.00	Time (in seconds) to decelerate the axis from configured maximum velocity to standstill without jerk limiter in emergency stop mode. The change will influence the tag <Axis name>. Config.DynamicDefaults.EmergencyDeceleration . For the effectiveness of the change, refer to the description of this tag.	
ChangeJerkTime	INPUT	BOOL	FALSE	TRUE	Change smoothing time according to the input parameter "JerkTime"
JerkTime	INPUT	REAL	0.25	Smoothing time (in seconds) used for the axis acceleration and deceleration ramps The change will influence the tag <Axis name>. Config.DynamicDefaults.Jerk . For the effectiveness of the change, refer to the description of this tag.	
Done	OUTPUT	BOOL	FALSE	TRUE	The changed values have been written to the technology data block. The description of the tags will show when the change becomes effective.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7477) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7477) for parameter "ErrorID"	

Note

At the input parameters "RampUpTime", "RampDownTime", "EmergencyRampTime" and "JerkTime", values can be entered which exceed the admissible limits of the resulting parameters: "Acceleration", "Deceleration", "Emergency stop deceleration" and "Jerk".

Ensure that your inputs are within the valid range, taking into consideration the equations and limits in section "Dynamic (Page 7381)".

MC_ReadParam

MC_ReadParam: Continuously read motion data of a positioning axis as of V4

Description

The Motion Control instruction "MC_ReadParam" enables continuous reading of motion data and status messages of an axis. The current value of the corresponding tags is determined at the start of the command.

The following motion data and status messages can be read:

- As of technology version V4:
  - Setpoint position of the axis
  - Setpoint and actual velocity of the axis
  - Current distance of axis from target position
  - Target position of the axis
- Additional as of technology version V5:
  - Actual position of the axis
  - Actual velocity of the axis
  - Current following error
  - Drive status
  - Encoder status
  - Status bits
  - Error bits

Requirements

The positioning axis technology object has been configured correctly.

Override response

A MC_ReadParam command cannot be aborted by any other Motion Control command.

A new MC_ReadParam command does not abort any active Motion Control commands.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Enable	INPUT	BOOL	FALSE	TRUE	Read the tag specified with the "Parameter" and store the value in the destination address specified with "Value".
				FALSE	Do not update assigned motion data
Parameter	INPUT	VARIANT (REAL)	-	VARIANT pointer to the value to be read. The following tags are permitted: • <Axis name>.Position • <Axis name>.Velocity • <Axis name>.ActualPosition • <Axis name>.ActualVelocity • <Axis name>.StatusPositioning.<Tag name> • <Axis name>.StatusDrive.<Tag name> • <Axis name>.StatusSensor.<Tag name> • <Axis name>.StatusBits.<Tag name> • <Axis name>.ErrorBits.<Tag name> The description of the tags named and the tag structures can be found in the Appendix Tags of the positioning axis technology object as of V4 (Page 7498).	
Value	INOUT	VARIANT (REAL)	-	VARIANT pointer to the target tag or destination address to which the read value is to be written.	
Valid	OUTPUT	BOOL	FALSE	TRUE	The read value is valid.
				FALSE	The read value is invalid.
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7477) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7477) for parameter "ErrorID"

MC_WriteParam

MC_WriteParam: Write tag of positioning axis as of V4

Description

Motion Control instruction "MC_WriteParam" enables the writing of tags of the positioning axis technology object in the user program. In contrast to the value assignment of the tags in the user program, "MC_WriteParam" can also change values of read-only tags.

You can learn about the tags, the conditions under which they can be written and the time at which they take effect in the description of the technology object tags (Page 7498).

With drive connection via PROFIdrive/analog output, some parameters require a restart of the technology object after writing with "MC_WriteParam". If a restart is required, this will be indicated in the tags of the technology object <Axis name>.StatusBits.RestartRequired. The change of the parameter value becomes effective with these parameters after the restart with the enabling of the technology object (MC_Power.Status = TRUE).

Requirements

- The positioning axis technology object has been configured correctly.
- To write tags that are read-only in the user program, the axis must be disabled.

Override response

A MC_WriteParam command cannot be aborted by any other Motion Control command.

A new MC_WriteParam command does not abort any active Motion Control commands.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Parameter	INPUT	VARIANT (BOOL, INT, DINT, REAL)	-	VARIANT pointer to the technology object tag (Page 7498) positioning axis (destination address) to be written	
Value	INPUT	VARIANT (BOOL, INT, DINT, REAL)	-	VARIANT pointer to the value to be written (source address)	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Done	OUTPUT	BOOL	FALSE	TRUE	Value was written
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7477) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7477) for parameter "ErrorID"

S7-1200 Motion Control V1...3

MC_Power

MC_Power: Enable, disable axis V1...3

Description

The Motion Control instruction "MC_Power" enables or disables an axis.

Requirements

- The axis technology object has been configured correctly.
- There is no pending enable-inhibiting error.

Override response

Execution of "MC_Power" cannot be aborted by a Motion Control command.

Disabling the axis (input parameter "Enable" = FALSE) aborts all Motion Control commands for the associated technology object in accordance with the selected "StopMode".

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis_1	-	Axis technology object	
Enable	INPUT	BOOL	FALSE	TRUE	Motion Control attempts to enable the axis.
				FALSE	All current jobs are interrupted in accordance with the "StopMode" configured. The axis is stopped and disabled.
StopMode	INPUT	INT	0	0	Emergency stop If a request to disable the axis is pending, the axis brakes at the configured emergency stop deceleration. The axis is disabled after reaching standstill.
				1	Immediate stop If a request to disable the axis is pending, this axis is disabled without deceleration. The pulse output is stopped immediately.
				2	Emergency stop with jerk control If a request to disable the axis is pending, the axis brakes at the configured emergency stop deceleration. If the jerk control is activated, the configured jerk is taken into account. The axis is disabled after reaching standstill.

Parameter	Declaration	Data type	Default value	Description	
Status	OUTPUT	BOOL	FALSE	Status of axis enable	
				FALSE	The axis is disabled. The axis does not execute Motion Control commands and does not accept any new commands (exception: MC_Reset command). The axis is not homed. Upon disabling, the status does not change to FALSE until the axis reaches a standstill.
				TRUE	The axis is enabled. The axis is ready to execute Motion Control commands. Upon axis enabling, the status does not change to TRUE until the signal "Drive ready" is pending. If the "Drive ready" drive interface was not configured in the axis configuration, the status changes to TRUE immediately.
Busy	OUTPUT	BOOL	FALSE	TRUE	"MC_Power" is active.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred in Motion Control instruction "MC_Power" or in the associated technology object. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7555) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7555) for parameter "ErrorID"	

Note

If the axis is switched off due to an error, it will be enabled again automatically after the error has been eliminated and acknowledged. This requires that the input parameter "Enable" has retained the value TRUE during this process.

Enabling an axis with configured drive interface

To enable the axis, follow these steps:

1. Check the requirements indicated above.
2. Initialize input parameter "StopMode" with the desired value. Set the input parameter "Enable" to TRUE.
   The enable output for "Drive enabled" changes to TRUE to enable the power to the drive.
   The CPU waits for the "Drive ready" signal of the drive.
   When the "Drive ready" signal is available at the configured Ready input of the CPU, the axis is enabled. The output parameter "Status" and the tag of the technology object <Axis name>.StatusBits.Enable indicate the value TRUE.

Enabling an axis without configured drive interface

To enable the axis, follow these steps:

1. Check the requirements indicated above.
2. Initialize input parameter "StopMode" with the desired value. Set the input parameter "Enable" to TRUE. The axis is enabled. The output parameter "Status" and the tag of the technology object <Axis name>.StatusBits.Enable indicate the value TRUE.

Disabling an axis

To disable an axis, you can follow the steps described below:

1. Bring the axis to a standstill.
   You can identify when the axis is at a standstill in the tag of the technology object <Axis name>.StatusBits.StandStill.
2. Set input parameter "Enable" to FALSE after standstill is reached.
3. If output parameters "Busy" and "Status" and the tag of technology object <Axis name>.StatusBits.Enable indicate the value FALSE, disabling of the axis is complete.

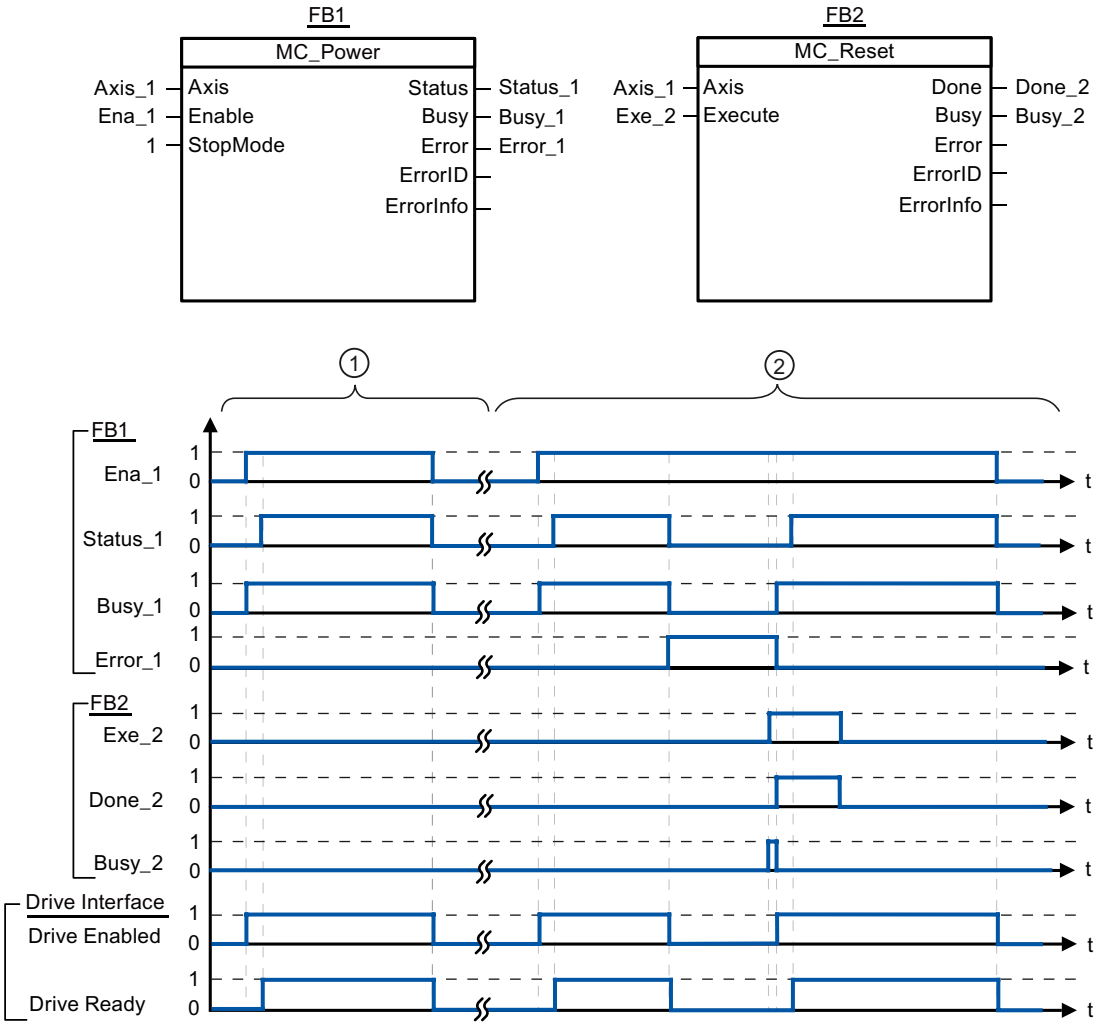
Function chart



①	An axis is enabled and then disabled again. When the drive has signaled "Drive ready" back to the CPU, the successful enable can be read out via "Status_1".
②	Following an axis enable, an error has occurred that caused the axis to be disabled. The error is eliminated and acknowledged with "MC_Reset". The axis is then enabled again.

See also

MC_Power: Enable, disable axis V1...3 (Page 3410)

MC_Reset

MC_Reset: Acknowledge fault V1...3

Description

Motion Control instruction "MC_Reset" can be used to acknowledge "Operating error with axis stop" and "Configuration error". The errors that require acknowledgement can be found in the "List of ErrorIDs and ErrorInfos" under "Remedy".

From version V3.0, the axis configuration can be downloaded to the work memory in RUN operating mode.

Requirements

- The axis technology object has been configured correctly.
- The cause of a pending configuration error requiring acknowledgement has been eliminated (for example, acceleration in positioning axis technology object has been changed to a valid value).

Override response

The MC_Reset command cannot be aborted by any other Motion Control command.

The new MC_Reset command does not abort any other active Motion Control commands.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis_1	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Restart	INPUT	BOOL	FALSE	(From version V3.0)	
				TRUE	Download the axis configuration from the load memory to the work memory. The command can only be executed when the axis is disabled. Refer to the notes on Download to the CPU (Page 7434).
				FALSE	Acknowledges pending errors
Done	OUTPUT	BOOL	FALSE	TRUE	Error has been acknowledged.
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7555) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7555) for parameter "ErrorID"	

Acknowledging an error requiring acknowledgement with MC_Reset

To acknowledge an error, follow these steps:

1. Check the requirements indicated above.
2. Start the acknowledgement of the error with a rising edge at input parameter "Execute".
3. If output parameter "Done" indicates the value TRUE and tag of technology object <Axis name>.StatusBits.Error the value FALSE, the error has been acknowledged.

MC_ChangeDynamic: Change dynamic settings of axis V2...3 (Page 3437)

MC_Home

MC_Home: Home axes, set reference point V1...3

Description

Motion Control instruction "MC_Home" is used to match the axis coordinates to the real, physical drive position. Homing is required for absolute positioning of the axis. The following types of homing can be executed:

- Active homing (Mode = 3)
  The homing procedure is executed automatically.
- Passive homing (Mode = 2)
  During passive homing, the "MC_Home" Motion Control instruction does not carry out any homing motion. The traversing motion required for this must be implemented by the user via other Motion Control instructions. When the homing switch is detected, the axis is homed.

- Direct homing absolute (Mode = 0)
  The current axis position is set to the value of parameter "Position".
- Direct homing relative (Mode = 1)
  The current axis position is offset by the value of parameter "Position".

Requirements

- The axis technology object has been configured correctly.
- The axis is enabled.
- No MC_CommandTable command may be active upon start with Mode = 0, 1, or 2.

Override response

The override response depends on the selected mode:

Mode = 0, 1

The MC_Home command cannot be aborted by any other Motion Control command.

The MC_Home command does not abort any active Motion Control commands. Position-related motion commands are resumed after homing according to the new homing position (value at input parameter: "Position").

Mode = 2

The MC_Home command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 2, 3

The new MC_Home command aborts the following active Motion Control command:

- MC_Home command Mode = 2

Position-related motion commands are resumed after homing according to the new homing position (value at input parameter: "Position").

Mode = 3

The MC_Home command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_Home command aborts the following active Motion Control commands:

- MC_Home command Mode = 2, 3
- MC_Halt command
- MC_MoveAbsolute command

- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis_1	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Position	INPUT	REAL	0.0	• Mode = 0, 2, and 3 Absolute position of axis after completion of the homing operation • Mode = 1 Correction value for the current axis position Limit values: $-1.0e^{12} \leq$ Position $\leq 1.0e^{12}$	
Mode	INPUT	INT	0	Homing mode	
				0	Direct homing absolute New axis position is the position value of parameter "Position".
				1	Direct homing relative New axis position is the current axis position + position value of parameter "Position".
				2	Passive homing Homing according to the axis configuration. Following homing, the value of parameter "Position" is set as the new axis position.
				3	Active homing Homing procedure in accordance with the axis configuration. Following homing, the value of parameter "Position" is set as the new axis position.
Done	OUTPUT	BOOL	FALSE	TRUE	Command completed
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7555) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7555) for parameter "ErrorID"	

Note

Axis homing is lost under the following conditions:

- Disabling of axis by the "MC_Power" Motion Control instruction
- Changeover between automatic mode and manual control
- Upon start of active homing. After successful completion of the homing operation, axis homing is again available.
- After POWER OFF -> POWER ON of the CPU
- After CPU restart (RUN-STOP -> STOP-RUN)

Homing an axis

To home the axis, follow these stops:

1. Check the requirements indicated above.
2. Initialize the necessary input parameters with values, and start the homing operation with a rising edge at input parameter "Execute"
3. If output parameter "Done" and technology object tag <Axis name>.StatusBits.HomingDone indicate the value TRUE, homing is complete.

MC_Halt

MC_Halt: Halt axes V1...3

Description

The "MC_Halt" Motion Control instruction stops all movements and brings the axis to a standstill with the configured deceleration. The standstill position is not defined.

Requirements

- The axis technology object has been configured correctly.
- The axis is enabled.

Override response

The MC_Halt command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_Halt command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis_1	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Done	OUTPUT	BOOL	FALSE	TRUE	Zero velocity reached
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.

Parameter	Declaration	Data type	Default value	Description	
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7555) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7555) for parameter "ErrorID"

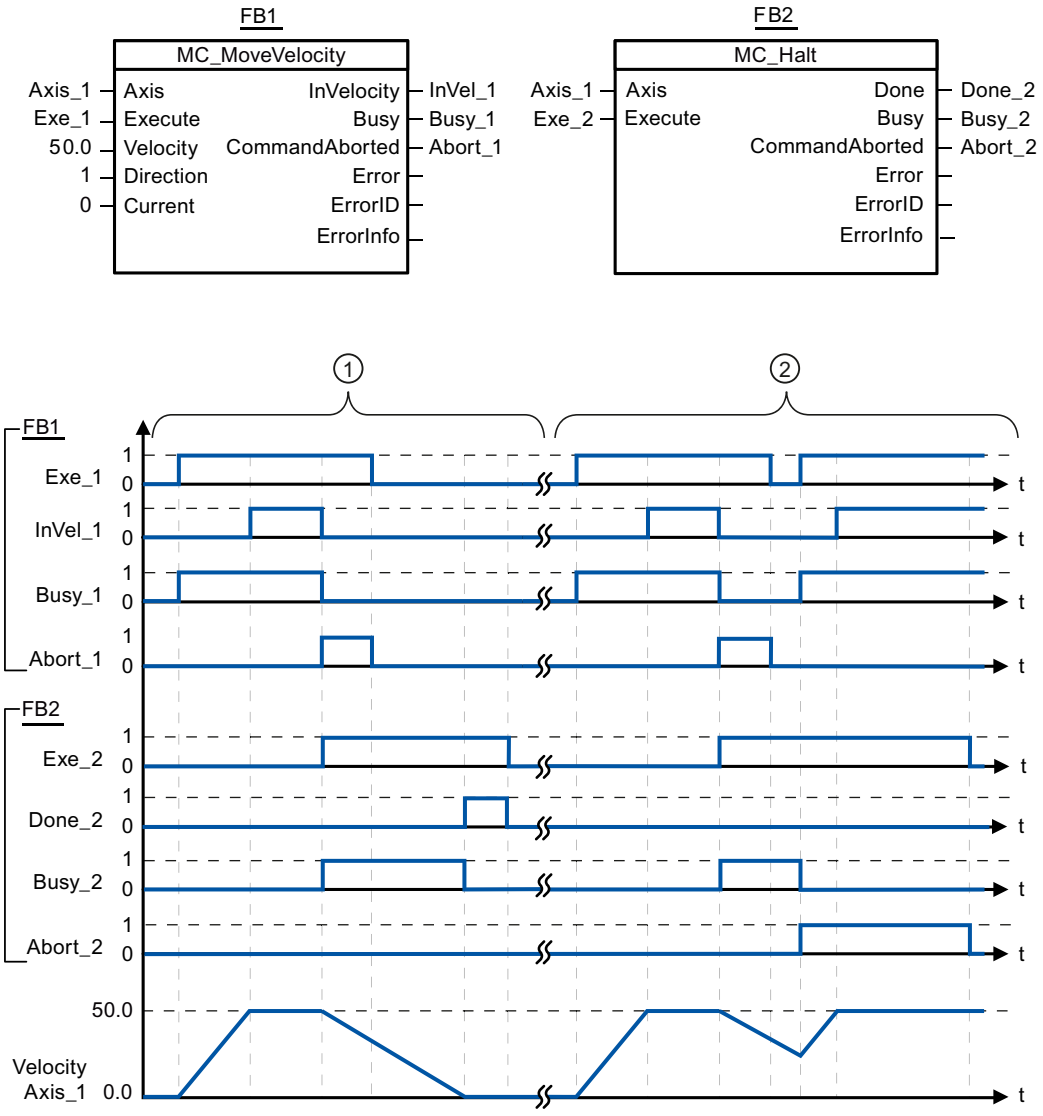
MC_Halt: Function chart V1...3

Function chart



The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 5.0

①	The axis is braked by an MC_Halt command until it comes to a standstill. The axis standstill is signaled via "Done_2".
②	While an MC_Halt command is braking the axis, this command is aborted by another motion command. The abort is signaled via "Abort_2".

MC_Halt: Halt axes V1...3 (Page 3419)

MC_MoveAbsolute

MC_MoveAbsolute: Absolute positioning of axes V1...3

Description

The "MC_MoveAbsolute" Motion Control instruction starts an axis positioning motion to move it to an absolute position.

Requirements

- The axis technology object has been configured correctly.
- The axis is enabled.
- The axis is homed.

Override response

The MC_MoveAbsolute command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_MoveAbsolute command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis_1	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Position	INPUT	REAL	0.0	Absolute target position Limit values: $-1.0e^{12} \leq$ Position $\leq 1.0e^{12}$	
Velocity	INPUT	REAL	10.0	Velocity of axis This velocity is not always reached on account of the configured acceleration and deceleration and the target position to be approached. Limit values: Start/stop velocity ≤ Velocity ≤ maximum velocity	
Done	OUTPUT	BOOL	FALSE	TRUE	Absolute target position reached
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7555) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7555) for parameter "ErrorID"

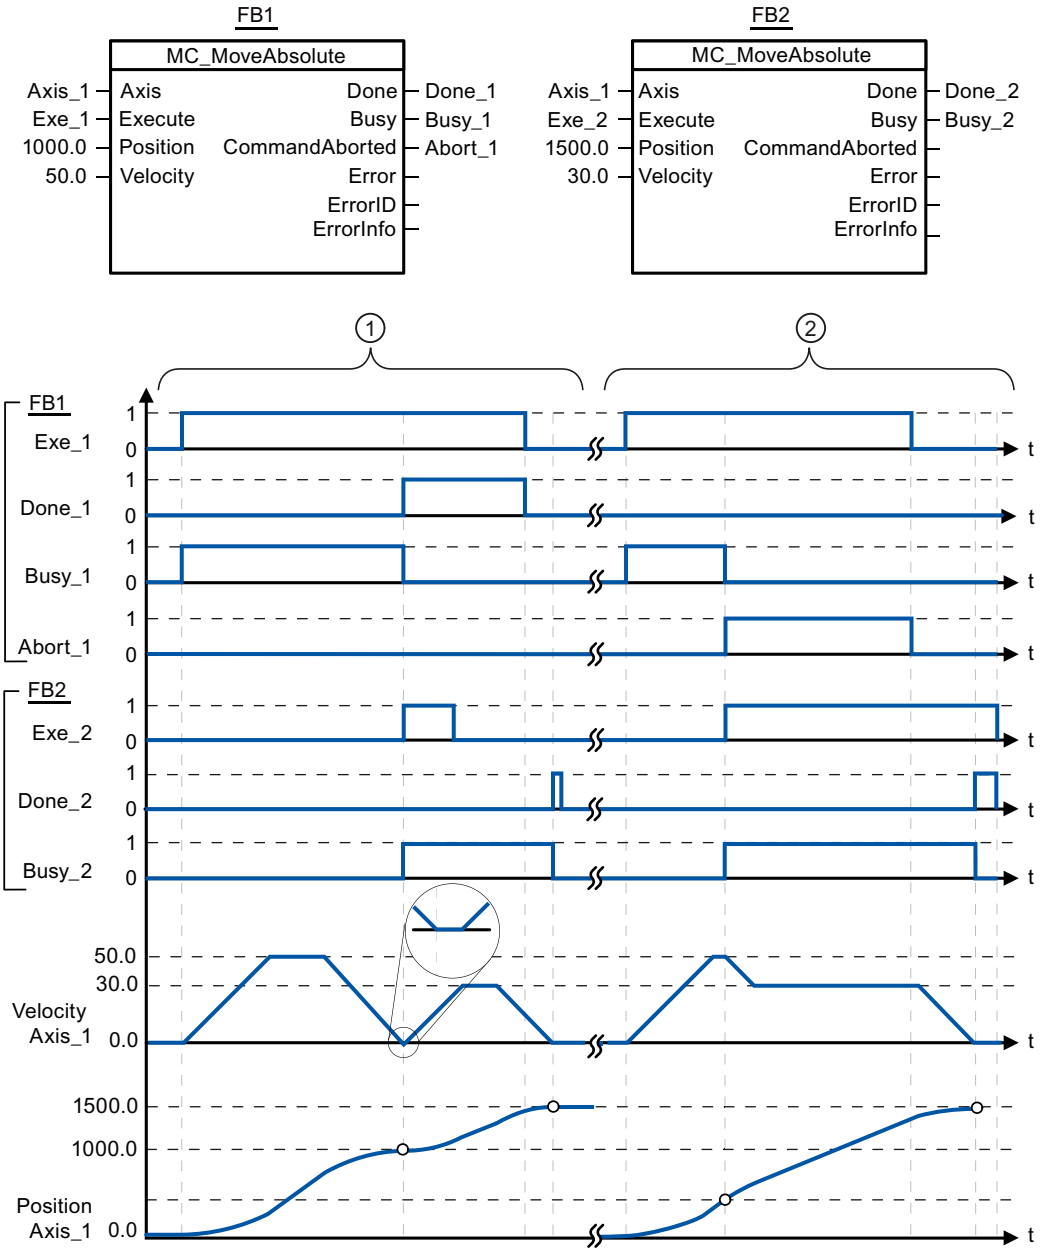
MC_ChangeDynamic: Change dynamic settings of axis V2...3 (Page 3437)

MC_MoveAbsolute: Function chart V1...3

Function chart



The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 10.0

①	An axis is moved to absolute position 1000.0 with an MC_MoveAbsolute command. When the axis reaches the target position, this is signaled via "Done_1". When "Done_1" = TRUE, another MC_MoveAbsolute command, with target position 1500.0, is started. Because of the response times (e.g., cycle time of user program, etc.), the axis comes to a standstill briefly (see zoomed-in detail). When the axis reaches the new target position, this is signaled via "Done_2".
②	An active MC_MoveAbsolute command is aborted by another MC_MoveAbsolute command. The abort is signaled via "Abort_1". The axis is then moved at the new velocity to the new target position 1500.0. When the new target position is reached, this is signaled via "Done_2".

See also

MC_MoveAbsolute: Absolute positioning of axes V1...3 (Page 3422)

MC_MoveRelative

MC_MoveRelative: Relative positioning of axes V1...3

Description

The "MC_MoveRelative" Motion Control instruction starts a positioning motion relative to the start position.

Requirements

- The axis technology object has been configured correctly.
- The axis is enabled.

Override response

The MC_MoveRelative command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_MoveRelative command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command

- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis_1	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Distance	INPUT	REAL	0.0	Travel distance for the positioning operation Limit values: $-1.0e^{12} \leq$ Distance $\leq 1.0e^{12}$	
Velocity	INPUT	REAL	10.0	Velocity of axis This velocity is not always reached on account of the configured acceleration and deceleration and the distance to be traveled. Limit values: Start/stop velocity ≤ Velocity ≤ maximum velocity	
Done	OUTPUT	BOOL	FALSE	TRUE	Target position reached
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7555) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7555) for parameter "ErrorID"

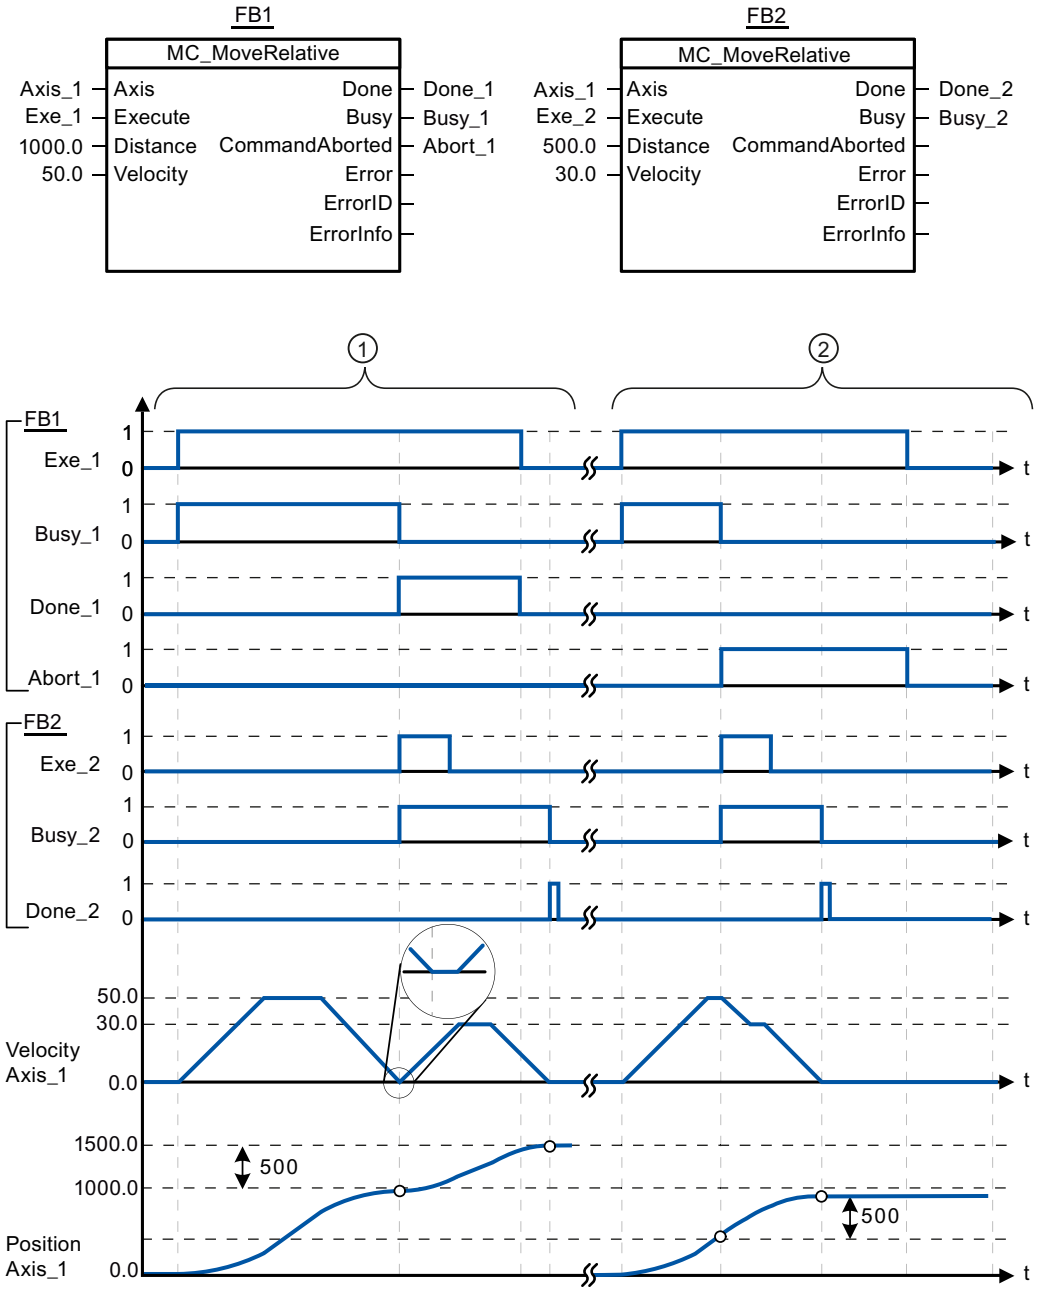
MC_MoveRelative: Function chart V1...3

Function chart



The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 10.0

①	The axis is moved by an MC_MoveRelative command by the distance ("Distance") 1000.0. When the axis reaches the target position, this is signaled via "Done_1". When "Done_1" = TRUE, another MC_MoveRelative command, with travel distance 500.0, is started. Because of the response times (e.g., cycle time of user program, etc.), the axis comes to a standstill briefly (see zoomed-in detail). When the axis reaches the new target position, this is signaled via "Done_2".
②	An active MC_MoveRelative command is aborted by another MC_MoveRelative command. The abort is signaled via "Abort_1". The axis is then moved at the new velocity by the new distance ("Distance") 500.0. When the new target position is reached, this is signaled via "Done_2".

MC_MoveVelocity

MC_MoveVelocity: Move axes at preset rotational speed V1...3

Description

Motion control instruction "MC_MoveVelocity" moves the axis constantly at the specified velocity.

Requirements

- The axis technology object has been configured correctly.
- The axis is enabled.

Override response

MC_MoveVelocity can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_MoveVelocity command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis_1	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Velocity	INPUT	REAL	10.0	Velocity specification for axis motion Limit values: Start/stop velocity ≤ |Velocity ≤ maximum velocity (Velocity = 0.0 is permitted)	
Direction	INPUT	INT	0	Direction specification	
				0	Direction of rotation corresponds to the sign of the value in parameter "Velocity"
				1	Positive direction of rotation (The sign of the value in parameter "Velocity" is ignored)
				2	Negative direction of rotation (The sign of the value in parameter "Velocity" is ignored)
Current	INPUT	BOOL	FALSE	Maintain current velocity	
				FALSE	"Maintain current velocity" is deactivated. The values of parameters "Velocity" and "Direction" are used.
				TRUE	"Maintain current velocity" is activated. The values in parameters "Velocity" and "Direction" are not taken into account. When the axis resumes motion at the current velocity, the "InVelocity" parameter returns the value TRUE.
InVelocity	OUTPUT	BOOL	FALSE	TRUE	• "Current" = FALSE: The velocity specified in parameter "Velocity" was reached. • "Current" = TRUE: The axis travels at the current velocity at the start time.
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.

Parameter	Declaration	Data type	Default value	Description	
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7555) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7555) for parameter "ErrorID"	

Behavior with zero setpoint velocity (Velocity = 0.0)

An MC_MoveVelocity command with "Velocity" = 0.0 (such as an MC_Halt command) aborts active motion commands and stops the axis with the configured deceleration.

When the axis comes to a standstill, output parameter "InVelocity" indicates TRUE for at least one program cycle.

"Busy" indicates the value TRUE during the deceleration process and changes to FALSE together with "InVelocity". If parameter "Execute" = TRUE is set, "InVelocity" and "Busy" are latched.

When the "MC_MoveVelocity" command is started, status bit "SpeedCommand" is set in the technology object. Status bit "ConstantVelocity" is set upon axis standstill. Both bits are adapted to the new situation when a new motion command is started.

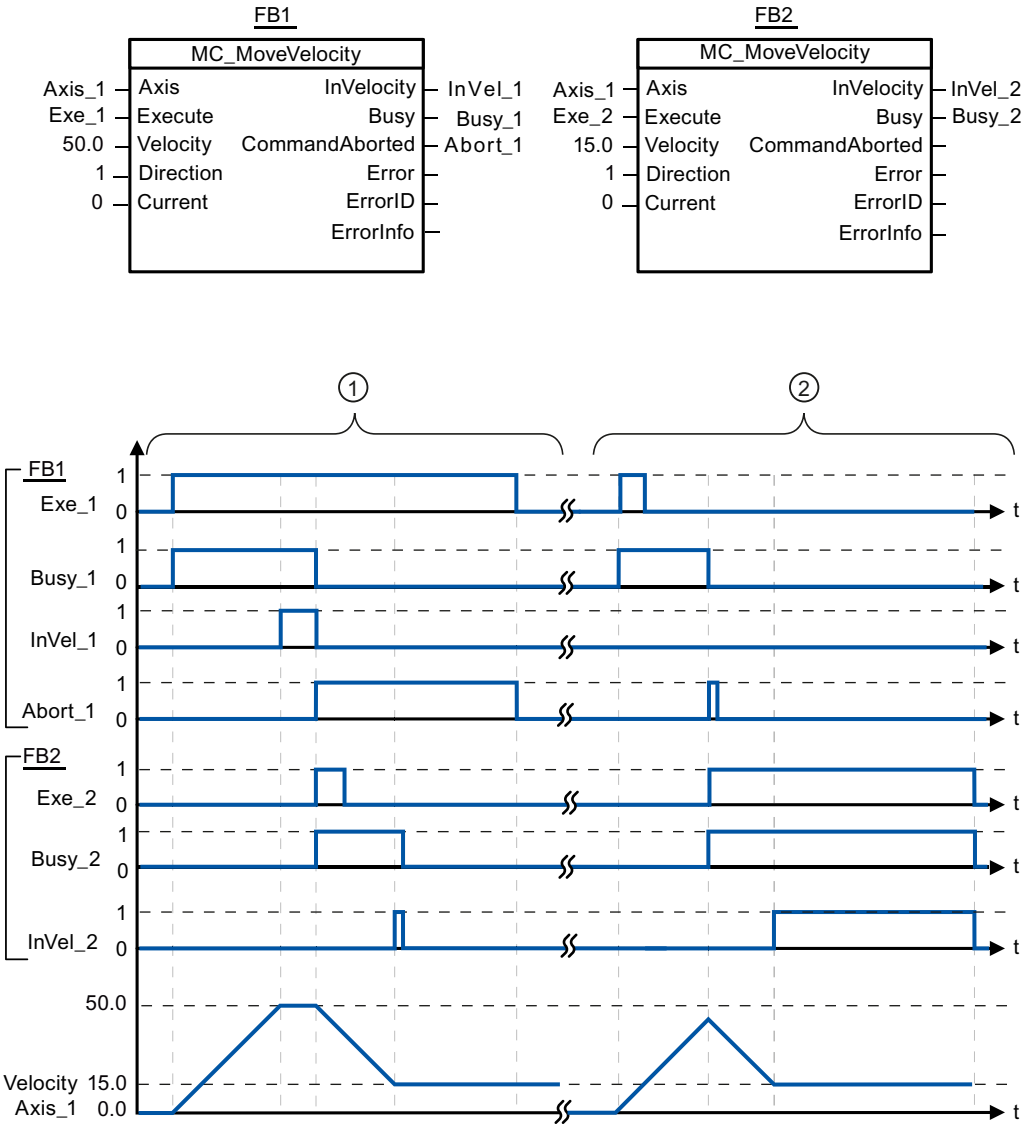
Function chart



The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 10.0

①	An active MC_MoveVelocity command signals via "InVel_1" that its target velocity has been reached. It is then aborted by another MC_MoveVelocity command. The abort is signaled via "Abort_1". When the new target velocity 15.0 is reached, this is signaled via "InVel_2". The axis then continues moving at the new constant velocity.
②	An active MC_MoveVelocity command is aborted by another MC_MoveVelocity command prior to reaching its target velocity. The abort is signaled via "Abort_1". When the new target velocity 15.0 is reached, this is signaled via "InVel_2". The axis then continues moving at the new constant velocity.

MC_MoveJog

MC_MoveJog: Move axes in jog mode V1...3

Description

Motion control instruction "MC_MoveJog" moves the axis constantly at the specified velocity in jog mode. You use this Motion Control instruction, for example, for testing and commissioning purposes.

Requirements

- The axis technology object has been configured correctly.
- The axis is enabled.

Override response

The MC_MoveJog command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_MoveJog command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis_1	-	Axis technology object	
JogForward	INPUT	BOOL	FALSE	As long as the parameter is TRUE, the axis moves in the positive direction at the velocity specified in parameter "Velocity".	
JogBackward	INPUT	BOOL	FALSE	As long as the parameter is TRUE, the axis moves in the negative direction at the velocity specified in parameter "Velocity".	
If both parameters are simultaneously TRUE, the axis stops with the configured deceleration. An error is indicated in parameters "Error", "ErrorID", and "ErrorInfo".					
Velocity	INPUT	REAL	10.0	Preset velocity for jog mode	
				Limit values, instruction version V1.0: Start/stop velocity ≤ |Velocity ≤ maximum velocity	
				Limits, instruction version V2.0: Start/stop velocity ≤ velocity ≤ maximum velocity	
InVelocity	OUTPUT	BOOL	FALSE	TRUE	The velocity specified in parameter "Velocity" was reached.
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7555) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7555) for parameter "ErrorID"

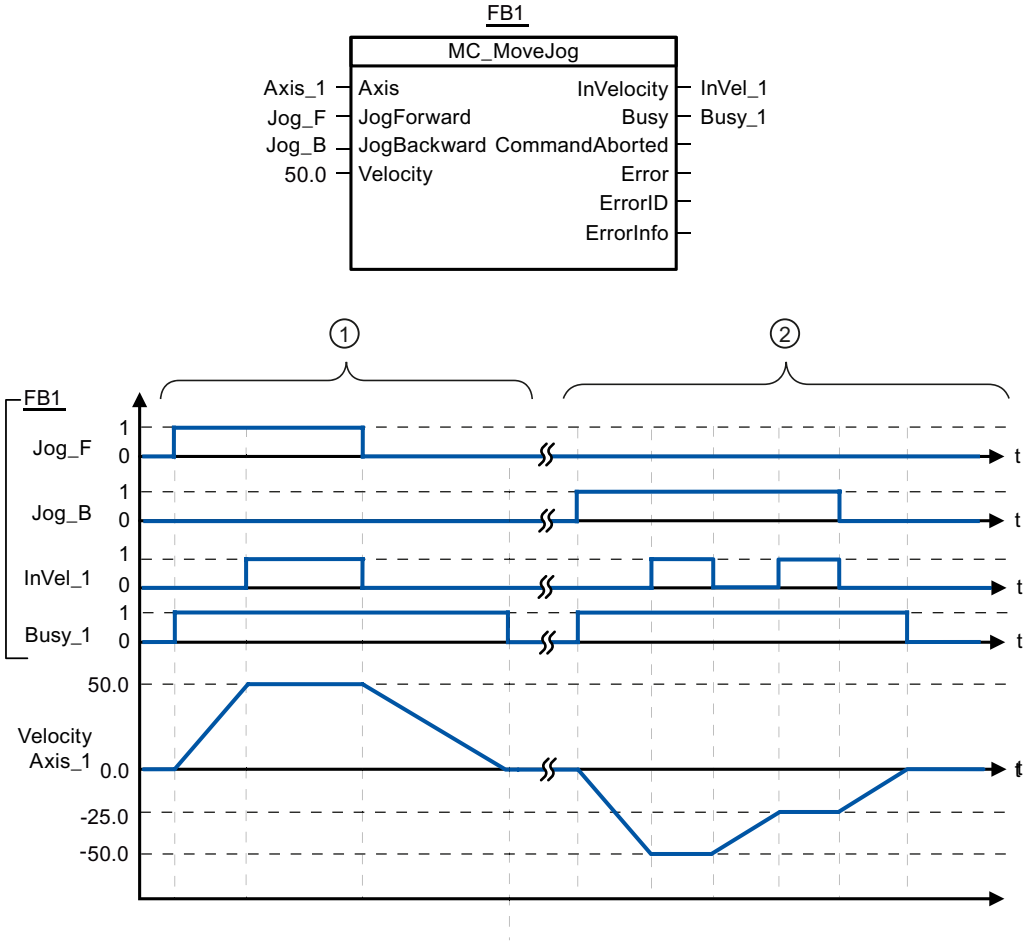
MC_MoveJog: Function chart V1...3

Function chart



The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 5.0

①	The axis is moved in the positive direction in jog mode via "Jog_F". When the target velocity 50.0 is reached, this is signaled via "InVelo_1". After " Jog_F" is reset, the axis brakes again until it comes to a standstill.
②	The axis is moved in the negative direction in jog mode via "Jog_B". When the target velocity 50.0 is reached, this is signaled via "InVelo_1". After " Jog_B" is reset, the axis brakes again until it comes to a standstill.

MC_MoveJog: Move axes in jog mode V1...3 (Page 3432)

MC_CommandTable

MC_CommandTable: Run axis commands as motion sequence V2...3

Description

The Motion Control instruction "MC_CommandTable" combines multiple individual axis control commands in one movement sequence.

Requirements

- The axis technology object has been inserted in V2 and correctly configured.
- The command table technology object has been inserted and correctly configured.
- The axis is enabled.

Override response

The MC_CommandTable command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_CommandTable command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The active Motion Control command is cancelled by the start of the first "Positioning Relative", "Positioning Absolute", "Velocity set point" or "Halt" command.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis_1	-	Axis technology object	
CommandTable	INPUT	TO_CommandTable_1	-	Command table technology object	
Execute	INPUT	BOOL	FALSE	Command table start with positive edge	
StartStep	INPUT	INT	1	Defines the step at which the execution of the command table should begin Limit values: 1 ≤ StartStep ≤ EndStep	
EndStep	INPUT	INT	32	Defines the step up to which the execution of command table should take place Limit values: StartStep ≤ EndStep ≤ 32	
Done	OUTPUT	BOOL	FALSE	TRUE	Command table has been successfully executed
Busy	OUTPU	BOOL	FALSE	TRUE	The command table is being executed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The command table was cancelled by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command table. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7555) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7555) for parameter "ErrorID"	
CurrentStep	OUTPUT	INT	0	Step in command table currently being executed	
StepCode	OUTPUT	WORD	16#0000	User-defined numerical value / bit pattern of the step currently being executed

MC_ChangeDynamic: Change dynamic settings of axis V2...3 (Page 3437)

MC_ChangeDynamic

MC_ChangeDynamic: Change dynamic settings of axis V2...3

Description

Motion Control instruction "MC_ChangeDynamic" allows you to change the following settings of the axis:

- Change the ramp-up time (acceleration) value
- Change the ramp-down time (deceleration) value
- Change the emergency stop ramp-down time (emergency stop deceleration) value
- Change the smoothing time (jerk) value

For the effectiveness of the change, refer to the description of the tag (Page 7568).

Requirements

- The axis technology object has been inserted in Version V2.
- The axis technology object has been configured correctly.

Override response

A MC_ChangeDynamic command cannot be aborted by any other Motion Control command.

A new MC_ChangeDynamic command does not abort any active Motion Control commands.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis_1	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
ChangeRampUp	INPUT	BOOL	FALSE	TRUE	Change ramp-up time in line with input parameter "RampUpTime"
RampUpTime	INPUT	REAL	5.00	Time (in seconds) to accelerate axis from standstill to configured maximum velocity without jerk limit. The change will influence the tag <Axis name>. Config.DynamicDefaults.Acceleration. For the effectiveness of the change, refer to the description of this tag.	
ChangeRampDown	INPUT	BOOL	FALSE	TRUE	Change ramp-down time in line with input parameter "RampDownTime"
RampDownTime	INPUT	REAL	5.00	Time (in seconds) to decelerate axis from the configured maximum velocity to standstill without jerk limiter. The change will influence the tag <Axis name>. Config.DynamicDefaults.Deceleration . For the effectiveness of the change, refer to the description of this tag.	

Parameter	Declaration	Data type	Default value	Description	
ChangeEmergency	INPUT	BOOL	FALSE	TRUE	Change emergency stop ramp-down time in line with input parameter "EmergencyRampTime"
EmergencyRampTime	INPUT	REAL	2.00	Time (in seconds) to decelerate the axis from configured maximum velocity to standstill without jerk limiter in emergency stop mode. The change will influence the tag <Axis name>. Config.DynamicDefaults.EmergencyDeceleration . For the effectiveness of the change, refer to the description of this tag.	
ChangeJerkTime	INPUT	BOOL	FALSE	TRUE	Change smoothing time according to the input parameter "JerkTime"
JerkTime	INPUT	REAL	0.25	Smoothing time (in seconds) used for the axis acceleration and deceleration ramps The change will influence the tag <Axis name>. Config.DynamicDefaults.Jerk . For the effectiveness of the change, refer to the description of this tag.	
Done	OUTPUT	BOOL	FALSE	TRUE	The changed values have been written to the technology data block. The description of the tags will show when the change becomes effective.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 7555) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 7555) for parameter "ErrorID"	

Note

At the input parameters "RampUpTime", "RampDownTime", "EmergencyRampTime" and "JerkTime", values can be entered which exceed the admissible limits of the resulting parameters: "Acceleration", "Deceleration", "Emergency stop deceleration" and "Jerk".

Please note the equations and limits in "Axis technology object" -> "Configuring the technology object" -> "Dynamics" and ensure that the values you input are within the valid range.

11.6.4.2 High-speed counters

CTRL_HSC: Control high-speed counters

Parameter

Parameters	Declaration	Data type	Memory area	Description
EN	INPUT	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	OUTPUT	BOOL	I, Q, M, D, L	Enable output
HSC	INPUT	HW_HSC	I, Q, M or constant	Hardware address of the high-speed counter (HW ID)
DIR	INPUT	BOOL	I, Q, M, D, L or constant	Enables the new count direction (see NEW_DIR)
CV	INPUT	BOOL	I, Q, M, D, L or constant	Enables the new count value (see NEW_CV)
RV	INPUT	BOOL	I, Q, M, D, L or constant	Enables the new reference value (see NEW_RV)
PERIOD	INPUT	BOOL	I, Q, M, D, L or constant	Enables the new period of a frequency measurement (see NEW_PERIOD)
NEW_DIR	INPUT	INT	I, Q, M, D, L or constant	Count direction loaded when DIR = TRUE.
NEW_CV	INPUT	DINT	I, Q, M, D, L or constant	Count value loaded when CV = TRUE.
NEW_RV	INPUT	DINT	I, Q, M, D, L or constant	Reference value loaded when RV = TRUE.
NEW_PERIOD	INPUT	INT	I, Q, M, D, L or constant	Period of the frequency measurement loaded when PERIOD = TRUE.
BUSY	OUTPUT	BOOL	I, Q, M, D, L	Processing status
STATUS	OUTPUT	WORD	I, Q, M, D, L	Status of the operation

Description

With the "Control high-speed counter" instruction, you can make parameter settings and control the high-speed counters supported by the CPU by loading new values into the counter. Execution of the instruction requires that a high-speed counter to be controlled is enabled. You cannot execute multiple "Control high-speed counter" instructions simultaneously in the program for a given high-speed counter.

You can load the following parameter values into a high-speed counter using the "Control high-speed counter" instruction:

- Count direction (NEW_DIR): The count direction defines whether a high-speed counter counts up or down. The count direction is defined by the following values at the NEW_DIR input: 1 = up, -1 = down.
  A change to the count direction with the "Control high-speed counter" instruction is only possible when direction control is set in the parameters by the program. The count direction specified at the NEW_DIR input is loaded into a high-speed counter when the bit at the DIR input is set.
- Count value (NEW_CV): The count value is the initial value at which a high-speed counter starts counting. The count value can be in the range -2147483648 to 2147483647.
  The count value specified at the NEW_CV input is loaded into a high-speed counter when the bit at the CV input is set.
- Reference value (NEW_RV): You can compare the reference value with the current counter value to trigger an alarm. Similar to the counter value, the reference value can be in the range -2147483648 to 2147483647.
  The reference value specified at the NEW_RV input is loaded into a high-speed counter when the bit at the RV input is set.
- Period of the frequency measurement (NEW_PERIOD): The period of the frequency measurement is specified by the following values at the NEW_PERIOD input: 10 = 0.01s, 100 = 0.1s, 1000 = 1s.
  The time period can be updated if the "Measure frequency" function for the specified high-speed counter is configured. The time period specified at the NEW_PERIOD input is loaded into a high-speed counter when the bit at the PERIOD input is set.

The "Control high-speed counter" instruction is only executed if the signal state at the EN input is "1". As long as the operation is executing, the bit at the BUSY output is set. Once the operation has executed completely, the bit at the BUSY output is reset.

The ENO enable output is set only when the EN enable input has signal state "1" and no errors occur during execution of the operation.

When inserting the "Control high-speed counter" instruction, an instance data block is created in which the operation data is saved.

STATUS parameter

At the STATUS output, you can query whether errors occurred during execution of the "Control high-speed counter" instruction. The following table shows the meaning of the values output at the STATUS output:

Error code (hexadecimal)	Description
0	No error
80A1	Hardware identifier of the high-speed counter invalid

Error code (hexadecimal)	Description
80B1	Count direction (NEW_DIR) invalid
80B2	Count value (NEW_CV) invalid
80B3	Reference value (NEW_RV) invalid
80B4	Period of the frequency measurement (NEW_PERIOD) invalid
80C0	Multiple access to the high-speed counter
80D0	The high-speed counter (HSC) is not enabled in the CPU hardware configuration.

CTRL_HSC_EXT: Control high-speed counter (extended)

Parameters

Parameters	Declaration	Data type	Memory area	Description
EN	INPUT	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	OUTPUT	BOOL	I, Q, M, D, L	Enable output
HSC	INPUT	HW_HSC	I, Q, M or constant	Hardware address of the high-speed counter (HW ID)
CTRL	INOUT	VARIANT	M, D	Use of a system data type (SDT)
DONE	OUTPUT	BOOL	I, Q, M, D, L	Feedback after successful processing instruction
BUSY	OUTPUT	BOOL	I, Q, M, D, L	Processing status
ERROR	OUTPUT	BOOL	I, Q, M, D, L	Feedback for faulty processing of the instruction
STATUS	OUTPUT	WORD	I, Q, M, D, L	Status of the operation

Description

With the "Control high-speed counter (extended)" instruction, you can control and assign parameters to the high-speed counters supported by the CPU via the software by loading new values into the counters. Execution of the instruction requires that a high-speed counter to be controlled is enabled. You cannot execute multiple "Control high-speed counter (extended)" instructions simultaneously in the program for a given high-speed counter.

The "Control high-speed counter (extended)" instruction is only executed if the signal state at the EN input is "1". As long as the operation is executing, the bit at the BUSY output is set. Once the operation has executed completely, the bit at the BUSY output is reset.

The ENO enable output is set only when the EN enable input has signal state "1" and no errors occur during execution of the operation.

When the "Control high-speed counter (extended)" instruction is inserted, an instance data block is created in which the operation data is saved.

Using the system data type HSC_Period

The "Control high-speed counter (extended)" instruction supports the system data type SDT 381 "HSC_Period" for the period measurement.

Byte	Parameters	Data type	Description
0 ... 3	ElapsedTime	UDINT	Time between the rising edges of Edge_Count
4 ... 7	EdgeCount	UDINT	Number of the rising edges within the Elapsed_Time. If Edge_Count = 0, the Elapsed_Time is the time since the last rising edge.
8.0	EnHSC	BOOL	Use as an enable input via gate control: • FALSE: Measurement stopped • TRUE: Measurement enabled
8.6	EnPeriod	BOOL	Update of the period • FALSE: No update • TRUE: Update period
10 ... 11	NewPeriod	INT	Interval of the period measurement in milliseconds. Permissible values are 10, 100 and 1000.

STATUS parameter

At the STATUS output, you can query whether errors occurred during execution of the "Control high-speed counter (extended)" instruction. The following table shows the meaning of the values output at the STATUS output:

Error code (hexadecimal)	Description
0	No error
80A1	Hardware identifier of the high-speed counter invalid
80C0	Multiple access to the high-speed counter
80D0	The high-speed counter (HSC) is not enabled in the CPU hardware configuration.

11.6.4.3 PID Control

PID_Compact

New features of PID_Compact

PID_Compact V2.2

- **Use with S7-1200**
  As of PID_Compact V2.2, the instruction with V2 functionality can also be used on S7-1200 with firmware version 4.0 or higher.

PID_Compact V2.0

- **Reaction to error**
  The reaction to error has been completely overhauled. PID_Compact now reacts in a more fault-tolerant manner in the default setting. This reaction is set when copying PID_Compact V1.X from an S7-1200 CPU to an S7-1500 CPU.

  Notice

  Your system may be damaged.

  If you use the default setting, PID_Compact remains in automatic mode when the process value limits are exceeded. This may damage your system.

  It is essential to configure how your controlled system reacts in the event of an error to protect your system from damage.

  The Error parameter indicates if an error is pending. When the error is no longer pending, Error = FALSE. The ErrorBits parameter shows which errors have occurred. Use ErrorAck to acknowledge the errors and warnings without restarting the controller or clearing the integral action. Switching operating modes no longer clears errors that are no longer pending.
  You can configure the reaction to error with SetSubstituteOutput and ActivateRecoverMode.
- **Substitute output value**
  You can configure a substitute output value that is to be output if an error occurs.
- **Switching the operating mode**
  You specify the operating mode at the Mode in/out parameter and use a rising edge at ModeActivate to start the operating mode. The sRet.i_Mode tag has been omitted.
- **Multi-instance capability**
  You can call up PID_Compact as multi-instance DB. No technology object is created in this case and no parameter assignment interface or commissioning interface is available. You must assign parameters for PID_Compact directly in the multi-instance DB and commission it via a watch table.
- **Startup characteristics**
  The operating mode specified at the Mode parameter is also started on a falling edge at Reset and during a CPU cold restart, if RunModeByStartup = TRUE.
- **ENO characteristics**
  ENO is set depending on the operating mode.
  If State = 0, then ENO = FALSE.
  If State ≠ 0, then ENO = TRUE.
- **Setpoint value specification during tuning**
  You configure the permitted fluctuation of the setpoint during tuning at the CancelTuningLevel tag.
- **Value range for output value limits**
  The value 0.0 no longer has to fall within the output value limits.
- **Pre-assigning the integral action**
  Using the tags IntegralResetMode and OverwriteInitialOutputValue, you can determine the pre-assignment of the integral action when switching from "Inactive" operating mode to "Automatic mode".
- **Switching a disturbance variable on**
  You can switch a disturbance variable on at the Disturbance parameter.

- **Default value of PID parameters**
  The following default settings have been changed:
  - Proportional action weighting (PWeighting) from 0.0 to 1.0
  - Derivative action weighting (DWeighting) from 0.0 to 1.0
  - Coefficient for derivative delay (TdFiltRatio) from 0.0 to 0.2
- **Renaming tags**
  The static tags have been given new names that are compatible with PID_3Step.

PID_Compact V1.2

- **Manual mode on CPU startup**
  If ManualEnable = TRUE when the CPU starts, PID_Compact starts in manual mode. A rising edge at ManualEnable is not necessary.
- **Pretuning**
  If the CPU is switched off during pretuning, pretuning starts again when the CPU is switched back on.

PID_Compact V1.1

- **Manual mode on CPU startup**
  When the CPU starts up, PID_Compact only switches to manual mode with a rising edge at ManualEnable. Without rising edge, PID_Compact starts in the last operating mode in which ManualEnable was FALSE.
- **Reaction to reset**
  A rising edge at Reset resets the errors and warnings and clears the integral action. A falling edge at Reset triggers a switchover to the most recently active operating mode.
- **Default of process value high limit**
  The default value of r_Pv_Hlm has been changed to 120.0.
- **Monitoring the sampling time**
  - An error is no longer output when the current sampling time is >= 1.5 x current mean value or when the current sampling time is <= 0.5 x current mean value. The sampling time may deviate much more in automatic mode.
  - PID_Compact is compatible with FW, V2.0 or higher.
- **Access to tags**
  The following tags can now be used in the user program.
  - i_Event_SUT
  - i_Event_TIR
  - r_Ctrl_Ioutv
- **Troubleshooting**
  PID_Compact now outputs the correct pulses when the shortest ON time is not equal to the shortest OFF time.

Compatibility with CPU and FW

The following table shows which version of PID_Compact can be used on which CPU.

CPU	FW	PID_Compact
S7-1200	≥ V4.x	V2.2 V1.2
S7-1200	≥ V3.X	V1.2 V1.1
S7-1200	≥ V2.X	V1.2 V1.1

CPU processing time and memory requirement PID_Compact V2.x

CPU processing time

Typical CPU processing times of the PID_Compact technology object as of Version V2.0, depending on CPU type.

CPU	Typ. CPU processing time PID_Compact V2.x
CPU 1211C ≥ V4.0	300 µs
CPU 1215C ≥ V4.0	300 µs
CPU 1217C ≥ V4.0	300 µs
CPU 1505S ≥ V1.0	45 µs
CPU 1510SP-1 PN ≥ V1.6	85 µs
CPU 1511-1 PN ≥ V1.5	85 µs
CPU 1512SP-1 PN ≥ V1.6	85 µs
CPU 1516-3 PN/DP ≥ V1.5	50 µs
CPU 1518-4 PN/DP ≥ V1.5	4 µs

Memory requirement

Memory requirement of an instance DB of the PID_Compact technology object as of Version V2.0.

	Memory requirement of the instance DB of PID_Compact V2.x
Load memory requirement	Approx. 12000 bytes

Total work memory requirement	788 bytes
Retentive work memory requirement	44 bytes

PID_Compact V2

Description of PID_Compact V2

Description

The PID_Compact instruction provides a PID controller with integrated tuning for actuators with proportional action.

The following operating modes are possible:

- Inactive
- Pretuning
- Fine tuning
- Automatic mode
- Manual mode
- Substitute output value with error monitoring

For a more detailed description of the operating modes, see the State parameter.

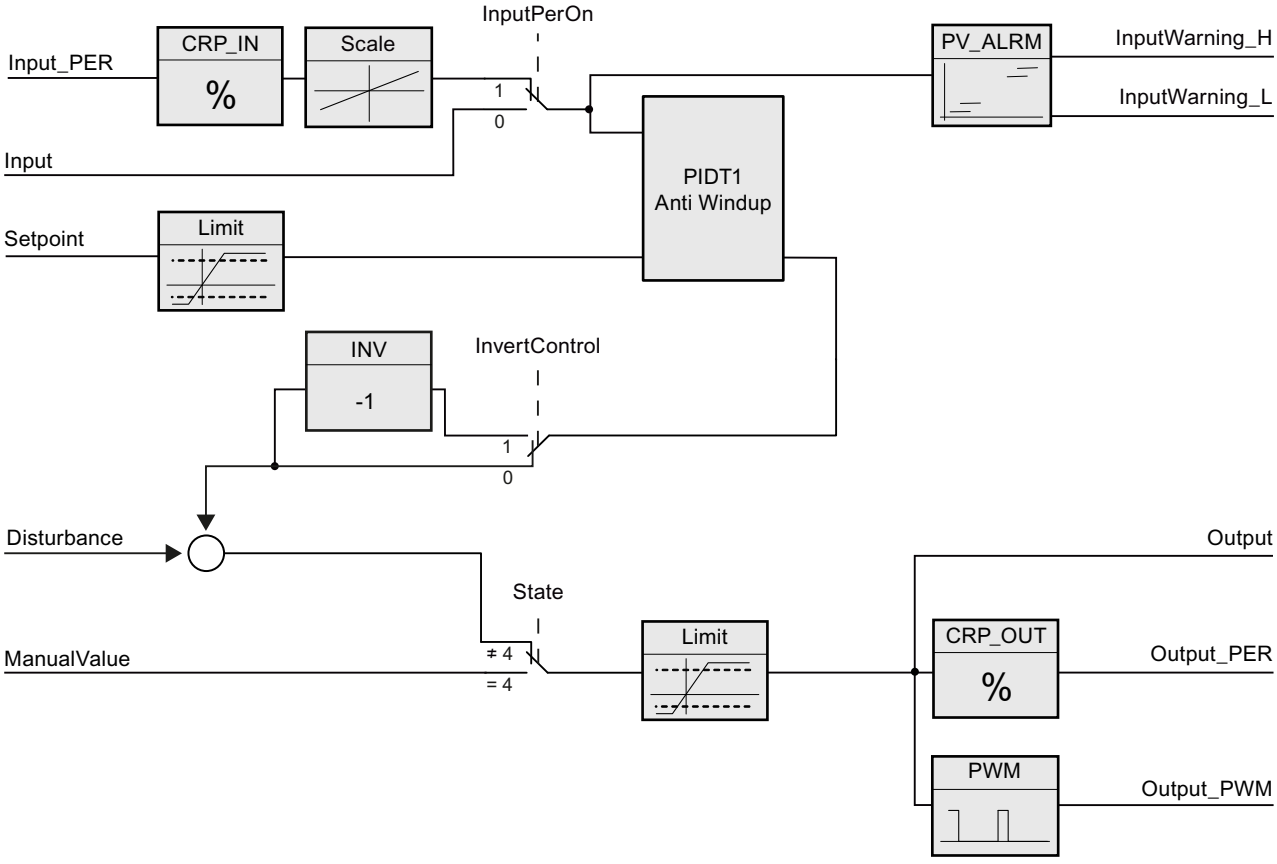
PID algorithm

PID_Compact is a PIDT1 controller with anti-windup and weighting of the proportional and derivative actions. The PID algorithm operates according to the following equation:

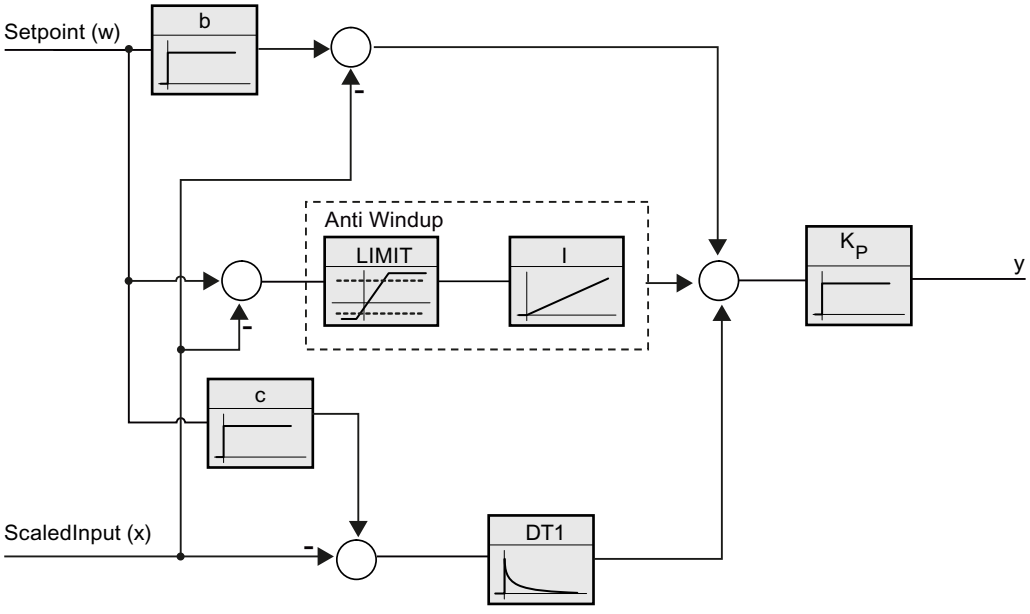
$$y = K_p \left[(b \cdot w - x) + \frac{1}{T_I \cdot s} (w - x) + \frac{T_D \cdot s}{a \cdot T_D \cdot s + 1} (c \cdot w - x) \right]$$

Symbol	Description
y	Output value of the PID algorithm
K_p	Proportional gain
s	Laplace operator
b	Proportional action weighting
w	Setpoint
x	Process value
T_I	Integral action time
T_D	Derivative action time
a	Derivative delay coefficient (derivative delay T1 = a × T_D)
c	Derivative action weighting

Block diagram of PID_Compact



Block diagram of PIDT1 with anti-windup



Call

PID_Compact is called in the constant time scale of a cycle interrupt OB.

If you call PID_Compact as a multi-instance DB, no technology object is created. No parameter assignment interface or commissioning interface is available. You must assign parameters for PID_Compact directly in the multi-instance DB and commission it via a watch table.

Download to device

The actual values of retentive variables are only updated when you download PID_Compact completely.

Downloading technology objects to device (Page 7204)

Startup

When the CPU starts up, PID_Compact starts in the operating mode that is saved in the Mode in/out parameter. To switch to "Inactive" operating mode during startup, set RunModeByStartup = FALSE.

Reaction to error

In automatic mode and during commissioning, the reaction to error depends on the SetSubstituteOutput and ActivateRecoverMode variables. In manual mode, the reaction is independent of SetSubstituteOutput and ActivateRecoverMode. If ActivateRecoverMode = TRUE, the reaction additionally depends on the error that occurred.

SetSubstituteOutput	ActivateRecoverMode	Configuration editor > output value > Set Output to	Reaction
Not relevant	FALSE	Zero (inactive)	Switch to "Inactive" mode (State = 0) The value 0.0 0 is transferred to the actuator.
FALSE	TRUE	Current output value while error is pending	Switch to "Substitute output value with error monitoring" mode (State = 5) The current output value is transferred to the actuator while the error is pending.
TRUE	TRUE	Substitute output value while error is pending	Switch to "Substitute output value with error monitoring" mode (State = 5) The value at SubstituteOutput is transferred to the actuator while the error is pending.

In manual mode, PID_Compact uses ManualValue as output value, unless ManualValue is invalid. If ManualValue is invalid, SubstituteOutput is used. If ManualValue and SubstituteOutput are invalid, Config.OutputLowerLimit is used.

The Error parameter indicates if an error is pending. When the error is no longer pending, Error = FALSE. The ErrorBits parameter shows which errors have occurred. ErrorBits is reset by a rising edge at Reset or ErrorAck.

PID_Compact V2 mode of operation

Monitoring process value limits

You specify the high limit and low limit of the process value in the Config.InputUpperLimit and Config.InputLowerLimit tags. If the process value is outside these limits, an error occurs (ErrorBits = 0001h).

You specify a high and low warning limit of the process value in the Config.InputUpperWarning and Config.InputLowerWarning tags. If the process value is outside these warning limits, a warning occurs (Warning = 0040h), and the InputWarning_H or InputWarning_L output parameter changes to TRUE.

Limiting the setpoint

You specify a high limit and low limit of the setpoint in the Config.SetpointUpperLimit and Config.SetpointLowerLimit tags. PID_Compact automatically limits the setpoint to the process value limits. You can limit the setpoint to a smaller range. PID_Compact checks whether this range falls within the process value limits. If the setpoint is outside these limits, the high or low limit is used as the setpoint, and output parameter SetpointLimit_H or SetpointLimit_L is set to TRUE.

The setpoint is limited in all operating modes.

Limiting the output value

You specify a high limit and low limit of the output value in the Config.OutputUpperLimit and Config.OutputLowerLimit tags. Output, ManualValue, and SubstituteOutput are limited to these values. The output value limits must match the control logic.

The valid output value limit values depend on the Output used.

Output	-100.0 to 100.0%
Output_PER	-100.0 to 100.0%
Output_PWM	0.0 to 100.0%

Rule:

OutputUpperLimit > OutputLowerLimit

Substitute output value

In the event of an error, PID_Compact can output a substitute output value that you define at the tag SubstituteOutput. The substitute output value must be within the output value limits.

Monitoring signal validity

The values of the following parameters are monitored for validity when used:

- Setpoint
- Input

- Input_PER
- Disturbance
- ManualValue
- SubstituteOutput
- Output
- Output_PER
- Output_PWM

Monitoring of the sampling time PID_Compact

Ideally, the sampling time is equivalent to the cycle time of the calling OB. The PID_Compact instruction measures the time interval between two calls. This is the current sampling time. On every switchover of operating mode and during the initial startup, the mean value is formed from the first 10 sampling times. Too great a difference between the current sampling time and this mean value triggers an error (Error = 0800h).

The error occurs during tuning if:

- New mean value >= 1.1 x old mean value
- New mean value <= 0.9 x old mean value

The error occurs in automatic mode if:

- New mean value >= 1.5 x old mean value
- New mean value <= 0.5 x old mean value

If you deactivate the sampling time monitoring (CycleTime.EnMonitoring = FALSE), you can also call PID_Compact in OB1. You must then accept a lower control quality due to the deviating sampling time.

Sampling time of the PID algorithm

The controlled system needs a certain amount of time to respond to changes in the output value. It is therefore not advisable to calculate the output value in every cycle. The sampling time of the PID algorithm represents the time between two calculations of the output value. It is calculated during tuning and rounded to a multiple of the cycle time. All other functions of PID_Compact are executed at every call.

If you use Output_PWM, the accuracy of the output signal is determined by the ratio of the PID algorithm sampling time to the cycle time of the OB. The cycle time should be at least 10 times the PID algorithm sampling time.

Control logic

An increase of the output value is generally intended to cause an increase in the process value. This is referred to as a normal control logic. For cooling and discharge control systems, it may be necessary to invert the control logic. PID_Compact does not work with negative proportional gain. If InvertControl = TRUE, an increasing control deviation causes a reduction in the output value. The control logic is also taken into account during pretuning and fine tuning.

Input parameters of PID_Compact V2

Table 11-81

Parameter	Data type	Default	Description
Setpoint	REAL	0.0	Setpoint of the PID controller in automatic mode
Input	REAL	0.0	A tag of the user program is used as the source of the process value. If you are using the Input parameter, then Config.InputPerOn = FALSE must be set.
Input_PER	INT	0	An analog input is used as the source of the process value. If you are using the Input_PER parameter, then Config.InputPerOn = TRUE must be set.
Disturbance	REAL	0.0	Disturbance variable or precontrol value
ManualEnable	BOOL	FALSE	• A FALSE -> TRUE edge activates "manual mode", while State = 4, Mode remain unchanged. As long as ManualEnable = TRUE, you cannot change the operating mode via a rising edge at ModeActivate or use the commissioning dialog. • A TRUE -> FALSE edge activates the operating mode that is specified by Mode. We recommend that you change the operating mode using ModeActivate only.
ManualValue	REAL	0.0	Manual value This value is used as the output value in manual mode. Values from Config.OutputLowerLimit to Config.OutputUpperLimit are permitted.
ErrorAck	BOOL	FALSE	• FALSE -> TRUE edge ErrorBits and Warning are reset.
Reset	BOOL	FALSE	Restarts the controller. • FALSE -> TRUE edge – Switch to "Inactive" mode – ErrorBits and Warnings are reset. – Integral action is cleared (PID parameters are retained) • As long as Reset = TRUE, PID_Compact remains in "Inactive" mode (State = 0). • TRUE -> FALSE edge PID_Compact switches to the operating mode that is saved in the Mode parameter.
ModeActivate	BOOL	FALSE	• FALSE -> TRUE edge PID_Compact switches to the operating mode that is saved in the Mode parameter.

Output parameters of PID_Compact V2

Table 11-82

Parameter	Data type	Default	Description
ScaledInput	REAL	0.0	Scaled process value
The "Output", "Output_PER", and "Output_PWM" outputs can be used concurrently.			
Output	REAL	0.0	Output value in REAL format
Output_PER	INT	0	Analog output value
Output_PWM	BOOL	FALSE	Pulse-width-modulated output value The output value is formed by by variable On and Off times.
SetpointLimit_H	BOOL	FALSE	If SetpointLimit_H = TRUE, the absolute setpoint high limit is reached (Setpoint ≥ Config.SetpointUpperLimit). The setpoint is limited to Config.SetpointUpperLimit .
SetpointLimit_L	BOOL	FALSE	If SetpointLimit_L = TRUE, the absolute setpoint low limit has been reached (Setpoint ≤ Config.SetpointLowerLimit). The setpoint is limited to Config.SetpointLowerLimit .
InputWarning_H	BOOL	FALSE	If InputWarning_H = TRUE, the process value has reached or exceeded the warning high limit.
InputWarning_L	BOOL	FALSE	If InputWarning_L = TRUE, the process value has reached or fallen below the warning low limit.
State	INT	0	The State parameter (Page 3462) shows the current operating mode of the PID controller. You can change the operating mode using the input parameter Mode and a rising edge at ModeActivate. • State = 0: Inactive • State = 1: Pretuning • State = 2: Fine tuning • State = 3: Automatic mode • State = 4: Manual mode • State = 5: Substitute output value with error monitoring
Error	BOOL	FALSE	If Error = TRUE, at least one error message is pending in this cycle.
ErrorBits	DWORD	DW#16#0	The ErrorBits parameter (Page 3466) shows which error messages are pending. ErrorBits is retentive and is reset upon a rising edge at Reset or ErrorAck.

In/out parameters of PID_Compact V2

Table 11-83

Parameter	Data type	Default	Description
Mode	INT	4	At Mode, specify the operating mode to which PID_Compact is to switch. Options are: • Mode = 0: Inactive • Mode = 1: Pretuning • Mode = 2: Fine tuning • Mode = 3: Automatic mode • Mode = 4: Manual mode The operating mode is activated by: • Rising edge at ModeActivate • Falling edge at Reset • Falling edge at ManualEnable • Cold restart of CPU if RunModeByStartup = TRUE Mode is retentive. A detailed description of the operating modes can be found in Parameters State and Mode V2 (Page 3462).

See also

Parameters State and Mode V2 (Page 3462)

Static tags of PID_Compact V2

You must not change variables that are not listed. These are used for internal purposes only.

Table 11-84

Tag	Data type	Default	Description
IntegralResetMode	INT	1	The tag IntegralResetMode determines how PIDCtrl.IntegralSum is pre-assigned when switching from "Inactive" operating mode to "Automatic mode". This setting only works for one cycle. Options are: • IntegralResetMode = 0: Smoothing The value of IntegralSum is pre-assigned so that the switchover is bumpless. • IntegralResetMode = 1: Deleting The value of IntegralSum is deleted. Any control deviation will cause a jump change of the output value. • IntegralResetMode = 2: Holding The value of IntegralSum is not changed. You can define a new value using the user program. • IntegralResetMode = 3: Pre-assigning The value of IntegralSum is automatically pre-assigned so that Output is calculated with reference to the value OverwriteInitialOutputValue. This setting is useful, for example, for an override controller.
OverwriteInitialOutputValue	REAL	0.0	If IntegralResetMode = 3, the value of IntegralSum is automatically pre-assigned so that Output = OverwriteInitialOutputValue in the next cycle.
RunModeByStartup	BOOL	TRUE	Activate operating mode at Mode parameter after CPU restart If RunModeByStartup = TRUE, PID_Compact starts in the operating mode saved in the Mode parameter after CPU startup. If RunModeByStartup = FALSE, PID_Compact remains in "Inactive" mode after CPU startup.
LoadBackUp	BOOL	FALSE	If LoadBackUp = TRUE, the last set of PID parameters is reloaded. The set was saved prior to the last tuning. LoadBackUp is automatically set back to FALSE.
PhysicalUnit	INT	0	Unit of measurement of the process value and setpoint, e.g., °C, or °F.
PhysicalQuantity	INT	0	Physical quantity of the process value and setpoint, e.g., temperature.
ActivateRecoverMode	BOOL	TRUE	The Tag ActivateRecoverMode V2 (Page 3468) determines the reaction to error.
Warning	DWORD	0	Tag Warning V2 (Page 3469) shows the warnings since Reset = TRUE or ErrorAck =TRUE. Warning is retentive.
Progress	REAL	0.0	Progress of tuning as a percentage (0.0 - 100.0)

Tag	Data type	Default	Description
CurrentSetpoint	REAL	0.0	CurrentSetpoint always displays the current setpoint. This value is frozen during tuning.
CancelTuningLevel	REAL	10.0	Permissible fluctuation of setpoint during tuning. Tuning is not canceled until: • Setpoint > CurrentSetpoint + CancelTuningLevel or • Setpoint < CurrentSetpoint - CancelTuningLevel
SubstituteOutput	REAL	0.0	Substitute output value When the following conditions are met, the substitute output value is used: • An error has occurred in automatic mode. • SetSubstituteOutput = TRUE • ActivateRecoverMode = TRUE
SetSubstituteOutput	BOOL	TRUE	If SetSubstituteOutput = TRUE and ActivateRecoverMode = TRUE, the substitute output value configured is output as long as an error is pending. If SetSubstituteOutput = FALSE and ActivateRecoverMode = TRUE, the actuator remains at the current output value as long as an error is pending. If ActivateRecoverMode = FALSE, SetSubstituteOutput is not effective. If SubstituteOutput is invalid (ErrorBits = 20000h), the substitute output value cannot be output.
Config.InputPerOn	BOOL	TRUE	If InputPerOn = TRUE, the Input_PER parameter is used. If InputPerOn = FALSE, the Input parameter is used.
Config.InvertControl	BOOL	FALSE	Invert control logic If InvertControl = TRUE, an increasing control deviation causes a reduction in the output value.
Config.InputUpperLimit	REAL	120.0	High limit of the process value Input and Input_PER are monitored to ensure adherence to this limit. At the I/O input, the process value can be a maximum of 18% higher than the standard range (overrange). This pre-assignment ensures that an error is no longer signaled due to a violation of the "Process value high limit". Only a wire-break and a short-circuit are recognized and PID_Compact reacts according to the configured reaction to error. InputUpperLimit > InputLowerLimit
Config.InputLowerLimit	REAL	0.0	Low limit of the process value Input and Input_PER are monitored to ensure adherence to this limit. InputLowerLimit < InputUpperLimit

Tag	Data type	Default	Description
Config.InputUpperWarning	REAL	3.402822e+38	Warning high limit of the process value If you set InputUpperWarning outside the process value limits, the configured absolute process value high limit is used as the warning high limit. If you configure InputUpperWarning within the process value limits, this value is used as the warning high limit. InputUpperWarning > InputLowerWarning InputUpperWarning ≤ InputUpperLimit
Config.InputLowerWarning	REAL	-3.402822e +38	Warning low limit of the process value If you set InputLowerWarning outside the process value limits, the configured absolute process value low limit is used as the warning low limit. If you configure InputLowerWarning within the process value limits, this value is used as the warning low limit. InputLowerWarning < InputUpperWarning InputLowerWarning ≥ InputLowerLimit
Config.OutputUpperLimit	REAL	100.0	High limit of output value For details, see OutputLowerLimit OutputUpperLimit > OutputLowerLimit
Config.OutputLowerLimit	REAL	0.0	Low limit of output value For Output and Output_PER, the range of values from -100.0 to +100.0, including zero, is valid. At -100.0, Output_PER = -27648; at +100.0, Output_PER = 27648. For Output_PWM, the value range 0.0 to +100.0 applies. The output value limits must match the control logic. OutputLowerLimit < OutputUpperLimit
Config.SetpointUpperLimit	REAL	3.402822e+38	High limit of setpoint If you configure SetpointUpperLimit outside the process value limits, the configured absolute process value high limit is used as the setpoint high limit. If you configure SetpointUpperLimit within the process value limits, this value is used as the setpoint high limit.
Config.SetpointLowerLimit	REAL	-3.402822e +38	Low limit of the setpoint If you set SetpointLowerLimit outside the process value limits, the configured process value absolute low limit is used as the setpoint low limit. If you set SetpointLowerLimit within the process value limits, this value is used as the setpoint low limit.
Config.MinimumOnTime	REAL	0.0	The minimum ON time of the pulse width modulation in seconds is rounded to MinimumOnTime = n×CycleTime.Value
Config.MinimumOffTime	REAL	0.0	The minimum OFF time of the pulse width modulation in seconds is rounded to MinimumOffTime = n×CycleTime.Value

Tag	Data type	Default	Description
Config.InputScaling.UpperPointIn	REAL	27648.0	Scaling Input_PER high Input_PER is converted to percent based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn.
Config.InputScaling.LowerPointIn	REAL	0.0	Scaling Input_PER low Input_PER is converted to percent based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn.
Config.InputScaling.UpperPointOut	REAL	100.0	Scaled high process value Input_PER is converted to percent based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn.
Config.InputScaling.LowerPointOut	REAL	0.0	Scaled low process value Input_PER is converted to percent based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn.
CycleTime.StartEstimation	BOOL	TRUE	If CycleTime.StartEstimation = TRUE, the automatic determination of the cycle time is started. CycleTime.StartEstimation = FALSE once measurement is complete.
CycleTime.EnEstimation	BOOL	TRUE	If CycleTime.EnEstimation = TRUE, the PID_Compact sampling time is calculated. If CycleTime.EnEstimation = FALSE, the PID_Compact sampling time is not calculated and you need to correct the configuration of CycleTime.Value manually.
CycleTime.EnMonitoring	BOOL	TRUE	If CycleTime.EnMonitoring = FALSE, the PID_Compact sampling time is not monitored. If it is not possible to execute PID_Compact within the sampling time, no error (ErrorBits=0800h) is output and PID_Compact does not switch to "Inactive" mode.
CycleTime.Value	REAL	0.1	PID_Compact sampling time in seconds CycleTime.Value is determined automatically and is usually equivalent to the cycle time of the calling OB.
CtrlParamsBackUp.Gain	REAL	1.0	Saved proportional gain You can reload values from the CtrlParamsBackUp structure with LoadBackUp = TRUE.
CtrlParamsBackUp.Ti	REAL	20.0	Saved integral action time [s]
CtrlParamsBackUp.Td	REAL	0.0	Saved derivative action time [s]
CtrlParamsBackUp.TdFiltRatio	REAL	0.2	Saved derivative delay coefficient
CtrlParamsBackUp.PWeighting	REAL	1.0	Saved proportional action weighting factor
CtrlParamsBackUp.DWeighting	REAL	1.0	Saved derivative action weighting factor
CtrlParamsBackUp.Cycle	REAL	1.0	Saved sampling time of PID algorithm

Tag	Data type	Default	Description
PIDSelfTune.SUT.CalculateParams	BOOL	FALSE	The properties of the controlled system are saved during tuning. If SUT.CalculateParams = TRUE, the parameters for pretuning are recalculated according to these properties. This enables you to change the parameter calculation method without having to repeat controller tuning. SUT.CalculateParams is set to FALSE after the calculation.
PIDSelfTune.SUT.TuneRule	INT	0	Methods used to calculate parameters during pretuning: • SUT.TuneRule = 0: PID according to Chien, Hrones and Reswick • SUT.TuneRule = 1: PI according to Chien, Hrones and Reswick
PIDSelfTune.SUT.State	INT	0	The SUT.State tag indicates the current phase of pretuning: • State = 0: Initialize pretuning • State = 100: Calculate standard deviation • State = 200: Determine point of inflection • State = 9900: Pretuning successful • State = 1: Pretuning not successful
PIDSelfTune.TIR.RunIn	BOOL	FALSE	With the RunIn tag, you can specify that fine tuning can also be performed without pretuning. • RunIn = FALSE Pretuning is started when fine tuning is started from inactive or manual mode. If the requirements for pretuning are not met, PID_Compact reacts as when RunIn = TRUE. If fine tuning is started from automatic mode, the system uses the existing PID parameters to control to the setpoint. Only then will fine tuning start. If pretuning is not possible, PID_Compact switches to the mode from which tuning was started. • RunIn = TRUE The pretuning is skipped. PID_Compact tries to reach the setpoint with minimum or maximum output value. This can produce increased overshoot. Fine tuning then starts automatically. RunIn is set to FALSE after fine tuning.
PIDSelfTune.TIR.CalculateParams	BOOL	FALSE	The properties of the controlled system are saved during tuning. If TIR.CalculateParams = TRUE, the parameters for fine tuning are recalculated according to these properties. This enables you to change the parameter calculation method without having to repeat controller tuning. TIR.CalculateParams is set to FALSE after the calculation.

Tag	Data type	Default	Description
PIDSelfTune.TIR.TuneRule	INT	0	Methods used to calculate parameters during fine tuning: • TIR.TuneRule = 0: PID automatic • TIR.TuneRule = 1: PID rapid • TIR.TuneRule = 2: PID slow • TIR.TuneRule = 3: Ziegler-Nichols PID • TIR.TuneRule = 4: Ziegler-Nichols PI • TIR.TuneRule = 5: Ziegler-Nichols P
PIDSelfTune.TIR.State	INT	0	The TIR.State tag indicates the current phase of fine tuning: • State = -100 Fine tuning is not possible. Pretuning will be performed first. • State = 0: Initialize fine tuning • State = 200: Calculate standard deviation • State = 300: Attempt to reach the setpoint • State = 400: Attempt to reach the setpoint with existing PID parameters (if pretuning was successful) • State = 500: Determine oscillation and calculate parameters • State = 9900: Fine tuning successful • State = 1: Fine tuning not successful
PIDCtrl.IntegralSum	REAL	0.0	Current integral action
Retain.CtrlParams.Gain	REAL	1.0	Active proportional gain To invert the control logic, use the Config.InvertControl tag. Negative values at Gain also invert the control logic. We recommend you use only InvertControl to set the control logic. The control logic is also inverted if InvertControl = TRUE and Gain < 0.0. Gain is retentive.
Retain.CtrlParams.Ti	REAL	20.0	• CtrlParams.Ti > 0.0: Active integral action time • CtrlParams.Ti = 0.0: Integral action is deactivated Ti is retentive.
Retain.CtrlParams.Td	REAL	0.0	• CtrlParams.Td > 0.0: Active derivative action time • CtrlParams.Td = 0.0: Derivative action is deactivated Td is retentive.

Tag	Data type	Default	Description
Retain.CtrlParams.TdFiltRatio	REAL	0.2	Active derivative delay coefficient The derivative delay coefficient delays the effect of the derivative action. Derivative delay = derivative action time × derivative delay coefficient • 0.0: Derivative action is effective for one cycle only and therefore almost not effective. • 0.5: This value has proved useful in practice for controlled systems with **one** dominant time constant. • > 1.0: The greater the coefficient, the longer the effect of the derivative action is delayed. TdFiltRatio is retentive.
Retain.CtrlParams.PWeighting	REAL	1.0	Active proportional action weighting The proportional action may weaken with changes to the setpoint. Values from 0.0 to 1.0 are applicable. • 1.0: Proportional action for setpoint change is fully effective • 0.0: Proportional action for setpoint change is not effective The proportional action is always fully effective when the process value is changed. PWeighting is retentive.
Retain.CtrlParams.DWeighting	REAL	1.0	Active derivative action weighting The derivative action may weaken with changes to the setpoint. Values from 0.0 to 1.0 are applicable. • 1.0: Derivative action is fully effective upon setpoint change • 0.0: Derivative action is not effective upon setpoint change The derivative action is always fully effective when the process value is changed. DWeighting is retentive.
Retain.CtrlParams.Cycle	REAL	1.0	Active sampling time of the PID algorithm CtrlParams.Cycle is calculated during tuning and rounded to an integer multiple of CycleTime.Value. Cycle is retentive.

Note

Change the tags listed in this table in "Inactive" mode to prevent malfunction of the PID controller.

Parameters State and Mode V2

Correlation of the parameters

The State parameter shows the current operating mode of the PID controller. You cannot change the State parameter.

With a rising edge at ModeActivate, PID_Compact switches to the operating mode saved in the Mode in-out parameter.

When the CPU is switched on or switches from Stop to RUN mode, PID_Compact starts in the operating mode that is saved in the Mode parameter. To leave PID_Compact in "Inactive" mode, set RunModeByStartup = FALSE.

Meaning of values

State / Mode	Description of operating mode
0	Inactive In "Inactive" operating mode, the output value 0.0 is always output, regardless of Config.OutputUpperLimit and Config.OutputLowerLimit. Pulse width modulation is off.
1	Pretuning The pretuning determines the process response to a jump change of the output value and searches for the point of inflection. The PID parameters are calculated from the maximum rate of rise and dead time of the controlled system. You obtain the best PID parameters when you perform pretuning and fine tuning. Pretuning requirements: • Inactive (State = 0), manual mode (State = 4), or automatic mode (State = 3) • ManualEnable = FALSE • Reset = FALSE • The process value must not be too close to the setpoint. |Setpoint - Input| > 0.3 * | Config.InputUpperLimit - Config.InputLowerLimit| and |Setpoint - Input| > 0.5 * |Setpoint| • The setpoint and the process value lie within the configured limits. The more stable the process value is, the easier it is to calculate the PID parameters and the more precise the result will be. Noise on the process value can be tolerated as long as the rate of rise of the process value is significantly higher compared to the noise. The setpoint is frozen in the CurrentSetpoint tag. Tuning is canceled when: • Setpoint > CurrentSetpoint + CancelTuningLevel or • Setpoint < CurrentSetpoint - CancelTuningLevel Before the PID parameters are recalculated, they are backed up and can be reactivated with LoadBackUp. The controller switches to automatic mode following successful pretuning. If pretuning is unsuccessful, the switchover of the operating mode is dependent on ActivateRecoverMode. The phase of pretuning is indicated with PIDSelfTune.SUT.State.

State / Mode	Description of operating mode
2	Fine tuning Fine tuning generates a constant, limited oscillation of the process value. The PID parameters are recalculated based on the amplitude and frequency of this oscillation. PID parameters from fine tuning usually have better master control and disturbance characteristics than PID parameters from pretuning. You obtain the best PID parameters when you perform pretuning and fine tuning. PID_Compact automatically attempts to generate an oscillation greater than the noise of the process value. Fine tuning is only minimally influenced by the stability of the process value. The setpoint is frozen in the CurrentSetpoint tag. Tuning is canceled when: • Setpoint > CurrentSetpoint + CancelTuningLevel or • Setpoint < CurrentSetpoint - CancelTuningLevel Before the PID parameters are recalculated, they are backed up and can be reactivated with LoadBackUp. Requirements for fine tuning: • No disturbances are expected. • The setpoint and the process value lie within the configured limits. • ManualEnable = FALSE • Reset = FALSE • Automatic (State = 3), inactive (State = 0) or manual (State = 4) mode Fine tuning proceeds as follows when started from: • Automatic mode (State = 3) Start fine tuning from automatic mode if you wish to improve the existing PID parameters through tuning. PID_Compact controls the system using the existing PID parameters until the control loop has stabilized and the requirements for fine tuning have been met. Only then will fine tuning start. • Inactive (State = 0) or manual mode (State = 4) If the requirements for pretuning are met, pretuning is started. The determined PID parameters will be used for control until the control loop has stabilized and the requirements for fine tuning have been met. If the process value for pretuning is already too near the setpoint or PIDSelfTune.TIR.RunIn = TRUE, an attempt is made to reach the setpoint with the minimum or maximum output value. This can produce increased overshoot. Only then will fine tuning start. The controller switches to automatic mode following successful fine tuning. If fine tuning is unsuccessful, the switchover of the operating mode is dependent on ActivateRecoverMode. The "Fine tuning" phase is indicated with PIDSelfTune.TIR.State.
3	Automatic mode In automatic mode, PID_Compact corrects the controlled system in accordance with the parameters specified. The controller switches to automatic mode if one the following requirements is fulfilled: • Pretuning successfully completed • Fine tuning successfully completed • Changing of the Mode in-out parameter to the value 3 and a rising edge at ModeActivate. The switchover from automatic mode to manual mode is only bumpless if carried out in the commissioning editor. The ActivateRecoverMode tag is taken into consideration in automatic mode.

State / Mode	Description of operating mode
4	Manual mode In manual mode, you specify a manual output value in the ManualValue parameter. You can also activate this operating mode using ManualEnable = TRUE. We recommend that you change the operating mode using Mode and ModeActivate only. The switchover from manual mode to automatic mode is bumpless. Manual mode is also possible when an error is pending.
5	Substitute output value with error monitoring The control algorithm is deactivated. The SetSubstituteOutput tag determines which output value is output in this operating mode. • SetSubstituteOutput = FALSE: Last valid output value • SetSubstituteOutput = TRUE: Substitute output value You cannot activate this operating mode using Mode = 5. In the event of an error, it is activated instead of "Inactive" operating mode if all the following conditions are met: • Automatic mode (Mode = 3) • ActivateRecoverMode = TRUE • One or more errors have occurred in which ActivateRecoverMode is effective. As soon as the errors are no longer pending, PID_Compact switches back to automatic mode.

ENO characteristics

If State = 0, then ENO = FALSE.

If State ≠ 0, then ENO = TRUE.

Automatic switchover of operating mode during commissioning

Automatic mode is activated following successful pretuning or fine tuning. The following table shows how Mode and State change during successful pretuning.

Cycle no.	Mode	State	Action
0	4	4	Set Mode = 1
1	1	4	Set ModeActivate = TRUE
1	4	1	Value of State is saved in Mode parameter Pretuning is started
n	4	1	Pretuning successfully completed
n	3	3	Automatic mode is started

PID_Compact automatically switches the operating mode in the event of an error. The following table shows how Mode and State change during pretuning with errors.

Cycle no.	Mode	State	Action
0	4	4	Set Mode = 1
1	1	4	Set ModeActivate = TRUE
1	4	1	Value of State is saved in Mode parameter Pretuning is started

Cycle no.	Mode	State	Action
n	4	1	Pretuning canceled
n	4	4	Manual mode is started

If ActivateRecoverMode = TRUE, the operating mode that is saved in the Mode parameter is activated. At the start of pretuning or fine tuning, PID_Compact has saved the value of State in the Mode in/out parameter. PID_Compact therefore switches to the operating mode from which tuning was started.

If ActivateRecoverMode = FALSE, the system switches to "Inactive" operating mode.

Output parameters of PID_Compact V2 (Page 3452)

Parameter ErrorBits V2

If several errors are pending simultaneously, the values of the ErrorBits are displayed with binary addition. The display of ErrorBits = 0003h, for example, indicates that the errors 0001h and 0002h are pending simultaneously.

In manual mode, PID_Compact uses ManualValue as output value. The exception is Errorbits = 10000h.

ErrorBits (DW#16#...)	Description
0000	There is no error.
0001	The "Input" parameter is outside the process value limits. • Input > Config.InputUpperLimit or • Input < Config.InputLowerLimit If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact remains in automatic mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact switches to the operating mode that is saved in the Mode parameter.
0002	Invalid value at "Input_PER" parameter. Check whether an error is pending at the analog input. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact outputs the configured substitute output value. As soon as the error is no longer pending, PID_Compact switches back to automatic mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact switches to the operating mode that is saved in the Mode parameter.
0004	Error during fine tuning. Oscillation of the process value could not be maintained. If ActivateRecoverMode = TRUE before the error occurred, PID_Compact cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0008	Error at start of pretuning. The process value is too close to the setpoint. Start fine tuning. If ActivateRecoverMode = TRUE before the error occurred, PID_Compact cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0010	The setpoint was changed during tuning. You can set the permitted fluctuation of the setpoint at the CancelTuningLevel tag. If ActivateRecoverMode = TRUE before the error occurred, PID_Compact cancels the tuning and switches to the operating mode that is saved in the Mode parameter.

ErrorBits (DW#16#...)	Description
0020	Pretuning is not permitted during fine tuning. If ActivateRecoverMode = TRUE before the error occurred, PID_Compact remains in fine tuning mode.
0080	Error during pretuning. Incorrect configuration of output value limits. Check whether the limits of the output value are configured correctly and match the control logic. If ActivateRecoverMode = TRUE before the error occurred, PID_Compact cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0100	Error during fine tuning resulted in invalid parameters. If ActivateRecoverMode = TRUE before the error occurred, PID_Compact cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0200	Invalid value at "Input" parameter: Value has an invalid number format. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact outputs the configured substitute output value. As soon as the error is no longer pending, PID_Compact switches back to automatic mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact switches to the operating mode that is saved in the Mode parameter.
0400	Calculation of output value failed. Check the PID parameters. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact outputs the configured substitute output value. As soon as the error is no longer pending, PID_Compact switches back to automatic mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact switches to the operating mode that is saved in the Mode parameter.
0800	Sampling time error: PID_Compact is not called within the sampling time of the cyclic interrupt OB. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact remains in automatic mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact switches to the operating mode that is saved in the Mode parameter.
1000	Invalid value at "Setpoint" parameter: Value has an invalid number format. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact outputs the configured substitute output value. As soon as the error is no longer pending, PID_Compact switches back to automatic mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact switches to the operating mode that is saved in the Mode parameter.
10000	Invalid value at ManualValue parameter. Value has an invalid number format. If ActivateRecoverMode = TRUE before an error occurred, PID_Compact uses SubstituteOutput as the output value. As soon as you specify a valid value in ManualValue, PID_Compact uses it as the output value.
20000	Invalid value at SubstituteOutput tag. Value has an invalid number format. PID_Compact uses the output value low limit as the output value. If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_Compact switches back to automatic mode.
40000	Invalid value at Disturbance parameter. Value has an invalid number format. If automatic mode was active and ActivateRecoverMode = TRUE before the error occurred, Disturbance is set to zero. PID_Compact remains in automatic mode. If pretuning or fine tuning mode was active and ActivateRecoverMode = TRUE before the error occurred, PID_Compact switches to the operating mode saved in the Mode parameter. If Disturbance in the current phase has no effect on the output value, tuning is not be canceled.

Tag ActivateRecoverMode V2

The ActivateRecoverMode tag determines the reaction to error. The Error parameter indicates if an error is pending. When the error is no longer pending, Error = FALSE. The ErrorBits parameter shows which errors have occurred.

Automatic mode

Notice

Your system may be damaged.

If ActivateRecoverMode = TRUE, PID_Compact remains in automatic mode even if there is an error and the process limit values are exceeded. This may damage your system.

It is essential to configure how your controlled system reacts in the event of an error to protect your system from damage.

ActivateRecoverMode	Description
FALSE	PID_Compact automatically switches to "Inactive" mode in the event of an error. The controller is only activated by a falling edge at Reset or a rising edge at ModeActivate.
TRUE	If errors occur frequently in automatic mode, this setting has a negative effect on the control response, because PID_Compact switches between the calculated output value and the substitute output value at each error. In this case, check the ErrorBits parameter and eliminate the cause of the error. If one or more of the following errors occur, PID_Compact stays in automatic mode: • 0001h: The "Input" parameter is outside the process value limits. • 0800h: Sampling time error • 40000h: Invalid value at parameter Disturbance. If one or more of the following errors occur, PID_Compact switches to "Substitute output value with error monitoring" mode: • 0002h: Invalid value at Input_PER parameter. • 0200h: Invalid value at Input parameter. • 0400h: Calculation of output value failed. • 1000h: Invalid value at Setpoint parameter. If the following error occurs, PID_Compact switches to "Substitute output value with error monitoring" mode and moves the actuator to Config.OutputLowerLimit: • 20000h: Invalid value at SubstituteOutput tag. Value has an invalid number format. This characteristics are independent of SetSubstituteOutput. As soon as the errors are no longer pending, PID_Compact switches back to automatic mode.

Pretuning and fine tuning

ActivateRecoverMode	Description
FALSE	PID_Compact automatically switches to "Inactive" mode in the event of an error. The controller is only activated by a falling edge at Reset or a rising edge at ModeActivate.
TRUE	If the following error occurs, PID_Compact remains in the active mode: • 0020h: Pretuning is not permitted during fine tuning. The following errors are ignored: • 10000h: Invalid value at ManualValue parameter. • 20000h: Invalid value at SubstituteOutput tag. When any other error occurs, PID_Compact cancels the tuning and switches to the mode from which tuning was started.

Manual mode

ActivateRecoverMode is not effective in manual mode.

Tag Warning V2

If several warnings are pending simultaneously, the values of the Warning tag are displayed with binary addition. The display of warning 0003h, for example, indicates that the warnings 0001h and 0002h are pending simultaneously.

Warning (DW#16#....)	Description
0000	No warning pending.
0001	The point of inflection was not found during pretuning.
0004	The setpoint was limited to the configured limits.
0008	Not all the necessary controlled system properties were defined for the selected method of calculation. Instead, the PID parameters were calculated using the TIR.TuneRule = 3 method.
0010	The operating mode could not be changed because Reset = TRUE or ManualEnable = TRUE.
0020	The cycle time of the calling OB limits the sampling time of the PID algorithm. Improve results by using shorter OB cycle times.
0040	The process value exceeded one of its warning limits.
0080	Invalid value at Mode. The operating mode is not switched.
0100	The manual value was limited to the limits of the controller output.
0200	The specified rule for tuning is not supported. No PID parameters are calculated.
1000	The substitute output value cannot be reached because it is outside the output value limits.

The following warnings are deleted as soon as the cause is eliminated:

- 0001h
- 0004h
- 0008h

- 0040h
- 0100h

All other warnings are cleared with a rising edge at Reset or ErrorAck.

PID_Compact V1

Description of PID_Compact V1

Description

The PID_Compact instruction provides a PID controller with integrated tuning for automatic and manual mode.

Call

PID_Compact is called in the constant interval of the cycle time of the calling OB (preferably in a cyclic interrupt OB).

Download to device

The actual values of retentive tags are only updated when you download PID_Compact completely.

Downloading technology objects to device (Page 7204)

Startup

At the startup of the CPU, PID_Compact starts in the operating mode that was last active. To retain PID_ Compact in "Inactive" mode, set sb_RunModeByStartup = FALSE.

Monitoring of the sampling time PID_Compact

Ideally, the sampling time is equivalent to the cycle time of the calling OB. The PID_Compact instruction measures the time interval between two calls. This is the current sampling time. On every switchover of operating mode and during the initial startup, the mean value is formed from the first 10 sampling times. If the current sampling time deviates too much from this mean value, Error = 0800 hex occurs and PID_Compact switches to "Inactive" mode.

PID_Compact, Version 1.1 or higher is set to "Inactive" mode during controller tuning under the following conditions:

- New mean value >= 1.1 x old mean value
- New mean value <= 0.9 x old mean value

In automatic mode, PID_Compact, Version 1.1 or higher, is set to "Inactive" mode under the following conditions:

- New mean value >= 1.5 x old mean value
- New mean value <= 0.5 x old mean value

During controller tuning and in automatic mode, PID_Compact 1.0 is set to "Inactive" operating mode under the following conditions:

- New mean value >= 1.1 x old mean value
- New mean value <= 0.9 x old mean value
- Current sampling time >= 1.5 x current mean value
- Current sampling time <= 0.5 x current mean value

Sampling time of the PID algorithm

The controlled system needs a certain amount of time to respond to changes in the output value. It is therefore not advisable to calculate the output value in every cycle. The sampling time of the PID algorithm represents the time between two calculations of the output value. It is calculated during tuning and rounded to a multiple of the cycle time. All other functions of PID_Compact are executed at every call.

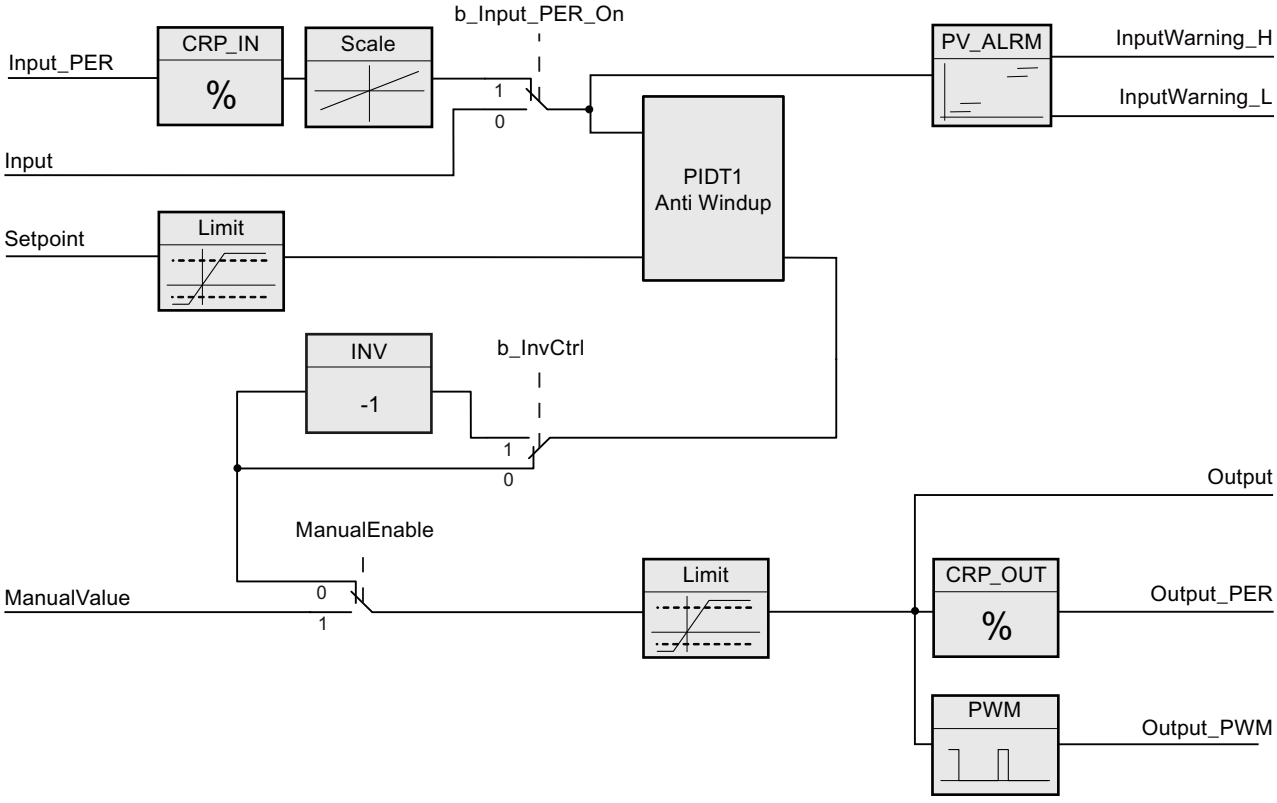
PID algorithm

PID_Compact is a PIDT1 controller with anti-windup and weighting of the proportional and derivative actions. The following equation is used to calculate the output value.

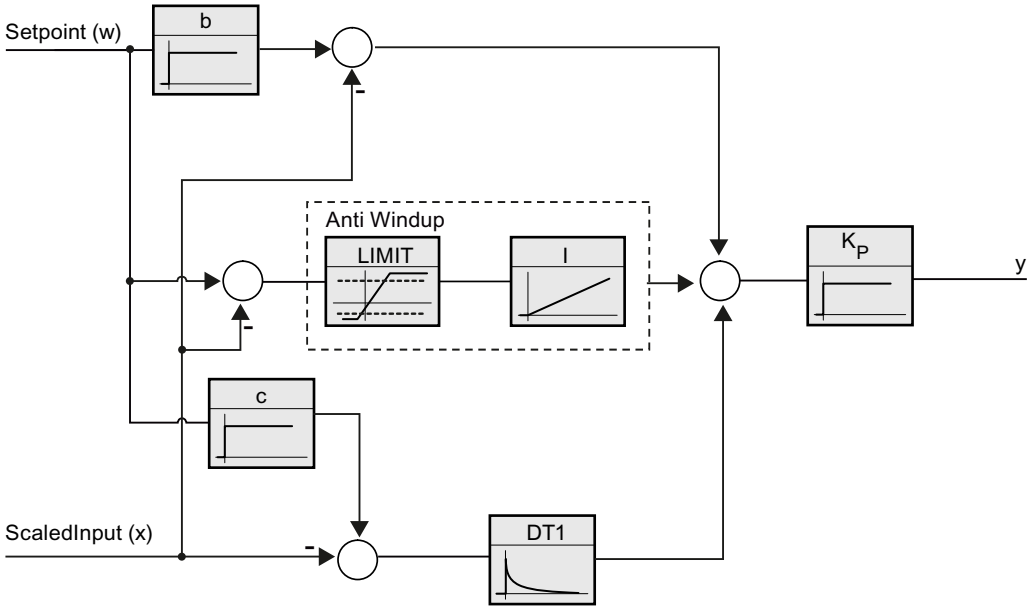
$$y = K_p \left[(b \cdot w - x) + \frac{1}{T_I \cdot s} (w - x) + \frac{T_D \cdot s}{a \cdot T_D \cdot s + 1} (c \cdot w - x) \right]$$

Symbol	Description
y	Output value
K_p	Proportional gain
s	Laplace operator
b	Proportional action weighting
w	Setpoint
x	Process value
T_I	Integral action time
a	Derivative delay coefficient (T1 = a × T_D)
	Derivative action time
c	Derivative action weighting

Block diagram of PID_Compact



Block diagram of PIDT1 with anti-windup



Reaction to error

If errors occur, they are output in parameter Error, and PID_Compact changes to "Inactive" mode. Reset the errors using the Reset parameter.

Control logic

An increase of the output value is generally intended to cause an increase in the process value. This is referred to as a normal control logic. For cooling and discharge control systems, it may be necessary to invert the control logic. PID_Compact does not work with negative proportional gain. If InvertControl = TRUE, an increasing control deviation causes a reduction in the output value. The control logic is also taken into account during pretuning and fine tuning.

Controller type (Page 7244)

Input parameters of PID_Compact V1

Table 11-85

Parameter	Data type	Default	Description
Setpoint	REAL	0.0	Setpoint of the PID controller in automatic mode
Input	REAL	0.0	A variable of the user program is used as source for the process value. If you are using parameter Input, then sPid_Cmpt.b_Input_PER_On = FALSE must be set.
Input_PER	WORD	W#16#0	Analog input as the source of the process value If you are using parameter Input_PER, then sPid_Cmpt.b_Input_PER_On = TRUE must be set.
ManualEnable	BOOL	FALSE	• A FALSE -> TRUE edge selects "Manual mode", while State = 4, sRet.i_Mode remains unchanged. • A TRUE -> FALSE edge selects the most recently active operating mode, State =sRet.i_Mode A change of sRet.i_Mode will not take effect during ManualEnable = TRUE. The change of sRet.i_Mode will only be considered upon a TRUE -> FALSE edge at ManualEnable . **PID_Compact V1.2 und PID_Compact V1.0** If at start of the CPU ManualEnable = TRUE, PID_Compact starts in manual mode. A rising edge (FALSE > TRUE) at ManualEnable is not necessary. **PID_Compact V1.1** At the start of the CPU, PID_Compact only switches to manual mode with a rising edge (FALSE->TRUE) at ManualEnable . Without rising edge, PID_Compact starts in the last operating mode in which ManualEnable was FALSE.
ManualValue	REAL	0.0	Manual value This value is used as the output value in manual mode.
Reset	BOOL	FALSE	The Reset parameter (Page 3483) restarts the controller.

Output parameters of PID_Compact V1

Table 11-86

Parameter	Data type	Default	Description
ScaledInput	REAL	0.0	Output of the scaled process value
Outputs "Output", "Output_PER", and "Output_PWM" can be used concurrently.			
Output	REAL	0.0	Output value in REAL format
Output_PER	WORD	W#16#0	Analog output value
Output_PWM	BOOL	FALSE	Pulse-width-modulated output value The output value is formed by minimum On and Off times.
SetpointLimit_H	BOOL	FALSE	If SetpointLimit_H = TRUE, the setpoint absolute high limit is reached. The setpoint in the CPU is limited to the configured setpoint absolute high limit. The configured process value absolute high limit is the default for the setpoint high limit. If you set sPid_Cmpt.r_Sp_Hlm to a value within the process value limits, this value is used as the setpoint high limit.
SetpointLimit_L	BOOL	FALSE	If SetpointLimit_L = TRUE, the setpoint absolute low limit has been reached. In the CPU, the setpoint is limited to the configured setpoint absolute low limit. The configured process value absolute low limit is the default setting for the setpoint low limit. If you set sPid_Cmpt.r_Sp_Llm to a value within the process value limits, this value is used as the setpoint low limit.
InputWarning_H	BOOL	FALSE	If InputWarning_H = TRUE, the process value has reached or exceeded the warning high limit.
InputWarning_L	BOOL	FALSE	If InputWarning_L = TRUE, the process value has reached or fallen below the warning low limit.
State	INT	0	The State parameter (Page 3479) shows the current operating mode of the PID controller. To change the operating mode, use variable sRet.i_Mode. • State = 0: Inactive • State = 1: pretuning • State = 2: fine tuning • State = 3: Automatic mode • State = 4: Manual mode
Error	DWORD	W#16#0	The Error parameter (Page 3482) indicates the error messages. Error = 0000: No error pending.

Static tags of PID_Compact V1

You must not change tags that are not listed. These are used for internal purposes only.

Table 11-87

Tag	Data type	Default	Description
sb_GetCycleTime	BOOL	TRUE	If sb_GetCycleTime = TRUE, the automatic determination of the cycle time is started. CycleTime.StartEstimation = FALSE once measurement is complete.
sb_EnCyclEstimation	BOOL	TRUE	If sb_EnCyclEstimation = TRUE, the sampling time PID_Compact is calculated.
sb_EnCyclMonitoring	BOOL	TRUE	If sb_EnCyclMonitoring = FALSE, the sampling time PID_Compact is not monitored. If it is not possible to execute PID_Compact within the sampling time, an 0800 error is not output and PID_Compact does not change to "Inactive" mode.
sb_RunModeByStartup	BOOL	TRUE	Activate Mode after CPU restart If sb_RunModeByStartup = FALSE, the controller will remain inactive after a CPU startup. After a CPU startup and if sb_RunModeByStartup = TRUE, the controller will return to the most recently active operating mode.
si_Unit	INT	0	Unit of measurement of the process value and setpoint, e.g., ºC, or ºF.
si_Type	INT	0	Physical quantity of the process value and setpoint, e.g., temperature.
sd_Warning	DWORD	DW#16#0	Variable sd_warning (Page 3484) displays the warnings generated since the reset, or since the last change of the operating mode.
sBackUp.r_Gain	REAL	1.0	Saved proportional gain You can reload values from the sBackUp structure with sPid_Cmpt.b_LoadBackUp = TRUE.
sBackUp.r_Ti	REAL	20.0	Saved integral action time [s]
sBackUp.r_Td	REAL	0.0	Saved derivative action time [s]
sBackUp.r_A	REAL	0.0	Saved derivative delay coefficient
sBackUp.r_B	REAL	0.0	Saved proportional action weighting factor
sBackUp.r_C	REAL	0.0	Saved derivative action weighting factor
sBackUp.r_Cycle	REAL	1.0	Saved sampling time of PID algorithm
sPid_Calc.r_Cycle	REAL	0.1	Sampling time of the PID_Compact instruction r_Cycle is determined automatically and usually equivalent to the cycle time of the calling OB.

Tag	Data type	Default	Description
sPid_Calc.b_RunIn	BOOL	FALSE	• b_RunIn = FALSE Pretuning is started when fine tuning is started from inactive or manual mode. If the requirements for pretuning are not met, PID_Compact reacts like b_RunIn = TRUE. If fine tuning is started from automatic mode, the system uses the existing PID parameters to control to the setpoint. Only then will fine tuning start. If pretuning is not possible, PID_Compact will change to "Inactive" mode. • b_RunIn = TRUE The pretuning is skipped. PID_3Compact tries to reach the setpoint with minimum or maximum output value. This can produce increased overshoot. Fine tuning then starts automatically. b_RunIn is set to FALSE after fine tuning.
sPid_Calc.b_CalcParamSUT	BOOL	FALSE	The parameters for pretuning will be recalculated if b_CalcParamSUT = TRUE. This enables you to change the parameter calculation method without having to repeat controller tuning. b_CalcParamSUT will be set to FALSE after calculation.
sPid_Calc.b_CalcParamTIR	BOOL	FALSE	The parameters for fine tuning will be recalculated if b_CalcParamTIR = TRUE. This enables you to change the parameter calculation method without having to repeat controller tuning. b_CalcParamTIR will be set to FALSE after calculation.
sPid_Calc.i_CtrlTypeSUT	INT	0	Methods used to calculate parameters during pretuning: • i_CtrlTypeSUT = 0: PID according to Chien, Hrones and Reswick • i_CtrlTypeSUT = 1: PI according to Chien, Hrones and Reswick
sPid_Calc.i_CtrlTypeTIR	INT	0	Methods used to calculate parameters during fine tuning: • i_CtrlTypeTIR = 0: PID automatic • i_CtrlTypeTIR = 1: PID rapid • i_CtrlTypeTIR = 2: PID slow • i_CtrlTypeTIR = 3: Ziegler-Nichols PID • i_CtrlTypeTIR = 4: Ziegler-Nichols PI • i_CtrlTypeTIR = 5: Ziegler-Nichols P
sPid_Calc.r_Progress	REAL	0.0	Progress of tuning as a percentage (0.0 - 100.0)

Tag	Data type	Default	Description
sPid_Cmpt.r_Sp_Hlm	REAL	+3.402822e +38	High limit of setpoint If you set sPid_Cmpt.r_Sp_Hlm outside the process value limits, the configured process value absolute high limit is used as the setpoint high limit. If you set sPid_Cmpt.r_Sp_Hlm within the process value limits, this value is used as the setpoint high limit.
sPid_Cmpt.r_Sp_Llm	REAL	-3.402822e +38	Low limit of the setpoint If you set sPid_Cmpt.r_Sp_Llm outside the process value limits, the configured process value absolute low limit is used as the setpoint low limit. If you set sPid_Cmpt.r_Sp_Llm within the process value limits, this value is used as the setpoint low limit.
sPid_Cmpt.r_Pv_Norm_IN_1	REAL	0.0	Scaling Input_PER low Input_PER is converted to percent based on the two value pairs r_Pv_Norm_OUT_1, r_Pv_Norm_IN_1 and r_Pv_Norm_OUT_2, r_Pv_Norm_IN_2 from the sPid_Cmpt structure.
sPid_Cmpt.r_Pv_Norm_IN_2	REAL	27648.0	Scaling Input_PER high Input_PER is converted to percent based on the two value pairs r_Pv_Norm_OUT_1, r_Pv_Norm_IN_1 and r_Pv_Norm_OUT_2, r_Pv_Norm_IN_2 from the sPid_Cmpt structure.
sPid_Cmpt.r_Pv_Norm_OUT_1	REAL	0.0	Scaled low process value Input_PER is converted to percent based on the two value pairs r_Pv_Norm_OUT_1, r_Pv_Norm_IN_1 and r_Pv_Norm_OUT_2, r_Pv_Norm_IN_2 from the sPid_Cmpt structure.
sPid_Cmpt.r_Pv_Norm_OUT_2	REAL	100.0	Scaled high process value Input_PER is converted to percent based on the two value pairs r_Pv_Norm_OUT_1, r_Pv_Norm_IN_1 and r_Pv_Norm_OUT_2, r_Pv_Norm_IN_2 from the sPid_Cmpt structure.
sPid_Cmpt.r_Lmn_Hlm	REAL	100.0	Output value high limit for output parameter "Output"
sPid_Cmpt.r_Lmn_Llm	REAL	0.0	Low output value limit for output parameter "Output"
sPid_Cmpt.b_Input_PER_On	BOOL	TRUE	If b_Input_PER_On = TRUE, then parameter Input_PER is used. If b_Input_PER_On = FALSE, then parameter Input is used.
sPid_Cmpt.b_LoadBackUp	BOOL	FALSE	Activate the back-up parameter set. If an optimization has failed, you can reactivate the previous PID parameters by setting this bit.
sPid_Cmpt.b_InvCtrl	BOOL	FALSE	Invert control logic With b_InvCtrl = TRUE, a rising control deviation reduces the output value.
sPid_Cmpt.r_Lmn_Pwm_PPTm	REAL	0.0	The minimum ON time of the pulse width modulation in seconds is rounded to r_Lmn_Pwm_PPTm = r_Cycle or r_Lmn_Pwm_PPTm = n*r_Cycle

Tag	Data type	Default	Description
sPid_Cmpt.r_Lmn_Pwm_PBTm	REAL	0.0	The minimum OFF time of the pulse width modulation in seconds is rounded to r_Lmn_Pwm_PBTm = r_Cycle or r_Lmn_Pwm_PBTm = n*r_Cycle
sPid_Cmpt.r_Pv_Hlm	REAL	120.0	High limit of the process value At the I/O input, the process value can be a maximum of 18% higher than the standard range (overrange). An error is no longer reported for a violation of the "Process value high limit". Only a wire-break and a short-circuit are recognized and the PID_Compact switches to "Inactive" mode. r_Pv_Hlm > r_Pv_Llm
sPid_Cmpt.r_Pv_Llm	REAL	0.0	Low limit of the process value r_Pv_Llm < r_Pv_Hlm
sPid_Cmpt.r_Pv_HWrn	REAL	+3.402822e +38	Warning high limit of the process value If you set r_Pv_HWrn outside the process value limits, the configured process value absolute high limit is used as the warning high limit. If you set r_Pv_HWrn within the process value limits, this value is used as the warning high limit. r_Pv_HWrn > r_Pv_LWrn r_Pv_HWrn ≤ r_Pv_Hlm
sPid_Cmpt.r_Pv_LWrn	REAL	-3.402822e +38	Warning low limit of the process value If you set r_Pv_LWrn outside the process value limits, the configured process value absolute low limit is used as the warning low limit. If you set r_Pv_LWrn within the process value limits, this value is used as the warning low limit. r_Pv_LWrn < r_Pv_HWrn r_Pv_LWrn ≥ r_Pv_LWrn
sParamCalc.i_Event_SUT	INT	0	Variable i_Event_SUT (Page 3485) indicates the current phase of "pretuning":
sParamCalc.i_Event_TIR	INT	0	Variable i_Event_TIR (Page 3485) indicates the current phase of "fine tuning":
sRet.i_Mode	INT	0	The operating mode is changed edge-triggered. The following operating mode is enabled on a change to • i_Mode = 0: "Inactive" (controller stop) • i_Mode = 1: "Pretuning" mode • i_Mode = 2: "Fine tuning" mode • i_Mode = 3: "Automatic mode" • i_Mode = 4: "Manual mode" i_Mode is retentive.
sRet.r_Ctrl_Gain	REAL	1.0	Active proportional gain Gain is retentive.

Tag	Data type	Default	Description
sRet.r_Ctrl_Ti	REAL	20.0	• r_Ctrl_Ti > 0.0: active integral action time • r_Ctrl_Ti = 0.0: Integral action is disabled r_Ctrl_Ti is retentive.
sRet.r_Ctrl_Td	REAL	0.0	• r_Ctrl_Td > 0.0: Active derivative action time • r_Ctrl_Td = 0.0: Derivative action is disabled r_Ctrl_Td is retentive.
sRet.r_Ctrl_A	REAL	0.0	Active derivative delay coefficient r_Ctrl_A is retentive.
sRet.r_Ctrl_B	REAL	0.0	Active proportional action weighting r_Ctrl_B is retentive.
sRet.r_Ctrl_C	REAL	0.0	Active derivative action weighting r_Ctrl_C is retentive.
sRet.r_Ctrl_Cycle	REAL	1.0	Active sampling time of the PID algorithm r_Ctrl_Cycle is calculated during controller tuning and rounded to an integer multiple of r_Cycle. r_Ctrl_Cycle is retentive.

Note

Change the tags listed in this table in "Inactive" mode to prevent malfunction of the PID controller. The "Inactive" mode is forced by setting variable "sRet.i_Mode" to "0".

Parameters State and sRet.i_Mode V1

Correlation of the parameters

The State parameter indicates the current operating mode of the PID controller. You cannot modify the State parameter.

You need to modify the sRet.i_Mode tag to change the operating mode. This also applies when the value for the new operating mode is already in sRet.i_Mode. First set sRet.i_Mode = 0 and then sRet.i_Mode = 3. Provided the current operating mode of the controller supports this change, State is set to the value of sRet.i_Mode.

When PID_Compact automatically switches the operating mode, the following applies: State ! = sRet.i_Mode.

Examples:

- Successful pretuning
  State = 3 and sRet.i_Mode = 1
- Error
  State = 0 and sRet.i_Mode remains at the same value, e.g sRet.i_Mode = 3
- ManualEnalbe = TRUE
  State = 4 and sRet.i_Mode remain at the previous value, for example, sRet.i_Mode = 3

Note

You wish to repeat successful fine tuning without exiting automatic mode with i_Mode = 0.

Setting sRet.i_Mode to an invalid value such as 9999 for one cycle has no effect on State. Set Mode = 2 in the next cycle. You can generate a change to sRet.i_Mode without first switching to "inactive" mode.

Meaning of values

State / sRet.i_Mode	Description of the operating mode
0	Inactive The controller is switched off. The controller was in "inactive" mode before pretuning was performed. The PID controller will change to "inactive" mode when running if an error occurs or if the "Deactivate controller" icon is clicked in the commissioning window.
1	Pretuning The pretuning determines the process response to a jump of the output value and searches for the point of inflection. The optimized PID parameters are calculated as a function of the maximum rate of rise and dead time of the controlled system. Pretuning requirements: • The controller is in inactive mode or manual mode • ManualEnable = FALSE • The process value must not be too close to the setpoint. |Setpoint - Input| > 0.3 * |sPid_Cmpt.r_Pv_Hlm - sPid_Cmpt.r_Pv_Llm| and |Setpoint - Input| > 0.5 * |Setpoint| • The setpoint may not be changed during pretuning. The higher the stability of the process value, the easier it is to calculate the PID parameters and increase precision of the result. Noise on the process value can be tolerated as long as the rate of rise of the process value is significantly higher compared to the noise. PID parameters are backed up before they are recalculated and can be reactivated with sPid_Cmpt.b_LoadBackUp. There is a change to automatic mode following successful pretuning and to "inactive" mode following unsuccessful pretuning. The phase of pretuning is indicated with Tag i_Event_SUT V1 (Page 3485).

State / sRet.i_Mode	Description of the operating mode
2	Fine tuning Fine tuning generates a constant, limited oscillation of the process value. The PID parameters are optimized based on the amplitude and frequency of this oscillation. The differences between the process response during pretuning and fine tuning are analyzed. All PID parameters are recalculated on the basis of the findings. PID parameters from fine tuning usually have better master control and disturbance behavior than PID parameters from pretuning. PID_Compact automatically attempts to generate an oscillation greater than the noise of the process value. Fine tuning is only minimally influenced by the stability of the process value. PID parameters are backed up before they are recalculated and can be reactivated with sPid_Cmpt.b_LoadBackUp. Requirements for fine tuning: • No disturbances are expected. • The setpoint and the process value lie within the configured limits. • The setpoint may not be changed during fine tuning. • ManualEnable = FALSE • Automatic (State = 3), inactive (State = 0) or manual (State = 4) mode Fine tuning proceeds as follows when started in: • Automatic mode (State = 3) Start fine tuning in automatic mode if you wish to improve the existing PID parameters using controller tuning. PID_Comact will regulate using the existing PID parameters until the control loop has stabilized and the requirements for fine tuning have been met. Only then will fine tuning start. • Inactive (State = 0) or manual (State = 4) mode If the requirements for pretuning are met, pretuning is started. The PID parameters established will be used for adjustment until the control loop has stabilized and the requirements for fine tuning have been met. Only then will fine tuning start. If pretuning is not possible, PID_Compact will change to "Inactive" mode. An attempt is made to reach the setpoint with a minimum or maximum output value if the process value for pretuning is already too near the setpoint or sPid_Calc.b_RunIn = TRUE. This can produce increased overshoot. The controller will change to "automatic mode" after successfully completed "fine tuning" and to "inactive" mode if "fine tuning" has not been successfully completed. The "Fine tuning" phase is indicated with Tag i_Event_TIR V1 (Page 3485).

State / sRet.i_Mode	Description of the operating mode
3	Automatic mode In automatic mode, PID_Compact corrects the controlled system in accordance with the parameters specified. The controller changes to automatic mode if one the following conditions is fulfilled: • Pretuning successfully completed • Fine tuning successfully completed • Change of variable sRet.i_Mode to the value 3. After CPU startup or change from Stop to RUN mode, PID_Compact will start in the most recently active operating mode. To retain PID_Compact in "Inactive" mode, set sb_RunModeByStartup = FALSE.
4	Manual mode In manual mode, you specify a manual output value in the ManualValue parameter. This operating mode is enabled if sRet.i_Mode = 4, or at the rising edge on ManualEnable. If ManualEnable changes to TRUE, only State will change. sRet.i_Mode will retain its current value. PID_Compact will return to the previous operating mode upon a falling edge at ManualEnable. The change to automatic mode is bumpless.

Parameter Error V1

If several errors are pending simultaneously, the values of the error codes are displayed with binary addition. The display of error code 0003, for example, indicates that the errors 0001 and 0002 are pending simultaneously.

Error (DW#16#...)	Description
0000	There is no error.
0001	The "Input" parameter is outside the process value limits. • Input > sPid_Cmpt.r_Pv_Hlm or • Input < sPid_Cmpt.r_Pv_Llm You cannot move the actuator again until you eliminate the error.
0002	Invalid value at "Input_PER" parameter. Check whether an error is pending at the analog input.
0004	Error during fine tuning. Oscillation of the process value could not be maintained.
0008	Error at start of pretuning. The process value is too close to the setpoint. Start fine tuning.
0010	The setpoint was changed during tuning.
0020	Pretuning is not permitted in automatic mode or during fine tuning.

Error (DW#16#...)	Description
0080	Incorrect configuration of output value limits. Check whether the limits of the output value are configured correctly and match the control logic.
0100	Error during tuning resulted in invalid parameters.
0200	Invalid value at "Input" parameter: Value has an invalid number format.
0400	Calculation of output value failed. Check the PID parameters.
0800	Sampling time error: PID_Compact is not called within the sampling time of the cyclic interrupt OB.
1000	Invalid value at "Setpoint" parameter: Value has an invalid number format.

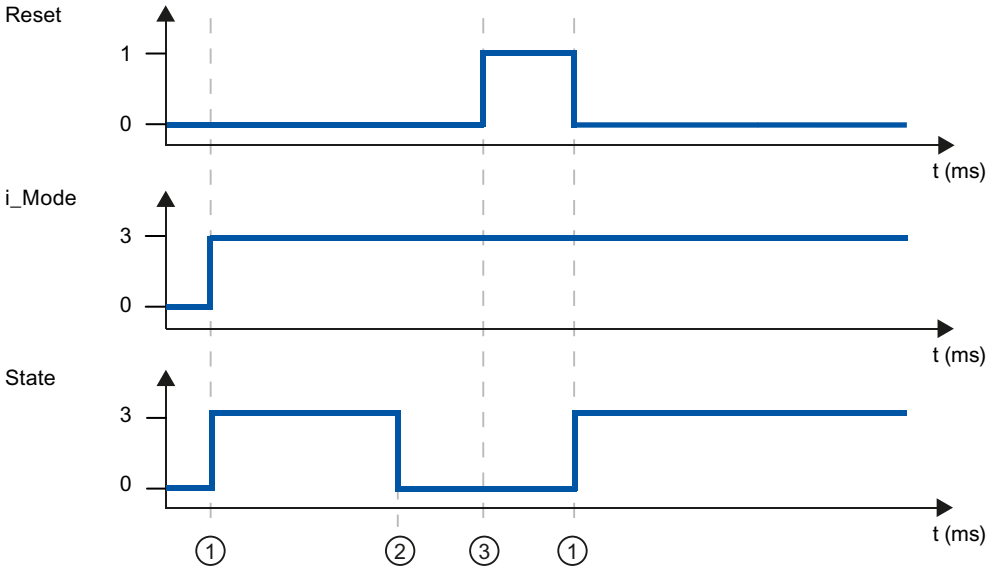
Parameter Reset V1

The response to Reset = TRUE depends on the version of the PID_Compact instruction.

Reset response PID_Compact V.1.1 or higher

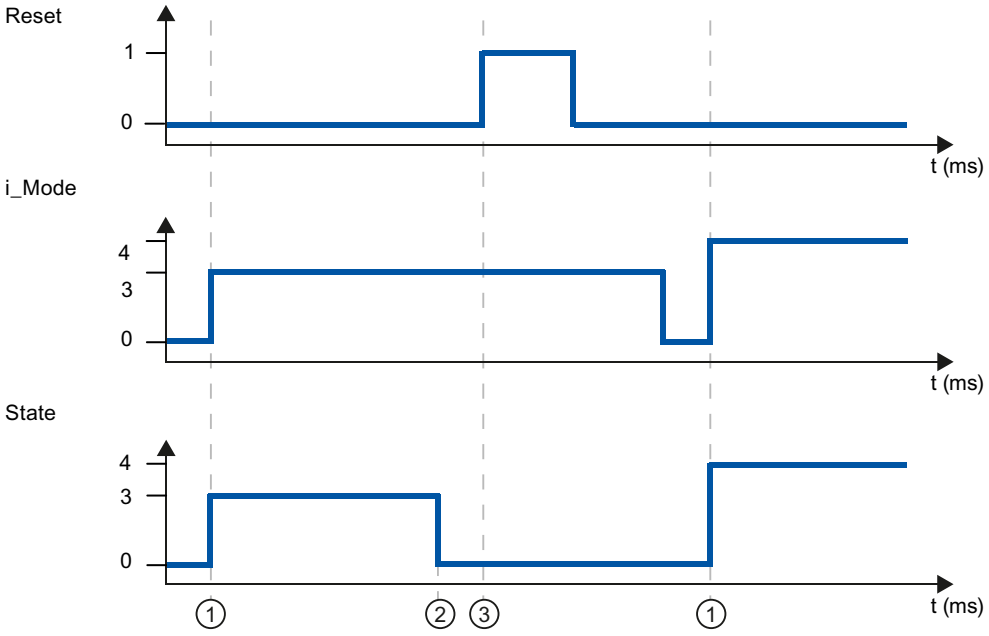
A rising edge at Reset resets the errors and warnings and clears the integral action. A falling edge at Reset triggers a change to the most recently active operating mode.



① Activation
② Error
③ Reset

Reset response PID_Compact V.1.0

A rising edge at Reset resets the errors and warnings and clears the integral action. The controller is not reactivated until the next edge at i_Mode.



① Activation
② Error
③ Reset

Tag sd_warning V1

If several warnings are pending, the values of variable sd_warning are displayed by means of binary addition. The display of warning 0003, for example, indicates that the warnings 0001 and 0002 are also pending.

sd_warning (DW#16#....)	Description
0000	No warning pending.
0001	The point of inflection was not found during pretuning.
0002	Oscillation increased during fine tuning.
0004	The setpoint was outside the set limits.
0008	Not all the necessary controlled system properties were defined for the selected method of calculation. The PID parameters were instead calculated using the "i_CtrlTypeTIR = 3" method.
0010	The operating mode could not be changed because ManualEnable = TRUE.
0020	The cycle time of the calling OB limits the sampling time of the PID algorithm. Improve results by using shorter OB cycle times.
0040	The process value exceeded one of its warning limits.

The following warnings are deleted as soon as the cause is dealt with:

- 0004
- 0020
- 0040

All other warnings are cleared with a rising edge at Reset.

Tag i_Event_SUT V1

i_Event_SUT	Name	Description
0	SUT_INIT	Initialize pretuning
100	SUT_STDABW	Calculate the standard deviation
200	SUT_GET_POI	Find the point of inflection

PID_3Step

New features of PID_3Step

PID_3Step V2.2

- **Use with S7-1200**
  As of PID_3Step V2.2, the instruction with V2 functionality can also be used on S7-1200 with firmware version 4.0 or higher.

PID_3Step V2.0

- **Reaction to error**
  The reaction to ActivateRecoverMode = TRUE has been completely overhauled. PID_3Step reacts in a more fault tolerant manner in the default setting.

  Notice

  Your system may be damaged.

  If you use the default setting, PID_3Step remains in automatic mode even if the process value limits are exceeded. This may damage your system.

  It is essential to configure how your controlled system reacts in the event of an error to protect your system from damage.

  You use the ErrorAck input parameter to acknowledge the errors and warnings without restarting the controller or clearing the integral action.
  Switching operating modes does not acknowledge errors that are no longer pending.

- **Switching the operating mode**
  You specify the operating mode at the Mode in/out parameter and use a rising edge at ModeActivate to start the operating mode. The Retain.Mode tag has been omitted.
  The transition time measurement can no longer be started with GetTransitTime.Start, but only with Mode = 6 and a rising edge at ModeActivate.

- **Multi-instance capability**
  You can call up PID_3Step as multi-instance DB. No technology object is created in this case and no parameter assignment interface or commissioning interface is available. You must assign parameters for PID_3Step directly in the multi-instance DB and commission it via a watch table.

- **Startup characteristics**
  The operating mode specified at the Mode parameter is also started on a falling edge at Reset and during a CPU cold restart, if RunModeByStartup = TRUE.

- **ENO characteristics**
  ENO is set depending on the operating mode.
  If State = 0, then ENO = FALSE.
  If State ≠ 0, then ENO = TRUE.

- **Manual mode**
  The Manual_UP and Manual_DN input parameters no longer function as edge-triggered parameters. Edge-triggered manual mode continues to be possible using the ManualUpInternal and ManualDnInternal tags.
  In "Manual mode without endstop signals" (Mode = 10), the endstop signals Actuator_H and Actuator_L are ignored even though they are activated.
- **Default value of PID parameters**
  The following default settings have been changed:
  - Proportional action weighting (PWeighting) from 0.0 to 1.0
  - Derivative action weighting (DWeighting) from 0.0 to 1.0
  - Coefficient for derivative delay (TdFiltRatio) from 0.0 to 0.2
- **Limiting of motor transition time**
  You configure the maximum percentage of the motor transition time that the actuator will travel in one direction in the Config.VirtualActuatorLimit tag.
- **Setpoint value specification during tuning**
  You configure the permitted fluctuation of the setpoint during tuning at the CancelTuningLevel tag.
- **Switching a disturbance variable on**
  You can switch a disturbance variable on at the Disturbance parameter.
- **Troubleshooting**
  If the endstop signals are not activated (ActuatorEndStopOn = FALSE), ScaledFeedback is determined without Actuator_H or Actuator_L.

PID_3Step V1.1

- **Manual mode on CPU startup**
  If ManualEnable = TRUE when the CPU starts, PID_3Step starts in manual mode. A rising edge at ManualEnable is not necessary.
- **Reaction to error**
  The ActivateRecoverMode tag is no longer effective in manual mode.
- **Troubleshooting**
  The Progress tag is reset following successful tuning or transition time measurement.

Compatibility with CPU and FW

The following table shows which version of PID_3Step can be used on which CPU.

CPU	FW	PID_3Step
S7-1200	≥ V4.X	V2.2 V1.1
S7-1200	≥ V3.X	V1.1 V1.0
S7-1200	≥ V2.X	V1.1 V1.0
S7-1200	≥ V1.X	-

CPU	FW	PID_3Step
S7-1500	≥ V1.5	V2.2 V2.1 V2.0
S7-1500	≥ V1.1	V2.1 V2.0
S7-1500	≥ V1.0	V2.0

CPU processing time and memory requirement PID_3Step V2.x

CPU processing time

Typical CPU processing times of the PID_3Step technology object as of Version V2.0, depending on CPU type.

CPU	Typ. CPU processing time PID_3Step V2.x
CPU 1211C ≥ V4.0	410 µs
CPU 1215C ≥ V4.0	410 µs
CPU 1217C ≥ V4.0	410 µs
CPU 1505S ≥ V1.0	50 µs
CPU 1510SP-1 PN ≥ V1.6	120 µs
CPU 1511-1 PN ≥ V1.5	120 µs
CPU 1512SP-1 PN ≥ V1.6	120 µs
CPU 1516-3 PN/DP ≥ V1.5	65 µs
CPU 1518-4 PN/DP ≥ V1.5	5 µs

Memory requirement

Memory requirement of an instance DB of the PID_3Step technology object as of Version V2.0.

	Memory requirement of the instance DB of PID_3Step V2.x
Load memory requirement	Approx. 15000 bytes
Total work memory requirement	1040 bytes
Retentive work memory requirement	60 bytes

PID_3Step V2

Description of PID_3Step V2

Description

You use the PID_3Step instruction to configure a PID controller with self tuning for valves or actuators with integrating behavior.

The following operating modes are possible:

- Inactive
- Pretuning
- Fine tuning
- Automatic mode
- Manual mode
- Approach substitute output value
- Transition time measurement
- Error monitoring
- Approach substitute output value with error monitoring
- Manual mode without endstop signals

For a more detailed description of the operating modes, see the State parameter.

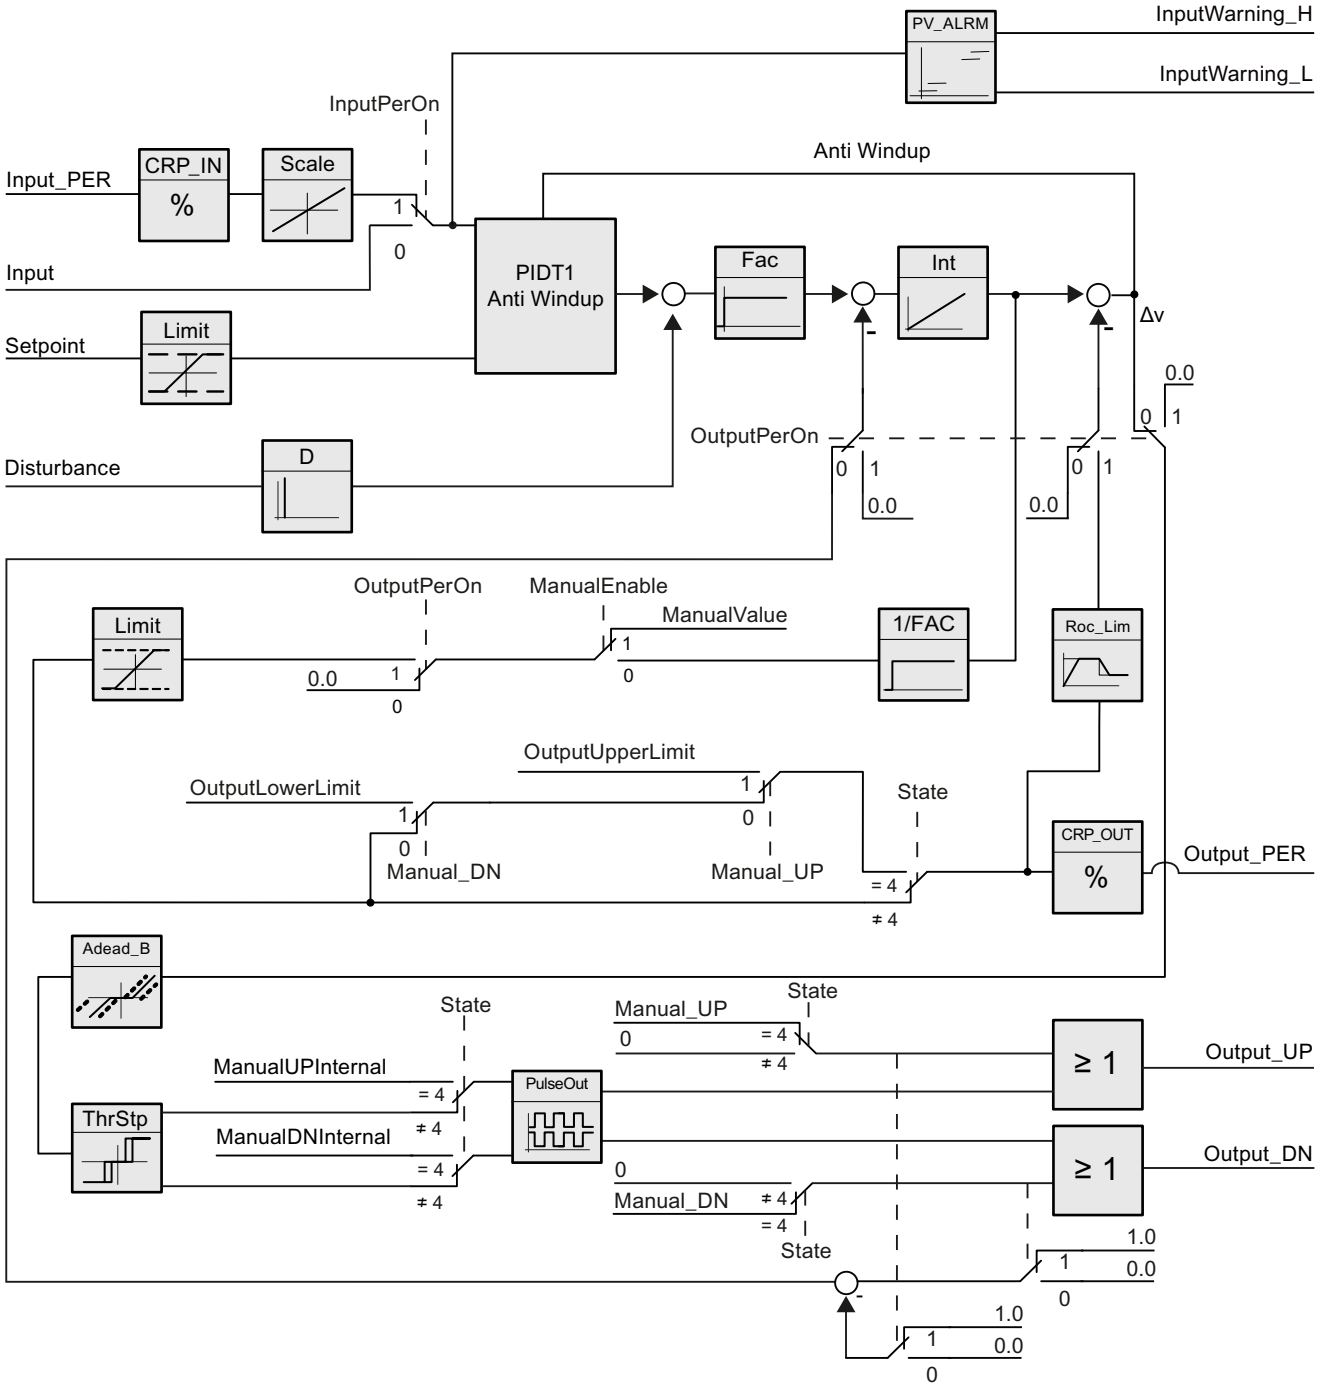
PID algorithm

PID_3Step is a PIDT1 controller with anti-windup and weighting of the proportional and derivative actions. The PID algorithm operates according to the following equation:

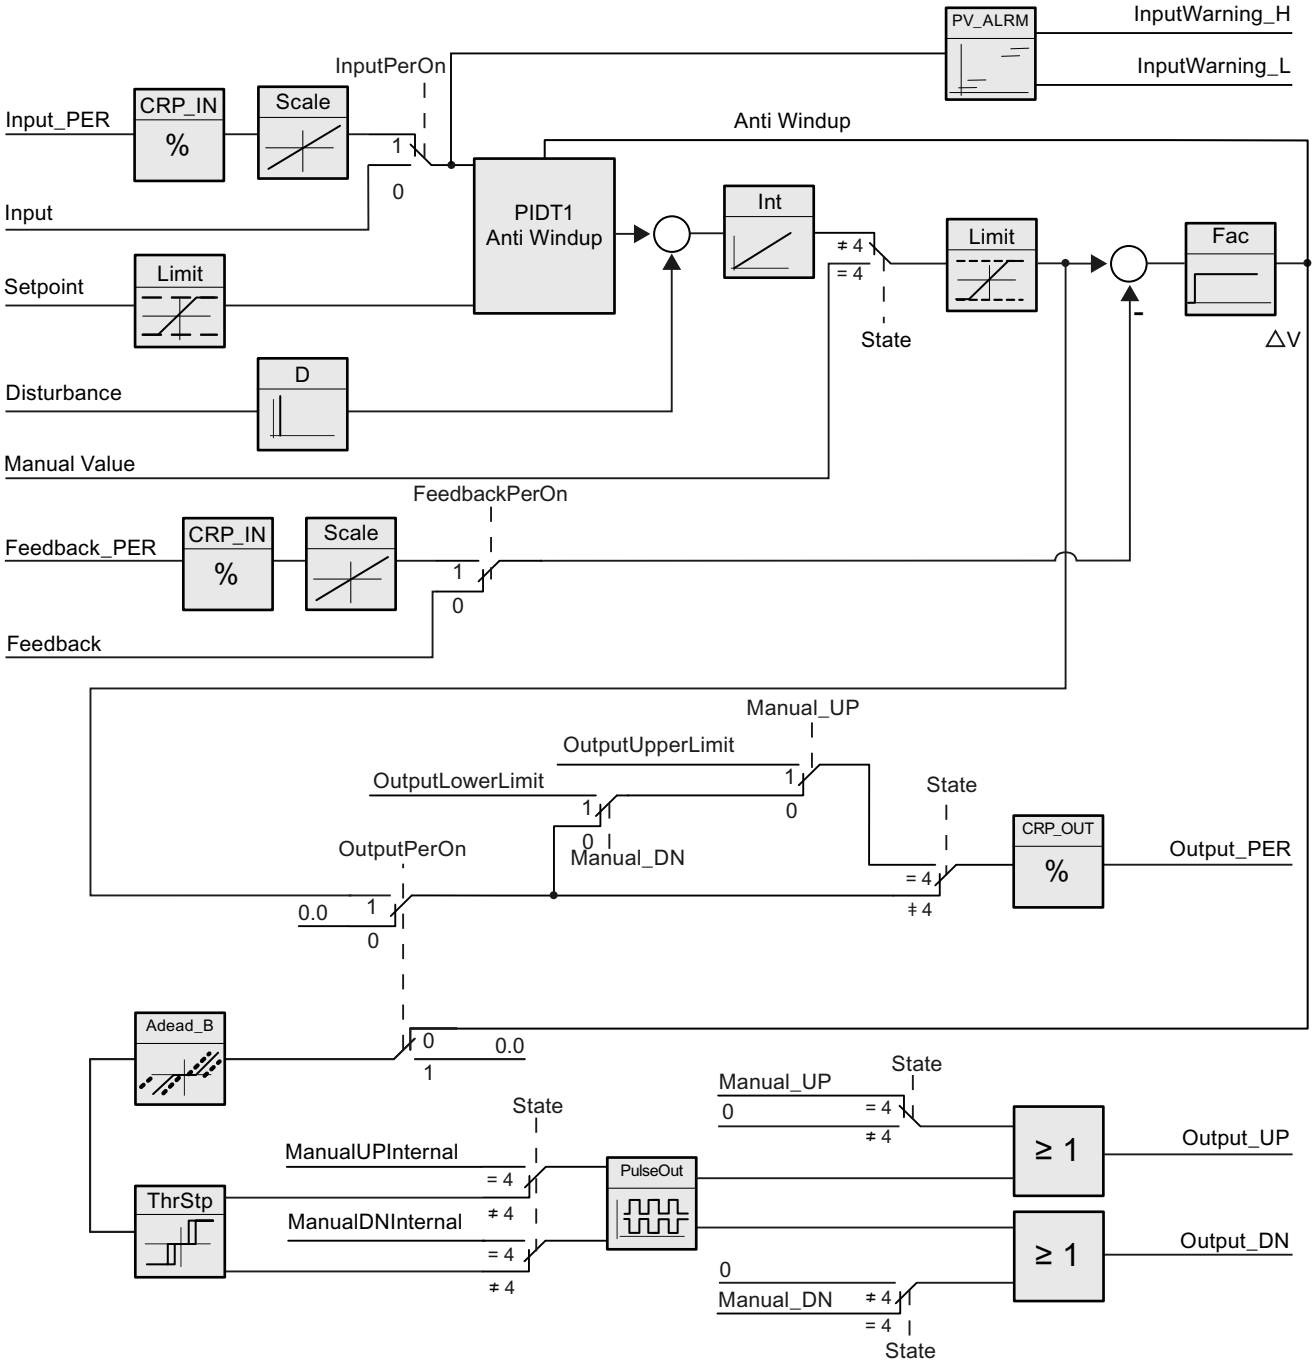
$$\Delta y = K_p \cdot s \cdot \left[(b \cdot w - x) + \frac{1}{T_I \cdot s} (w - x) + \frac{T_D \cdot s}{a \cdot T_D \cdot s + 1} (c \cdot w - x) \right]$$

Symbol	Description
Δy	Output value of the PID algorithm
K_p	Proportional gain
s	Laplace operator
b	Proportional action weighting
w	Setpoint
x	Process value
T_I	Integral action time
T_D	Derivative action time
a	Derivative delay coefficient (derivative delay T1 = a × T_D)
c	Derivative action weighting

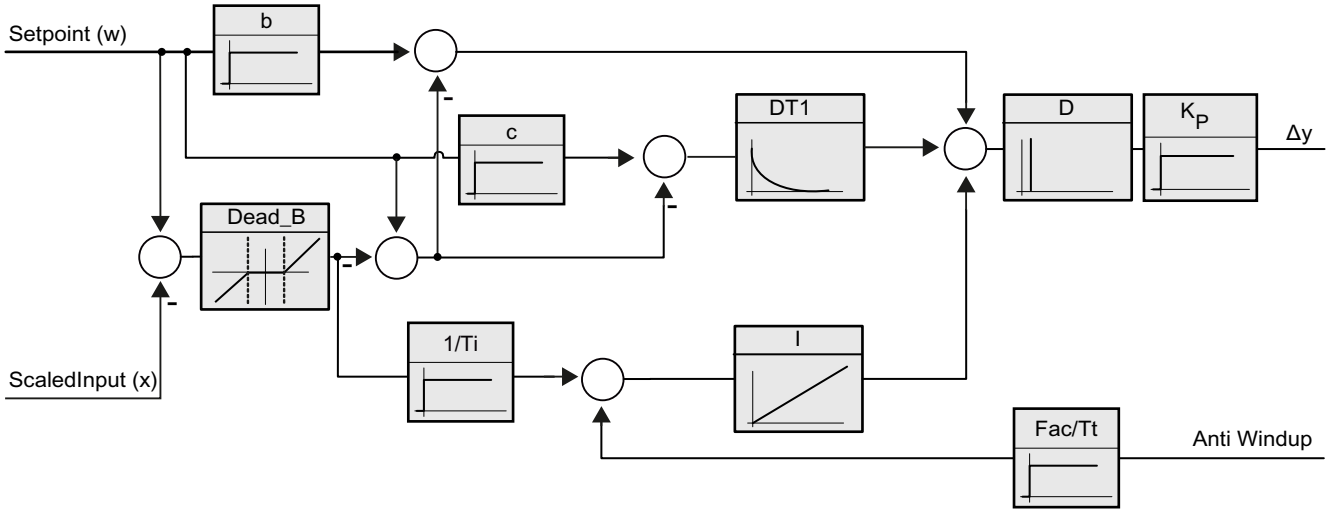
Block diagram without position feedback



Block diagram with position feedback



Block diagram of PIDT1 with anti-windup



Call

PID_3Step is called in the constant time scale of a cycle interrupt OB.

If you call PID_3Step as a multi-instance DB, no technology object is created. No parameter assignment interface or commissioning interface is available. You must assign parameters for PID_3Step directly in the multi-instance DB and commission it via a watch table.

Download to device

The actual values of retentive tags are only updated when you download PID_3Step completely.

Downloading technology objects to device (Page 7204)

Startup

When the CPU starts up, PID_3Step starts in the operating mode that is saved in the Mode in/out parameter. To leave PID_3Step in "Inactive" mode, set RunModeByStartup = FALSE.

Reaction to error

In automatic mode and during commissioning, the reaction to error depends on the ErrorBehaviour and ActivateRecoverMode tags. In manual mode, the reaction is independent of ErrorBehaviour and ActivateRecoverMode. If ActivateRecoverMode = TRUE, the reaction additionally depends on the error that occurred.

ErrorBehaviour	ActivateRecoverMode	Configuration editor > actuator setting > Set Output to	Reaction
FALSE	FALSE	Current output value	Switch to "Inactive" mode (State = 0) The actuator remains in the current position.
FALSE	TRUE	Current output value while error is pending	Switch to "Error monitoring" mode (State = 7) The actuator remains in the current position while the error is pending.
TRUE	FALSE	Substitute output value	Switch to "Approach substitute output value" mode (State = 5) The actuator moves to the configured substitute output value. Switch to "Inactive" mode (State = 0) The actuator remains in the current position.
TRUE	TRUE	Substitute output value while error is pending	Switch to "Approach substitute output value with error monitoring" mode (State = 8) The actuator moves to the configured substitute output value. Switch to "Error monitoring" mode (State = 7)

In manual mode, PID_3Step uses ManualValue as output value, unless the following errors occur:

- 2000h: Invalid value at Feedback_PER parameter.
- 4000h: Invalid value at Feedback parameter.
- 8000h: Error during digital position feedback.

You can only change the position of the actuator with Manual_UP and Manual_DN, not with ManualValue.

The Error parameter indicates whether an error has occurred in this cycle. The ErrorBits parameter shows which errors have occurred. ErrorBits is reset by a rising edge at Reset or ErrorAck.

Parameters State and Mode V2 (Page 3509)

Parameter ErrorBits V2 (Page 3514)

Configuring PID_3Step V2 (Page 7259)

Mode of operation of PID_3Step V2

Monitoring process value limits

You specify the high limit and low limit of the process value in the Config.InputUpperLimit and Config.InputLowerLimit variables. If the process value is outside these limits, an error occurs (ErrorBits = 0001h).

You specify a high and low warning limit of the process value in the Config.InputUpperWarning and Config.InputLowerWarning variables. If the process value is outside these warning limits, a warning occurs (Warning = 0040h), and the InputWarning_H or InputWarning_L output parameter changes to TRUE.

Limiting the setpoint

You specify a high limit and low limit of the setpoint in the Config.SetpointUpperLimit and Config.SetpointLowerLimit variables. PID_3Step automatically limits the setpoint to the process value limits. You can limit the setpoint to a smaller range. PID_3Step checks whether this range falls within the process value limits. If the setpoint is outside these limits, the high or low limit is used as the setpoint, and output parameter SetpointLimit_H or SetpointLimit_L is set to TRUE.

The setpoint is limited in all operating modes.

Limiting the output value

You specify a high limit and low limit of the output value in the Config.OutputUpperLimit and Config.OutputLowerLimit variables. The output value limits must be within "Low endstop" and "High endstop".

- High endstop: Config.FeedbackScaling.UpperPointOut
- Low endstop: Config.FeedbackScaling.LowerPointOut

Rule:

UpperPointOut ≥ OutputUpperLimit > OutputLowerLimit ≥ LowerPointOut

The valid values for "High endstop" and "Low endstop" depend upon:

- FeedbackOn
- FeedbackPerOn
- OutputPerOn

OutputPerOn	FeedbackOn	FeedbackPerOn	LowerPointOut	UpperPointOut
FALSE	FALSE	FALSE	Cannot be set (0.0%)	Cannot be set (100.0%)
FALSE	TRUE	FALSE	-100.0% or 0.0%	0.0% or +100.0%
FALSE	TRUE	TRUE	-100.0% or 0.0%	0.0% or +100.0%
TRUE	FALSE	FALSE	Cannot be set (0.0%)	Cannot be set (100.0%)
TRUE	TRUE	FALSE	-100.0% or 0.0%	0.0% or +100.0%
TRUE	TRUE	TRUE	-100.0% or 0.0%	0.0% or +100.0%

If OutputPerOn = FALSE and FeedbackOn = FALSE, you cannot limit the output value. Output_UP and Output_DN are then reset at Actuator_H = TRUE or Actuator_L = TRUE. If endstop signals are also not present, Output_UP and Output_DN are reset after a travel time of Config.VirtualActuatorLimit × Retain.TransitTime/100.

The output value is 27648 at 100% and -27648 at -100%. PID_3Step must be able to close the valve completely.

Substitute output value

If an error has occurred, PID_3Step can output a substitute output value and move the actuator to a safe position that is specified in the SavePosition tag. The substitute output value must be within the output value limits.

Monitoring signal validity

The values of the following parameters are monitored for validity when used:

- Setpoint
- Input
- Input_PER
- Input_PER
- Feedback
- Feedback_PER
- Disturbance
- ManualValue
- SavePosition
- Output_PER

Monitoring the PID_3Step sampling time

Ideally, the sampling time is equivalent to the cycle time of the calling OB. The PID_3Step instruction measures the time interval between two calls. This is the current sampling time. On every switchover of operating mode and during the initial startup, the mean value is formed from the first 10 sampling times. Too great a difference between the current sampling time and this mean value triggers an error (ErrorBits = 0800h).

The error occurs during tuning if:

- New mean value >= 1.1 x old mean value
- New mean value <= 0.9 x old mean value

The error occurs in automatic mode if:

- New mean value >= 1.5 x old mean value
- New mean value <= 0.5 x old mean value

If you deactivate the sampling time monitoring (CycleTime.EnMonitoring = FALSE), you can also call PID_3Step in OB1. You must then accept a lower control quality due to the deviating sampling time.

Sampling time of the PID algorithm

The controlled system needs a certain amount of time to respond to changes in the output value. It is therefore not advisable to calculate the output value in every cycle. The sampling time of the PID algorithm represents the time between two calculations of the output value. It is calculated during tuning and rounded to a multiple of the cycle time. All other functions of PID_3Step are executed at every call.

Measuring the motor transition time

The motor transition time is the time in seconds the motor requires to move the actuator from the closed to the opened state. The actuator is moved in one direction for a maximum time of Config.VirtualActuatorLimit × Retain.TransitTime/100. PID_3Step requires the motor transition time to be as accurate as possible for good controller results. The data in the actuator documentation contains average values for this type of actuator. The value for the specific actuator used may differ. You can measure the motor transition time during commissioning. The output value limits are not taken into consideration during the motor transition time measurement. The actuator can travel to the high or the low endstop.

Control logic

An increase of the output value is generally intended to cause an increase in the process value. This is referred to as a normal control logic. For cooling and discharge control systems, it may be necessary to invert the control logic. PID_3Step does not work with negative proportional gain. If InvertControl = TRUE, an increasing control deviation causes a reduction in the output value. The control logic is also taken into account during pretuning and fine tuning.

TIR.TuneRuleTIR	TIR.TuneRule	Renamed
Retain.Mode	Mode	Function Declaration of static for in-out parameters

Input parameters of PID_3Step V2

Table 11-88

Parameter	Data type	Default	Description
Setpoint	REAL	0.0	Setpoint of the PID controller in automatic mode
Input	REAL	0.0	A tag of the user program is used as the source of the process value. If you are using the Input parameter, then Config.InputPerOn = FALSE must be set.
Input_PER	INT	0	An analog input is used as the source of the process value. If you are using the Input_PER parameter, then Config.InputPerOn = TRUE must be set.
Actuator_H	BOOL	FALSE	Digital position feedback of the valve for the high endstop If Actuator_H = TRUE, the valve is at the high endstop and is no longer moved towards this direction.
Actuator_L	BOOL	FALSE	Digital position feedback of the valve for the low endstop If Actuator_L = TRUE, the valve is at the low endstop and is no longer moved towards this direction.
Feedback	REAL	0.0	Position feedback of the valve If you are using the Feedback parameter, then Config.FeedbackPerOn = FALSE must be set.

Parameter	Data type	Default	Description
Feedback_PER	INT	0	Analog position feedback of a valve If you are using the Feedback_PER parameter, then Config.FeedbackPerOn = TRUE must be set. Feedback_PER is scaled based on the tags: • Config.FeedbackScaling.LowerPointIn • Config.FeedbackScaling.UpperPointIn • Config.FeedbackScaling.LowerPointOut • Config.FeedbackScaling.UpperPointOut
Disturbance	REAL	0.0	Disturbance tag or precontrol value
ManualEnable	BOOL	FALSE	• A FALSE -> TRUE edge activates "manual mode", while State = 4, Mode remain unchanged. As long as ManualEnable = TRUE, you cannot change the operating mode via a rising edge at ModeActivate or use the commissioning dialog. • A TRUE -> FALSE edge activates the operating mode that is specified by Mode. We recommend that you change the operating mode using ModeActivate only.
ManualValue	REAL	0.0	In manual mode, the absolute position of the valve is specified. ManualValue is only evaluated if you are using Output_PER, **or** if position feedback is available.
Manual_UP	BOOL	FALSE	• Manual_UP = TRUE The valve is opened even if you are using Output_PER or a position feedback. The valve is no longer moved if the high endstop has been reached. See also Config.VirtualActuatorLimit • Manual_UP = FALSE If you are using Output_PER or a position feedback, the valve is moved to ManualValue. Otherwise, the valve is no longer moved. If Manual_UP and Manual_DN are set to TRUE simultaneously, the valve is not moved.
Manual_DN	BOOL	FALSE	• Manual_DN = TRUE The valve is closed even if you are using Output_PER or a position feedback. The valve is no longer moved if the low endstop has been reached. See also Config.VirtualActuatorLimit • Manual_DN = FALSE If you are using Output_PER or a position feedback, the valve is moved to ManualValue. Otherwise, the valve is no longer moved.
ErrorAck	BOOL	FALSE	• FALSE -> TRUE edge ErrorBits and Warning are reset.

Parameter	Data type	Default	Description
Reset	BOOL	FALSE	Restarts the controller. • FALSE -> TRUE edge – Switch to "Inactive" mode – ErrorBits and Warning are reset. – Integral action is cleared (PID parameters are retained) • As long as Reset = TRUE, PID_3Step remains in "Inactive" mode (State = 0). • TRUE -> FALSE edge PID_3Step switches to the operating mode that is saved in the Mode parameter.
ModeActivate	BOOL	FALSE	• FALSE -> TRUE edge PID_3Step switches to the operating mode that is saved in the Mode parameter.

Output parameters of PID_3Step V2

Table 11-89

Parameter	Data type	Default	Description
ScaledInput	REAL	0.0	Scaled process value
ScaledFeedback	REAL	0.0	Scaled position feedback For an actuator without position feedback, the position of the actuator indicated by ScaledFeedback is very imprecise. ScaledFeedback may only be used for rough estimation of the current position in this case.
Output_UP	BOOL	FALSE	Digital output value for opening the valve If Config.OutputPerOn = FALSE, the Output_UP parameter is used.
Output_DN	BOOL	FALSE	Digital output value for closing the valve If Config.OutputPerOn = FALSE, the Output_DN parameter is used.
Output_PER	INT	0	Analog output value If Config.OutputPerOn = TRUE, Output_PER is used.
SetpointLimit_H	BOOL	FALSE	If SetpointLimit_H = TRUE, the absolute setpoint high limit is reached (Setpoint ≥ Config.SetpointUpperLimit). The setpoint is limited to Config.SetpointUpperLimit .
SetpointLimit_L	BOOL	FALSE	If SetpointLimit_L = TRUE, the absolute setpoint low limit has been reached (Setpoint ≤ Config.SetpointLowerLimit). The setpoint is limited to Config.SetpointLowerLimit .
InputWarning_H	BOOL	FALSE	If InputWarning_H = TRUE, the process value has reached or exceeded the warning high limit.
InputWarning_L	BOOL	FALSE	If InputWarning_L = TRUE, the process value has reached or fallen below the warning low limit.

Parameter	Data type	Default	Description
State	INT	0	The State parameter (Page 3509) shows the current operating mode of the PID controller. You can change the operating mode using the input parameter Mode and a rising edge at ModeActivate. • State = 0: Inactive • State = 1: Pretuning • State = 2: Fine tuning • State = 3: Automatic mode • State = 4: Manual mode • State = 5: Approach substitute output value • State = 6: Transition time measurement • State = 7: Error monitoring • State = 8: Approach substitute output value with error monitoring • State = 10: Manual mode without end stop signals
Error	BOOL	FALSE	If Error = TRUE, at least one error message is pending in this cycle.
ErrorBits	DWORD	DW#16#0	The ErrorBits parameter (Page 3514) shows which error messages are pending. ErrorBits is retentive and is reset upon a rising edge at Reset or ErrorAck.

Parameters State and Mode V2 (Page 3509)

Parameter ErrorBits V2 (Page 3514)

In-out parameters of PID_3Step V2

Table 11-90

Parameter	Data type	Default	Description
Mode	INT	4	At the Mode parameter, you specify the operating mode to which PID_3Step is to switch. Options are: • Mode = 0: Inactive • Mode = 1: Pretuning • Mode = 2: Fine tuning • Mode = 3: Automatic mode • Mode = 4: Manual mode • Mode = 6: Transition time measurement • Mode = 10: Manual mode without endstop signals The operating mode is activated by: • Rising edge at ModeActivate • Falling edge at Reset • Falling edge at ManualEnable • Cold restart of CPU if RunModeByStartup = TRUE Mode is retentive. A detailed description of the operating modes can be found in Parameters State and Mode V2 (Page 3509).

Static tags of PID_3Step V2

You must not change tags that are not listed. These are used for internal purposes only.

Tag	Data type	Default	Description
ManualUpInternal	BOOL	FALSE	In manual mode, each rising edge opens the valve by 5% of the total control range or for the duration of the minimum motor transition time. ManualUpInternal is only evaluated if you are not using Output_PER or a position feedback. This tag is used in the commissioning dialog.
ManualDnInternal	BOOL	FALSE	In manual mode, every rising edge closes the valve by 5% of the total control range or for the duration of the minimum motor transition time. ManualDnInternal is only evaluated if you are not using Output_PER or position feedback. This tag is used in the commissioning dialog.
ActivateRecoverMode	BOOL	TRUE	The ActivateRecoverMode V2 (Page 3517) tag determines the reaction to error.
RunModeByStartup	BOOL	TRUE	Activate operating mode at Mode parameter after CPU restart If RunModeByStartup = TRUE, PID_3Step starts in the operating mode saved in the Mode parameter after CPU startup. If RunModeByStartup = FALSE, PID_3Step remains in "Inactive" mode after CPU startup.
LoadBackUp	BOOL	FALSE	If LoadBackUp = TRUE, the last set of PID parameters is reloaded. The set was saved prior to the last tuning. LoadBackUp is automatically set back to FALSE.

Tag	Data type	Default	Description
PhysicalUnit	INT	0	Unit of measurement of the process value and setpoint, e.g., °C, or °F.
PhysicalQuantity	INT	0	Physical quantity of the process value and setpoint, e.g., temperature
ErrorBehaviour	BOOL	FALSE	If ErrorBehaviour = FALSE and an error has occurred, the valve stays at its current position and the controller switches directly to "Inactive" or "Error monitoring" mode. If ErrorBehaviour = TRUE and an error occurs, the actuator moves to the substitute output value and only then switches to "Inactive" or "Error monitoring" mode. If the following errors occur, you can no longer move the valve to a configured substitute output value. • 2000h: Invalid value at Feedback_PER parameter. • 4000h: Invalid value at Feedback parameter. • 8000h: Error during digital position feedback. • 20000h: Invalid value at SavePosition tag.
Warning	DWORD	DW#16#0	The Warning tag (Page 3509) shows the warnings since Reset = TRUE or ErrorAck =TRUE. Warning is retentive. Cyclic warnings (for example, process value warning) are shown until the cause of the warning is removed. They are automatically deleted once their cause has gone. Non-cyclic warnings (for example, point of inflection not found) remain and are deleted like errors.
SavePosition	REAL	0.0	Substitute output value If ErrorBehaviour = TRUE, the actuator is moved to a position that is safe for the plant when an error occurs. As soon as the substitute output value has been reached, PID_3Step switches the operating mode according to ActivateRecoverMode.
CurrentSetpoint	REAL	0.0	Currently active setpoint. This value is frozen at the start of tuning.
CancelTuningLevel	REAL	10.0	Permissible fluctuation of setpoint during tuning. Tuning is not canceled until: • Setpoint > CurrentSetpoint + CancelTuningLevel or • Setpoint < CurrentSetpoint - CancelTuningLevel
Progress	REAL	0.0	Progress of tuning as a percentage (0.0 - 100.0)
Config.InputPerOn	BOOL	TRUE	If InputPerOn = TRUE, the Input_PER parameter is used. If InputPerOn = FALSE, the Input parameter is used.
Config.OutputPerOn	BOOL	FALSE	If OutputPerOn = TRUE, the Output_PER parameter is used. If OutputPerOn = FALSE, the Ouput_UP and Output_DN parameters are used.
Config.InvertControl	BOOL	FALSE	Invert control logic If InvertControl = TRUE, an increasing control deviation causes a reduction in the output value.
Config.FeedbackOn	BOOL	FALSE	If FeedbackOn = FALSE, a position feedback is simulated. Position feedback is generally activated when FeedbackOn = TRUE.

Tag	Data type	Default	Description
Config.FeedbackPerOn	BOOL	FALSE	FeedbackPerOn is only effective when FeedbackOn = TRUE. If FeedbackPerOn = TRUE, the analog input is used for the position feedback (Feedback_PER parameter). If FeedbackPerOn = FALSE, the Feedback parameter is used for the position feedback.
Config.ActuatorEndStopOn	BOOL	FALSE	If ActuatorEndStopOn = TRUE, the digital position feedback Actuator_L and Actuator_H are taken into consideration.
Config.InputUpperLimit	REAL	120.0	High limit of the process value Input and Input_PER are monitored to ensure adherence to this limit. At the I/O input, the process value can be a maximum of 18% higher than the standard range (overrange). An error is no longer signaled due to a violation of the "Process value high limit". Only a wire-break and a short-circuit are recognized and PID_3Step reacts according to the configured reaction to error. InputUpperLimit > InputLowerLimit
Config.InputLowerLimit	REAL	0.0	Low limit of the process value InputLowerLimit < InputUpperLimit
Config.InputUpperWarning	REAL	+3.402822e+38	Warning high limit of the process value If you set InputUpperWarning outside the process value limits, the configured absolute process value high limit is used as the warning high limit. If you configure InputUpperWarning within the process value limits, this value is used as the warning high limit. InputUpperWarning > InputLowerWarning InputUpperWarning ≤ InputUpperLimit
Config.InputLowerWarning	REAL	-3.402822e+38	Warning low limit of the process value If you set InputLowerWarning outside the process value limits, the configured absolute process value low limit is used as the warning low limit. If you configure InputLowerWarning within the process value limits, this value is used as the warning low limit. InputLowerWarning < InputUpperWarning InputLowerWarning ≥ InputLowerLimit
Config.OutputUpperLimit	REAL	100.0	High limit of output value For details, see OutputLowerLimit
Config.OutputLowerLimit	REAL	0.0	Low limit of output value If OutputPerOn = TRUE or FeedbackOn = TRUE, the range of values from -100% to +100%, including zero, is valid. At -100%, Output = -27648; at +100% Output = 27648 If OutputPerOn = FALSE, the range of values from 0% to 100% is valid. The valve is completely closed at 0% and completely opened at 100%.
Config.SetpointUpperLimit	REAL	+3.402822e+38	High limit of setpoint If you set SetpointUpperLimit outside the process value limits, the configured absolute process value high limit is preassigned as the setpoint high limit. If you configure SetpointUpperLimit within the process value limits, this value is used as the setpoint high limit.

Tag	Data type	Default	Description
Config.SetpointLowerLimit	REAL	-3.402822e+38	Low limit of the setpoint If you set SetpointLowerLimit outside the process value limits, the configured absolute process value low limit is preassigned as the setpoint low limit. If you set SetpointLowerLimit within the process value limits, this value is used as the setpoint low limit.
Config.MinimumOnTime	REAL	0.0	Minimum ON time Minimum time in seconds for which the servo drive must be switched on.
Config.MinimumOffTime	REAL	0.0	Minimum OFF time Minimum time in seconds for which the servo drive must be switched off.
Config.VirtualActuatorLimit	REAL	150.0	If all the following conditions have been satisfied, the actuator is moved in one direction for the maximum period of VirtualActuatorLimit × Retain.TransitTime/100 and the warning 2000h is output: • Config.OutputPerOn = FALSE • Config.ActuatorEndStopOn = FALSE • Config.FeedbackOn = FALSE If Config.OutputPerOn = FALSE and Config.ActuatorEndStopOn = TRUE or Config.FeedbackOn = TRUE, only the warning 2000h is output. If Config.OutputPerOn = TRUE, VirtualActuatorLimit is not taken into consideration.
Config.InputScaling.UpperPointIn	REAL	27648.0	Scaling Input_PER high Input_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the InputScaling structure.
Config.InputScaling.LowerPointIn	REAL	0.0	Scaling Input_PER low Input_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the InputScaling structure.
Config.InputScaling.UpperPointOut	REAL	100.0	Scaled high process value Input_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the InputScaling structure.
Config.InputScaling.LowerPointOut	REAL	0.0	Scaled low process value Input_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the InputScaling structure.
Config.FeedbackScaling.UpperPointIn	REAL	27648.0	Scaling Feedback_PER high Feedback_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the FeedbackScaling structure.
Config.FeedbackScaling.LowerPointIn	REAL	0.0	Scaling Feedback_PER low Feedback_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the FeedbackScaling structure.

Tag	Data type	Default	Description
Config.FeedbackScaling.UpperPointOut	REAL	100.0	High endstop Feedback_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the FeedbackScaling structure.
Config.FeedbackScaling.LowerPointOut	REAL	0.0	Low endstop Feedback_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the FeedbackScaling structure.
GetTransitTime.InvertDirection	BOOL	FALSE	If InvertDirection = FALSE, the valve is fully opened, closed, and then reopened in order to determine the valve transition time. If InvertDirection = TRUE, the valve is fully closed, opened, and then closed again.
GetTransitTime.SelectFeedback	BOOL	FALSE	If SelectFeedback = TRUE, then Feedback_PER, or Feedback is taken into consideration in the transition time measurement. If SelectFeedback = FALSE, then Actuator_H and Actuator_L are taken into consideration in the transition time measurement.
GetTransitTime.State	INT	0	Current phase of the transition time measurement • State = 0: Inactive • State = 1: Open valve completely • State = 2: Close valve completely • State = 3: Move valve to target position (NewOutput) • State = 4: Transition time measurement successfully completed • State = 5: Transition time measurement canceled
GetTransitTime.NewOutput	REAL	0.0	Target position for transition time measurement with position feedback The target position must be between "High endstop" and "Low endstop". The difference between NewOutput and ScaledFeedback must be at least 50% of the permissible control range.
CycleTime.StartEstimation	BOOL	TRUE	If StartEstimation = TRUE, the measurement of the PID_3Step sampling time is started. CycleTime.StartEstimation = FALSE once measurement is complete.
CycleTime.EnEstimation	BOOL	TRUE	If EnEstimation = TRUE, the PID_3Step sampling time is calculated. If CycleTime.EnEstimation = FALSE, the PID_3Step sampling time is not calculated and you need to correct the configuration of CycleTime.Value manually.
CycleTime.EnMonitoring	BOOL	TRUE	If EnMonitoring = TRUE, the PID_3Step sampling time is monitored. If it is not possible to execute PID_3Step within the sampling time, the error 0800h is output and the operating mode is switched. ActivateRecoverMode and ErrorBehaviour determine which operating mode is switched to. If EnMonitoring = FALSE, the PID_3Step sampling time is not monitored, the error 0800h is not output, and the operating mode is not switched.
CycleTime.Value	REAL	0.1	PID_3Step sampling time in seconds CycleTime.Value is determined automatically and is usually equivalent to the cycle time of the calling OB.

Tag	Data type	Default	Description
CtrlParamsBackUp.SetByUser	BOOL	FALSE	Saved value of Retain.CtrlParams.SetByUser You can reload values from the CtrlParamsBackUp structure with LoadBackUp = TRUE.
CtrlParamsBackUp.Gain	REAL	1.0	Saved proportional gain
CtrlParamsBackUp.Ti	REAL	20.0	Saved integral action time in seconds
CtrlParamsBackUp.Td	REAL	0.0	Saved derivative action time in seconds
CtrlParamsBackUp.TdFiltRatio	REAL	0.2	Saved derivative delay coefficient
CtrlParamsBackUp.PWeighting	REAL	1.0	Saved proportional action weighting
CtrlParamsBackUp.DWeighting	REAL	1.0	Saved derivative action weighting
CtrlParamsBackUp.Cycle	REAL	1.0	Saved sampling time of PID algorithm in seconds
CtrlParamsBackUp.InputDeadBand	REAL	0.0	Saved deadband width of the control deviation
PIDSelfTune.SUT.CalculateParams	BOOL	FALSE	The properties of the controlled system are saved during tuning. If CalculateParams = TRUE, the PID parameters are recalculated on the basis of these properties. The PID parameters are calculated using the method set in TuneRule. CalculateParams is set to FALSE following calculation.
PIDSelfTune.SUT.TuneRule	INT	1	Methods used to calculate parameters during pretuning: • SUT.TuneRule = 0: PID rapid I • SUT.TuneRule = 1: PID slow I • SUT.TuneRule = 2: Chien, Hrones and Reswick PID • SUT.TuneRule = 3: Chien, Hrones, Reswick PI • SUT.TuneRule = 4: PID rapid II • SUT.TuneRule = 5: PID slow II
PIDSelfTune.SUT.State	INT	0	The SUT.State tag indicates the current phase of pretuning: • State = 0: Initialize pretuning • State = 50: Determine start position without position feedback • State = 100: Calculate standard deviation • State = 200: Determine point of inflection • State = 300: Determine rise time • State = 9900: Pretuning successful • State = 1: Pretuning not successful

Tag	Data type	Default	Description
PIDSelfTune.TIR.RunIn	BOOL	FALSE	With the RunIn tag, you can specify that fine tuning can also be performed without pretuning. • RunIn = FALSE Pretuning is started when fine tuning is started from inactive or manual mode. If fine tuning is started from automatic mode, the system uses the existing PID parameters to control to the setpoint. Only then will fine tuning start. If pretuning is not possible, PID_3Step switches to the mode from which tuning was started. • RunIn = TRUE The pretuning is skipped. PID_3Step attempts to reach the setpoint with the minimum or maximum output value. This can produce increased overshoot. Only then will fine tuning start. RunIn is set to FALSE after fine tuning.
PIDSelfTune.TIR.Calculate-Params	BOOL	FALSE	The properties of the controlled system are saved during tuning. If CalculateParams = TRUE, the PID parameters are recalculated on the basis of these properties. The PID parameters are calculated using the method set in TuneRule. CalculateParams is set to FALSE following calculation.
PIDSelfTune.TIR.TuneRule	INT	0	Methods used to calculate parameters during fine tuning: • TIR.TuneRule = 0: PID automatic • TIR.TuneRule = 1: PID rapid • TIR.TuneRule = 2: PID slow • TIR.TuneRule = 3: Ziegler-Nichols PID • TIR.TuneRule = 4: Ziegler-Nichols PI • TIR.TuneRule = 5: Ziegler-Nichols P
PIDSelfTune.TIR.State	INT	0	The TIR.State tag indicates the current phase of fine tuning: • State = -100 Fine tuning is not possible. Pretuning will be performed first. • State = 0: Initialize fine tuning • State = 200: Calculate standard deviation • State = 300: Attempt to reach the setpoint with the maximum or minimum output value • State = 400: Attempt to reach the setpoint with existing PID parameters (if pretuning was successful) • State = 500: Determine oscillation and calculate parameters • State = 9900: Fine tuning successful • State = 1: Fine tuning not successful
Retain.TransitTime	REAL	30.0	Motor transition time in seconds Time in seconds the actuating drive requires to move the valve from the closed to the opened state. TransitTime is retentive.

Tag	Data type	Default	Description
Retain.CtrlParams.SetByUser	BOOL	FALSE	If SetByUser = FALSE, the PID parameters are determined automatically and PID_3Step operates with a deadband at the output value. The deadband width is calculated during tuning on the basis of the standard deviation of the output value and saved in Retain.CtrlParams.OutputDeadBand. If SetByUser = TRUE, the PID parameters are entered manually and PID_3 Step operates without a deadband at the output value. Retain.CtrlParams.OutputDeadBand = 0.0 SetByUser is retentive.
Retain.CtrlParams.Gain	REAL	1.0	Active proportional gain To invert the control logic, use the Config.InvertControl tag. Negative values at Gain also invert the control logic. We recommend you use only InvertControl to set the control logic. The control logic is also inverted if InvertControl = TRUE and Gain < 0.0. Gain is retentive.
Retain.CtrlParams.Ti	REAL	20.0	• Ti > 0.0: Active integral action time in seconds • Ti = 0.0: Integral action is deactivated Ti is retentive.
Retain.CtrlParams.Td	REAL	0.0	• Td > 0.0: Active derivative action time in seconds • Td = 0.0: Derivative action is deactivated Td is retentive.
Retain.CtrlParams.TdFiltRatio	REAL	0.2	Active derivative delay coefficient The derivative delay coefficient delays the effect of the derivative action. Derivative delay = derivative action time × derivative delay coefficient • 0.0: Derivative action is effective for one cycle only and therefore almost not effective. • 0.5: This value has proved useful in practice for controlled systems with **one** dominant time constant. • > 1.0: The greater the coefficient, the longer the effect of the derivative action is delayed. TdFiltRatio is retentive.
Retain.CtrlParams.PWeighting	REAL	1.0	Active proportional action weighting The proportional action may weaken with changes to the setpoint. Values from 0.0 to 1.0 are applicable. • 1.0: Proportional action for setpoint change is fully effective • 0.0: Proportional action for setpoint change is not effective The proportional action is always fully effective when the process value is changed. PWeighting is retentive.

Tag	Data type	Default	Description
Retain.CtrlParams.DWeighting	REAL	1.0	Active derivative action weighting The derivative action may weaken with changes to the setpoint. Values from 0.0 to 1.0 are applicable. • 1.0: Derivative action is fully effective upon setpoint change • 0.0: Derivative action is not effective upon setpoint change The derivative action is always fully effective when the process value is changed. DWeighting is retentive.
Retain.CtrlParams.Cycle	REAL	1.0	Active sampling time of PID algorithm in seconds, rounded to an integer multiple of the cycle time of the calling OB. Cycle is retentive.
Retain.CtrlParams.InputDeadBand	REAL	0.0	Deadband width of the control deviation InputDeadBand is retentive.

Note

Change the tags listed in this table in "Inactive" mode to prevent malfunction of the PID controller.

Parameters State and Mode V2

Correlation of the parameters

The State parameter shows the current operating mode of the PID controller. You cannot change the State parameter.

With a rising edge at ModeActivate, PID_3Step switches to the operating mode saved in the Mode in-out parameter.

When the CPU is switched on or switches from Stop to RUN mode, PID_3Step starts in the operating mode that is saved in the Mode parameter. To leave PID_3Step in "Inactive" mode, set RunModeByStartup = FALSE.

Meaning of values

State	Description of operating mode
0	Inactive The controller is switched off and no longer changes the valve position.
1	Pretuning The pretuning determines the process response to a pulse of the output value and searches for the point of inflection. The PID parameters are calculated from the maximum rate of rise and dead time of the controlled system. You obtain the best PID parameters when you perform pretuning and fine tuning. Pretuning requirements: • The motor transition time has been configured or measured. • Inactive (State = 0), manual mode (State = 4), or automatic mode (State = 3) • ManualEnable = FALSE • Reset = FALSE • The setpoint and the process value lie within the configured limits. The more stable the process value is, the easier it is to calculate the PID parameters and the more precise the result will be. Noise on the process value can be tolerated as long as the rate of rise of the process value is significantly higher as compared to the noise. This is most likely the case in operating modes "Inactive" and "manual mode". The setpoint is frozen in the CurrentSetpoint tag. Tuning is canceled when: • Setpoint > CurrentSetpoint + CancelTuningLevel or • Setpoint < CurrentSetpoint - CancelTuningLevel Before the PID parameters are recalculated, they are backed up and can be reactivated with LoadBackUp. The controller switches to automatic mode following successful pretuning. If pretuning is unsuccessful, the switchover of operating mode is dependent on ActivateRecoverMode and ErrorBehaviour. The pretuning phase is indicated with the SUT.State tag.

State	Description of operating mode
2	Fine tuning Fine tuning generates a constant, limited oscillation of the process value. The PID parameters are recalculated based on the amplitude and frequency of this oscillation. PID parameters from fine tuning usually have better master control and disturbance characteristics than PID parameters from pretuning. You obtain the best PID parameters when you perform pretuning and fine tuning. PID_3Step automatically attempts to generate an oscillation greater than the noise of the process value. Fine tuning is only minimally influenced by the stability of the process value. The setpoint is frozen in the CurrentSetpoint tag. Tuning is canceled when: • Setpoint > CurrentSetpoint + CancelTuningLevel or • Setpoint < CurrentSetpoint - CancelTuningLevel The PID parameters are backed up before fine tuning. They can be reactivated with LoadBackUp. Requirements for fine tuning: • The motor transition time has been configured or measured. • The setpoint and the process value lie within the configured limits. • ManualEnable = FALSE • Reset = FALSE • Automatic (State = 3), inactive (State = 0) or manual (State = 4) mode Fine tuning proceeds as follows when started from: • Automatic mode (State = 3) Start fine tuning from automatic mode if you wish to improve the existing PID parameters through tuning. PID_3Step controls the system using the existing PID parameters until the control loop has stabilized and the requirements for fine tuning have been met. Only then will fine tuning start. • Inactive (State = 0) or manual mode (State = 4) If the requirements for pretuning are met, pretuning is started. The determined PID parameters will be used for control until the control loop has stabilized and the requirements for fine tuning have been met. If PIDSelfTune.TIR.RunIn = TRUE, pretuning is skipped and an attempt is made to reach the setpoint with the minimum or maximum output value. This can produce increased overshoot. Fine tuning then starts automatically. The controller switches to automatic mode following successful fine tuning. If fine tuning is unsuccessful, the switchover of operating mode is dependent on ActivateRecoverMode and ErrorBehaviour. The fine tuning phase is indicated with the TIR.State tag.
3	Automatic mode In automatic mode, PID_3Step controls the controlled system in accordance with the parameters specified. The controller switches to automatic mode if one the following requirements is fulfilled: • Pretuning successfully completed • Fine tuning successfully completed • Changing of the Mode in-out parameter to the value 3 and a rising edge at ModeActivate. The switchover from automatic mode to manual mode is only bumpless if carried out in the commissioning editor. The ActivateRecoverMode tag is taken into consideration in automatic mode.

State	Description of operating mode
4	Manual mode In manual mode, you specify manual output values in the Manual_UP and Manual_DN parameters or ManualValue parameter. Whether or not the actuator can be moved to the output value in the event of an error is described in the ErrorBits parameter. You can also activate this operating mode using ManualEnable = TRUE. We recommend that you change the operating mode using Mode and ModeActivate only. The switchover from manual mode to automatic mode is bumpless. Manual mode is also possible when an error is pending.
5	Approach substitute output value This operating mode is activated in the event of an error, if Errorbehaviour = TRUE and ActivateRecoverMode = FALSE.. PID_3Step moves the actuator to the substitute output value and then switches to "Inactive" mode.
6	Transition time measurement The time that the motor needs to completely open the valve from the closed condition is determined. This operating mode is activated when Mode = 6 and ModeActivate = TRUE is set. If endstop signals are used to measure the transition time, the valve will be opened completely from its current position, closed completely, and opened completely again. If GetTransitTime.InvertDirection = TRUE, this behavior is inverted. If position feedback is used to measure the transition time, the actuator will be moved from its current position to a target position. The output value limits are not taken into consideration during the transition time measurement. The actuator can travel to the high or the low endstop.
7	Error monitoring The control algorithm is switched off and no longer changes the valve position. This operating mode is activated instead of "Inactive" mode in the event of an error. All the following conditions must be met: • Automatic mode (Mode = 3) • Errorbehaviour = FALSE • ActivateRecoverMode = TRUE • One or more errors have occurred in which ActivateRecoverMode (Page 3517) is effective. As soon as the errors are no longer pending, PID_3Step switches back to automatic mode.
8	Approach substitute output value with error monitoring This operating mode is activated instead of "approach substitute output value" mode when an error occurs. PID_3Step moves the actuator to the substitute output value and then switches to "error monitoring" mode. All the following conditions must be met: • Automatic mode (Mode = 3) • Errorbehaviour = TRUE • ActivateRecoverMode = TRUE • One or more errors have occurred in which ActivateRecoverMode (Page 3517) is effective. As soon as the errors are no longer pending, PID_3Step switches back to automatic mode.
10	Manual mode without endstop signals The endstop signals are **not** taken into consideration, even though Config.ActuatorEndStopOn = TRUE. The output value limits are not taken into consideration. Otherwise, PID_3Step behaves the same as in manual mode.

ENO characteristics

If State = 0, then ENO = FALSE.

If State ≠ 0, then ENO = TRUE.

Automatic switchover of operating mode during commissioning

Automatic mode is activated following successful pretuning or fine tuning. The following table shows how Mode and State change during successful pretuning.

Cycle no.	Mode	State	Action
0	4	4	Set Mode = 1
1	1	4	Set ModeActivate = TRUE
1	4	1	Value of State is saved in Mode parameter Pretuning is started
n	4	1	Pretuning successfully completed
n	3	3	Automatic mode is started

PID_3Step automatically switches the operating mode in the event of an error. The following table shows how Mode and State change during pretuning with errors.

Cycle no.	Mode	State	Action
0	4	4	Set Mode = 1
1	1	4	Set ModeActivate = TRUE
1	4	1	Value of State is saved in Mode parameter Pretuning is started
n	4	1	Pretuning canceled
n	4	4	Manual mode is started

If ActivateRecoverMode = TRUE, the operating mode that is saved in the Mode parameter is activated. At the start of transition time measurement, pretuning, or fine tuning, PID_3Step saved the value of State in the Mode in/out parameter. PID_3Step therefore switches to the operating mode from which transition time measurement or tuning was started.

If ActivateRecoverMode = FALSE, "Inactive" or "Approach substitute output value" mode is activated.

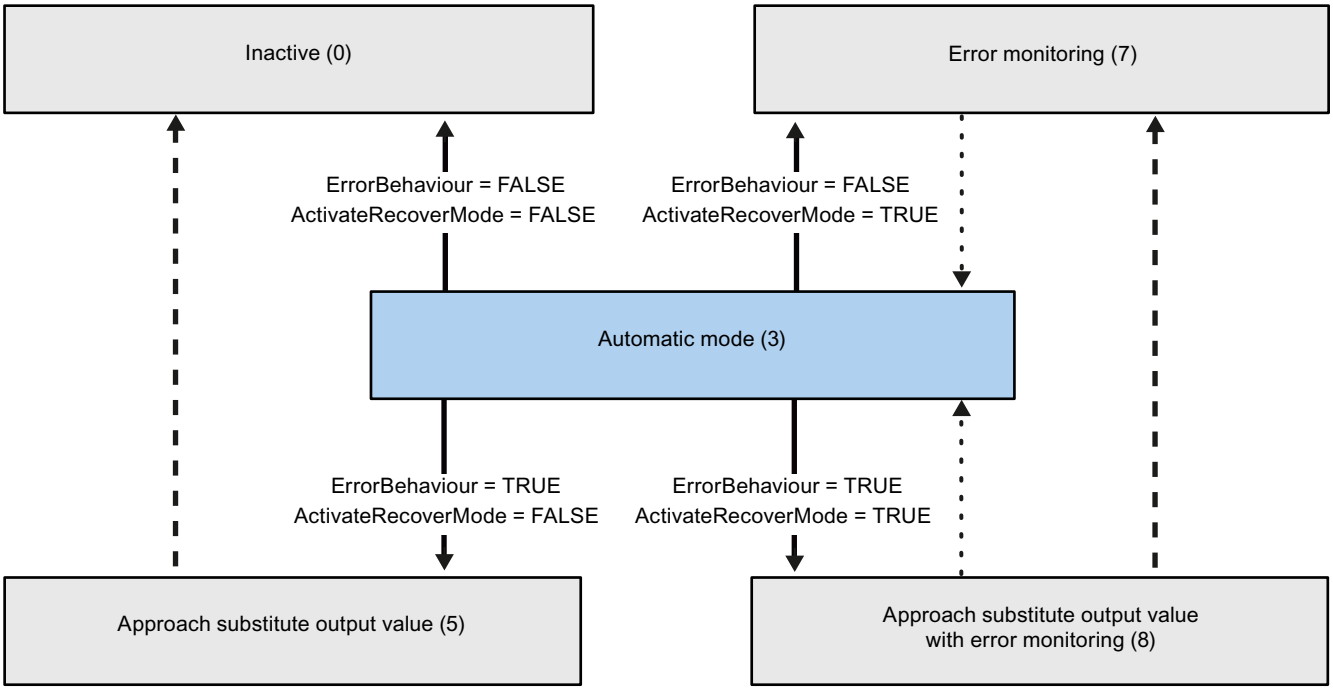
Automatic switchover of operating mode after transition time measurement

If ActivateRecoverMode = TRUE, the operating mode that is saved in the Mode parameter is activated after successful transition time measurement.

If ActivateRecoverMode = FALSE, the system switches to "Inactive" operating mode after successful transition time measurement.

Automatic switchover of operating mode in automatic mode

PID_3Step automatically switches the operating mode in the event of an error. The following diagram illustrates the influence of ErrorBehaviour and ActivateRecoverMode on this switchover of operating mode.



Automatic switchover of operating mode in the event of an error

Automatic switchover of operating mode once the current operation has been completed.

Automatic switchover of operating mode when error is no longer pending.

Parameter ErrorBits V2 (Page 3514)

Parameter ErrorBits V2

If several errors are pending simultaneously, the values of the ErrorBits are displayed with binary addition. The display of ErrorBits = 0003h, for example, indicates that the errors 0001h and 0002h are pending simultaneously.

If there is a position feedback, PID_3Step uses ManualValue as output value in manual mode. The exception is Errorbits = 10000h.

ErrorBits (DW#16#...)	Description
0000	There is no error.
0001	The "Input" parameter is outside the process value limits. • Input > Config.InputUpperLimit or • Input < Config.InputLowerLimit If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_3Step remains in automatic mode. If pretuning, fine tuning, or transition time measurement mode and ActivateRecoverMode = TRUE were active before the error occurred, PID_3Step switches to the operating mode that is saved in the Mode parameter.
0002	Invalid value at "Input_PER" parameter. Check whether an error is pending at the analog input. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_3Step switches to "Approach substitute output value with error monitoring" or "Error monitoring" mode. As soon as the error is no longer pending, PID_3Step switches back to automatic mode. If pretuning, fine tuning, or transition time measurement mode and ActivateRecoverMode = TRUE were active before the error occurred, PID_3Step switches to the operating mode that is saved in the Mode parameter.
0004	Error during fine tuning. Oscillation of the process value could not be maintained. If ActivateRecoverMode = TRUE before the error occurred, PID_3Step cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0010	The setpoint was changed during tuning. You can set the permitted fluctuation of the setpoint at the CancelTuningLevel tag. If ActivateRecoverMode = TRUE before the error occurred, PID_3Step cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0020	Pretuning is not permitted during fine tuning. If ActivateRecoverMode = TRUE before the error occurred, PID_3Step remains in fine tuning mode.
0080	Error during pretuning. Incorrect configuration of output value limits. Check whether the limits of the output value are configured correctly and match the control logic. If ActivateRecoverMode = TRUE before the error occurred, PID_3Step cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0100	Error during fine tuning resulted in invalid parameters. If ActivateRecoverMode = TRUE before the error occurred, PID_3Step cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0200	Invalid value at "Input" parameter: Value has an invalid number format. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_3Step switches to "Approach substitute output value with error monitoring" or "Error monitoring" mode. As soon as the error is no longer pending, PID_3Step switches back to automatic mode. If pretuning, fine tuning, or transition time measurement mode and ActivateRecoverMode = TRUE were active before the error occurred, PID_3Step switches to the operating mode that is saved in the Mode parameter.

ErrorBits (DW#16#...)	Description
0400	Calculation of output value failed. Check the PID parameters. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_3Step switches to "Approach substitute output value with error monitoring" or "Error monitoring" mode. As soon as the error is no longer pending, PID_3Step switches back to automatic mode. If pretuning, fine tuning, or transition time measurement mode and ActivateRecoverMode = TRUE were active before the error occurred, PID_3Step switches to the operating mode that is saved in the Mode parameter.
0800	Sampling time error: PID_3Step is not called within the sampling time of the cyclic interrupt OB. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_3Step remains in automatic mode. If pretuning, fine tuning, or transition time measurement mode and ActivateRecoverMode = TRUE were active before the error occurred, PID_3Step switches to the operating mode that is saved in the Mode parameter.
1000	Invalid value at "Setpoint" parameter: Value has an invalid number format. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_3Step switches to "Approach substitute output value with error monitoring" or "Error monitoring" mode. As soon as the error is no longer pending, PID_3Step switches back to automatic mode. If pretuning, fine tuning, or transition time measurement mode and ActivateRecoverMode = TRUE were active before the error occurred, PID_3Step switches to the operating mode that is saved in the Mode parameter.
2000	Invalid value at Feedback_PER parameter. Check whether an error is pending at the analog input. The actuator cannot be moved to the substitute output value and remains in its current position. In manual mode, you can change the position of the actuator only with Manual_UP and Manual_DN, and not with ManualValue. If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_3Step switches back to automatic mode. If pretuning, fine tuning, or transition time measurement mode and ActivateRecoverMode = TRUE were active before the error occurred, PID_3Step switches to the operating mode that is saved in the Mode parameter.
4000	Invalid value at Feedback parameter. Value has an invalid number format. The actuator cannot be moved to the substitute output value and remains in its current position. In manual mode, you can change the position of the actuator only with Manual_UP and Manual_DN, and not with ManualValue. If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_3Step switches back to automatic mode. If pretuning, fine tuning, or transition time measurement mode and ActivateRecoverMode = TRUE were active before the error occurred, PID_3Step switches to the operating mode that is saved in the Mode parameter.

ErrorBits (DW#16#...)	Description
8000	Error during digital position feedback. Actuator_H = TRUE and Actuator_L = TRUE. The actuator cannot be moved to the substitute output value and remains in its current position. Manual mode is not possible in this state. In order to move the actuator from this state, you must deactivate the "Actuator endstop" (Config.ActuatorEndStopOn = FALSE) or switch to manual mode without endstop signals (Mode = 10). If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_3Step switches back to automatic mode. If pretuning, fine tuning, or transition time measurement mode and ActivateRecoverMode = TRUE were active before the error occurred, PID_3Step switches to the operating mode that is saved in the Mode parameter.
10000	Invalid value at ManualValue parameter. Value has an invalid number format. The actuator cannot be moved to the manual value and remains in its current position. Specify a valid value in ManualValue or move the actuator in manual mode with Manual_UP and Manual_DN.
20000	Invalid value at SavePosition tag. Value has an invalid number format. The actuator cannot be moved to the substitute output value and remains in its current position.
40000	Invalid value at Disturbance parameter. Value has an invalid number format. If automatic mode was active and ActivateRecoverMode = TRUE before the error occurred, Disturbance is set to zero. PID_3Step remains in automatic mode. If pretuning or fine tuning mode was active and ActivateRecoverMode = TRUE before the error occurred, PID_3Step switches to the operating mode saved in the Mode parameter. If Disturbance in the current phase has no effect on the output value, tuning is not be canceled. The error has no effect during transition time measurement.

Tag ActivateRecoverMode V2

The ActivateRecoverMode tag determines the reaction to error. The Error parameter indicates if an error is pending. When the error is no longer pending, Error = FALSE. The ErrorBits parameter shows which errors have occurred.

Notice

Your system may be damaged.

If ActivateRecoverMode = TRUE, PID_3Step remains in automatic mode even if the process limit values are exceeded. This may damage your system.

It is essential to configure how your controlled system reacts in the event of an error to protect your system from damage.

Automatic mode

ActivateRecoverMode	Description
FALSE	In the event of an error, PID_3Step switches to "Inactive" or "Approach substitute output value" mode. The controller is only activated by a falling edge at Reset or a rising edge at ModeActivate.
TRUE	If errors occur frequently in automatic mode, this setting has a negative effect on the control response, because PID_3Step switches between the calculated output value and the substitute output value at each error. In this case, check the ErrorBits parameter and eliminate the cause of the error. If one or more of the following errors occur, PID_3Step stays in automatic mode: • 0001h: The "Input" parameter is outside the process value limits. • 0800h: Sampling time error • 40000h: Invalid value at Disturbance parameter. If one or more of the following errors occur, PID_3Step switches to "Approach substitute output value with error monitoring" or "Error monitoring" mode: • 0002h: Invalid value at Input_PER parameter. • 0200h: Invalid value at Input parameter. • 0400h: Calculation of output value failed. • 1000h: Invalid value at Setpoint parameter. If one or more of the following errors occur, PID_3Step can no longer move the actuator: • 2000h: Invalid value at Feedback_PER parameter. • 4000h: Invalid value at Feedback parameter. • 8000h: Error during digital position feedback. • 20000h: Invalid value at SavePosition tag. Value has an invalid number format. The characteristics are independent of ErrorBehaviour. As soon as the errors are no longer pending, PID_3Step switches back to automatic mode.

Pretuning, fine tuning, and transition time measurement

ActivateRecoverMode	Description
FALSE	In the event of an error, PID_3Step switches to "Inactive" or "Approach substitute output value" mode. The controller is only activated by a falling edge at Reset or a rising edge at ModeActivate. The controller changes to "Inactive" mode after successful transition time measurement.
TRUE	If the following error occurs, PID_3Step remains in the active mode: • 0020h: Pretuning is not permitted during fine tuning. The following errors are ignored: • 10000h: Invalid value at ManualValue parameter. • 20000h: Invalid value at SavePosition tag. When any other error occurs, PID_3Step cancels the tuning and switches to the mode from which tuning was started.

Manual mode

ActivateRecoverMode is not effective in manual mode.

Tag Warning V2

If several warnings are pending simultaneously, their values are displayed with binary addition. The display of warning 0005h, for example, indicates that the warnings 0001h and 0004h are pending simultaneously.

Warning (DW#16#...)	Description
0000	No warning pending.
0001	The point of inflection was not found during pretuning.
0004	The setpoint was limited to the configured limits.
0008	Not all the necessary controlled system properties were defined for the selected method of calculation. Instead, the PID parameters were calculated using the TIR.TuneRule = 3 method.
0010	The operating mode could not be changed because Reset = TRUE or ManualEnable = TRUE.
0020	The cycle time of the calling OB limits the sampling time of the PID algorithm. Improve results by using shorter OB cycle times.
0040	The process value exceeded one of its warning limits.
0080	Invalid value at Mode. The operating mode is not switched.
0100	The manual value was limited to the limits of the controller output.
0200	The specified rule for tuning is not supported. No PID parameters are calculated.
0400	The transition time cannot be measured because the actuator settings do not match the selected measuring method.
0800	The difference between the current position and the new output value is too small for transition time measurement. This can produce incorrect results. The difference between the current output value and new output value must be at least 50% of the entire control range.
1000	The substitute output value cannot be reached because it is outside the output value limits.
2000	The actuator was moved in one direction for longer than Config.VirtualActuatorLimit × Retain.TransitTime. Check whether the actuator has reached an endstop signal.

The following warnings are deleted as soon as the cause is eliminated:

- 0001h
- 0004h
- 0008h
- 0040h
- 0100h
- 2000h

All other warnings are cleared with a rising edge at Reset or ErrorAck.

PID_3Step V1

Description PID_3Step V1

Description

You use the PID_3Step instruction to configure a PID controller with self tuning for valves or actuators with integrating behavior.

The following operating modes are possible:

- Inactive
- Pretuning
- Fine tuning
- Automatic mode
- Manual mode
- Approach substitute output value
- Transition time measurement
- Approach substitute output value with error monitoring
- Error monitoring

For a more detailed description of the operating modes, see the State parameter.

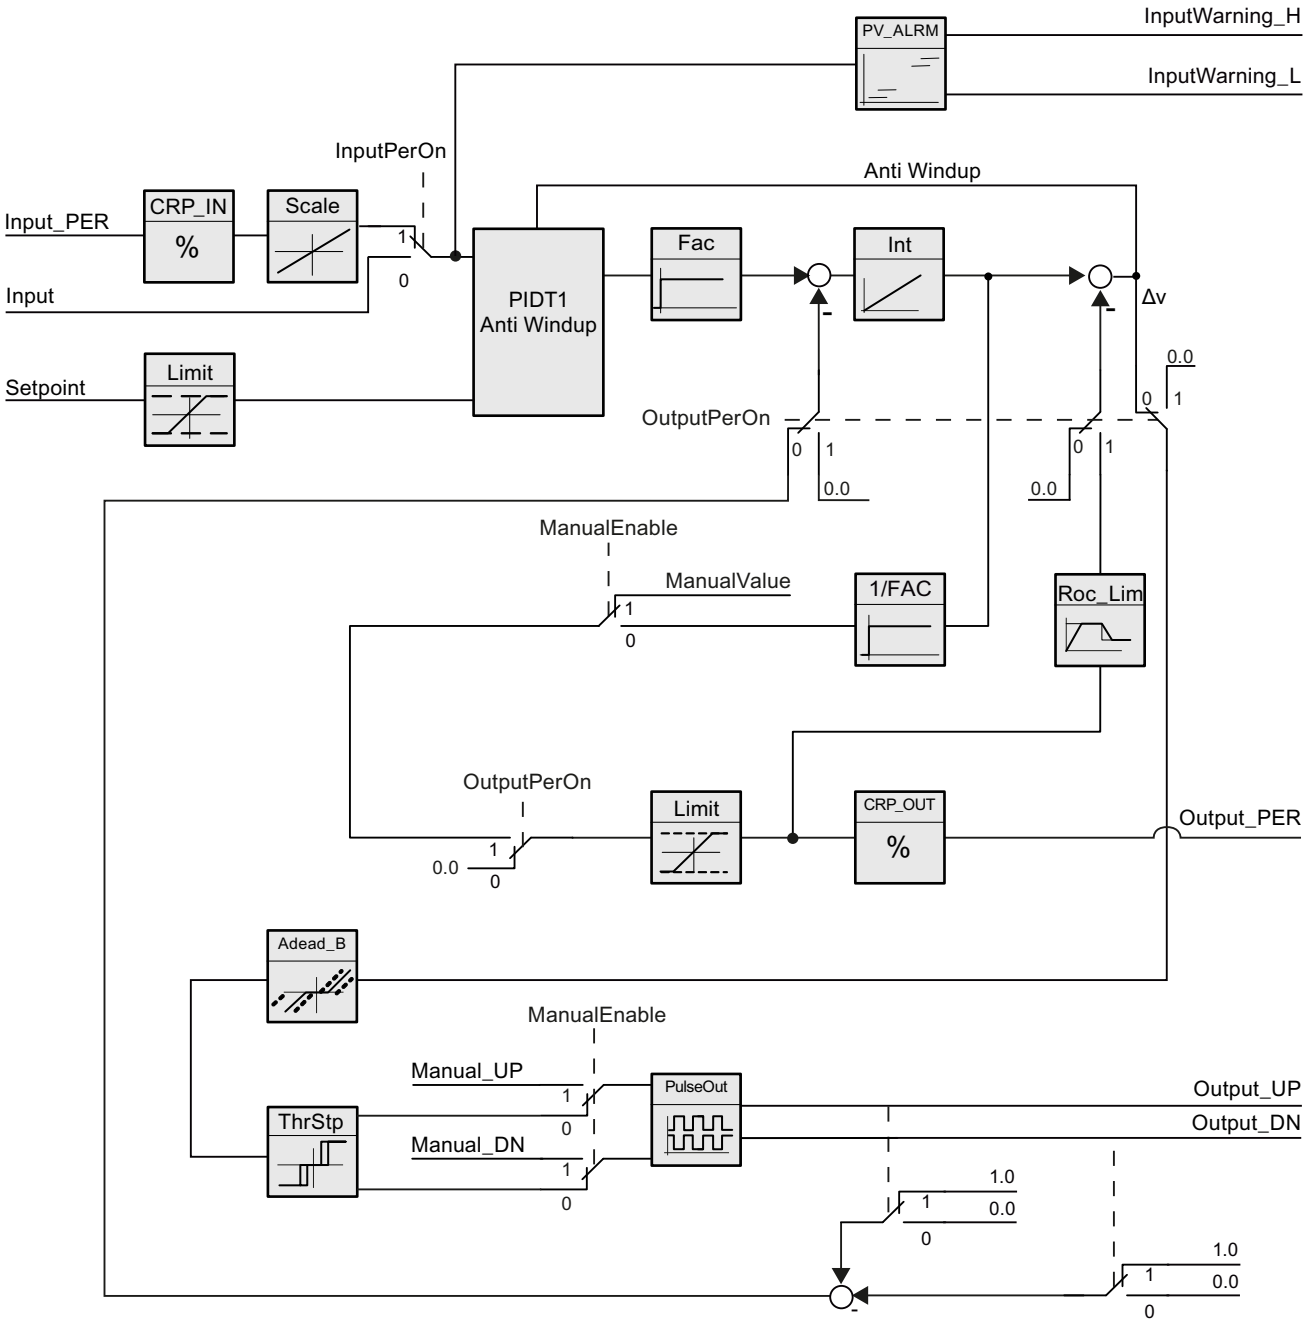
PID algorithm

PID_3Step is a PIDT1 controller with anti-windup and weighting of the proportional and derivative actions. The following equation is used to calculate the output value.

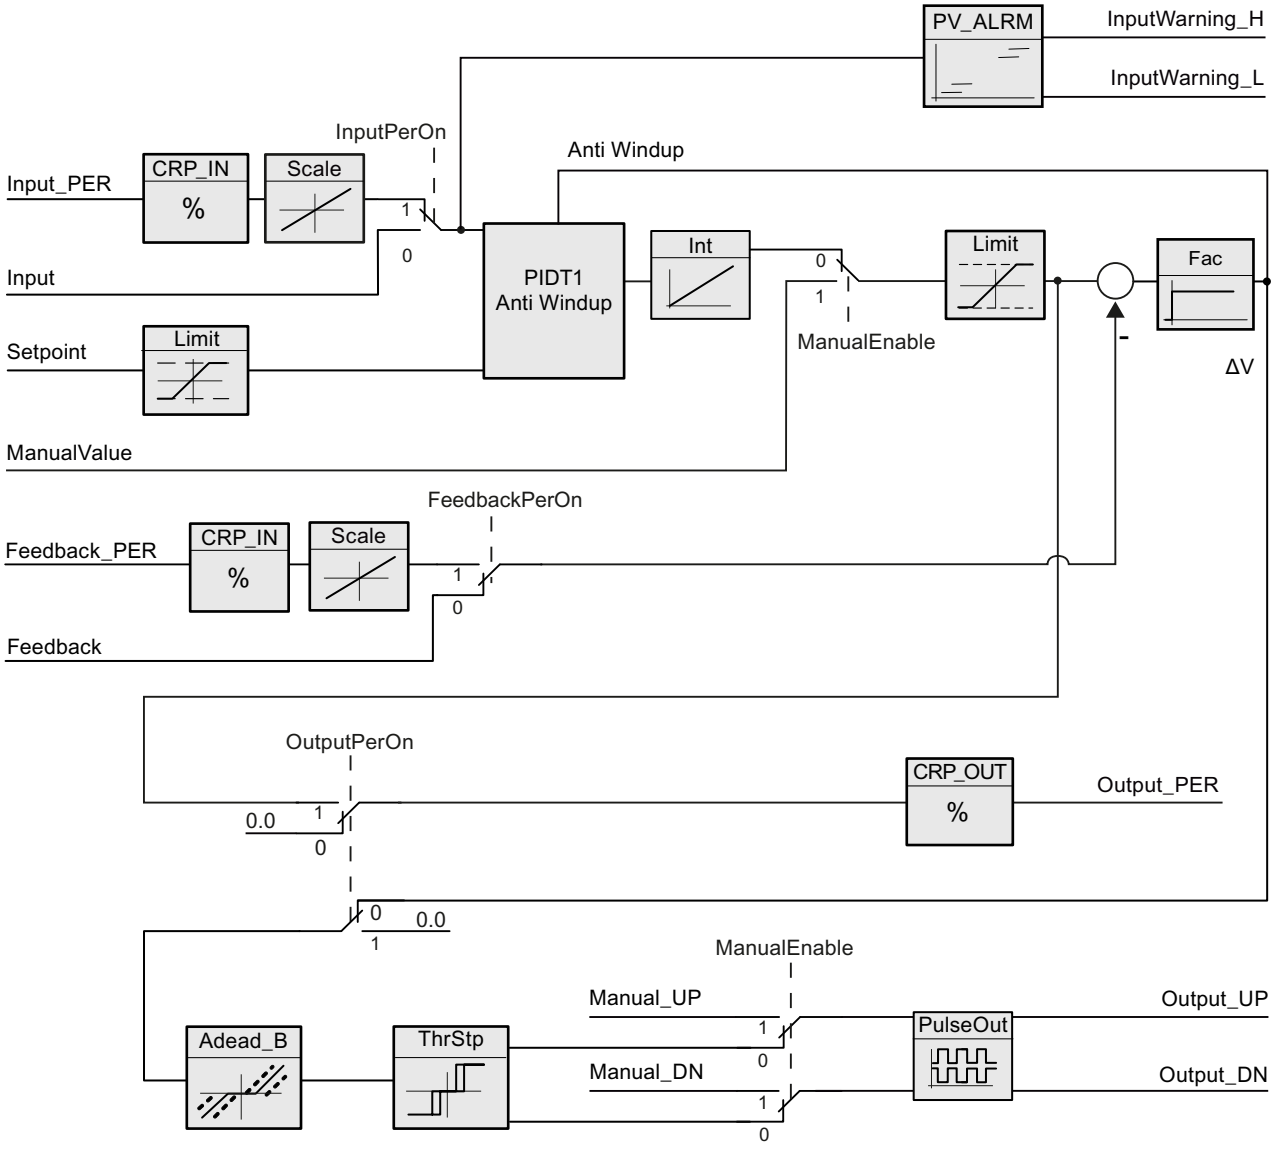
$$\Delta y = K_p \cdot s \cdot \left[(b \cdot w - x) + \frac{1}{T_I \cdot s} (w - x) + \frac{T_D \cdot s}{a \cdot T_D \cdot s + 1} (c \cdot w - x) \right]$$

Symbol	Description
y	Output value
K_p	Proportional gain
s	Laplace operator
b	Proportional action weighting
w	Setpoint
x	Process value
T_I	Integral action time
a	Derivative delay coefficient (T1 = a × T_D)
T_D	Derivative action time
c	Derivative action weighting

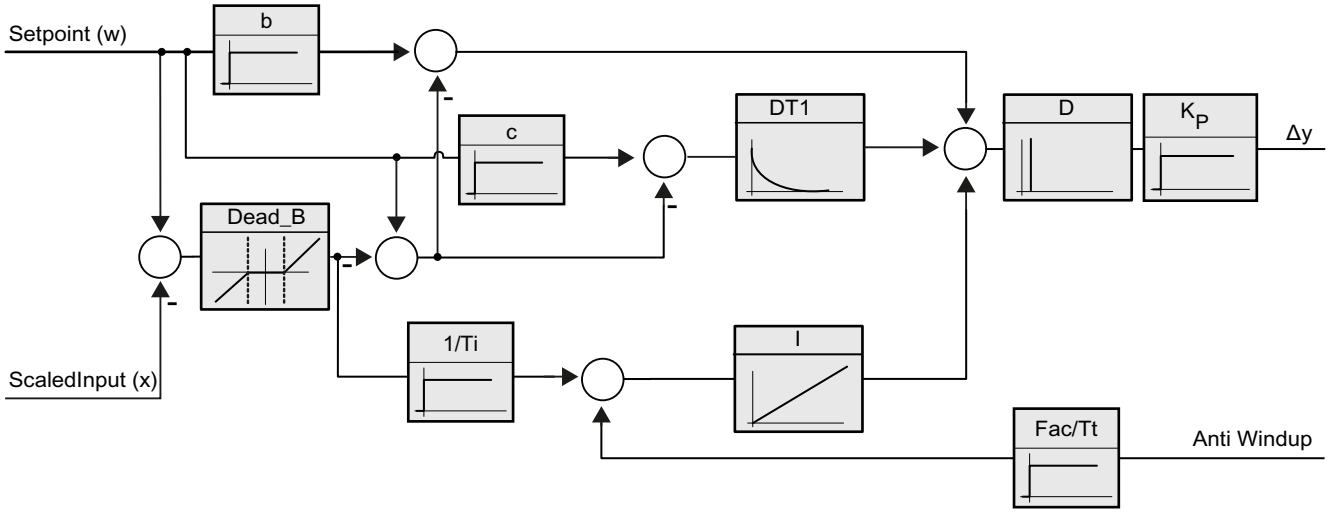
Block diagram without position feedback



Block diagram with position feedback



Block diagram of PIDT1 with anti-windup



Call

PID_3Step is called in a constant time interval of the cycle time of the calling OB (preferably in a cyclic interrupt OB).

Download to device

The actual values of retentive tags are only updated when you download PID_3Step completely.

Downloading technology objects to device (Page 7204)

Startup

At the startup of the CPU, PID_3Step starts in the operating mode that was last active. To leave PID_3Step in "Inactive" mode, set RunModeByStartup = FALSE.

Reaction to error

If errors occur, these are output in the Error parameter. You configure the reaction of PID_3Step using the ErrorBehaviour and ActivateRecoverMode tags.

ErrorBehaviour	ActivateRecoverMode	Actuator setting configuration Set Output to	Reaction
0	FALSE	Current output value	Switch to "Inactive" mode (Mode = 0)
0	TRUE	Current output value while error is pending	Switch to "Error monitoring" mode (Mode = 7)

ErrorBehaviour	ActivateRecoverMode	Actuator setting configuration Set Output to	Reaction
1	FALSE	Substitute output value	Switch to "Approach substitute output value" mode (Mode = 5) Switch to "Inactive" mode (Mode = 0)
1	TRUE	Substitute output value while error is pending	Switch to "Approach substitute output value with error monitoring" mode (Mode = 8) Switch to "Error monitoring" mode (Mode = 7)

The ErrorBits parameter shows which errors have occurred.

Parameter ErrorBits V1 (Page 3544)

Configuring PID_3Step V1 (Page 7276)

Operating principle PID_3Step V1

Monitoring process value limits

You specify the high limit and low limit of the process value in the Config.InputUpperLimit and Config.InputLowerLimit tags. If the process value is outside these limits, an error occurs (ErrorBits = 0001hex).

You specify a high and low warning limit of the process value in the Config.InputUpperWarning and Config.InputLowerWarning tags. If the process value is outside these warning limits, a warning occurs (Warnings = 0040hex), and the InputWarning_H or InputWarning_L output parameter changes to TRUE.

Limiting the setpoint

You specify a high limit and low limit of the setpoint in the Config.SetpointUpperLimit and Config.SetpointLowerLimit tags. PID_3Step automatically limits the setpoint to the process value limits. You can limit the setpoint to a smaller range. PID_3Step checks whether this range falls within the process value limits. If the setpoint is outside these limits, the high or low limit is used as the setpoint, and output parameter SetpointLimit_H or SetpointLimit_L is set to TRUE.

The setpoint is limited in all operating modes.

Limiting the output value

You specify a high limit and low limit of the output value in the Config.OutputUpperLimit and Config.OutputLowerLimit tags. The output value limits must be within "Low endstop" and "High endstop".

- High endstop: Config.FeedbackScaling.UpperPointOut
- Low endstop: Config.FeedbackScaling.LowerPointOut

Rule:

UpperPointOut ≥ OutputUpperLimit > OutputLowerLimit ≥ LowerPointOut

The valid values for "High endstop" and "Low endstop" depend upon:

- FeedbackOn
- FeedbackPerOn
- OutputPerOn

OutputPerOn	FeedbackOn	FeedbackPerOn	LowerPointOut	UpperPointOut
FALSE	FALSE	FALSE	Cannot be set (0.0%)	Cannot be set (100.0%)
FALSE	TRUE	FALSE	-100.0% or 0.0%	0.0% or +100.0%
FALSE	TRUE	TRUE	-100.0% or 0.0%	0.0% or +100.0%
TRUE	FALSE	FALSE	Cannot be set (100.0%)	Cannot be set (100.0%)
TRUE	TRUE	FALSE	-100.0% or 0.0%	0.0% or +100.0%
TRUE	TRUE	TRUE	-100.0% or 0.0%	0.0% or +100.0%

If OutputPerOn = FALSE and FeedbackOn = FALSE, you cannot limit the output value. The digital outputs are reset with Actuator_H = TRUE or Actuator_L = TRUE, or after a travel time amounting to 110% of the motor transition time.

The output value is 27648 at 100% and -27648 at -100%. PID_3Step must be able to close the valve completely. Therefore, zero must be included in the output value limits.

Substitute output value

If an error has occurred, PID_3Step can output a substitute output value and move the actuator to a safe position that is specified in the SavePosition tag. The substitute output value must be within the output value limits.

Monitoring signal validity

The values of the following parameters are monitored for validity:

- Setpoint
- Input
- Input_PER
- Feedback
- Feedback_PER
- Output

Monitoring the PID_3Step sampling time

Ideally, the sampling time is equivalent to the cycle time of the calling OB. The PID_3Step instruction measures the time interval between two calls. This is the current sampling time. On every switchover of operating mode and during the initial startup, the mean value is formed from the first 10 sampling times. Too great a difference between the current sampling time and this mean value triggers an error (ErrorBits = 0800 hex).

PID_3Step is set to "Inactive" mode during tuning under the following conditions:

- New mean value >= 1.1 x old mean value
- New mean value <= 0.9 x old mean value

In automatic mode, PID_3Step is set to "Inactive" mode under the following conditions:

- New mean value >= 1.5 x old mean value
- New mean value <= 0.5 x old mean value

Sampling time of the PID algorithm

The controlled system needs a certain amount of time to respond to changes in the output value. It is therefore not advisable to calculate the output value in every cycle. The sampling time of the PID algorithm represents the time between two calculations of the output value. It is calculated during tuning and rounded to a multiple of the cycle time. All other functions of PID_3Step are executed at every call.

Measuring the motor transition time

The motor transition time is the time in seconds the motor requires to move the actuator from the closed to the opened state. The maximum time that the actuator is moved in one direction is 110% of the motor transition time. PID_3Step requires the motor transition time to be as accurate as possible for good controller results. The data in the actuator documentation contains average values for this type of actuator. The value for the specific actuator used may differ. You can measure the motor transition time during commissioning. The output value limits are not taken into consideration during the motor transition time measurement. The actuator can travel to the high or the low endstop.

Control logic

An increase of the output value is generally intended to cause an increase in the process value. This is referred to as a normal control logic. For cooling and discharge control systems, it may be necessary to invert the control logic. PID_3Step does not work with negative proportional gain. If InvertControl = TRUE, an increasing control deviation causes a reduction in the output value. The control logic is also taken into account during pretuning and fine tuning.

Configuring PID_3Step V1 (Page 7276)

PID_3Step V1 input parameters

Table 11-91

Parameters	Data type	Default	Description
Setpoint	REAL	0.0	Setpoint of the PID controller in automatic mode
Input	REAL	0.0	A variable of the user program is used as source for the process value. If you are using parameter Input, then Config.InputPer-On = FALSE must be set.
Input_PER	WORD	W#16#0	An analog input is used as source for the process value. If you are using parameter Input_PER, then Config.InputPer-On = TRUE must be set.
Actuator_H	BOOL	FALSE	Digital position feedback of the valve for the high endstop If Actuator_H = TRUE, the valve is at the high endstop and is no longer moved towards this direction.
Actuator_L	BOOL	FALSE	Digital position feedback of the valve for the low endstop If Actuator_L = TRUE, the valve is at the low endstop and is no longer moved towards this direction.
Feedback	REAL	0.0	Position feedback of the valve If you are using parameter Feedback, then Config.Feedback-PerOn = FALSE must be set.
Feedback_PER	WORD	W#16#0	Analog feedback of the valve position If you are using parameter Feedback_PER, then Config.FeedbackPerOn = TRUE must be set. Feedback_PER is scaled based on the variables: • Config.FeedbackScaling.LowerPointIn • Config.FeedbackScaling.UpperPointIn • Config.FeedbackScaling.LowerPointOut • Config.FeedbackScaling.UpperPointOut
ManualEnable	BOOL	FALSE	• A FALSE -> TRUE edge selects "Manual mode", while State = 4, Retain.Mode remains unchanged. • A TRUE -> FALSE edge selects the most recently active operating mode A change of Retain.Mode will not take effect during ManualEnable = TRUE. The change of Retain.Mode will only be considered upon a TRUE -> FALSE edge at ManualEnable . **PID_3Step V1.1**If at start of the CPU ManualEnable = TRUE, PID_3Step starts in manual mode. A rising edge (FALSE > TRUE) at ManualEnable is not necessary. **PID_3Step V1.0** At the start of the CPU, PID_3Step only switches to manual mode with a rising edge (FALSE->TRUE) at ManualEnable . Without rising edge, PID_3Step starts in the last operating mode in which ManualEnable was FALSE.
ManualValue	REAL	0.0	In manual mode, you specify the absolute position of the valve. ManualValue will only be evaluated if you are using OutputPer, **or** if position feedback is available.

Parameters	Data type	Default	Description
Manual_UP	BOOL	FALSE	In manual mode, every rising edge opens the valve by 5% of the total control range, or for the duration of the minimum motor transition time. Manual_UP is evaluated only if you are not using Output_PER and there is no position feedback available.
Manual_DN	BOOL	FALSE	In manual mode, every rising edge closes the valve by 5% of the total control range, or for the duration of the minimum motor transition time. Manual_DN is evaluated only if you are not using Output_PER and there is no position feedback available.
Reset	BOOL	FALSE	Restarts the controller. • FALSE -> TRUE edge – Change to "Inactive" mode – Intermediate controller values are reset (PID parameters are retained) • TRUE -> FALSE edge Change in most recent active mode

PID_3Step V1 output parameters

Table 11-92

Parameter	Data type	Default	Description
ScaledInput	REAL	0.0	Scaled process value
ScaledFeedback	REAL	0.0	Scaled position feedback For an actuator without position feedback, the position of the actuator indicated by ScaledFeedback is very imprecise. ScaledFeedback may only be used for rough estimation of the current position in this case.
Output_UP	BOOL	FALSE	Digital output value for opening the valve If Config.OutputPerOn = FALSE, the Output_UP parameter is used.
Output_DN	BOOL	FALSE	Digital output value for closing the valve If Config.OutputPerOn = FALSE, the Output_DN parameter is used.
Output_PER	WORD	W#16#0	Analog output value If Config.OutputPerOn = TRUE, Output_PER is used.
SetpointLimit_H	BOOL	FALSE	If SetpointLimit_H = TRUE, the absolute setpoint high limit is reached. In the CPU, the setpoint is limited to the configured absolute setpoint high limit. The configured absolute process value high limit is the default for the setpoint high limit. If you configure Config.SetpointUpperLimit to a value within the process value limits, this value is used as the setpoint high limit.
SetpointLimit_L	BOOL	FALSE	If SetpointLimit_L = TRUE, the absolute setpoint low limit has been reached. In the CPU, the setpoint is limited to the configured absolute setpoint low limit. The configured absolute process value low limit is the default setting for the setpoint low limit. If you configure Config.SetpointLowerLimit to a value within the process value limits, this value is used as the setpoint low limit.

Parameter	Data type	Default	Description
InputWarning_H	BOOL	FALSE	If InputWarning_H = TRUE, the process value has reached or exceeded the warning high limit.
InputWarning_L	BOOL	FALSE	If InputWarning_L = TRUE, the process value has reached or fallen below the warning low limit.
State	INT	0	The State parameter (Page 3537) shows the current operating mode of the PID controller. You change the operating mode with the Retain.Mode tag. • State = 0: Inactive • State = 1: Pretuning • State = 2: Fine tuning • State = 3: Automatic mode • State = 4: Manual mode • State = 5: Approach substitute output value • State = 6: Transition time measurement • State = 7: Error monitoring • State = 8: Approach substitute output value with error monitoring
Error	BOOL	FALSE	If Error = TRUE, at least one error message is pending.
ErrorBits	DWORD	DW#16#0	The ErrorBits parameter (Page 3544) indicates the error messages.

PID_3Step V1 static tags

You must not change tags that are not listed. These are used for internal purposes only.

Table 11-93

Tag	Data type	Default	Description
ActivateRecoverMode	BOOL	TRUE	The ActivateRecoverMode tag (Page 3545) determines the reaction to error.
RunModeByStartup	BOOL	TRUE	Activate Mode after CPU restart If RunModeByStartup = TRUE, the controller returns to the last active operating mode after a CPU restart. If RunModeByStartup = FALSE, the controller remains inactive after a CPU restart.
PhysicalUnit	INT	0	Unit of measurement of the process value and setpoint, e.g., °C, or °F.
PhysicalQuantity	INT	0	Physical quantity of the process value and setpoint, e.g., temperature.

Tag	Data type	Default	Description
ErrorBehaviour	INT	0	If ErrorBehaviour = 0 and an error has occurred, the valve stays at its current position and the controller switches directly to "Inactive" or "Error monitoring" mode. If ErrorBehaviour = 1 and an error occurs, the actuator moves to the substitute output value and only then switches to "Inactive" or "Error monitoring" mode. If the following errors occur, you can no longer move the valve to a configured substitute output value. • 2000h: Invalid value at Feedback_PER parameter. • 4000h: Invalid value at Feedback parameter. • 8000h: Error during digital position feedback.
Warning	DWORD	DW#16#0	The Warning tag (Page 3537) displays the warnings generated since a Reset or since the last switchover of operating mode. Cyclic warnings (for example, process value warning) are shown until the cause of the warning is removed. They are automatically deleted once their cause has gone. Non-cyclic warnings (for example, point of inflection not found) remain and are deleted like errors.
SavePosition	REAL	0.0	Substitute output value If ErrorBehaviour = 1 and an error occurs, the actuator moves to a safe position for the plant and only then switches to "Inactive" mode.
CurrentSetpoint	REAL	0.0	Currently active setpoint. This value is frozen at the start of tuning.
Progress	REAL	0.0	Progress of tuning as a percentage (0.0 - 100.0)
Config.InputPerOn	BOOL	TRUE	If InputPerOn = TRUE, the Input_PER parameter is used. If InputPerOn = FALSE, the Input parameter is used.
Config.OutputPerOn	BOOL	FALSE	If OutputPerOn = TRUE, the Output_PER parameter is used. If OutputPerOn = FALSE, the Ouput_UP and Output_DN parameters are used.
Config.LoadBackUp	BOOL	FALSE	If LoadBackUp = TRUE, the last set of PID parameters is reloaded. This set was saved prior to the last tuning operation. LoadBackUp is automatically reset to FALSE.
Config.InvertControl	BOOL	FALSE	Invert control logic If InvertControl = TRUE, an increasing control deviation causes a reduction in the output value.
Config.FeedbackOn	BOOL	FALSE	If FeedbackOn = FALSE, a position feedback is simulated. Position feedback is generally activated when FeedbackOn = TRUE.
Config.FeedbackPerOn	BOOL	FALSE	FeedbackPerOn is only effective when FeedbackOn = TRUE. If FeedbackPerOn = TRUE, the analog input is used for the position feedback (Feedback_PER parameter). If FeedbackPerOn = FALSE, the Feedback parameter is used for the position feedback.
Config.ActuatorEndStopOn	BOOL	FALSE	If ActuatorEndStopOn = TRUE, the digital position feedback Actuator_L and Actuator_H are taken into consideration.

Tag	Data type	Default	Description
Config.InputUpperLimit	REAL	120.0	High limit of the process value At the I/O input, the process value can be a maximum of 18% higher than the standard range (overrange). An error is no longer signaled due to a violation of the "Process value high limit". Only a wire-break and a short-circuit are recognized and PID_3Step reacts according to the configured reaction to error. InputUpperLimit > InputLowerLimit
Config.InputLowerLimit	REAL	0.0	Low limit of the process value InputLowerLimit < InputUpperLimit
Config.InputUpperWarning	REAL	+3.402822e+38	Warning high limit of the process value If you set InputUpperWarning outside the process value limits, the configured absolute process value high limit is used as the warning high limit. If you configure InputUpperWarning within the process value limits, this value is used as the warning high limit. InputUpperWarning > InputLowerWarning InputUpperWarning ≤ InputUpperLimit
Config.InputLowerWarning	REAL	-3.402822e+38	Warning low limit of the process value If you set InputLowerWarning outside the process value limits, the configured absolute process value low limit is used as the warning low limit. If you configure InputLowerWarning within the process value limits, this value is used as the warning low limit. InputLowerWarning < InputUpperWarning InputLowerWarning ≥ InputLowerLimit
Config.OutputUpperLimit	REAL	100.0	High limit of output value For details, see OutputLowerLimit
Config.OutputLowerLimit	REAL	0.0	Low limit of output value If OutputPerOn = TRUE or FeedbackOn = TRUE, the range of values from -100% to +100%, including zero, is valid. At -100%, Output = -27648; at +100%, Output = 27648 If OutputPerOn = FALSE, the range of values from 0% to 100% is valid. The valve is completely closed at 0% and completely opened at 100%.
Config.SetpointUpperLimit	REAL	+3.402822e+38	High limit of setpoint If you set SetpointUpperLimit outside the process value limits, the configured absolute process value high limit is preassigned as the setpoint high limit. If you configure SetpointUpperLimit within the process value limits, this value is used as the setpoint high limit.
Config.SetpointLowerLimit	REAL	-3.402822e+38	Low limit of the setpoint If you set SetpointLowerLimit outside the process value limits, the configured absolute process value low limit is preassigned as the setpoint low limit. If you set SetpointLowerLimit within the process value limits, this value is used as the setpoint low limit.

Tag	Data type	Default	Description
Config.MinimumOnTime	REAL	0.0	Minimum ON time Minimum time in seconds for which the servo drive must be switched on.
Config.MinimumOffTime	REAL	0.0	Minimum OFF time Minimum time in seconds for which the servo drive must be switched off.
Config.TransitTime	REAL	30.0	Motor transition time Time in seconds the actuating drive requires to move the valve from the closed to the opened state.
Config.InputScaling.UpperPointIn	REAL	27648.0	Scaling Input_PER high Input_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the InputScaling structure.
Config.InputScaling.LowerPointIn	REAL	0.0	Scaling Input_PER low Input_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the InputScaling structure.
Config.InputScaling.UpperPointOut	REAL	100.0	Scaled high process value Input_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the InputScaling structure.
Config.InputScaling.LowerPointOut	REAL	0.0	Scaled low process value Input_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the InputScaling structure.
Config.FeedbackScaling.UpperPointIn	REAL	27648.0	Scaling Feedback_PER high Feedback_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the FeedbackScaling structure.
Config.FeedbackScaling.LowerPointIn	REAL	0.0	Scaling Feedback_PER low Feedback_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the FeedbackScaling structure.
Config.FeedbackScaling.UpperPointOut	REAL	100.0	High endstop Feedback_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the FeedbackScaling structure.
Config.FeedbackScaling.LowerPointOut	REAL	0.0	Low endstop Feedback_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the FeedbackScaling structure.
GetTransitTime.InvertDirection	BOOL	FALSE	If InvertDirection = FALSE, the valve is fully opened, closed, and then reopened in order to determine the valve transition time. If InvertDirection = TRUE, the valve is fully closed, opened, and then closed again.

Tag	Data type	Default	Description
GetTransitTime.SelectFeedback	BOOL	FALSE	If SelectFeedback = TRUE, then Feedback_PER, or Feedback is taken into consideration in the transition time measurement. If SelectFeedback = FALSE, then Actuator_H and Actuator_L are taken into consideration in the transition time measurement.
GetTransitTime.Start	BOOL	FALSE	If Start = TRUE, the transition time measurement is started.
GetTransitTime.State	INT	0	Current phase of the transition time measurement • State = 0: Inactive • State = 1: Open valve completely • State = 2: Close valve completely • State = 3: Move valve to target position (NewOutput) • State = 4: Transition time measurement successfully completed • State = 5: Transition time measurement canceled
GetTransitTime.NewOutput	REAL	0.0	Target position for transition time measurement with position feedback The target position must be between "High endstop" and "Low endstop". The difference between NewOutput and ScaledFeedback must be at least 50% of the permissible control range.
CycleTime.StartEstimation	BOOL	TRUE	If StartEstimation = TRUE, the measurement of the PID_3Step sampling time is started. CycleTime.StartEstimation = FALSE once measurement is complete.
CycleTime.EnEstimation	BOOL	TRUE	If EnEstimation = TRUE, the PID_3Step sampling time is calculated.
CycleTime.EnMonitoring	BOOL	TRUE	If EnMonitoring = TRUE, the PID_3Step sampling time is monitored. If it is not possible to execute PID_3Step within the sampling time, the error 0800h is output and the operating mode is switched. ActivateRecoverMode and ErrorBehaviour determine which operating mode is switched to. If EnMonitoring = FALSE, the PID_3Step sampling time is not monitored, the error 0800h is not output, and the operating mode is not switched.
CycleTime.Value	REAL	0.1	PID_3Step sampling time in seconds CycleTime.Value is determined automatically and is usually equivalent to the cycle time of the calling OB.
CtrlParamsBackUp.SetByUser	BOOL	FALSE	Saved value of Retain.CtrlParams.SetByUser. You can reload values from the CtrlParamsBackUp structure with Config.LoadBackUp = TRUE.
CtrlParamsBackUp.Gain	REAL	1.0	Saved proportional gain
CtrlParamsBackUp.Ti	REAL	20.0	Saved integral action time
CtrlParamsBackUp.Td	REAL	0.0	Saved derivative action time
CtrlParamsBackUp.TdFiltRatio	REAL	0.0	Saved derivative delay coefficient
CtrlParamsBackUp.PWeighting	REAL	0.0	Saved proportional action weighting
CtrlParamsBackUp.DWeighting	REAL	0.0	Saved derivative action weighting
CtrlParamsBackUp.Cycle	REAL	1.0	Saved sampling time of PID algorithm
CtrlParamsBackUp.InputDeadBand	REAL	0.0	Saved dead band width of the control deviation

Tag	Data type	Default	Description
PIDSelfTune.SUT.Calculate-SUTParams	BOOL	FALSE	The properties of the controlled system are saved during tuning. If CalculateSUTParams = TRUE, the PID parameters are recalculated on the basis of these properties. The PID parameters are calculated using the method set in TuneRuleSUT. CalculateSUTParams is set to FALSE following calculation.
PIDSelfTune.SUT.TuneRule-SUT	INT	1	Methods used to calculate parameters during pretuning: • TuneRuleSUT = 0: PID rapid I • TuneRuleSUT = 1: PID slow I • TuneRuleSUT = 2: Chien, Hrones and Reswick PID • TuneRuleSUT = 3TuneRuleSUT = 3: Chien, Hrones, Reswick PI • TuneRuleSUT = 4: PID rapid II • TuneRuleSUT = 5: PID slow II
PIDSelfTune.SUT.State	INT	0	The SUT.State tag indicates the current phase of pretuning:
PIDSelfTune.TIR.RunIn	BOOL	FALSE	• RunIn = FALSE Pretuning is started when fine tuning is started from inactive or manual mode. If fine tuning is started from automatic mode, the system uses the existing PID parameters to control to the setpoint. Only then will fine tuning start. If pretuning is not possible, PID_3Step switches to "Inactive" mode. • RunIn = TRUE The pretuning is skipped. PID_3Step attempts to reach the setpoint with the minimum or maximum output value. This can produce increased overshoot. Only then will fine tuning start. RunIn is set to FALSE after fine tuning.
PIDSelfTune.TIR.Calculate-TIRParams	BOOL	FALSE	The properties of the controlled system are saved during tuning. If CalculateTIRParams = TRUE, the PID parameters are recalculated on the basis of these properties. The PID parameters are calculated using the method set in TuneRuleTIR. CalculateTIRParams is set to FALSE following calculation.
PIDSelfTune.TIR.TuneRule-TIR	INT	0	Methods used to calculate parameters during fine tuning: • TuneRuleTIR = 0: PID automatic • TuneRuleTIR = 1: PID rapid • TuneRuleTIR = 2: PID slow • TuneRuleTIR = 3: Ziegler-Nichols PID • TuneRuleTIR = 4: Ziegler-Nichols PI • TuneRuleTIR = 5: Ziegler-Nichols P
PIDSelfTune.TIR.State	INT	0	The TIR.State tag indicates the current phase of "fine tuning":

Tag	Data type	Default	Description
Retain.Mode	INT	0	A change to the value of Retain.Mode initiates a switch to another operating mode. The following operating mode is enabled upon a change of Mode to: • Mode = 0: Inactive • Mode = 1: Pretuning • Mode = 2: Fine tuning • Mode = 3: Automatic mode • Mode = 4: Manual mode • Mode = 5: Approach substitute output value • Mode = 6: Transition time measurement • Mode = 7Mode = 7: Error monitoring • Mode = 8: Approach substitute output value with error monitoring Mode is retentive.
Retain.CtrlParams.SetByUser	BOOL	FALSE	If SetByUser = FALSE, the PID parameters are determined automatically and PID_3Step operates with a dead band at the output value. The dead band width is calculated during tuning on the basis of the standard deviation of the output value and saved in Retain.CtrlParams.OutputDeadBand. If SetByUser = TRUE, the PID parameters are entered manually and PID_3 Step operates without a dead band at the output value. Retain.CtrlParams.OutputDeadBand = 0.0 SetByUser is retentive.
Retain.CtrlParams.Gain	REAL	1.0	Active proportional gain Gain is retentive.
Retain.CtrlParams.Ti	REAL	20.0	• Ti > 0.0: Active integral action time • Ti = 0.0: Integral action is deactivated Ti is retentive.
Retain.CtrlParams.Td	REAL	0.0	• Td > 0.0: Active derivative action time • Td = 0.0: Derivative action is deactivated Td is retentive.
Retain.CtrlParams.TdFiltRatio	REAL	0.0	Active derivative delay coefficient TdFiltRatio is retentive.
Retain.CtrlParams.PWeighting	REAL	0.0	Active proportional action weighting PWeighting is retentive.
Retain.CtrlParams.DWeighting	REAL	0.0	Active derivative action weighting DWeighting is retentive.
Retain.CtrlParams.Cycle	REAL	1.0	Active sampling time of PID algorithm in seconds, rounded to an integer multiple of the cycle time of the calling OB. Cycle is retentive.
Retain.CtrlParams.InputDeadBand	REAL	0.0	Dead band width of the control deviation InputDeadBand is retentive.

Note

Change the tags listed in this table in "Inactive" mode to prevent malfunction of the PID controller. "Inactive" mode is forced by setting the "Retain.Mode" tag to "0".

Parameter State and Retain.Mode V1

Correlation of the parameters

The State parameter shows the current operating mode of the PID controller. You cannot change the State parameter.

To switch from one operating mode to another, you must change the Retain.Mode tag. This also applies when the value for the new operating mode is already in Retain.Mode. For example, set Retain.Mode = 0 first and then Retain.Mode = 3. Provided the current operating mode of the controller permits this switchover, State will be set to the value of Retain.Mode.

When PID_3Step automatically switches from one operating mode to another, the following applies: State != Retain.Mode.

Examples:

- After successful pretuning
  State = 3 and Retain.Mode = 1
- In the event of an error
  State = 0 and Retain.Mode remain at the previous value, for example, Retain.Mode = 3
- ManualEnalbe = TRUE
  State = 4 and Retain.Mode remain at the previous value, e.g., Retain.Mode = 3

Note

You want, for example, to repeat successful fine tuning without exiting automatic mode with Mode = 0.

Setting Retain.Mode to an invalid value such as 9999 for one cycle has no effect on State. Set Mode = 2 in the next cycle. In this way, you can generate a change to Retain.Mode without first switching to "Inactive" mode.

Meaning of values

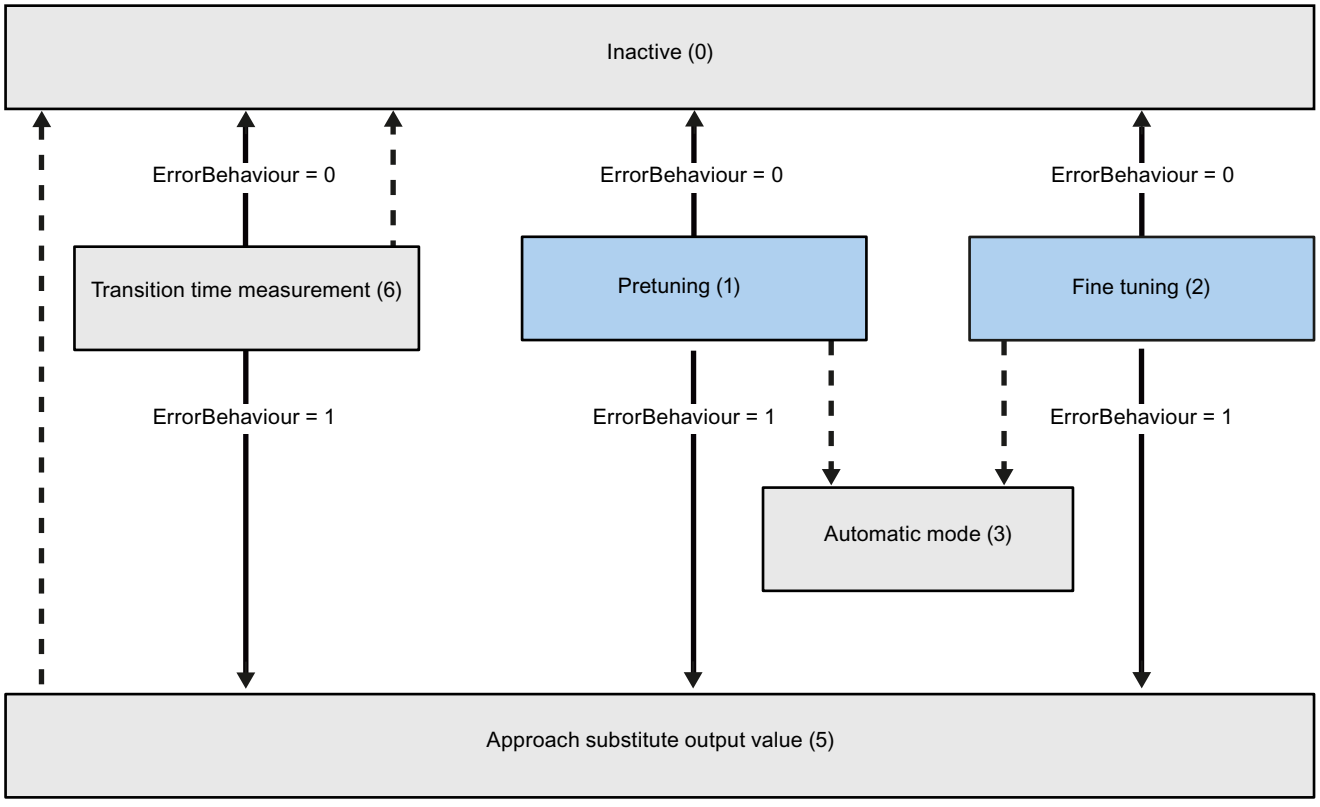
State / Retain.Mode	Description
0	Inactive The controller is switched off and no longer changes the valve position.
1	Pretuning The pretuning determines the process response to a pulse of the output value and searches for the point of inflection. The optimized PID parameters are calculated as a function of the maximum rate of rise and dead time of the controlled system. Pretuning requirements: • State = 0 or State = 4 • ManualEnable = FALSE • The motor transition time has been configured or measured. • The setpoint and the process value lie within the configured limits. The more stable the process value is, the easier it is to calculate the PID parameters and the more precise the result will be. Noise on the process value can be tolerated as long as the rate of rise of the process value is significantly higher as compared to the noise. Before the PID parameters are recalculated, they are backed up and can be reactivated with Config.Load-BackUp. The setpoint is frozen in the CurrentSetpoint tag. The controller switches to automatic mode following successful pretuning and to "Inactive" mode following unsuccessful pretuning. The pretuning phase is indicated with the SUT.State tag.

State / Retain.Mode	Description
2	Fine tuning Fine tuning generates a constant, limited oscillation of the process value. The PID parameters are tuned based on the amplitude and frequency of this oscillation. The differences between the process response during pretuning and fine tuning are analyzed. All PID parameters are recalculated from the results. PID parameters from fine tuning usually have better master control and disturbance characteristics than PID parameters from pretuning. PID_3Step automatically attempts to generate an oscillation greater than the noise of the process value. Fine tuning is only minimally influenced by the stability of the process value. The PID parameters are backed up before fine tuning. They can be reactivated with Config.LoadBackUp. The setpoint is frozen in the CurrentSetpoint tag. Requirements for fine tuning: • The motor transition time has been configured or measured. • The setpoint and the process value lie within the configured limits. • ManualEnable = FALSE • Automatic (State = 3), inactive (State = 0) or manual (State = 4) mode Fine tuning proceeds as follows when started from: • Automatic mode (State = 3) Start fine tuning from automatic mode if you wish to improve the existing PID parameters through tuning. PID_3Step controls the system using the existing PID parameters until the control loop has stabilized and the requirements for fine tuning have been met. Only then will fine tuning start. • Inactive (State = 0) or manual mode (State = 4) Pretuning is always started first. The determined PID parameters will be used for control until the control loop has stabilized and the requirements for fine tuning have been met. If PIDSelfTune.TIR.RunIn = TRUE, pretuning is skipped and an attempt is made to reach the setpoint with the minimum or maximum output value. This can produce increased overshoot. Fine tuning then starts automatically. The controller switches to automatic mode following successful fine tuning. If fine tuning was not successful, the controller switches to "Inactive" mode. The fine tuning phase is indicated with the TIR.State tag.
3	Automatic mode In automatic mode, PID_3Step controls the controlled system in accordance with the parameters specified. The controller switches to automatic mode if one the following requirements is fulfilled: • Pretuning successfully completed • Fine tuning successfully completed • Changing the Retain.Mode tag to the value 3. When the CPU is switched on or switches from Stop to RUN mode, PID_3Step starts in the most recently active operating mode. To leave PID_3Step in "Inactive" mode, set RunModeByStartup = FALSE. The ActivateRecoverMode tag is taken into consideration in automatic mode.

State / Retain.Mode	Description
4	Manual mode In manual mode, you specify manual output values in the Manual_UP and Manual_DN parameters or ManualValue parameter. Whether or not the actuator can be moved to the output value in the event of an error is described in the ErrorBits parameter. This operating mode is enabled if Retain.Mode = 4, or on a rising edge at ManualEnable. If ManualEnable changes to TRUE, only State changes. Retain.Mode retains its current value. On a falling edge at ManualEnable, PID_3Step returns to the previous operating mode. The switchover to automatic mode is bumpless. **PID_3Step V1.1** Manual mode is always possible in the event of an error. **PID_3Step V1.0** Manual mode is dependent on the ActivateRecoverMode tag in the event of an error.
5	Approach substitute output value This operating mode is activated in the event of an error or when Reset = TRUE if Errorbehaviour = 1 and ActivateRecoverMode = FALSE.. PID_3Step moves the actuator to the substitute output value and then switches to "Inactive" mode.
6	Transition time measurement The time that the motor needs to completely open the valve from the closed condition is determined. This operating mode is activated when GetTransitTime.Start = TRUE is set. If endstop signals are used to measure the transition time, the valve will be opened completely from its current position, closed completely, and opened completely again. If GetTransitTime.InvertDirection = TRUE, this behavior is inverted. If position feedback is used to measure the transition time, the actuator will be moved from its current position to a target position. The output value limits are not taken into consideration during the transition time measurement. The actuator can travel to the high or the low endstop.
7	Error monitoring The control algorithm is switched off and no longer changes the valve position. This operating mode is activated instead of "Inactive" mode in the event of an error. All the following conditions must be met: • Mode = 3 (automatic mode) • Errorbehaviour = 0 • ActivateRecoverMode = TRUE • One or more errors have occurred in which ActivateRecoverMode (Page 3545) is effective. As soon as the errors are no longer pending, PID_3Step switches back to automatic mode.
8	Approach substitute output value with error monitoring This operating mode is activated instead of "Approach substitute output value" mode in the event of an error. PID_3Step moves the actuator to the substitute output value and then switches to "Error monitoring" mode. All the following conditions must be met: • Mode = 3 (automatic mode) • Errorbehaviour = 1 • ActivateRecoverMode = TRUE • One or more errors have occurred in which ActivateRecoverMode (Page 3545) is effective. As soon as the errors are no longer pending, PID_3Step switches back to automatic mode.

Automatic switchover of operating mode during commissioning

PID_3Step automatically switches the operating mode in the event of an error. The following diagram illustrates the influence of ErrorBehaviour on the switchover of operating mode from transition time measurement, pretuning, and fine tuning modes.

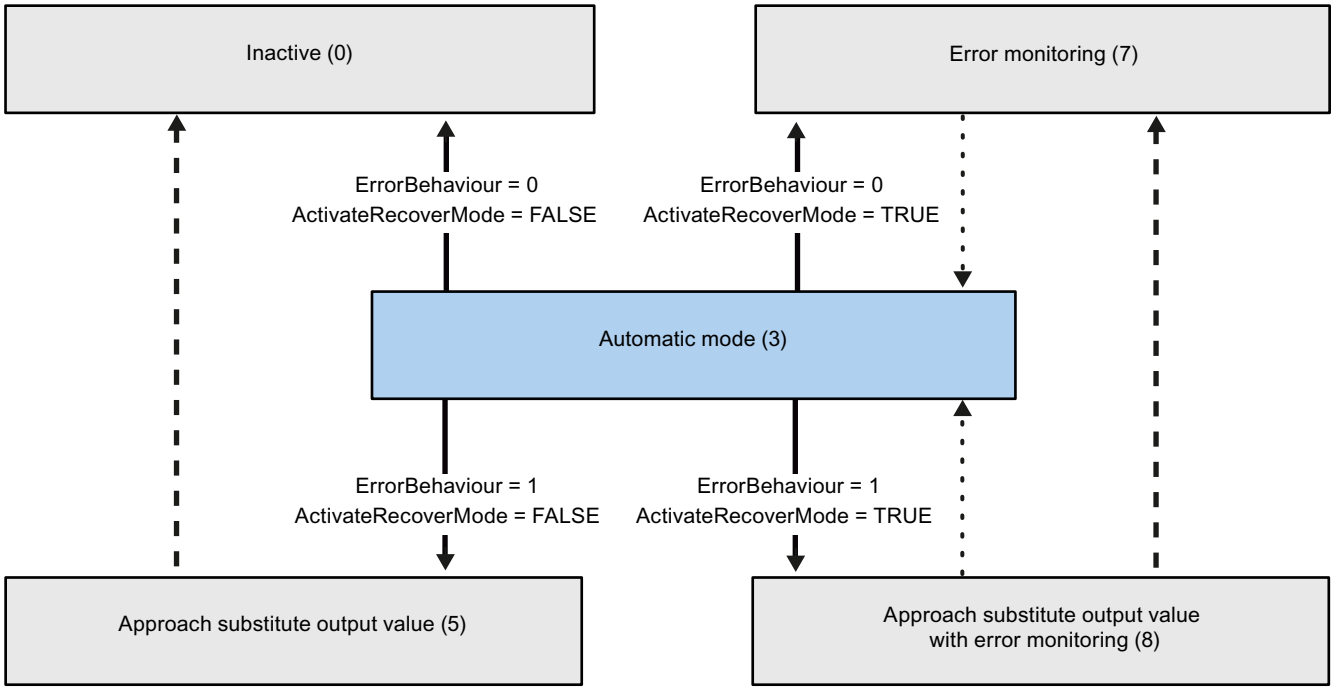


Automatic switchover of operating mode in the event of an error

Automatic switchover of operating mode once the current operation has been completed.

Automatic switchover of operating mode in automatic mode (PID_3Step V1.1)

PID_3Step automatically switches the operating mode in the event of an error. The following diagram illustrates the influence of ErrorBehaviour and ActivateRecoverMode on this switchover of operating mode.

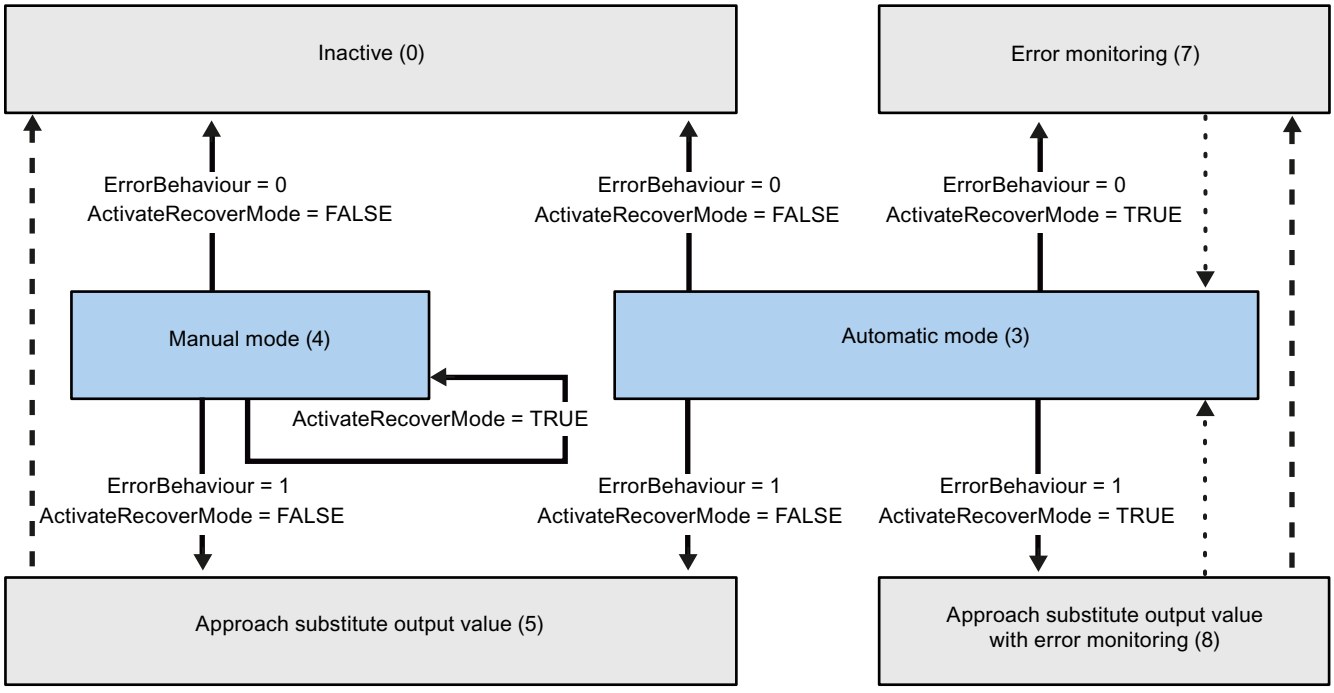


Automatic switchover of operating mode in the event of an error

Automatic switchover of operating mode once the current operation has been completed.

Automatic switchover of operating mode in automatic and manual modes (PID_3Step V1.0)

PID_3Step automatically switches the operating mode in the event of an error. The following diagram illustrates the influence of ErrorBehaviour and ActivateRecoverMode on this switchover of operating mode.



Automatic switchover of operating mode in the event of an error

Automatic switchover of operating mode once the current operation has been completed.

Automatic switchover of operating mode when error is no longer pending.

Parameter ErrorBits V1 (Page 3544)

Parameter ErrorBits V1

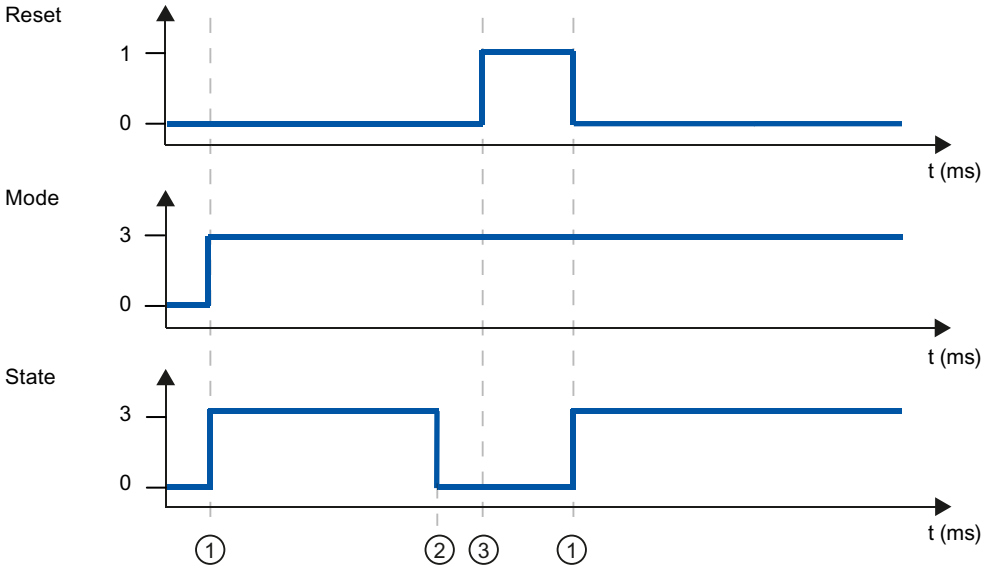
If several errors are pending simultaneously, the values of the error codes are displayed with binary addition. The display of error code 0003, for example, indicates that the errors 0001 and 0002 are pending simultaneously.

ErrorBits (DW#16#...)	Description
0000	There is no error.
0001	The "Input" parameter is outside the process value limits. • Input > Config.InputUpperLimit or • Input < Config.InputLowerLimit If ActivateRecoverMode = TRUE and ErrorBehaviour = 1, the actuator moves to the substitute output value. If ActivateRecoverMode = TRUE and ErrorBehaviour = 0, the actuator stops in its current position. If ActivateRecoverMode = FALSE, the actuator stops in its current position. PID_3Step V1.1 You can move the actuator in manual mode. PID_3Step V1.0 Manual mode is not possible in this state. You cannot move the actuator again until you eliminate the error.
0002	Invalid value at "Input_PER" parameter. Check whether an error is pending at the analog input. If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_3Step switches back to automatic mode.
0004	Error during fine tuning. Oscillation of the process value could not be maintained.
0020	Pretuning is not permitted in automatic mode or during fine tuning.
0080	Error during pretuning. Incorrect configuration of output value limits. Check whether the limits of the output value are configured correctly and match the control logic.
0100	Error during fine tuning resulted in invalid parameters.
0200	Invalid value at "Input" parameter: Value has an invalid number format. If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_3Step switches back to automatic mode.
0400	Calculation of output value failed. Check the PID parameters.
0800	Sampling time error: PID_3Step is not called within the sampling time of the cyclic interrupt OB. If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_3Step switches back to automatic mode.
1000	Invalid value at "Setpoint" parameter: Value has an invalid number format. If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_3Step switches back to automatic mode.
2000	Invalid value at Feedback_PER parameter. Check whether an error is pending at the analog input. The actuator cannot be moved to the substitute output value and remains in its current position. Manual mode is not possible in this state. You must deactivate position feedback (Config. FeedbackOn = FALSE) to move the actuator from this state. If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_3Step switches back to automatic mode.

ErrorBits (DW#16#...)	Description
4000	Invalid value at Feedback parameter. Value has an invalid number format. The actuator cannot be moved to the substitute output value and remains in its current position. Manual mode is not possible in this state. You must deactivate position feedback (Config. FeedbackOn = FALSE) to move the actuator from this state. If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_3Step switches back to automatic mode.
8000	Error during digital position feedback. Actuator_H = TRUE and Actuator_L = TRUE. The actuator cannot be moved to the substitute output value and remains in its current position. Manual mode is not possible in this state. In order to move the actuator from this state, you must deactivate the "Actuator endstop" (Config.ActuatorEndStopOn = FALSE). If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_3Step switches back to automatic mode.

Parameter Reset V1

A rising edge at Reset resets the errors and warnings and clears the integral action. A falling edge at Reset triggers a change to the most recently active operating mode.



① Activation
② Error
③ Reset

Tag ActivateRecoverMode V1

The effect of the ActivateRecoverMode variable depends on the version of the PID_3Step.

Behavior in version 1.1

The ActivateRecoverMode variable determines the behavior in the event of an error in automatic mode. ActivateRecoverMode is not effective during pretuning, fine tuning and transition time measurement.

ActivateRecoverMode	Description
FALSE	In the event of an error, PID_3Step switches to "Inactive" or "Approach substitute output value" operating mode. The controller is activated by a reset or a change in Retain.Mode.
TRUE	If errors occur frequently in automatic mode, this setting has a negative effect on the control response. In this case, check the ErrorBits parameter and eliminate the cause of the error. If one or more errors occur, PID_3Step switches to "Approach substitute output value with error monitoring" or "Error monitoring" mode: • 0002h: Invalid value at parameter Input_PER. • 0200h: Invalid value at parameter Input. • 0800h: Sampling time error • 1000h: Invalid value at parameter Setpoint. • 2000h: Invalid value at parameter Feedback_PER. • 4000h: Invalid value at parameter Feedback. • 8000h: Error in digital position feedback. With errors 2000h, 4000h and 8000h, PID_3Step **cannot** approach the configured substitute output value. As soon as the errors are no longer pending, PID_3Step switches back to automatic mode.

Behavior in version 1.0

The ActivateRecoverMode variable determines the behavior in the event of an error in automatic and manual mode. ActivateRecoverMode is not effective during pretuning, fine tuning and transition time measurement.

ActivateRecoverMode	Description
FALSE	In the event of an error, PID_3Step switches to "Inactive" or "Approach substitute output value" operating mode. The controller is activated by a reset or a change in Retain.Mode.
TRUE	**Errors in automatic mode** If errors occur frequently in automatic mode, this setting has a negative effect on the control response. In this case, check the ErrorBits parameter and eliminate the cause of the error. If one or more errors occur, PID_3Step switches to "Approach substitute output value with error monitoring" or "Error monitoring" mode: • 0002h: Invalid value at parameter Input_PER. • 0200h: Invalid value at parameter Input. • 0800h: Sampling time error • 1000h: Invalid value at parameter Setpoint. • 2000h: Invalid value at parameter Feedback_PER. • 4000h: Invalid value at parameter Feedback. • 8000h: Error in digital position feedback. With errors 2000h, 4000h and 8000h, PID_3Step **cannot** approach the configured substitute output value. As soon as the errors are no longer pending, PID_3Step switches back to automatic mode. **Errors in manual mode** If one or more of the following errors occur, PID_3Step stays in manual mode: • 0002h: Invalid value at parameter Input_PER. • 0200h: Invalid value at parameter Input. • 0800h: Sampling time error • 1000h: Invalid value at parameter Setpoint. • 2000h: Invalid value at parameter Feedback_PER. • 4000h: Invalid value at parameter Feedback. • 8000h: Error in digital position feedback. With errors 2000h, 4000h and 8000h, you **cannot** move the valve to a suitable position.

Tag Warning V1

If several warnings are pending simultaneously, their values are displayed with binary addition. The display of warning 0003, for example, indicates that the warnings 0001 and 0002 are pending simultaneously.

Warning (DW#16#...)	Description
0000	No warning pending.
0001	The point of inflection was not found during pretuning.
0002	Oscillation increased during fine tuning.
0004	The setpoint was limited to the configured limits.
0008	Not all the necessary controlled system properties were defined for the selected method of calculation. The PID parameters were instead calculated using the TuneRuleTIR = 3 method.
0010	The operating mode could not be changed because ManualEnable = TRUE.
0020	The cycle time of the calling OB limits the sampling time of the PID algorithm. Improve results by using shorter OB cycle times.
0040	The process value exceeded one of its warning limits.
0080	Invalid value at Retain.Mode. The operating mode is not switched.
0100	The manual value was limited to the limits of the controller output.
0200	The rule used for tuning produces an incorrect result, or is not supported.
0400	Method selected for transition time measurement not suitable for actuator. The transition time cannot be measured because the actuator settings do not match the selected measuring method.
0800	The difference between the current position and the new output value is too small for transition time measurement. This can produce incorrect results. The difference between the current output value and new output value must be at least 50% of the entire control range.
1000	The substitute output value cannot be reached because it is outside the output value limits.

The following warnings are deleted as soon as the cause is eliminated:

- 0004
- 0020
- 0040
- 0100

All other warnings are cleared with a rising edge at Reset.

Tag SUT.State V1

SUT.State	Name	Description
0	SUT_INIT	Initialize pretuning
50	SUT_TPDN	Determine start position without position feedback
100	SUT_STDABW	Calculate the standard deviation
200	SUT_GET_POI	Find the point of inflection
300	SUT_GET_RISETM	Determine the rise time

SUT.State	Name	Description
9900	SUT_IO	Pretuning successful
1	SUT_NIO	Pretuning not successful

Tag TIR.State V1

TIR.State	Name	Description
-100	TIR_FIRST_SUT	Fine tuning is not possible. Pretuning will be executed first.
0	TIR_INIT	Initialize fine tuning
200	TIR_STDABW	Calculate the standard deviation
300	TIR_RUN_IN	Attempt to reach the setpoint with the maximum or minimum output value
400	TIR_CTRLN	Attempt to reach the setpoint with the existing PID parameters (if pretuning has been successful)

PID_Temp

Compatibility with CPU and FW

The following table shows which version of PID_Temp can be used on which CPU.

CPU	FW	PID_Temp
S7-1200	≥ V4.1	V1.0
S7-1500	≥ V1.7	V1.0

CPU processing time and memory requirement PID_Temp V1

CPU processing time

Typical CPU processing times of the PID_Temp technology object as of Version 1.0, depending on CPU type.

CPU	Typ. CPU processing time PID_Temp V1
CPU 1211C ≥ V4.1	580 µs
CPU 1215C ≥ V4.1	580 µs
CPU 1217C ≥ V4.1	580 µs
CPU 1505S ≥ V1.0	50 µs
CPU 1510SP-1 PN ≥ V1.7	130 µs
CPU 1511-1 PN ≥ V1.7	130 µs
CPU 1512SP-1 PN ≥ V1.7	130 µs

CPU 1516-3 PN/DP ≥ V1.7	75 µs
CPU 1518-4 PN/DP ≥ V1.7	6 µs

Memory requirement

Memory requirement of an instance DB of the PID_Temp technology object as of Version V1.0.

	Memory requirement of the instance DB of PID_Temp V1
Load memory requirement	Approx. 17000 bytes
Total work memory requirement	1280 bytes
Retentive work memory requirement	100 bytes

PID_Temp

Description of PID_Temp

Description

The PID_Temp instruction provides a PID controller with integrated tuning for temperature processes. PID_Temp can be used for pure heating or heating/cooling applications.

The following operating modes are possible:

- Inactive
- Pretuning
- Fine tuning
- Automatic mode
- Manual mode
- Substitute output value with error monitoring

For a more detailed description of the operating modes, see the State parameter.

PID algorithm

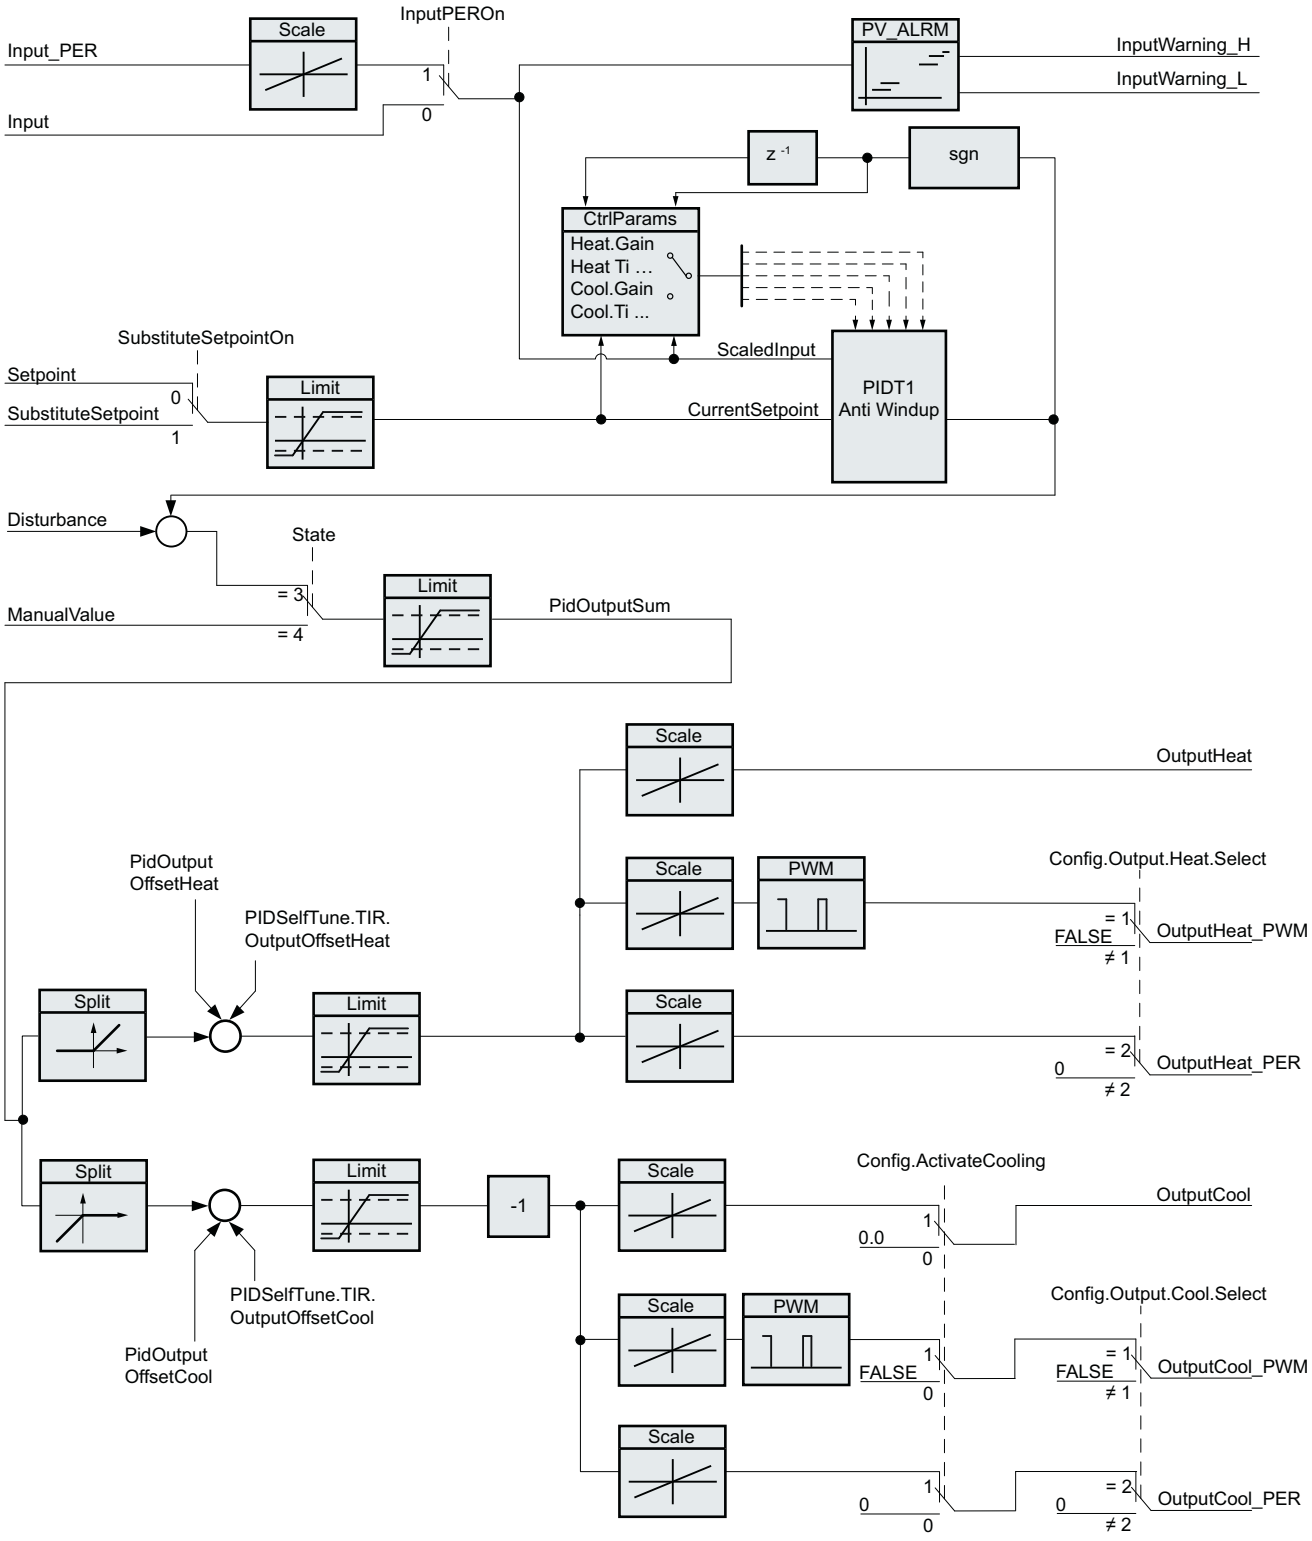
PID_Temp is a PIDT1 controller with anti-windup and weighting of the proportional and derivative actions. The PID algorithm operates according to the following equation (control zone and deadband deactivated):

$$y = K_p \left[(b \cdot w - x) + \frac{1}{T_I \cdot s} (w - x) + \frac{T_D \cdot s}{a \cdot T_D \cdot s + 1} (c \cdot w - x) \right]$$

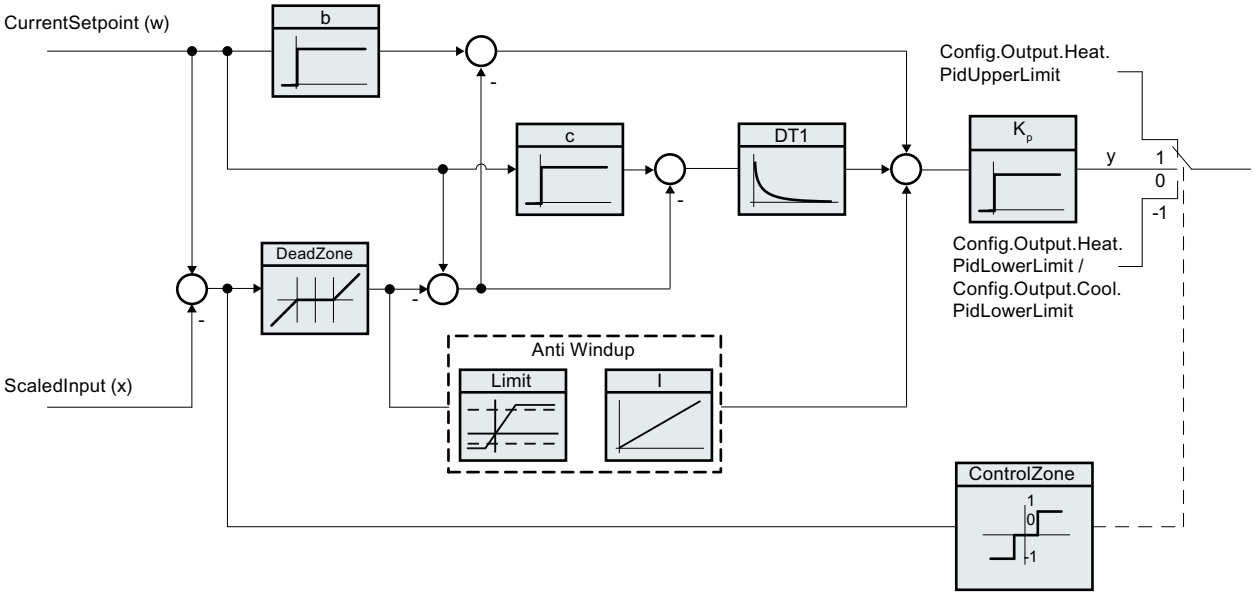
The table below shows the meaning of the icons used in the equation and in the subsequent figures.

Icon	Description	Associated parameters of the PID_Temp instruction
y	Output value of the PID algorithm	-
K_p	Proportional gain	Retain.CtrlParams.Heat.Gain Retain.CtrlParams.Cool.Gain CoolFactor
s	Laplace operator	-
b	Proportional action weighting	Retain.CtrlParams.Heat.PWeighting Retain.CtrlParams.Cool.PWeighting
w	Setpoint	CurrentSetpoint
x	Process value	ScaledInput
T_I	Integral action time	Retain.CtrlParams.Heat.Ti Retain.CtrlParams.Cool.Ti
T_D	Derivative action time	Retain.CtrlParams.Heat.Td Retain.CtrlParams.Cool.Td
a	Derivative delay coefficient (derivative delay T1 = a × T_D)	Retain.CtrlParams.Heat.TdFiltRatio Retain.CtrlParams.Cool.TdFiltRatio
c	Derivative action weighting	Retain.CtrlParams.Heat.DWeighting Retain.CtrlParams.Cool.DWeighting
DeadZone	Deadband width	Retain.CtrlParams.Heat.DeadZone Retain.CtrlParams.Cool.DeadZone
ControlZone	Control zone width	Retain.CtrlParams.Heat.ControlZone Retain.CtrlParams.Cool.ControlZone

PID_Temp block diagram



Block diagram of PIDT1 with anti-windup



Call

PID_Temp is called in the constant time scale of a cyclic interrupt OB.

If you call PID_Temp as a multi-instance DB, no technology object is created. No parameter assignment interface or commissioning interface is available. You must assign parameters for PID_Temp directly in the multi-instance DB and commission it via a watch table.

Download to device

The process values of retentive variables are only updated when you download PID_Temp completely.

Download technology object to device (Page 7204)

Startup

When the CPU starts up, PID_Temp starts in the operating mode that is saved in the Mode in/out parameter. To switch to "Inactive" operating mode during startup, set RunModeByStartup = FALSE.

Reaction to error

The behavior in the case of an error is determined by the tags SetSubstituteOutput and ActivateRecoverMode. If ActivateRecoverMode = TRUE, the behavior also depends on the error that occurred.

SetSubstituteOutput	ActivateRecoverMode	Configuration editor > Basic settings of output > Set PidOutputSum to	Reaction
Not relevant	FALSE	Zero (Inactive)	Switch to "Inactive" (State = 0) mode The output value of the PID algorithm and all outputs for heating and cooling are set to 0. The scaling of the outputs for heating and cooling is not active.
FALSE	TRUE	Current value for error while error is pending	Switch to "Substitute output value with error monitoring" mode (State = 5) The current output value is transferred to the actuator while the error is pending.
TRUE	TRUE	Substitute output value while error is pending	Switch to "Substitute output value with error monitoring" mode (State = 5) The value at SubstituteOutput is transferred to the actuator while the error is pending.

In manual mode, PID_Temp uses ManualValue as output value, unless ManualValue is invalid.

- If ManualValue is invalid, SubstituteOutput is used.
- If ManualValue and SubstituteOutput are invalid, Config.Output.Heat.PidLowerLimit is used.

The Error parameter indicates if an error is pending. When the error is no longer pending, Error = FALSE. The ErrorBits parameter shows which errors have occurred. ErrorBits is reset by a rising edge at Reset or ErrorAck.

Functional description of PID_Temp

Monitoring process value limits

You specify the high limit and low limit of the process value in the Config.InputUpperLimit and Config.InputLowerLimit tags. If the process value is outside these limits, an error occurs (ErrorBits = 0000001h).

You specify a high and low warning limit of the process value in the Config.InputUpperWarning and Config.InputLowerWarning tags. If the process value is outside these warning limits, a warning occurs (Warning = 0000040h), and the InputWarning_H or InputWarning_L output parameter changes to TRUE.

Limiting the setpoint

You specify a high limit and low limit of the setpoint in the Config.SetpointUpperLimit and Config.SetpointLowerLimit tags. PID_Temp automatically limits the setpoint to the process value limits. You can limit the setpoint to a smaller area. PID_Temp checks whether this area is within the process value limits. If the setpoint is outside these limits, the high or low limit is used as the setpoint, and output parameter SetpointLimit_H or SetpointLimit_L is set to TRUE.

The setpoint is limited in all operating modes.

Substitute setpoint

You can specify a substitute setpoint at the SubstituteSetpoint tag and activate it with SubstituteSetpointOn = TRUE. In this way, you can temporarily specify the setpoint directly, for example for a slave controller in a cascade, without having to change the user program. The limits set for the setpoint also apply to the substitute setpoint.

Heating and cooling

With the default setting, PID_Temp only uses the outputs for heating (OutputHeat, OutputHeat_PWM, OutputHeat_PER). The output value of the PID algorithm (PidOutputSum) is scaled and output at the outputs for heating. You specify with Config.Output.Heat.Select if OutputHeat_PWM or OutputHeat_PER is calculated. OutputHeat is always calculated.

With Config.ActivateCooling = TRUE, you can also activate the outputs for cooling (OutputCool, OutputCool_PWM, OutputCool_PER). Positive output values of the PID algorithm (PidOutputSum) are scaled and output at the outputs for heating. Negative output values of the PID algorithm are scaled and output at the outputs for cooling. You specify with Config.Output.Cool.Select if OutputCool_PWM or OutputCool_PER is calculated. OutputCool is always calculated.

Two methods are available to calculate the PID output value with activated cooling:

- Cooling factor (Config.AdvancedCooling = FALSE):
  The output value calculation for cooling takes place with the PID parameters for heating, taking into consideration the configurable cooling factor Config.CoolFactor. This method is suitable if the heating and cooling actuator have similar time responses but different gains. When you select this method, pretuning and fine tuning for cooling as well as the PID parameter set for cooling are not available. You can only execute the tuning for heating.
- PID parameter switching (Config.AdvancedCooling = TRUE):
  The output value calculation for cooling takes place by means of a separate PID parameter set. Based on the calculated output value and the control deviation, the PID algorithm decides whether the PID parameter for heating or cooling is used. This method is suitable if the heating and cooling actuator have different time responses and different gains. Pretuning and fine tuning for cooling are only available when you select this method.

Output value limits and scaling

Depending on the operating mode, the PID output value (PidOutputSum) is calculated automatically by the PID algorithm or defined by the manual value (ManualValue) or the configured substitute output value (SubstituteOutput).

The PID output value is limited according to the configuration:

- If cooling is deactivated (Config.ActivateCooling = FALSE), Config.Output.Heat.PidUpperLimit is the high limit and Config.Output.Heat.PidLowerLimit the low limit.
- If cooling is activated (Config.ActivateCooling = TRUE), Config.Output.Heat.PidUpperLimit is the high limit and Config.Output.Cool.PidLowerLimit the low limit.

The PID output value is scaled and output at the outputs for heating and cooling. Scaling can be defined separately for each output and is specified in the structures Config.Output.Heat or Config.Output.Cool with 2 value pairs each:

Output	Value pair	Parameter
OutputHeat	Value pair 1	High limit PID output value (heating) Config.Output.Heat.PidUpperLimit, Scaled high output value (heating) Config.Output.Heat.UpperScaling
	Value pair 2	Low limit PID output value (heating) Config.Output.Heat.PidLowerLimit, Scaled low output value (heating) Config.Output.Heat.LowerScaling
OutputHeat_PWM	Value pair 1	High limit PID output value (heating) Config.Output.Heat.PidUpperLimit, Scaled high PWM output value (heating) Config.Output.Heat.PwmUpperScaling
	Value pair 2	Low limit PID output value (heating) Config.Output.Heat.PidLowerLimit, Scaled low PWM output value (heating) Config.Output.Heat.PwmLowerScaling
OutputHeat_PER	Value pair 1	High limit PID output value (heating) Config.Output.Heat.PidUpperLimit, Scaled high analog output value (heating) Config.Output.Heat.PerUpperScaling
	Value pair 2	Low limit PID output value (heating) Config.Output.Heat.PidLowerLimit, Scaled low analog output value (heating) Config.Output.Heat.PerLowerScaling
OutputCool	Value pair 1	Low limit PID output value (cooling) Config.Output.Cool.PidLowerLimit, Scaled high output value (cooling) Config.Output.Cool.UpperScaling
	Value pair 2	High limit PID output value (cooling) Config.Output.Cool.PidUpperLimit, Scaled low output value (cooling) Config.Output.Cool.LowerScaling

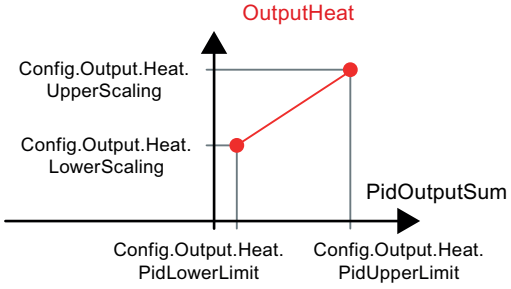
Output	Value pair	Parameter
OutputCool_PWM	Value pair 1	Low limit PID output value (cooling) Config.Output.Cool.PidLowerLimit, Scaled high PWM output value (cooling) Config.Output.Cool.PwmUpperScaling
	Value pair 2	High limit PID output value (cooling) Config.Output.Cool.PidUpperLimit, Scaled low PWM output value (cooling) Config.Output.Cool.PwmLowerScaling
OutputCool_PER	Value pair 1	Low limit PID output value (cooling) Config.Output.Cool.PidLowerLimit, Scaled high analog output value (cooling) Config.Output.Cool.PerUpperScaling
	Value pair 2	High limit PID output value (cooling) Config.Output.Cool.PidUpperLimit, Scaled low analog output value (cooling) Config.Output.Cool.PerLowerScaling

If cooling is activated (Config.ActivateCooling = TRUE), Config.Output.Heat.PidLowerLimit must have the value 0.0.

Config.Output.Cool.PidUpperLimit must always have the value 0.0.

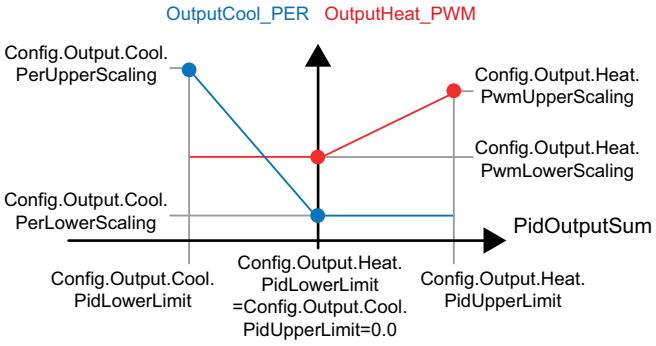
Example:

Output scaling when using output OutputHeat (cooling deactivated; Config.Output.Heat.PidLowerLimit may be unequal to 0.0):



Example:

Output scaling when using output OutputHeat_PWM and OutputCool_PER (cooling activated; Config.Output.Heat.PidLowerLimit must be 0.0):



With the exception of the "Inactive" operating mode, the value at an output is always located between its scaled high output value and scaled low output value, for example, for OutputHeat always between Config.Output.Heat.UpperScaling and Config.Output.Heat.LowerScaling.

If you want to limit the value at the associated output, you must also adjust these scaling values.

Cascading

PID_Temp supports you when you use cascade control (see: Program creation (Page 7323)).

Substitute output value

In the event of an error, PID_Temp can output a substitute output value that you define at the SubstituteOutput tag. The substitute output value must be within the limits for the PID output value. The values at the outputs for heating and cooling resulting from the substitute output value are the result of the configured output scaling.

Monitoring signal validity

The values of the following parameters are monitored for validity when used:

- Setpoint
- SubstituteSetpoint
- Input
- Input_PER
- Disturbance
- ManualValue
- SubstituteOutput
- PID parameters in the structures Retain.CtrlParams.Heat and Retain.CtrlParams.Cool.

Monitoring the sampling time PID_Temp

Ideally, the sampling time is equivalent to the cycle time of the cyclic interrupt OB. The PID_Temp instruction measures the time interval between two calls. This is the current sampling time. On every switchover of operating mode and during the initial startup, the mean value is formed from the first 10 sampling times. Too great a difference between the current sampling time and this mean value triggers an error (Error = 0000800h).

The error occurs during tuning if:

- New mean value >= 1.1 x old mean value
- New mean value <= 0.9 x old mean value

The error occurs in automatic mode if:

- New mean value >= 1.5 x old mean value
- New mean value <= 0.5 x old mean value

If you deactivate the sampling time monitoring (CycleTime.EnMonitoring = FALSE), you can also call PID_Temp in OB1. You must then accept a lower control quality due to the deviating sampling time.

Sampling time of the PID algorithm

The controlled system needs a certain amount of time to respond to changes in the output value. It is therefore not advisable to calculate the output value in every cycle. The sampling time of the PID algorithm represents the time between two calculations of the output value. It is calculated during tuning and rounded to a multiple of the cycle time of the cyclic interrupt OB (sampling time PID_Temp). All other functions of the PID_Temp are executed at every call.

If cooling and PID parameter switching are activated, PID_Temp uses a separate sampling time of the PID algorithm for heating and cooling. In all other configurations, only the sampling time of the PID algorithm for heating is used.

If you use OutputHeat_PWM or OutputCool_PWM, the sampling time of the PID algorithm is used as time period of the pulse width modulation. The accuracy of the output signal is determined by the ratio of the PID algorithm sampling time to the cycle time of the OB. The cycle time should be no more than a tenth of the PID algorithm sampling time.

If the PID algorithm sampling time and thus the time period of the pulse width modulation is very high when you use OutputHeat_PWM or OutputCool_PWM, you can define a deviating shorter time period at the Config.Output.Heat.PwmPeriode or Config.Output.Cool.PwmPeriode parameters to improve the smoothness of the process value.

Control logic

PID_Temp can be used for heating or heating/cooling applications and always works with normal control logic.

An increase of the PID output value (PidOutputSum) is intended to increase the process value. The values at the outputs for heating and cooling resulting from the PID output value are the result of the configured output scaling.

An inverted control logic or negative proportional gain are not supported.

If you only need an output value for your application in which an increase is to reduce the process value (for example, discharge control), you can use PID_Compact with inverted control logic.

Input parameters of PID_Temp

Parameter	Data type	Default	Description
Setpoint	REAL	0.0	Setpoint of the PID controller in automatic mode Valid range of values: Config.SetpointUpperLimit ≥ Setpoint ≥ Config.SetpointLowerLimit Config.InputUpperLimit ≥ Setpoint ≥ Config.InputLowerLimit
Input	REAL	0.0	A tag of the user program is used as the source of the process value. If you are using the Input parameter, Config.InputPerOn = FALSE must be set.
Input_PER	INT	0	An analog input is used as the source of the process value. If you are using the Input_PER parameter, Config.InputPerOn = TRUE must be set.
Disturbance	REAL	0.0	Disturbance variable or precontrol value
ManualEnable	BOOL	FALSE	• A FALSE -> TRUE edge activates "Manual mode", State = 4, Mode remains unchanged. As long as ManualEnable = TRUE, you cannot change the operating mode via a rising edge at ModeActivate or use the commissioning dialog. • A TRUE -> FALSE edge activates the operating mode that is specified by Mode. We recommend that you change the operating mode using Mode and ModeActivate only.
ManualValue	REAL	0.0	Manual value This value is used in manual mode as PID output value (PidOutputSum). The values at the outputs for heating and cooling resulting from this manual value are the result of the configured output scaling (structures Config.Output.Heat and Config.Output.Cool). For controllers with activated cooling output (Config.ActivateCooling = TRUE), define: • a positive manual value to output the value at the outputs for heating • a negative manual value to output the value at the outputs for cooling The permitted value range is determined by the configuration. • Cooling output deactivated (Config.ActivateCooling = FALSE): Config.Output.Heat.PidUpperLimit ≥ ManualValue ≥ Config.Output.Heat.PidLowerLimit • Cooling output activated (Config.ActivateCooling = TRUE): Config.Output.Heat.PidUpperLimit ≥ ManualValue ≥ Config.Output.Cool.PidLowerLimit
ErrorAck	BOOL	FALSE	• FALSE -> TRUE edge ErrorBits and Warning are reset.

Parameter	Data type	Default	Description
Reset	BOOL	FALSE	Restarts the controller. • FALSE -> TRUE edge – Switch to "Inactive" mode – ErrorBits and Warning are reset. – Integral action is cleared (PID parameters are retained) • As long as Reset = TRUE, – PID_Tempremains in "Inactive" mode (State = 0). – you cannot change the operating mode with Mode and ModeActivate or ManualEnable – you cannot use the commissioning dialog. • TRUE -> FALSE edge PID_Temp switches to the operating mode that is saved in the Mode parameter.
ModeActivate	BOOL	FALSE	• FALSE -> TRUE edge PID_Temp switches to the operating mode that is saved at the Mode input.

Output parameters of PID_Temp

Parameter	Data type	Default	Description
ScaledInput	REAL	0.0	Scaled process value
OutputHeat	REAL	0.0	Output value (heating) in REAL format The PID output value (PidOutputSum) is scaled with the two value pairs Config.Output.Heat.PidUpperLimit, Config.Output.Heat.UpperScaling and Config.Output.Heat.PidLowerLimit, Config.Output.Heat.LowerScaling and output in REAL format at OutputHeat. OutputHeat is always calculated.
OutputCool	REAL	0.0	Output value (cooling) in REAL format The PID output value (PidOutputSum) is scaled with the two value pairs Config.Output.Cool.PidUpperLimit, Config.Output.Cool.LowerScaling and Config.Output.Cool.PidLowerLimit, Config.Output.Cool.UpperScaling and output in REAL format at OutputCool. OutputCool is only calculated if the cooling output is activated (Config.ActivateCooling = TRUE).
OutputHeat_PER	INT	0	Analog output value (heating) The PID output value (PidOutputSum) is scaled with the two value pairs Config.Output.Heat.PidUpperLimit, Config.Output.Heat.PerUpperScaling and Config.Output.Heat.PidLowerLimit, Config.Output.Heat.PerLowerScaling and output as analog value at OutputHeat_PER. OutputHeat_PER is only calculated if Config.Output.Heat.Select = 2.

Parameter	Data type	Default	Description
Output-Cool_PER	INT	0	Analog output value (cooling) The PID output value (PidOutputSum) is scaled with the two value pairs Config.Output.Cool.PidUpperLimit, Config.Output.Cool.PerLowerScaling and Config.Output.Cool.PidLowerLimit, Config.Output.Cool.PerUpperScaling and output as analog value at OutputCool_PER. OutputCool_PER is only calculated if the cooling output is activated (Config.ActivateCooling = TRUE) and Config.Output.Cool.Select = 2.
OutputHeat_PWM	BOOL	FALSE	Pulse-width modulated output value (heating) The PID output value (PidOutputSum) is scaled with the two value pairs Config.Output.Heat.PidUpperLimit, Config.Output.Heat.PwmUpperScaling and Config.Output.Heat.PidLowerLimit, Config.Output.Heat.PwmLowerScaling and output as pulse-width modulated value (variable switch on and switch off times) at OutputHeat_PWM. OutputHeat_PWM is only calculated if Config.Output.Heat.Select = 1.
Output-Cool_PWM	BOOL	FALSE	Pulse-width modulated output value (cooling) The PID output value (PidOutputSum) is scaled with the two value pairs Config.Output.Cool.PidUpperLimit, Config.Output.Cool.PwmLowerScaling and Config.Output.Cool.PidLowerLimit, Config.Output.Cool.PwmUpperScaling and output as pulse-width modulated value (variable switch on and switch off times) at OutputCool_PWM. OutputCool_PWM is only calculated if the cooling output is activated (Config.ActivateCooling = TRUE) and Config.Output.Cool.Select = 1.
SetpointLimit_H	BOOL	FALSE	If SetpointLimit_H = TRUE, the absolute setpoint high limit is reached (Setpoint ≥ Config.SetpointUpperLimit) or Setpoint ≥ Config.InputUpperLimit. The setpoint high limit is the minimum of Config.SetpointUpperLimit and Config.InputUpperLimit.
SetpointLimit_L	BOOL	FALSE	If SetpointLimit_L = TRUE, the absolute setpoint low limit is reached (Setpoint ≤ Config.SetpointLowerLimit) or Setpoint ≤ Config.InputLowerLimit. The setpoint low limit is the maximum of Config.SetpointLowerLimit and Config.InputLowerLimit.
InputWarning_H	BOOL	FALSE	If InputWarning_H = TRUE, the process value has reached or exceeded the warning high limit (ScaledInput ≥ Config.InputUpperWarning).
InputWarning_L	BOOL	FALSE	If InputWarning_L = TRUE, the process value has reached or fallen below the warning low limit (ScaledInput ≤ Config.InputLowerWarning).
State	INT	0	The PID_Temp state and mode parameters (Page 3591) shows the current operating mode of the PID controller. You can change the operating mode using the input parameter Mode and a rising edge at ModeActivate. For pretuning and fine tuning, you specify with Heat.EnableTuning and Cool.EnableTuning whether tuning takes place for heating or cooling. • State = 0: Inactive • State = 1: Pretuning • State = 2: Fine tuning • State = 3: Automatic mode • State = 4: Manual mode • State = 5: Substitute output value with error monitoring

Parameter	Data type	Default	Description
Error	BOOL	FALSE	If Error = TRUE, at least one error message is pending in this cycle.
ErrorBits	DWORD	DW#16#0	The PID_Temp ErrorBits parameter (Page 3599) shows the pending error messages. ErrorBits is retentive and is reset with a rising edge at Reset or ErrorAck.

PID_Temp in/out parameters

Parameter	Data type	Default	Description
Mode	INT	4	At Mode, specify the operating mode to which PID_Temp is to switch. Options are: • Mode = 0: Inactive • Mode = 1: Pretuning • Mode = 2: Fine tuning • Mode = 3: Automatic mode • Mode = 4: Manual mode The operating mode is activated by: • Rising edge at ModeActivate • Falling edge at Reset • Falling edge at ManualEnable • Cold restart of CPU if RunModeByStartup = TRUE For pretuning and fine tuning, you specify with Heat.EnableTuning and Cool.EnableTuning whether tuning takes place for heating or cooling. Mode is retentive. A detailed description of the operating modes can be found in State and Mode parameters (Page 3591).
Master	DWORD	DW#16#0	Interface for cascade control If this PID_Temp instance is used as slave controller in a cascade (Config.Cascade.IsSlave = TRUE), assign the Master parameter at the instruction call with the Slave parameter of the master controller. Example: Call of a slave controller "PID_Temp_2" with master controller "PID_Temp_1" in SCL: --- `"PID_Temp_2"(Master := "PID_Temp_1".Slave, Setpoint := "PID_Temp_1".OutputHeat);` --- You use this interface to exchange slave controller information about operating mode, limit and substitute setpoint with your master controller. Keep in mind that the call of the master controller has to take place before the call of the slave controller in the same cyclic interrupt OB. Assignment: • Bits 0 to 15: Unassigned • Bits 16 to 23 – Limit counter: A slave controller whose output value is limited increments this counter. Depending on the configured number of slaves (Config.Cascade.CountSlaves) and of the anti-windup mode (Config.Cascade.AntiWindUpMode), the master controller reacts accordingly. • Bit 24 – Automatic mode of the slave controllers: TRUE, if all slave controllers are in automatic mode • Bit 25 – Substitute setpoint of the slave controllers: TRUE, if a slave controller has activated the substitute setpoint (SubstituteSetpointOn = TRUE)

Parameter	Data type	Default	Description
Slave	DWORD	DW#16#0	Interface for cascade control You use this interface to exchange slave controller information about operating mode, limit and substitute setpoint with your master controller. See description of Master parameter

PID_Temp static tags

You must not change tags that are not listed. These are used for internal purposes only.

Tag	Data type	Default	Description
IntegralResetMode	Int	1	The IntegralResetMode tag determines the default setting of the integral action PIDCtrl.IOutputOld when you change the operating mode from "Inactive" to "Automatic mode". This setting only works for one cycle. • IntegralResetMode = 0: Smoothing The value is assigned in such a way that the switchover is bumpless. • IntegralResetMode = 1: Deleting The value is cleared. Any control deviation will cause a jump change of the output value. • IntegralResetMode = 2: Holding The value is not changed. You can define a new value using the user program. • IntegralResetMode = 3: Pre-assigning The value is automatically pre-assigned as if PidOutputSum = OverwriteInitialOutputValue in the last cycle. This setting is useful, for example, for an override controller.
OverwriteInitialOutputValue	REAL	0.0	If IntegralResetMode = 3, the value of PIDCtrl.IOutputOld is pre-assigned as if "PidOutputSum" = "OverwriteInitialOutputValue" in the last cycle.
RunModeByStartup	BOOL	TRUE	Activate operating mode at Mode parameter after CPU restart • If RunModeByStartup = TRUE, PID_Temp starts in the operating mode saved in the Mode parameter after CPU startup. • If RunModeByStartup = FALSE, PID_Temp remains in "Inactive" mode after CPU startup.
LoadBackUp	BOOL	FALSE	If LoadBackUp = TRUE, the last set of PID parameters is reloaded from the CtrlParamsBackUp structure. The set was saved prior to the last tuning. LoadBackUp is automatically set back to FALSE. The acceptance is bumpless.

Tag	Data type	Default	Description
SetSubstitu-teOutput	BOOL	TRUE	Selection of the output value while an error is pending (State = 5): • If SetSubstituteOutput = TRUE and ActivateRecoverMode = TRUE, the configured substitute output value SubstituteOutput is output as PID output value as long as an error is pending. • If SetSubstituteOutput = FALSE and ActivateRecoverMode = TRUE, the actuator remains at the current PID output value as long as an error is pending. • If ActivateRecoverMode = FALSE, SetSubstituteOutput is not effective. • If SubstituteOutput is invalid (ErrorBits = 0020000h), the substitute output value cannot be output. In this case, the low limit of the PID output value for heating (Config.Output.Heat.PidLowerLimit) is used as PID output value.
PhysicalUnit	INT	0	Unit of measurement of the process value and setpoint, e.g., ºC, or ºF. This parameter is used for display in the editors and does not influence the control algorithm.
Physical-Quantity	INT	0	Physical quantity of the process value and setpoint, e.g., temperature. This parameter is used for display in the editors and does not influence the control algorithm.
ActivateRe-coverMode	BOOL	TRUE	The ActivateRecoverMode tag determines the reaction to error.
Warning	DWORD	0	The Warning tag shows the warnings since Reset = TRUE or ErrorAck =TRUE. Warning is retentive.
Progress	REAL	0.0	Progress of current tuning phase as a percentage (0.0 - 100.0)
CurrentSet-point	REAL	0.0	CurrentSetpoint always displays the currently effective setpoint. This value is frozen during tuning.
CancelTu-ningLevel	REAL	10.0	Permissible fluctuation of setpoint during tuning. Tuning is not canceled until: • Setpoint > CurrentSetpoint + CancelTuningLevel or • Setpoint < CurrentSetpoint - CancelTuningLevel

Tag	Data type	Default	Description
SubstituteOutput	REAL	0.0	The substitute output value is used as PID output value as long as the following conditions are met: • One or more errors are pending in automatic mode for which ActivateRecoverMode is in effect • SetSubstituteOutput = TRUE • ActivateRecoverMode = TRUE The values at the outputs for heating and cooling resulting from the substitute output value are the result of the configured output scaling (structures Config.Output.Heat and Config.Output.Cool). For controllers with activated cooling output (Config.ActivateCooling = TRUE), define: • a positive substitute output value to output the value at the outputs for heating • a negative substitute output value to output the value at the outputs for cooling The permitted value range is determined by the configuration. • Cooling output deactivated (Config.ActivateCooling = FALSE): Config.Output.Heat.PidUpperLimit ≥ SubstituteOutput ≥ Config.Output.Heat.PidLowerLimit • Cooling output activated (Config.ActivateCooling = TRUE): Config.Output.Heat.PidUpperLimit ≥ SubstituteOutput ≥ Config.Output.Cool.PidLowerLimit
PidOutputSum	REAL	0.0	PID output value PidOutputSum displays the output value of the PID algorithm. Depending on the operating mode, it is either calculated automatically or defined by the manual value or the configured substitute output value. The values at the outputs for heating and cooling resulting from the PID output value are the result of the configured output scaling (structures Config.Output.Heat and Config.Output.Cool). The PidOutputSum is limited as defined in the configuration. • Cooling output deactivated (Config.ActivateCooling = FALSE): Config.Output.Heat.PidUpperLimit ≥ PidOutputSum ≥ Config.Output.Heat.PidLowerLimit • Cooling output activated (ConfigActivateCooling = TRUE): Config.Output.Heat.PidUpperLimit ≥ PidOutputSum ≥ Config.Output.Cool.PidLowerLimit
PidOutputOffsetHeat	REAL	0.0	Offset of the PID output value heating PidOutputOffsetHeat is added to the value that results from PidOutputSum for the heating branch. Enter a positive value for PidOutputOffsetHeat to receive a positive offset at the outputs for heating. The resulting values at the outputs for heating are the result of the configured output scaling (Config.Output.Heat structure). This offset can be used for actuators which need a fixed minimum value, for example, fans with minimum speed.

Tag	Data type	Default	Description
PidOutputOffsetCool	REAL	0.0	Offset of the PID output value cooling PidOutputOffsetCool is added to the value that results from PidOutputSum for the cooling branch. Enter a negative value for PidOutputOffsetCool to receive a positive offset at the outputs for cooling. The resulting values at the outputs for cooling are the result of the configured output scaling (Config.Output.Cool structure). This offset can be used for actuators which need a fixed minimum value, for example, fans with minimum speed.
SubstituteSetpointOn	BOOL	FALSE	Activates the substitute setpoint as controller setpoint. • FALSE = the Setpoint parameter is used. • TRUE = the SubstituteSetpoint parameter is used as setpoint SubstituteSetpointOn can be used to specify the setpoint of a slave controller in a cascade directly without having to change the user program.
SubstituteSetpoint	REAL	0.0	Substitute setpoint If SubstituteSetpointOn = TRUE, the SubstituteSetpoint parameter is used as setpoint. Valid range of values: Config.SetpointUpperLimit ≥ SubstituteSetpoint ≥ Config.SetpointLowerLimit, Config.InputUpperLimit ≥ SubstituteSetpoint ≥ Config.InputLowerLimit
DisableCooling	BOOL	FALSE	DisableCooling = TRUE deactivates the cooling branch for heating/cooling controllers (Config.ActivateCooling = TRUE) in Automatic mode by setting PidOutputSum to 0.0 as low limit. PidOutputOffsetCool and the output scaling for the cooling outputs remain active. DisableCooling can be used for tuning of multi-zone applications to temporarily deactivate the cooling branch as long as all controllers have not completed their tuning yet. This parameter is set/reset by the user manually and is not automatically reset by the PID_Temp instruction.
AllSlaveAutomaticState	BOOL	FALSE	If this PID_Temp instance is used as master controller in a cascade (Config.Cascade.IsMaster = TRUE), AllSlaveAutomaticState = TRUE indicates that all slave controllers are in automatic mode. Tuning, manual mode or automatic mode of the master controller can only be executed accurately if all slave controllers are in automatic mode. AllSlaveAutomaticState is only determined if you interconnect the master controller and slave controller with the master and slave parameters. For details, see the Master parameter.
NoSlaveSubstituteSetpoint	BOOL	FALSE	If this PID_Temp instance is used as master controller in a cascade (Config.Cascade.IsMaster = TRUE), NoSlaveSubstituteSetpoint = TRUE indicates that no slave controller has activated its substitute setpoint. Tuning, manual mode or automatic mode of the master controller can only be executed accurately if no slave controller has activated its substitute setpoint. NoSlaveSubstituteSetpoint is only determined if you interconnect the master controller and slave controller with the master and slave parameters. For details, see the Master parameter.

Tag	Data type	Default	Description
Heat.EnableTuning	BOOL	TRUE	Enabling of tuning for heating Heat.EnableTuning must be set for the following tunings (at the same time or prior to the start with Mode and ModeActivate): • Pretuning heating • Pretuning heating and cooling • Fine tuning heating This parameter is not automatically reset by the PID_Temp instruction.
Cool.EnableTuning	BOOL	FALSE	Enabling of tuning for cooling Cool.EnableTuning must be set for the following tunings (simultaneously with or prior to the start with Mode and ModeActivate): • Pretuning cooling • Pretuning heating and cooling • Fine tuning cooling Only effective if the cooling output and PID parameter switching are activated ("Config.ActivateCooling" = TRUE and "Config.AdvancedCooling" = TRUE). This parameter is not automatically reset by the PID_Temp instruction.
Config.InputPerOn	BOOL	TRUE	If InputPerOn = TRUE, the Input_PER parameter is used for detecting the process value. If InputPerOn = FALSE, the Input parameter is used.
Config.InputUpperLimit	REAL	120.0	High limit of the process value Input and Input_PER are monitored to ensure adherence to this limit. If the limit is exceeded, an error is output and the reaction is determined by ActivateRecoverMode. At the I/O input, the process value can be a maximum of 18% higher than the nominal range (overrange). This means the limit cannot be exceeded when you use an I/O input with the pre-setting for high limit and process value scaling. When pretuning is started, the difference between high and low limit of the process value is checked to determine whether the distance between setpoint and process value meets the necessary requirements. InputUpperLimit > InputLowerLimit
Config.InputLowerLimit	REAL	0.0	Low limit of the process value Input and Input_PER are monitored to ensure adherence to this limit. If the limit is undershot, an error is output and the reaction is determined by ActivateRecoverMode. InputLowerLimit < InputUpperLimit
Config.InputUpperWarning	REAL	3.402822e+38	Warning high limit of the process value Input and Input_PER are monitored to ensure adherence to this limit. If the limit is exceeded, a warning is output at the Warning parameter. • If you set InputUpperWarning outside the process value limits, the configured absolute process value high limit is used as the warning high limit. • If you configure InputUpperWarning within the process value limits, this value is used as the warning high limit. InputUpperWarning > InputLowerWarning

Tag	Data type	Default	Description
Config.InputLowerWarning	REAL	-3.402822e+38	Warning low limit of the process value Input and Input_PER are monitored to ensure adherence to this limit. If the limit is undershot, a warning is output at the Warning parameter. • If you set InputLowerWarning outside the process value limits, the configured absolute process value low limit is used as the warning low limit. • If you configure InputLowerWarning within the process value limits, this value is used as the warning low limit. InputLowerWarning < InputUpperWarning
Config.SetpointUpperLimit	REAL	3.402822e+38	High limit of setpoint Setpoint and SubstituteSetpoint are monitored to ensure adherence to this limit. If the limit is exceeded, a warning is output at the Warning parameter. • If you configure SetpointUpperLimit outside the process value limits, the configured absolute process value high limit is used as the setpoint high limit. • If you configure SetpointUpperLimit within the process value limits, this value is used as the setpoint high limit. SetpointUpperLimit > SetpointLowerLimit
Config.SetpointLowerLimit	REAL	-3.402822e+38	Low limit of the setpoint Setpoint and SubstituteSetpoint are monitored to ensure adherence to this limit. If the limit is undershot, a warning is output at the Warning parameter. • If you set SetpointLowerLimit outside the process value limits, the configured process value absolute low limit is used as the setpoint low limit. • If you configure SetpointLowerLimit within the process value limits, this value is used as the setpoint low limit. SetpointLowerLimit < SetpointUpperLimit
Config.ActivateCooling	BOOL	FALSE	Activate cooling output • Config.ActivateCooling = FALSE Only the outputs for heating are used. • Config.ActivateCooling = TRUE The outputs for heating and cooling are used. If you are using the cooling output, the controller must not be configured as master controller (Config.Cascade.IsMaster must be FALSE) .

Tag	Data type	Default	Description
Config.AdvancedCooling	BOOL	TRUE	Method for heating/cooling • Cooling factor (Config.AdvancedCooling = FALSE) The output value calculation for cooling takes place with the PID parameters for heating (Retain.CtrlParams.Heat structure) taking into consideration the configurable cooling factor Config.CoolFactor. This method is suitable if the heating and cooling actuator have similar time responses but different gains. Pretuning and fine tuning for cooling are not available when you select this method. You can only execute the tuning for heating. • PID parameter switching (Config.AdvancedCooling = TRUE) The output value calculation for cooling takes place by means of a separate PID parameter set (Retain.CtrlParams.Cool structure). This method is suitable if the heating and cooling actuator have different time responses and different gains. Pretuning and fine tuning for cooling are only available when you select this method (Mode = 1 or 2, Cool.EnableTuning = TRUE). Config.AdvancedCooling is only calculated if the cooling output is activated (Config.ActivateCooling = TRUE).
Config.CoolFactor	REAL	1.0	Cooling factor If Config.AdvancedCooling = FALSE, Config.CoolFactor is considered as factor in the calculation of the output value for cooling. Different gains of the heating and cooling actuator can be considered in this way. Config.CoolFactor is not set automatically or adjusted during tuning. You must correctly configure Config.CoolFactor manually with the ratio "heating actuator gain/cooling actuator gain". Example: Config.CoolFactor = 2.0 means that the gain of the heating actuator is twice as high as the gain of the cooling actuator. Config.CoolFactor is only effective if the cooling output is activated (Config.ActivateCooling = TRUE) and cooling factor is selected as method for heating/cooling (Config.AdvancedCooling = FALSE). Config.CoolFactor > 0.0
Config.InputScaling.UpperPointIn	REAL	27648.0	Scaling Input_PER high Input_PER is scaled based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn. Only effective if Input_PER is used for process value detection (Config.InputPerOn = TRUE). UpperPointIn > LowerPointIn
Config.InputScaling.LowerPointIn	REAL	0.0	Scaling Input_PER low Input_PER is scaled based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn. Only effective if Input_PER is used for process value detection (Config.InputPerOn = TRUE). LowerPointIn < UpperPointIn

Tag	Data type	Default	Description
Config.InputScaling.UpperPointOut	REAL	100.0	Scaled high process value Input_PER is scaled based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn. Only effective if Input_PER is used for process value detection (Config.InputPerOn = TRUE). UpperPointOut > LowerPointOut
Config.InputScaling.LowerPointOut	REAL	0.0	Scaled low process value Input_PER is scaled based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn. Only effective if Input_PER is used for process value detection (Config.InputPerOn = TRUE). LowerPointOut < UpperPointOut
Config.Output.Heat.Select	INT	1	Selecting the output value for heating Config.Output.Heat.Select specifies which outputs are used for heating: • Heat.Select = 0 - OutputHeat is used • Heat.Select = 1 - OutputHeat and OutputHeat_PWM are used • Heat.Select = 2 -OutputHeat and OutputHeat_PER are used Outputs that are not used are not calculated and remain at their default value.
Config.Output.Heat.PwmPeriode	REAL	0.0	Time period of the pulse width modulation (PWM) for heating (OutputHeat_PWM output) in seconds: • Heat.PwmPeriode = 0.0 The sampling time of the PID algorithm for heating (Retain.CtrlParams.Heat.Cycle) is used as time period of the PWM. • Heat.PwmPeriode > 0.0 The value is rounded off to an integer multiple of the PID_Temp sampling time (CycleTime.Value) and used as time period of the PWM. This setting can be used to improve the smoothing of the process value with a long sampling time of the PID algorithm. The value must meet the following conditions: – Heat.PwmPeriode ≤ Retain.CtrlParams.Heat.Cycle, – Heat.PwmPeriode > Config.Output.Heat.MinimumOnTime – Heat.PwmPeriode > Config.Output.Heat.MinimumOffTime
Config.Output.Heat.PidUpperLimit	REAL	100.0	High limit of the PID output value for heating The PID output value (PidOutputSum) is limited to the high limit. Heat.PidUpperLimit forms a value pair together with the following parameters for scaling of the PID output value (PidOutputSum) to the outputs for heating: • Heat.UpperScaling for OutputHeat • Heat.PwmUpperScaling for OutputHeat_PWM • Heat.PerUpperScaling for OutputHeat_PER If you want to limit the value at the associated output, you must also adjust these scaling values. Heat.PidUpperLimit > Heat.PidLowerLimit

Tag	Data type	Default	Description
Config.Output.Heat.PidLowerLimit	REAL	0.0	Low limit of the PID output value for heating For controllers with **deactivated** cooling output (Config.ActivateCooling = FALSE), the PID output value (PidOutputSum) is limited to this low limit. For controllers with **activated** cooling output (Config.ActivateCooling = TRUE), the value must be 0.0. Heat.PidLowerLimit forms a value pair together with the following parameters for scaling of the PID output value (PidOutputSum) to the outputs for heating: • Heat.LowerScaling for OutputHeat • Heat.PwmLowerScaling for OutputHeat_PWM • Heat.PerLowerScaling for OutputHeat_PER If you want to limit the value at the associated output, you must also adjust these scaling values. The permitted value range is determined by the configuration. • Cooling output deactivated (Config.ActivateCooling = FALSE): Heat.PidLowerLimit < Heat.PidUpperLimit • Cooling output activated (Config.ActivateCooling = TRUE): Heat.PidLowerLimit = 0.0
Config.Output.Heat.UpperScaling	REAL	100.0	Scaled high output value for heating Heat.UpperScaling and Heat.PidUpperLimit form a value pair for scaling of the PID output value (PidOutputSum) to the output value for heating (OutputHeat). The OutputHeat value is always located between Heat.UpperScaling and Heat.LowerScaling. Heat.UpperScaling ≠ Heat.LowerScaling
Config.Output.Heat.LowerScaling	REAL	0.0	Scaled low output value for heating Heat.LowerScaling and Heat.PidLowerLimit form a value pair for scaling of the PID output value (PidOutputSum) to the output value for heating (OutputHeat). The OutputHeat value is always located between Heat.UpperScaling and Heat.LowerScaling. Heat.UpperScaling ≠ Heat.LowerScaling
Config.Output.Heat.PwmUpperScaling	REAL	100.0	Scaled high PWM output value for heating Heat.PwmUpperScaling and Heat.PidUpperLimit form a value pair for scaling of the PID output value (PidOutputSum) to the pulse-width modulated output value for heating (OutputHeat_PWM). The OutputHeat_PWM value is always located between Heat.PwmUpperScaling and Heat.PWMLowerScaling. Heat.PwmUpperScaling is only effective if OutputHeat_PWM is selected as output for heating (Heat.Select = 1) 100.0 ≥ Heat.PwmUpperScaling ≥ 0.0 Heat.PwmUpperScaling ≠ Heat.PwmLowerScaling

Tag	Data type	Default	Description
Config.Output.Heat.PwmLowerScaling	REAL	0.0	Scaled low PWM output value for heating Heat.PwmLowerScaling and Heat.PidLowerLimit form a value pair for scaling of the PID output value (PidOutputSum) to the pulse-width modulated output value for heating (OutputHeat_PWM). The OutputHeat_PWM value is always located between Heat.PwmUpperScaling and Heat.PwmLowerScaling. Heat.PwmLowerScaling is only effective if OutputHeat_PWM is selected as output for heating (Heat.Select = 1) 100.0 ≥ Heat.PwmLowerScaling ≥ 0.0 Heat.PwmUpperScaling ≠ Heat.PwmLowerScaling
Config.Output.Heat.PerUpperScaling	REAL	27648.0	Scaled high analog output value for heating Heat.PerUpperScaling and Heat.PidUpperLimit form a value pair for scaling of the PID output value (PidOutputSum) to the analog output value for heating (OutputHeat_PER). The OutputHeat_PER value is always located between Heat.PerUpperScaling and Heat.PerLowerScaling. Heat.PerUpperScaling is only effective if OutputHeat_PER is selected as output for heating (Heat.Select = 2) 32511.0 ≥ Heat.PerUpperScaling ≥ -32512.0 Heat.PerUpperScaling ≠ Heat.PerLowerScaling
Config.Output.Heat.PerLowerScaling	REAL	0.0	Scaled low analog output value for heating Heat.PerLowerScaling and Heat.PidLowerLimit form a value pair for scaling of the PID output value (PidOutputSum) to the analog output value for heating (OutputHeat_PER). The OutputHeat_PER value is always located between Heat.PerUpperScaling and Heat.PerLowerScaling. Heat.PerLowerScaling is only effective if OutputHeat_PER is selected as output for heating (Heat.Select = 2) 32511.0 ≥ Heat.PerLowerScaling ≥ -32512.0 Heat.PerUpperScaling ≠ Heat.PerLowerScaling
Config.Output.Heat.MinimumOnTime	REAL	0.0	Minimum on time of the pulse width modulation for heating (OutputHeat_PWM output) A PWM pulse is never shorter than this value. The value is rounded off to: Heat.MinimumOnTime = n × CycleTime.Value Heat.MinimumOnTime is only effective if the output for heating OutputHeat_PWM is selected (Heat.Select = 1)". 100000.0 ≥ Heat.MinimumOnTime ≥ 0.0
Config.Output.Heat.MinimumOffTime	REAL	0.0	Minimum off time of the pulse width modulation for heating (OutputHeat_PWM output) A PWM pause is never shorter than this value. The value is rounded off to: Heat.MinimumOffTime = n × CycleTime.Value Heat.MinimumOffTime is only effective if the output for heating OutputHeat_PWM is selected (Heat.Select = 1)". 100000.0 ≥ Heat.MinimumOffTime ≥ 0.0

Tag	Data type	Default	Description
Config.Output.Cool.Select	INT	1	Selecting the output value for cooling Config.Output.Cool.Select specifies which outputs are used for cooling: • Cool.Select = 0 - OutputCool is used • Cool.Select = 1 -OutputCool and OutputCool_PWM are used • Cool.Select = 2 - OutputCool and OutputCool_PER are used Outputs that are not used are not calculated and remain at their default value. Only effective if the cooling output is activated (Config.ActivateCooling = TRUE).
Config.Output.Cool.PwmPeriode	REAL	0.0	Time period of the pulse width modulation for cooling (OutputCool_PWM output) in seconds: • Cool.PwmPeriode = 0.0 and Config.AdvancedCooling = FALSE: sampling time of the PID algorithm for heating (Retain.CtrlParams.Heat.Cycle) is used as time period of the PWM. • Cool.PwmPeriode = 0.0 and Config.AdvancedCooling = TRUE: The sampling time of the PID algorithm for cooling (Retain.CtrlParams.Cool.Cycle) is used as time period of the PWM. • Cool.PwmPeriode > 0.0: The value is rounded off to an integer multiple of the PID_Temp sampling time (CycleTime.Value) and used as time period of the PWM. This setting can be used to improve the smoothing of the process value with a long sampling time of the PID algorithm. The value must meet the following conditions: – Cool.PwmPeriode ≤ Retain.CtrlParams.Cool.Cycle or Retain.CtrlParams.Heat.Cycle – Cool.PwmPeriode > Config.Output.Cool.MinimumOnTime – Cool.PwmPeriode > Config.Output.Cool.MinimumOffTime Only effective if the cooling output is activated (Config.ActivateCooling = TRUE).
Config.Output.Cool.PidUpperLimit	REAL	0.0	High limit of the PID output value for cooling The value must be 0.0. Cool.PidUpperLimit forms a value pair together with the following parameters for scaling of the PID output value (PidOutputSum) to the outputs for cooling: • Cool.LowerScaling for OutputCool • Cool.PwmLowerScaling for OutputCool_PWM • Cool.PerLowerScaling for OutputCool_PER If you want to limit the value at the associated output, you must also adjust these scaling values. Only effective if the cooling output is activated (Config.ActivateCooling = TRUE). Cool.PidUpperLimit = 0.0

Tag	Data type	Default	Description
Config.Output.Cool.PidLowerLimit	REAL	-100.0	Low limit of the PID output value for cooling For controllers with activated cooling output (Config.ActivateCooling = TRUE), the PID output value (PidOutputSum) is limited to this low limit. Cool.PidLowerLimit forms a value pair together with the following parameters for scaling of the PID output value (PidOutputSum) to the outputs for cooling: • Cool.UpperScaling for OutputCool • Cool.PwmUpperScaling for OutputCool_PWM • Cool.PerUpperScaling for OutputCool_PER If you want to limit the value at the associated output, you must also adjust these scaling values. Only effective if the cooling output is activated (Config.ActivateCooling = TRUE). Cool.PidLowerLimit < Cool.PidUpperLimit
Config.Output.Cool.UpperScaling	REAL	100.0	Scaled high output value for cooling Cool.UpperScaling and Cool.PidLowerLimit form a value pair for scaling of the PID output value (PidOutputSum) to the output value for cooling (OutputCool). The OutputCool value is always located between Cool.UpperScaling and Cool.LowerScaling. Only effective if the cooling output is activated (Config.ActivateCooling = TRUE). Cool.UpperScaling ≠ Cool.LowerScaling
Config.Output.Cool.LowerScaling	REAL	0.0	Scaled low output value for cooling Cool.LowerScaling and Cool.PidUpperLimit form a value pair for scaling of the PID output value (PidOutputSum) to the output value for cooling (OutputCool). The OutputCool value is always located between Cool.UpperScaling and Cool.LowerScaling. Only effective if the cooling output is activated (Config.ActivateCooling = TRUE). Cool.UpperScaling ≠ Cool.LowerScaling
Config.Output.Cool.PwmUpperScaling	REAL	100.0	Scaled high PWM output value for cooling Cool.PwmUpperScaling and Cool.PidLowerLimit form a value pair for scaling of the PID output value (PidOutputSum) to the pulse-width modulated output value for cooling (OutputCool_PWM). The OutputCool_PWM value is always located between Cool.PwmUpperScaling and Cool.PwmLowerScaling. Cool.PwmUpperScaling is only effective if the cooling output is activated (Config.ActivateCooling = TRUE) and OutputCool_PWM is selected as output for cooling (Cool.Select = 1). 100.0 ≥ Cool.PwmUpperScaling ≥ 0.0 Cool.PwmUpperScaling ≠ Cool.PwmLowerScaling

Tag	Data type	Default	Description
Config.Output.Cool.PwmLowerScaling	REAL	0.0	Scaled low PWM output value for cooling Cool.PwmLowerScaling and Cool.PidUpperLimit form a value pair for scaling of the PID output value (PidOutputSum) to the pulse-width modulated output value for cooling (OutputCool_PWM). The OutputCool_PWM value is always located between Cool.PwmUpperScaling and CoolPwm.LowerScaling. Cool.PwmLowerScaling is only effective if the cooling output is activated (Config.ActivateCooling = TRUE) and OutputCool_PWM is selected as output for cooling (Cool.Select = 1). 100.0 ≥ Cool.PwmLowerScaling ≥ 0.0 Cool.PwmUpperScaling ≠ Cool.PwmLowerScaling
Config.Output.Cool.PerUpperScaling	REAL	27648.0	Scaled high analog output value for cooling Cool.PerUpperScaling and Cool.PidLowerLimit form a value pair for scaling of the PID output value (PidOutputSum) to the analog output value for cooling (OutputCool_PER). The OutputCool_PER value is always located between Cool.PerUpperScaling and Cool.PerLowerScaling. Cool.PerUpperScaling is only effective if the cooling output is activated (Config.ActivateCooling = TRUE) and OutputCool_PER is selected as output for cooling (Cool.Select = 2). 32511.0 ≥ Cool.PerUpperScaling ≥ -32512.0 Cool.PerUpperScaling ≠ Cool.PerLowerScaling
Config.Output.Cool.PerLowerScaling	REAL	0.0	Scaled low analog output value for cooling Cool.PerLowerScaling and Cool.PidUpperLimit form a value pair for scaling of the PID output value (PidOutputSum) to the analog output value for cooling (OutputCool_PER). The OutputCool_PER value is always located between Cool.PerUpperScaling and Cool.PerLowerScaling. Cool.PerLowerScaling is only effective if the cooling output is activated (Config.ActivateCooling = TRUE) and OutputCool_PER is selected as output for cooling (Cool.Select = 2). 32511.0 ≥ Cool.PerLowerScaling ≥ -32512.0 Cool.PerUpperScaling ≠ Cool.PerLowerScaling
Config.Output.Cool.MinimumOnTime	REAL	0.0	Minimum on time of the pulse width modulation for cooling (OutputCool_PWM output) A PWM pulse is never shorter than this value. The value is rounded off to: Cool.MinimumOnTime = n × CycleTime.Value Cool.MinimumOnTime is only effective if the output for cooling OutputCool_PWM is selected (Cool.Select = 1). Only effective if the cooling output is activated (Config.ActivateCooling = TRUE). 100000.0 ≥ Cool.MinimumOnTime ≥ 0.0

Tag	Data type	Default	Description
Config.Output.Cool.MinimumOffTime	REAL	0.0	Minimum off time of the pulse width modulation for cooling (OutputCool_PWM output) A PWM pause is never shorter than this value. The value is rounded off to: Cool.MinimumOffTime = n × CycleTime.Value Cool.MinimumOffTime is only effective if the output for cooling OutputCool_PWM is selected (Cool.Select = 1). Only effective if the cooling output is activated (Config.ActivateCooling = TRUE). 100000.0 ≥ Cool.MinimumOffTime ≥ 0.0
If you are using PID_Temp in a cascade, the master controller and slave controller exchange information via the master and slave parameters. You need to make the interconnection. For details, see the Master parameter.			
Config.Cascade.IsMaster	BOOL	FALSE	The controller is master in a cascade and provides the slave setpoint. Set IsMaster = TRUE if you are using this PID_Temp instance as master controller in a cascade. A master controller defines the setpoint of a slave controller with its output. A PID_Temp instance can be master controller and slave controller at the same time. If the controller is used as master controller, the cooling output must be deactivated (Config.ActivateCooling = FALSE).
Config.Cascade.IsSlave	BOOL	FALSE	The controller is slave in a cascade and provides the master setpoint. Set IsSlave = TRUE if you are using this PID_Temp instance as slave controller in a cascade. A slave controller receives its setpoint (Setpoint parameter) from the output of its master controller (OutputHeat parameter). A PID_Temp instance can be master controller and slave controller at the same time.
Config.Cascade.AntiWindUpMode	INT	1	Anti-windup behavior in the cascade Options are: • Anti-windup = 0 The AntiWindUp functionality is deactivated. The master controller does not respond to the limit of its slave controllers. • Anti-windup = 1 The integral action of the master controller is reduced in the ratio "Slaves in limit" to "Number of slaves" ("CountSlaves" parameter). This means the effects of the limit are reduced to the control response. • Anti-windup = 2 The integral action of the master controller is held as soon as a slave controller is in the limit. Only effective if the controller is configured as master controller (Config.Cascade.IsMaster = TRUE).
Config.Cascade.CountSlaves	INT	1	Number of subordinate slaves Here you enter the number of directly subordinate slave controllers which receive their setpoint from this master controller. Only effective if the controller is configured as master controller (Config.Cascade.IsMaster = TRUE). 255 ≥ CountSlaves ≥ 1

Tag	Data type	Default	Description
CycleTime.StartEstimation	BOOL	TRUE	If CycleTime.EnEstimation = TRUE, CycleTime.StartEstimation = TRUE starts automatic determination of the PID_Temp sampling time (cycle time of the calling OB). CycleTime.StartEstimation = FALSE is set once measurement is complete.
CycleTime.EnEstimation	BOOL	TRUE	If CycleTime.EnEstimation = TRUE, the PID_Temp sampling time is determined automatically. If CycleTime.EnEstimation = FALSE, the sampling time PID_Temp is not determined automatically and must be configured correctly manually with CycleTime.Value.
CycleTime.EnMonitoring	BOOL	TRUE	If CycleTime.EnMonitoring = FALSE, the PID_Temp sampling time is not monitored. If PID_Temp cannot be executed within the sampling time, no error (ErrorBits=0000800h) is output and PID_Temp does not respond as configured with ActivateRecoverMode.
CycleTime.Value	REAL	0.1	PID_Temp sampling time (cycle time of the calling OB) in seconds CycleTime.Value is determined automatically and is usually equivalent to the cycle time of the calling OB.
You can reload values from the CtrlParamsBackUp structure with LoadBackUp = TRUE.			
CtrlParamsBackUp.SetByUser	BOOL	FALSE	Saved value of Retain.CtrlParams.SetByUser
CtrlParamsBackUp.Heat.Gain	REAL	1.0	Saved proportional gain for heating
CtrlParamsBackUp.Heat.Ti	REAL	20.0	Saved integral action time for heating in seconds
CtrlParamsBackUp.Heat.Td	REAL	0.0	Saved derivative action time for heating in seconds
CtrlParamsBackUp.Heat.TdFiltRatio	REAL	0.2	Saved derivative delay coefficient for heating
CtrlParamsBackUp.Heat.PWeighting	REAL	1.0	Saved weighting of the proportional action for heating
CtrlParamsBackUp.Heat.DWeighting	REAL	1.0	Saved weighting of the derivative action for heating
CtrlParamsBackUp.Heat.Cycle	REAL	1.0	Saved sampling time of the PID algorithm for heating in seconds
CtrlParamsBackUp.Heat.ControlZone	REAL	3.402822e+38	Saved control zone width for heating

Tag	Data type	Default	Description
CtrlParams-Back-Up.Heat.DeadZone	REAL	0.0	Saved deadband width for heating
CtrlParams-Back-Up.Cool.Gain	REAL	1.0	Saved proportional gain for cooling
CtrlParams-Back-Up.Cool.Ti	REAL	20.0	Saved integral action time for cooling in seconds
CtrlParams-Back-Up.Cool.Td	REAL	0.0	Saved derivative action time for cooling in seconds
CtrlParams-Back-Up.Cool.TdFiltRatio	REAL	0.2	Saved derivative delay coefficient for cooling
CtrlParams-Back-Up.Cool.PWeighting	REAL	1.0	Saved proportional action weighting factor for cooling
CtrlParams-Back-Up.Cool.DWeighting	REAL	1.0	Saved derivative action weighting factor for cooling
CtrlParams-Back-Up.Cool.Cycle	REAL	1.0	Saved sampling time of the PID algorithm for cooling in seconds
CtrlParams-Back-Up.Cool.ControlZone	REAL	3.402822e+38	Saved control zone width for cooling
CtrlParams-Back-Up.Cool.DeadZone	REAL	0.0	Saved deadband width for cooling
PIDSelf-Tune.SUT.Calculate-Param-sHeat	BOOL	FALSE	The properties of the heating branch of the controlled system are saved during pretuning for heating. If SUT.CalculateParamsHeat = TRUE, the PID parameters for heating are recalculated on the basis of these properties (Retain.CtrlParams.Heat structure). This enables you to change the parameter calculation method (PIDSelfTune.SUT.TuneRuleHeat parameter) without having to repeat the tuning. SUT.CalculateParamsHeat is set to FALSE after the calculation. Only possible if the pretuning was successful (SUT.ProcParHeatOk = TRUE).

Tag	Data type	Default	Description
PIDSelf-Tune.SUT.Calculate-ParamsCool	BOOL	FALSE	The properties of the cooling branch of the controlled system are saved during tuning for cooling. If SUT.CalculateParamsCool = TRUE, the PID parameters for cooling are recalculated on the basis of these properties (Retain.CtrlPar-ams.Cool structure). This enables you to change the parameter calculation method (PIDSelfTune.SUT.TuneRuleCool parameter) without having to repeat the tuning. SUT.CalculateParamsCool is set to FALSE after the calculation. Only possible if the pretuning was successful (SUT.ProcParCoolOk = TRUE). Only effective if Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE.
PIDSelf-Tune.SUT.T uneRule-Heat	INT	2	Method for PID parameter calculation with pretuning for heating Options are: • SUT.TuneRuleHeat = 0: PID to CHR • SUT.TuneRuleHeat = 1: PI to CHR • SUT.TuneRuleHeat = 2: PID for temperature processes to CHR (results in a longer and rather asymptomatic control response with fewer overshoots than SUT.TuneRuleHeat = 0) (CHR = Chien, Hrones and Reswick) Only with SUT.TuneRuleHeat = 2 is the control zone Retain.CtrlPar-ams.Heat.ControlZone automatically set during pretuning for heating.
PIDSelf-Tune.SUT.T uneRule-Cool	INT	2	Method for PID parameter calculation with pretuning for cooling Options are: • SUT.TuneRuleCool = 0: PID to CHR • SUT.TuneRuleCool = 1: PI to CHR • SUT.TuneRuleCool = 2: PID for temperature processes to CHR (results in a longer and rather asymptomatic control response with fewer overshoots than SUT.TuneRuleCool = 0) (CHR = Chien, Hrones and Reswick) Only with SUT.TuneRuleCool = 2 is the control zone Retain.CtrlPar-ams.Cool.ControlZone automatically set during pretuning for cooling. SUT.TuneRuleCool is only effective if the cooling output and PID parameter switching are activated (Config.ActivateCooling = TRUE, Config.AdvancedCool-ing = TRUE).

Tag	Data type	Default	Description
PIDSelf-Tune.SUT.State	INT	0	The SUT.State tag indicates the current phase of pretuning: • State = 0: Initialize pretuning • State = 100: Calculate standard deviation for heating • State = 200: Calculate standard deviation for cooling • State = 300: Determine point of inflection for heating • State = 400: Determine point of inflection for cooling • State = 500: Set heating to setpoint after reaching point of inflection • State = 600: Set cooling to setpoint after reaching point of inflection • State = 700: Compare efficiency of the heating actuator and cooling actuator • State = 800: Heating and cooling activated • State = 900: Cooling activated • State = 1000: Determine delay time after switching off heating • State = 9900: Pretuning successful • State = 1: Pretuning not successful
PIDSelf-Tune.SUT.ProcParHeatOk	BOOL	FALSE	TRUE: The calculation of the process parameters for pretuning heating was successful. This tag is set during tuning. It must be TRUE for calculation of the PID parameters for heating.
PIDSelf-Tune.SUT.ProcParCoolOk	BOOL	FALSE	TRUE: The calculation of the process parameters for pretuning cooling was successful. This tag is set during tuning. It must be TRUE for calculation of the PID parameters for cooling.
PIDSelf-Tune.SUT.AdaptDelay-Time	INT	0	The AdaptDelayTime tag determines the adaptation of the delay time for heating at the operating point (for "Pretuning heating" and "Pretuning heating and cooling"). Options are: • SUT.AdaptDelayTime = 0: No adaptation of delay time. The SUT.State = 1000 phase is skipped. This option results in a shorter tuning time than with SUT.AdaptDelayTime = 1. • SUT.AdaptDelayTime = 1: Adaptation of the delay time to the setpoint in SUT.State = 1000 phase by switching off heating temporarily. This option results in a longer tuning time than with SUT.AdaptDelayTime = 0. It can improve the control response if the process behavior depends significantly on the operating point (non-linearity). This option should not be used for multi-zone applications with strong thermal connections.

Tag	Data type	Default	Description
PIDSelf-Tune.SUT.Cooling-Mode	INT	0	The CoolingMode tag determines the manipulated variable output to determine the cooling parameters (for pretuning heating and cooling). Options are: • SUT.CoolingMode = 0: Switch off heating and switch on cooling after reaching the setpoint. The SUT.State = 700 phase is skipped. Phase SUT.State = 500 is followed by phase SUT.State = 900. This option can improve the control response if the gain of the cooling actuator is low compared to the gain of the heating actuator. It results in a shorter tuning time than with SUT.CoolingMode = 1 or 2. • SUT.CoolingMode = 1: Switch on cooling in addition to heating after reaching the setpoint. The SUT.State = 700 phase is skipped. Phase SUT.State = 500 is followed by phase SUT.State = 800. This option can improve the control response if the gain of the cooling actuator is high compared to the gain of the heating actuator. • SUT.CoolingMode = 2: After heating up to the setpoint, a decision is automatically made in phase SUT.State = 700 as to whether heating is switched off. Phase SUT.State = 500 is followed by phase SUT.State = 700 and then SUT.State = 800 or SUT.State = 900. This option requires more time than options 0 and 1.
PIDSelf-Tune.TIR.RunIn	BOOL	FALSE	Use the RunIn tag to specify the sequence of fine tuning during start from automatic mode. • RunIn = FALSE If fine tuning is started from automatic mode, the system uses the existing PID parameters to control to the setpoint (TIR.State = 500 or 600). Only then will fine tuning start. • RunIn = TRUE PID_Temp tries to reach the setpoint with minimum or maximum output value (TIR.State = 300 or 400). This can produce increased overshoot. Fine tuning then starts automatically. RunIn is set to FALSE after fine tuning. During start of fine tuning from Inactive or Manual mode, PID_Temp reacts as described under RunIn = TRUE.
PIDSelf-Tune.TIR.CalculateParamsHeat	BOOL	FALSE	The properties of the heating branch of the controlled system are saved during fine tuning for heating. If TIR.CalculateParamsHeat= TRUE, the PID parameters for heating are recalculated on the basis of these properties (Retain.CtrlParams.Heat structure). This enables you to change the parameter calculation method (PIDSelfTune.TIR.TuneRuleHeat parameter) without having to repeat the tuning. TIR.CalculateParamsHeat is set to FALSE after the calculation. Only possible if fine tuning heating was successful beforehand (TIR.ProcParHeatOk = TRUE).

Tag	Data type	Default	Description
PIDSelf-Tune.TIR.CalculateParamsCool	BOOL	FALSE	The properties of the cooling branch of the controlled system are saved during fine tuning for cooling. If TIR.CalculateParamsCool= TRUE, the PID parameters for cooling are recalculated on the basis of these properties (Retain.CtrlParams.Cool structure). This enables you to change the parameter calculation method (PIDSelfTune.TIR.TuneRuleCool parameter) without having to repeat the tuning. TIR.CalculateParamsCool is set to FALSE after the calculation. Only possible if fine tuning cooling was successful beforehand (TIR.ProcParCoolOk = TRUE). Only effective if Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE
PIDSelf-Tune.TIR.TuneRule-Heat	INT	0	Method for parameter calculation during fine tuning for heating Options are: • TIR.TuneRuleHeat = 0: PID automatic • TIR.TuneRuleHeat = 1: PID fast (faster control response with higher amplitudes of the output value than with TIR.TuneRuleHeat = 2) • TIR.TuneRuleHeat = 2: PID slow (slower control response with lower amplitudes of the output value than with TIR.TuneRuleHeat = 1) • TIR.TuneRuleHeat = 3: ZN PID • TIR.TuneRuleHeat = 4: ZN PI • TIR.TuneRuleHeat = 5: ZN P (ZN=Ziegler-Nichols) To be able to repeat the calculation of the PID parameters for heating with TIR.CalculateParamsHeat and TIR.TuneRuleHeat = 0, 1 or 2, the previous fine tuning also has to have been executed with TIR.TuneRuleHeat = 0, 1 or 2. If this is not the case, TIR.TuneRuleHeat = 3 is used. The recalculation of the PID parameters for heating with TIR.CalculateParamsHeat and TIR.TuneRuleHeat = 3, 4 or 5 is always possible.
PIDSelf-Tune.TIR.TuneRule-Cool	INT	0	Method for parameter calculation during fine tuning for cooling Options are: • TIR.TuneRuleCool = 0: PID automatic • TIR.TuneRuleCool = 1: PID fast (faster control response with higher amplitudes of the output value than with TIR.TuneRuleCool = 2) • TIR.TuneRuleCool = 2: PID slow (slower control response with lower amplitudes of the output value than with TIR.TuneRuleCool = 1) • TIR.TuneRuleCool = 3: ZN PID • TIR.TuneRuleCool = 4: ZN PI • TIR.TuneRuleCool = 5: ZN P (ZN=Ziegler-Nichols) To be able to repeat the calculation of the PID parameters for cooling with TIR.CalculateParamsCool and TIR.TuneRuleCool = 0, 1 or 2, the previous fine tuning also has to have been executed with TIR.TuneRuleCool = 0, 1 or 2. If this is not the case, TIR.TuneRuleCool = 3 is used. The recalculation of the PID parameters for cooling with TIR.CalculateParamsCool and TIR.TuneRuleCool = 3, 4 or 5 is always possible. Only effective if the cooling output and PID parameter switching are activated (ConfigActivateCooling = TRUE and Config.AdvancedCooling = TRUE).

Tag	Data type	Default	Description
PIDSelf-Tune.TIR.State	INT	0	The TIR.State tag indicates the current phase of "fine tuning": • State = 0: Initialize fine tuning • State = 100: Calculate standard deviation for heating • State = 200: Calculate standard deviation for cooling • State = 300: Attempting to reach setpoint for heating with two-step control • State = 400: Attempting to reach setpoint for cooling with two-step control • State = 500: Attempting to reach setpoint for heating with PID control • State = 600: Attempting to reach setpoint for cooling with PID control • State = 700: Calculate standard deviation for heating • State = 800: Calculate standard deviation for cooling • State = 900: Determine oscillation and calculate parameters for heating • State = 1000: Determine oscillation and calculate parameters for cooling • State = 9900: Fine tuning successful • State = 1: Fine tuning not successful
PIDSelf-Tune.TIR.ProcParHeatOk	BOOL	FALSE	TRUE: The calculation of the process parameters for fine tuning heating was successful. This tag is set during tuning. It must be met for calculation of the PID parameters for heating.
PIDSelf-Tune.TIR.ProcParCoolOk	BOOL	FALSE	TRUE: The calculation of the process parameters for fine tuning cooling was successful. This tag is set during tuning. It must be met for calculation of the PID parameters for cooling.
PIDSelf-Tune.TIR.OutputOffsetHeat	REAL	0.0	Tuning offset heating of the PID output value TIR.OutputOffsetHeat is added to the value that results from PidOutputSum for the heating branch. To receive a positive offset at the outputs for heating, define a positive value for TIR.OutputOffsetHeat. The resulting values at the outputs for heating are the result of the configured output scaling (Struktur Config.Output.Heat). This tuning offset can be used in controllers with activated cooling output and PID parameter switching (Config.ActivateCooling = TRUE, Config.Advanced-Cooling = TRUE) for fine tuning cooling. If the outputs for cooling are not active at the setpoint that is to be tuned (PidOutputSum > 0.0), fine tuning cooling is not possible. In this case, define a positive tuning offset heating which is greater than the PID output value (PidOutputSum) at the setpoint in the steady state before you start tuning. This step increases the values at the outputs for heating and activates the outputs for cooling (PidOutputSum < 0.0). Fine tuning cooling is now possible. When fine tuning is complete, TIR.OutputOffsetHeat is reset to 0.0. Major changes at TIR.OutputOffsetHeat in one step can result in temporary overshoots. Config.Output.Heat.PidUpperLimit ≥ PIDSelfTune.TIR.OutputOffsetHeat ≥ Config.Output.Heat.PidLowerLimit

Tag	Data type	Default	Description
PIDSelf-Tune.TIR.OutputOffset-Cool	REAL	0.0	Tuning offset cooling of the PID output value TIR.OutputOffsetCool is added to the value that results from PidOutputSum for the cooling branch. To receive a positive offset at the outputs for cooling, define a negative value for TIR.OutputOffsetCool. The resulting values at the outputs for cooling are the result of the configured output scaling (Struktur Config.Output.Coool). This tuning offset can be used in controllers with activated cooling output (Config.ActivateCooling = TRUE) for fine tuning heating. If the outputs for heating are not active at the setpoint that is to be tuned (PidOutputSum < 0.0), fine tuning heating is not possible. In this case, define a negative tuning offset cooling which is less than the PID output value (PidOutputSum) at the setpoint in the steady state before you start tuning. This step increases the values at the outputs for cooling and activates the outputs for heating (PidOutputSum > 0.0). Fine tuning heating is now possible. When fine tuning is complete, TIR.OutputOffsetCool is reset to 0.0. Major changes at TIR.OutputOffsetCool in one step can result in temporary overshoots. Config.Output.Cool.PidUpperLimit ≥ PIDSelfTune.TIR.OutputOffsetCool ≥ Config.Output.Cool.PidLowerLimit
PIDSelf-Tune.TIR.WaitForControlIn	BOOL	FALSE	Waiting with fine tuning after reaching the setpoint If TIR.WaitForControlIn = TRUE, fine tuning waits in between reaching the setpoint (TIR.State = 500 or 600) and calculation of the standard deviation (TIR.State = 700 or 800) until a FALSE -> TRUE edge is given at TIR.FinishControlIn. TIR.WaitForControlIn can be used for simultaneous fine tuning of several controllers in multi-zone applications to synchronize tuning of the individual zones. It ensures that all zones have reached their setpoints before the actual tuning starts. The influence of thermal connections between the zones on tuning can be reduced in this way. TIR.WaitForControlIn is only effective if fine tuning is started from automatic mode with PIDSelfTune.TIR.RunIn = FALSE.
PIDSelf-Tune.TIR.ControlIn-Ready	BOOL	FALSE	If TIR.WaitForControlIn = TRUE, PID_Temp sets TIR.ControlInReady = TRUE as soon as the setpoint has been reached and waits with additional tuning steps until a FALSE -> TRUE edge is given at TIR.FinishControlIn.
PIDSelf-Tune.TIR.FinishControlIn	BOOL	FALSE	If TIR.ControlInReady = TRUE, a FALSE -> TRUE edge at TIR.FinishControlIn stops the wait and fine tuning resumes.
PIDCtr.IOutputOld	REAL	0.0	Integral action in last cycle
Retain.CtrlParams.SetByUser	BOOL	FALSE	If the PID parameters are entered manually in the configuration editor, SetByUser = TRUE. This parameter is used for display in the editors and does not influence the control algorithm. SetByUser is retentive.

Tag	Data type	Default	Description
Retain.CtrlParams.Heat.Gain	REAL	1.0	Active proportional gain for heating Heat.Gain is retentive. Heat.Gain ≥ 0.0
Retain..CtrlParams.Heat.Ti	REAL	20.0	Active integral action time for heating in seconds The integral action for heating is switched off with Heat.CtrlParams.Ti = 0.0. Heat.Ti is retentive. 100000.0 ≥ Heat.Ti ≥ 0.0
Retain.CtrlParams.Heat.Td	REAL	0.0	Active derivative action time for heating in seconds The derivative action for heating is switched off with Heat.CtrlParams.Td = 0.0. Heat.Td is retentive. 100000.0 ≥ Heat.Td ≥ 0.0
Retain.CtrlParams.Heat.TdFiltRatio	REAL	0.2	Active derivative delay coefficient for heating The derivative delay coefficient delays the effect of the derivative action. Derivative delay = derivative action time × derivative delay coefficient • 0.0: Derivative action is effective for one cycle only and therefore almost not effective. • 0.5: This value has proved useful in practice for controlled systems with one dominant time constant. • > 1.0: The greater the coefficient, the longer the effect of the derivative action is delayed. Heat.TdFiltRatio is retentive. Heat.TdFiltRatio ≥ 0.0
Retain.CtrlParams.Heat.PWeighting	REAL	1.0	Active weighting of the proportional action for heating The proportional action may weaken with changes to the setpoint. Values from 0.0 to 1.0 are applicable. • 1.0: Proportional action for setpoint change is fully effective • 0.0: Proportional action for setpoint change is not effective The proportional action is always fully effective when the process value is changed. Heat.PWeighting is retentive. 1.0 ≥ Heat.PWeighting ≥ 0.0
Retain.CtrlParams.Heat.DWeighting	REAL	1.0	Active weighting of the derivative action for heating The derivative action may weaken with changes to the setpoint. Values from 0.0 to 1.0 are applicable. • 1.0: Derivative action is fully effective upon setpoint change • 0.0: Derivative action is not effective upon setpoint change The derivative action is always fully effective when the process value is changed. Heat.DWeighting is retentive. 1.0 ≥ Heat.DWeighting ≥ 0.0

Tag	Data type	Default	Description
Retain.CtrlParams.Heat.Cycle	REAL	1.0	Active sampling time of the PID algorithm for heating in seconds CtrlParams.Heat.Cycle is calculated during tuning and rounded to an integer multiple of CycleTime.Value. If Config.Output.Heat.PwmPeriode = 0.0, Heat.Cycle is used as time period of the pulse width modulation for heating. If Config.Output.Cool.PwmPeriode = 0.0 and Config.AdvancedCooling = FALSE, Heat.Cycle is used as time period of the pulse width modulation for cooling. Heat.Cycle is retentive. 100000.0 ≥ Heat.Cycle > 0.0
Retain.CtrlParams.Heat.ControlZone	REAL	3.402822e+38	Active control zone width for heating The control zone for heating is switched off with Heat.ControlZone = 3.402822e+38. Heat.ControlZone is only set automatically during pretuning heating or pretuning heating and cooling if PIDSelfTune.SUT.TuneRuleHeat = 2 is selected as method of the parameter calculation. For controllers with deactivated cooling output (Config.ActivateCooling = FALSE) or controllers with activated cooling output and cooling factor (Config.AdvancedCooling = FALSE), the control zone is symmetrically located between Setpoint – Heat.ControlZone and Setpoint + Heat.ControlZone. For controllers with activated cooling output and PID parameter switching (Config.ActivateCooling = TRUE, Config.AdvancedCooling = TRUE), the control zone is located between Setpoint – Heat.ControlZone and Setpoint + Cool.ControlZone. Heat.ControlZone is retentive. Heat.ControlZone > 0.0
Retain.CtrlParams.Heat.DeadZone	REAL	0.0	Active deadband width for heating (see PID parameters (Page 7307)) The deadband for heating is switched off with Heat.DeadZone = 0.0. Heat.DeadZone is not set automatically or adjusted during tuning. You must correctly configure Heat.DeadZone manually. For controllers with deactivated cooling output (Config.ActivateCooling = FALSE) or controllers with activated cooling output and cooling factor (Config.AdvancedCooling = FALSE), the deadband is symmetrically located between Setpoint – Heat.DeadZone and Setpoint + Heat.DeadZone. For controllers with activated cooling output and PID parameter switching (Config.ActivateCooling = TRUE, Config.AdvancedCooling = TRUE), the deadband is located between Setpoint – Heat.DeadZone and Setpoint + Cool.DeadZone. Heat.DeadZone is retentive. Heat.DeadZone ≥ 0.0
Retain.CtrlParams.Cool.Gain	REAL	1.0	Active proportional gain for cooling Cool.Gain is retentive. Only effective if the cooling output and PID parameter switching are activated (Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE). Cool.Gain ≥ 0.0

Tag	Data type	Default	Description
Retain.CtrlParams.Cool.Ti	REAL	20.0	Active integral action time for cooling in seconds The integral action for cooling is switched off with Cool.CtrlParams.Ti = 0.0. Cool.Ti is retentive. Only effective if the cooling output and PID parameter switching are activated (Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE). 100000.0 ≥ Cool.Ti ≥ 0.0
Retain.CtrlParams.Cool.Td	REAL	0.0	Active derivative action time for cooling in seconds The derivative action for cooling is switched off with Cool.CtrlParams.Td = 0.0. Cool.Td is retentive. Only effective if the cooling output and PID parameter switching are activated (Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE). 100000.0 ≥ Cool.Td ≥ 0.0
Retain.CtrlParams.Cool.TdFiltRatio	REAL	0.2	Active derivative delay coefficient for cooling The derivative delay coefficient delays the effect of the derivative action. Derivative delay = derivative action time × derivative delay coefficient • 0.0: Derivative action is effective for one cycle only and therefore almost not effective. • 0.5: This value has proved useful in practice for controlled systems with one dominant time constant. • > 1.0: The greater the coefficient, the longer the effect of the derivative action is delayed. Cool.TdFiltRatio is retentive. Only effective if the cooling output and PID parameter switching are activated (Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE). Cool.TdFiltRatio ≥ 0.0
Retain.CtrlParams.Cool.PWeighting	REAL	1.0	Active weighting of the proportional action for cooling The proportional action may weaken with changes to the setpoint. Values from 0.0 to 1.0 are applicable. • 1.0: Proportional action for setpoint change is fully effective • 0.0: Proportional action for setpoint change is not effective The proportional action is always fully effective when the process value is changed. Cool.PWeighting is retentive. Only effective if the cooling output and PID parameter switching are activated (Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE). 1.0 ≥ Cool.PWeighting ≥ 0.0

Tag	Data type	Default	Description
Retain.CtrlParams.Cool.DWeighting	REAL	1.0	Active weighting of the derivative action for cooling The derivative action may weaken with changes to the setpoint. Values from 0.0 to 1.0 are applicable. • 1.0: Derivative action is fully effective upon setpoint change • 0.0: Derivative action is not effective upon setpoint change The derivative action is always fully effective when the process value is changed. Cool.DWeighting is retentive. Only effective if the cooling output and PID parameter switching are activated (Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE). 1.0 ≥ Cool.DWeighting ≥ 0.0
Retain.CtrlParams.Cool.Cycle	REAL	1.0	Active sampling time of the PID algorithm for cooling in seconds CtrlParams.Cool.Cycle is calculated during tuning and rounded off to an integer multiple of CycleTime.. If Config.Output.Cool.PwmPeriode = 0.0 and Config.AdvancedCooling = TRUE, Cool.Cycle is used as time period of the pulse width modulation for cooling. If Config.Output.Cool.PwmPeriode = 0.0 and Config.AdvancedCooling = FALSE, Heat.Cycle is used as time period of the pulse width modulation for cooling. Cool.Cycle is retentive. Only effective if the cooling output and PID parameter switching are activated (Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE). 100000.0 ≥ Cool.Cycle > 0.0
Retain.CtrlParams.Cool.ControlZone	REAL	3.402822e+38	Active control zone width for cooling The control zone for cooling is switched off with Cool.ControlZone = 3.402822e+38. Cool.ControlZone is only set automatically during pretuning cooling or pretuning heating and cooling if PIDSelfTune.SUT.TuneRuleCool = 2 is selected as method of the parameter calculation. Cool.ControlZone is retentive. Only effective if the cooling output and PID parameter switching are activated (Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE). Cool.ControlZone > 0.0
Retain.CtrlParams.Cool.DeadZone	REAL	0.0	Active deadband width for cooling (see PID parameters (Page 7307)) The deadband for cooling is switched off with Cool.DeadZone = 0.0. Cool.DeadZone is not set automatically or adjusted during tuning. You must correctly configure Cool.DeadZone manually. Cool.DeadZone is retentive. Only effective if the cooling output and PID parameter switching are activated (Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE). Cool.DeadZone ≥ 0.0

Note

Change the tags listed in this table in "Inactive" mode to prevent malfunction of the PID controller.

Multi-zone controlling with PID_Temp (Page 7327)

PID_Temp state and mode parameters

Correlation of the parameters

The State parameter shows the current operating mode of the PID controller. You cannot change the State parameter.

With a rising edge at ModeActivate, PID_Temp switches to the operating mode saved in the Mode in-out parameter.

Heat.EnableTuning and Cool.EnableTuning specify for pretuning and fine tuning, if tuning takes place for heating or cooling.

If the CPU is switched on or switches from Stop to RUN mode, PID_Temp starts in the operating mode that is saved in the Mode parameter. To leave PID_Temp in "Inactive" mode, set RunModeByStartup = FALSE.

Meaning of values

State / Mode	Description of operating mode
0	**Inactive** The following output values are output in "Inactive" mode: • 0.0 as PID output value (PidOutputSum) • 0.0 as output value for heating (OutputHeat) and output value for cooling (OutputCool) • 0 as analog output value for heating (OutputHeat_PER) and analog output value for cooling (OutputCool_PER) • FALSE as PWM output value for heating (OutputHeat_PWM) and PWM output value for cooling (OutputCool_PWM) This does not depend on the configured output value limits and scaling in the structures Config.Output.Heat and Config.Output.Cool.

State / Mode	Description of operating mode
1	**Pretuning** The pretuning determines the process response to a jump change of the output value and searches for the point of inflection. The PID parameters are calculated from the maximum rate of rise and dead time of the controlled system. You obtain the best PID parameters when you perform pretuning and fine tuning. PID_Temp offers different pretuning types, depending on the configuration: • Pretuning heating: A jump change is output at the output value heating, the PID parameters for heating are calculated (Retain.CtrlParams.Heat structure), and control to the setpoint then takes place in automatic mode. If the process behavior strongly depends on the operating point, an adaptation of the delay time can be activated at the setpoint with PIDSelfTune.SUT.AdaptDelayTime. • Pretuning heating and cooling: A jump change is output at the output value heating. As soon as the process value is close to the setpoint, a jump change is output at the output value cooling. The PID parameters for heating (Retain.CtrlParams.Heat structure) and cooling (Retain.CtrlParams.Cool structure) are calculated. Then, control to the setpoint takes place in automatic mode. If the process behavior strongly depends on the operating point, an adaptation of the delay time can be activated at the setpoint with PIDSelfTune.SUT.AdaptDelayTime. Depending on the effect of the cooling actuator compared to the heating actuator, the quality of tuning can be influenced by whether or not the heating and cooling outputs are operated simultaneously during tuning. You can specify this with PIDSelfTune.SUT.CoolingMode. • Pretuning cooling: A jump change is output at the output value cooling and the PID parameters for cooling are calculated (Struktur Retain.CtrlParams.Cool). Then, control to the setpoint takes place in automatic mode. If you want to tune the PID parameters for heating and cooling, you can expect a better control response with "pretuning heating" followed by "pretuning cooling" rather than with "pretuning heating and cooling". However, pretuning in two steps takes longer. **General requirements for pretuning:** • The PID_Temp instruction is called in a cyclic interrupt OB. • Inactive (State = 0), manual mode (State = 4), or automatic mode (State = 3) • ManualEnable = FALSE • Reset = FALSE • The setpoint and the process value lie within the configured limits. **Requirements for pretuning heating:** • Heat.EnableTuning = TRUE • Cool.EnableTuning = FALSE • The process value must not be too close to the setpoint. |Setpoint - Input| > 0.3 * |Config.InputUpperLimit - Config.InputLowerLimit| and |Setpoint - Input| > 0.5 * |Setpoint| • The setpoint is greater than the process value.

State / Mode	Description of operating mode
	Setpoint > Input **Requirements for pretuning heating and cooling:** • Heat.EnableTuning = TRUE· • Cool.EnableTuning = TRUE • The cooling output is activated (Config.ActivateCooling = TRUE). • The PID parameter switching is activated (Config.AdvancedCooling = TRUE). • The process value must not be too close to the setpoint. |Setpoint - Input| > 0.3 * |Config.InputUpperLimit - Config.InputLowerLimit| and |Setpoint - Input| > 0.5 * |Setpoint| • The setpoint is greater than the process value. Setpoint > Input **Requirements for pretuning cooling:** • Heat.EnableTuning = FALSE· • Cool.EnableTuning = TRUE· • The cooling output is activated (Config.ActivateCooling = TRUE). • The PID parameter switching is activated (Config.AdvancedCooling = TRUE). • A "pretuning heating" or "pretuning heating and cooling" has been successful (PIDSelfTune.SUT.ProcParHeatOk = TRUE), if possible at the same setpoint. • The process value must be close to the setpoint. |Setpoint - Input| < 0.05 * |Config.InputUpperLimit - Config.InputLowerLimit| The more stable the process value is, the easier it is to calculate the PID parameters and the more precise the result will be. Noise on the process value can be tolerated as long as the rate of rise of the process value is significantly higher compared to the noise. This is most likely the case in operating modes "Inactive" or "Manual mode". The setpoint is frozen in the CurrentSetpoint tag. Tuning is canceled when: • Setpoint > CurrentSetpoint + CancelTuningLevel or • Setpoint < CurrentSetpoint - CancelTuningLevel The method for calculation of the PID parameters can be specified separately for heating and cooling with PIDSelfTune.SUT.TuneRuleHeat and PIDSelfTune.SUT.TuneRuleCool. Before the PID parameters are recalculated, they are backed up in the CtrlParamsBackUp structure and can be reactivated with LoadBackUp. After successful pretuning, the switch is made to automatic mode. After unsuccessful pretuning, the switch to the mode is determined by ActivateRecoverMode. The phase of pretuning is indicated with PIDSelfTune.SUT.State.

State / Mode	Description of operating mode
2	**Fine tuning** Fine tuning generates a constant, limited oscillation of the process value. The PID parameters are tuned for the operating point from the amplitude and frequency of this oscillation. PID parameters from fine tuning usually have better master control and disturbance characteristics than PID parameters from pretuning. You obtain the best PID parameters when you perform pretuning and fine tuning. PID_Temp automatically attempts to generate an oscillation greater than the noise of the process value. Fine tuning is only minimally influenced by the stability of the process value. PID_Temp offers different fine tuning types, depending on the configuration: • Fine tuning heating: PID_Temp generates an oscillation of the process value with periodic changes at the output value heating and calculates the PID parameters for heating (Struktur Retain.CtrlParams.Heat). • Fine tuning cooling: PID_Temp generates an oscillation of the process value with periodic changes at the output value cooling and calculates the PID parameters for cooling (Struktur Retain.CtrlParams.Cool). **Temporary tuning offset for heating/cooling controllers** If PID_Temp is used as heating/cooling controller (Config.ActivateCooling = TRUE), the PID output value (PidOutputSum) at the setpoint must meet the following requirements for a process value oscillation to be generated and fine tuning to be successful: • Positive PID output value for fine tuning heating • Negative PID output value for fine tuning cooling If this requirement is not met, you can define a temporary offset for fine tuning which is output at the output with the opposite effect: • Offset for cooling output (PIDSelfTune.TIR.OutputOffsetCool) with fine tuning heating. Define a negative tuning offset cooling which is less than the PID output value (PidOutputSum) at the setpoint in the steady state before you start tuning. • Offset for heating output (PIDSelfTune.TIR.OutputOffsetHeat) with fine tuning cooling. Define a positive tuning offset heating which is greater than the PID output value (PidOutputSum) at the setpoint in the steady state before you start tuning. The defined offset is balanced by the PID algorithm so that the process value remains at the setpoint. This means the size of the offset can be adapted accordingly with the PID output value so that it meets the requirements listed above. To avoid larger overshoots of the process value when defining the offset, it can also be increased in several steps. If PID_Temp exits the fine tuning mode, the tuning offset is reset. Example for definition of an offset for fine tuning cooling: • Without offset: – Setpoint = Process value (ScaledInput) = 80°C – PID output value (PidOutputSum) = 30.0 – Output value heating (OutputHeat) = 30.0 – Output value cooling (OutputCool) = 0.0 An oscillation of the process value around the setpoint cannot be created with the cooling output alone. Fine tuning would fail here. • With definition of an offset for heating output (PIDSelfTune.TIR.OutputOffsetHeat) = 80.0 – Setpoint = process value (ScaledInput) = 80°C – PID output value (PidOutputSum) = -50.0

State / Mode	Description of operating mode
	– Output value heating (OutputHeat) = 80.0 – Output value cooling (OutputCool) = -50.0 By defining an offset for the heating output, the cooling output can now create an oscillation of the process value around the setpoint. This means fine tuning can take place successfully. **General requirements for fine tuning:** • The PID_Temp instruction is called in a cyclic interrupt OB. • No disturbances are expected. • The setpoint and the process value lie within the configured limits. • The control loop has stabilized at the operating point. The operating point is reached when the process value corresponds to the setpoint. • ManualEnable = FALSE • Reset = FALSE • Automatic (State = 3), inactive (State = 0) or manual (State = 4) mode **Requirements for fine tuning heating:** • Heat.EnableTuning = TRUE • Cool.EnableTuning = FALSE • If PID_Temp is configured as heating/cooling controller (Config.ActivateCooling = TRUE), the heating output must be active at the operating point at which tuning is to take place (PidOutputSum > 0.0 (see tuning offset)). **Requirements for fine tuning cooling:** • Heat.EnableTuning = FALSE • Cool.EnableTuning = TRUE • The cooling output is activated (Config.ActivateCooling = TRUE). • The PID parameter switching is activated (Config.AdvancedCooling = TRUE) • The cooling output must be active at the operating point at which tuning is to take place (PidOutputSum < 0.0 (see tuning offset)). **The course of fine tuning is determined by the mode from which it is started:** • Automatic mode (State = 3) with PIDSelfTune.TIR.RunIn = FALSE (default) Start fine tuning from automatic mode if you wish to improve the existing PID parameters through tuning. PID_Temp controls the system using the existing PID parameters until the control loop has stabilized and the requirements for fine tuning have been met. Only then will fine tuning start. • Inactive (State = 0), manual mode (State = 4), or automatic mode (State = 3) with PIDSelfTune.TIR.RunIn = TRUE Attempts are made to reach the setpoint with the minimum or maximum output value: – with minimum or maximum output value heating for fine tuning heating – with minimum or maximum output value cooling for fine tuning cooling. This can produce increased overshoot. Fine tuning starts when the setpoint is reached.

State / Mode	Description of operating mode
	If the setpoint cannot be reached, PID_Temp does not automatically abort tuning. The setpoint is frozen in the CurrentSetpoint tag. Tuning is canceled when: • Setpoint > CurrentSetpoint + CancelTuningLevel or • Setpoint < CurrentSetpoint - CancelTuningLevel The method for calculation of the PID parameters can be specified separately for heating and cooling with PIDSelfTune.TIR.TuneRuleHeat and PIDSelfTune.TIR.TuneRuleCool. Before the PID parameters are recalculated, they are backed up in the CtrlParamsBackUp structure and can be reactivated with LoadBackUp. The controller changes to automatic mode after successful fine tuning. After unsuccessful fine tuning, the switch to the mode is determined by ActivateRecoverMode. The "Fine tuning" phase is indicated with PIDSelfTune.TIR.State.
3	**Automatic mode** In automatic mode, PID_Temp corrects the controlled system in accordance with the parameters specified. The controller switches to automatic mode if one the following requirements is met: • Pretuning successfully completed • Fine tuning successfully completed • Changing of the Mode in-out parameter to the value 3 and a rising edge at ModeActivate. The switchover from automatic mode to manual mode is only bumpless if carried out in the commissioning editor. The ActivateRecoverMode tag is taken into consideration in automatic mode.
4	**Manual mode** In manual mode, you specify a manual PID output value in the ManualValue parameter. The values at the outputs for heating and cooling resulting from this manual value are the result of the configured output scaling. You can also activate this operating mode using ManualEnable = TRUE. We recommend that you change the operating mode using Mode and ModeActivate only. The switchover from manual mode to automatic mode is bumpless. The ActivateRecoverMode tag is taken into consideration in manual mode.
5	**Substitute output value with error monitoring** The control algorithm is deactivated. The SetSubstituteOutput tag determines which PID output value (PidOutputSum) is output in this operating mode. • SetSubstituteOutput = FALSE: Last valid PID output value • SetSubstituteOutput = TRUE: Substitute output value (SubstituteOutput) You cannot activate this operating mode using Mode = 5. In the event of an error, it is activated instead of "Inactive" operating mode if all the following conditions are met: • Automatic mode (State = 3) • ActivateRecoverMode = TRUE • One or more errors have occurred in which ActivateRecoverMode is effective. As soon as the errors are no longer pending, PID_Temp switches back to automatic mode.

ENO characteristics

If State = 0, then ENO = FALSE.

If State ≠ 0, then ENO = TRUE.

Automatic switchover of operating mode during commissioning

Automatic mode is activated following successful pretuning or fine tuning. The following table shows how Mode and State change during successful pretuning.

Cycle no.	Mode	State	Action
0	4	4	Set Mode = 1
1	1	4	Set ModeActivate = TRUE
1	4	1	Value of State is saved in Mode parameter Pretuning is started
n	4	1	Pretuning successfully completed
n	3	3	Automatic mode is started

PID_Temp automatically switches the operating mode in the event of an error.

The following table shows how Mode and State change during pretuning with errors.

Cycle no.	Mode	State	Action
0	4	4	Set Mode = 1
1	1	4	Set ModeActivate = TRUE
1	4	1	Value of State is saved in Mode parameter Pretuning is started
n	4	1	Pretuning canceled
n	4	4	Manual mode is started

If ActivateRecoverMode = TRUE, the operating mode that is saved in the Mode parameter is activated. When you start pretuning or fine tuning, PID_Temp has saved the value of State in the Mode in-out parameter. This means PID_Temp switches to the mode from which tuning was started.

If ActivateRecoverMode = FALSE, the system switches to "Inactive" operating mode.

PID_Temp in/out parameters (Page 3564)

PID_Temp ErrorBits parameter

If several errors are pending simultaneously, the values of the ErrorBits are displayed with binary addition. The display of ErrorBits = 0000003h, for example, indicates that the errors 0000001h and 0000002h are pending simultaneously.

ErrorBits (DW#16#...)	Description
0000000	There is no error.
0000001	The "Input" parameter is outside the process value limits. • Input > Config.InputUpperLimit or • Input < Config.InputLowerLimit If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp remains in automatic mode. If manual mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp remains in manual mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp switches to the operating mode that is saved in the Mode parameter.
0000002	Invalid value at "Input_PER" parameter. Check whether an error is pending at the analog input. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp outputs the configured substitute output value. As soon as the error is no longer pending, PID_Temp switches back to automatic mode. If manual mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp remains in manual mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp switches to the operating mode that is saved in the Mode parameter.
0000004	Error during fine tuning. Oscillation of the process value could not be maintained. If PID_Temp is used as heating-cooling controller (Config.ActivateCooling = TRUE), the PID output value (PidOutputSum) at the setpoint must be positive for fine tuning heating and negative • for fine tuning cooling to be able • to generate actual value oscillation If this requirement is not met, use the tuning offsets (PIDSelfTune.TIR.OutputOffsetCool and PIDSelf-Tune.TIR.OutputOffsetHeat tags), see Fine tuning (Page 7316). If ActivateRecoverMode was = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0000008	Error at start of pretuning. The process value is too close to the setpoint or greater than the setpoint. Start fine tuning. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0000010	The setpoint was changed during tuning. You can set the permitted fluctuation of the setpoint at the CancelTuningLevel tag. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0000020	Pretuning is not permitted during fine tuning. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp remains in fine tuning mode.
0000040	Error during pretuning. Cooling could not reduce the process value. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.

ErrorBits (DW#16#...)	Description
0000100	Error during fine tuning resulted in invalid parameters. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0000200	Invalid value at "Input" parameter: Value has an invalid number format. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp outputs the configured substitute output value. As soon as the error is no longer pending, PID_Temp switches back to automatic mode. If manual mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp remains in manual mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp switches to the operating mode that is saved in the Mode parameter.
0000400	Calculation of output value failed. Check the PID parameters. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp outputs the configured substitute output value. As soon as the error is no longer pending, PID_Temp switches back to automatic mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp switches to the operating mode that is saved in the Mode parameter.
0000800	Sampling time error: PID_Temp is not called within the sampling time of the cyclic interrupt OB. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp remains in automatic mode. If manual mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp remains in manual mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp switches to the operating mode that is saved in the Mode parameter.
0001000	Invalid value at "Setpoint" parameter or "SubstituteSetpoint": Value has an invalid number format. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp outputs the configured substitute output value. As soon as the error is no longer pending, PID_Temp switches back to automatic mode. If manual mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp remains in manual mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp switches to the operating mode that is saved in the Mode parameter.
0010000	Invalid value at ManualValue parameter. Value has an invalid number format. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp remains in manual mode and uses SubstituteOutput as PID output value. As soon as you specify a valid value in ManualValue, PID_Temp uses it as the PID output value.
0020000	Invalid value at SubstituteOutput tag. Value has an invalid number format. PID_Temp remains in the "Substitute output value with error monitoring" mode or manual mode and uses the low limit of the PID output value for heating (Config.Output.Heat.PidLowerLimit) as PID output value. As soon as you specify a valid value in SubstituteOutput, PID_Temp uses it as the PID output value.
0040000	Invalid value at Disturbance parameter. Value has an invalid number format. If automatic mode was active and ActivateRecoverMode = TRUE before the error occurred, Disturbance is set to zero. PID_Temp remains in automatic mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp switches to the operating mode that is saved in the Mode parameter. If Disturbance in the current phase has no effect on the output value, tuning is not be canceled.

ErrorBits (DW#16#...)	Description
0200000	Error in Master in the cascade: Slaves are not in automatic mode or have activated substitute setpoint and prevent tuning of the master. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0400000	Fine tuning heating is not permitted while cooling is active. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0800000	The process value must be close to the setpoint to start pretuning cooling. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
1000000	Error at start of tuning: Heat.EnableTuning and Cool.EnableTuning are not set or do not match the configuration. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
2000000	Pretuning cooling requires successful pretuning heating. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
4000000	Error at start of fine tuning: Heat.EnableTuning and Cool.EnableTuning must not be set simultaneously. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
8000000	Error during calculation of the PID parameters resulted in invalid parameters. The invalid parameters are discarded and the original PID parameters are retained unchanged. We can distinguish between the following cases: • If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp remains in automatic mode. • If manual mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp remains in manual mode. • If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp switches to the operating mode that is saved in the Mode parameter.

PID_Temp ActivateRecoverMode tag

The ActivateRecoverMode tag determines the reaction to error. The Error parameter indicates if an error is pending. When the error is no longer pending, Error = FALSE. The ErrorBits parameter shows which errors have occurred.

Automatic mode and manual mode

Notice

Your system may be damaged.

If ActivateRecoverMode = TRUE, PID_Temp remains in automatic mode or in manual mode even if there is an error and the process limit values are exceeded.

This may damage your system.

It is essential to configure how your controlled system reacts in the event of an error to protect your system from damage.

ActivateRecoverMode	Description
FALSE	PID_Temp switches to "Inactive" mode in the event of an error. The controller is only activated by a falling edge at Reset or a rising edge at ModeActivate.
TRUE	**Automatic mode** If errors occur frequently in automatic mode, this setting has a negative effect on the control response, because PID_Temp switches between the calculated PID output value and the substitute output value at each error. In this case, check the ErrorBits parameter and eliminate the cause of the error. If one or several of the following errors occur and automatic mode was active before the error occurred, PID_Temp remains in automatic mode: • 0000001h: The "Input" parameter is outside the process value limits. • 0000800h: Sampling time error • 0040000h: Invalid value at Disturbance parameter. • 8000000h: Error during calculation of the PID parameters If one or several of the following errors occur and automatic mode was active before the error occurred, PID_Temp switches to "Substitute output value with error monitoring" mode: • 0000002h: Invalid value at Input_PER parameter. • 0000200h: Invalid value at Input parameter. • 0000400h: Calculation of output value failed. • 0001000h: Invalid value at Setpoint parameter or SubstituteSetpoint. As soon as the errors are no longer pending, PID_Temp switches back to automatic mode. If the following error occurs in "Substitute output value with error monitoring" mode, PID_Temp sets the PID output value to Config.Output.Heat.PidLowerLimit as long as this error is pending: • 0020000h: Invalid value at SubstituteOutput tag. Value has an invalid number format. This behavior is independent of SetSubstituteOutput.
	Manual mode If one or several errors occur and manual mode was active before the error occurred, PID_Temp remains in manual mode. If the following error occurs in manual mode, as long as this error is pending, PID_Temp sets the PID output value to SubstituteOutput: • 0010000h: Invalid value at ManualValue parameter. Value has an invalid number format. If the error 0010000h is pending in manual mode and the following error occurs, PID_Temp sets the PID output value to Config.Output.Heat.PidLowerLimit as long as this error is pending: • 0020000h: Invalid value at SubstituteOutput tag. Value has an invalid number format. This behavior is independent of SetSubstituteOutput.

Pretuning and fine tuning

ActivateRecoverMode	Description
FALSE	PID_Temp switches to "Inactive" mode in the event of an error. The controller is only activated by a falling edge at Reset or a rising edge at ModeActivate.
TRUE	If the following error occurs, PID_Temp remains in the active mode: • 0000020h: Pretuning is not permitted during fine tuning. The following errors are ignored: • 0010000h: Invalid value at ManualValue parameter. • 0020000h: Invalid value at SubstituteOutput tag. When any other error occurs, PID_Temp cancels the tuning and switches to the mode from which tuning was started.

PID_Temp Warning tag

If several warnings are pending simultaneously, the values of the Warning tag are displayed with binary addition. If the warning 0000003h is displayed, for example, the warnings 0000001h and 0000002h are pending simultaneously.

Warning (DW#16#....)	Description
0000000	No warning pending.
0000001	The point of inflection was not found during pretuning.
0000004	The setpoint was limited to the configured limits.
0000008	Not all the necessary controlled system properties were defined for the selected method of calculation. Instead, the PID parameters were calculated using the TIR.TuneRuleHeat method or TIR.TuneRuleCool = 3.
0000010	The operating mode could not be changed because Reset = TRUE or ManualEnable = TRUE.
0000020	The cycle time of the calling OB limits the sampling time of the PID algorithm. Improve results by using shorter OB cycle times.
0000040	The process value exceeded one of its warning limits.
0000080	Invalid value at Mode. The operating mode is not switched.
0000100	The manual value was limited to the limits of the PID output value.
0000200	The specified rule for tuning is not supported. No PID parameters are calculated.
0001000	The substitute output value cannot be reached because it is outside the output value limits.
0004000	The specified number of the output value for heating and/or cooling is not supported. Only the output OutputHeat or OutputCool is used.
0008000	Invalid value at PIDSelfTune.SUT.AdaptDelayTime. The default value 0 is used.
0010000	Invalid value at PIDSelfTune.SUT.CoolingMode. The default value 0 is used.
0020000	The activation of cooling (Config.ActivateCooling tag) is not supported by the controller that is used as master (Config.Cascade.IsMaster tag). PID_Temp works as heating controller. Set the Config.ActivateCooling tag to FALSE.
0040000	Invalid value at Retain.CtrlParams.Heat.Gain, Retain.CtrlParams.Cool.Gain or Config.CoolFactor. PID_Temp supports only positive values for proportional gain (heating and cooling) and cooling factor. Automatic mode remains active with PID output value 0.0. The integral component is stopped.

The following warnings are deleted as soon as the cause has been remedied or you repeat the action with valid parameters:

- 0000001h
- 0000004h
- 0000008h
- 0000040h
- 0000100h

All other warnings are cleared with a rising edge at Reset or ErrorAck.

PwmPeriode tag

If the PID algorithm sampling time (Retain.CtrlParams.Heat.Cycle or Retain.CtrlParams.Heat.Cycle) and thus the time period of the pulse width modulation is very high when you use OutputHeat_PWM or OutputCool_PWM, you can define a deviating shorter time period at the Config.Output.Heat.PwmPeriode or Config.Output.Cool.PwmPeriode parameters to improve the smoothness of the process value.

Time period of the pulse width modulation at OutputHeat_PWM

Time period of the PWM at output OutputHeat_PWM depending on Config.Output.Heat.PwmPeriode:

- Heat.PwmPeriode = 0.0 (default)
  The sampling time of the PID algorithm for heating (Retain.CtrlParams.Heat.Cycle) is used as time period of the PWM.
- Heat.PwmPeriode > 0.0
  The value is rounded off to an integer multiple of the PID_Temp sampling time (CycleTime.Value) and used as time period of the PWM.
  The value must meet the following conditions:
  - Heat.PwmPeriode ≤ Retain.CtrlParams.Heat.Cycle
  - Heat.PwmPeriode > Config.Output.Heat.MinimumOnTime
  - Heat.PwmPeriode > Config.Output.Heat.MinimumOffTime

Time period of the pulse width modulation at OutputCool_PWM

Time period of the PWM at output OutputCool_PWM depending on Config.Output.Cool.PwmPeriode and the method for heating/cooling:

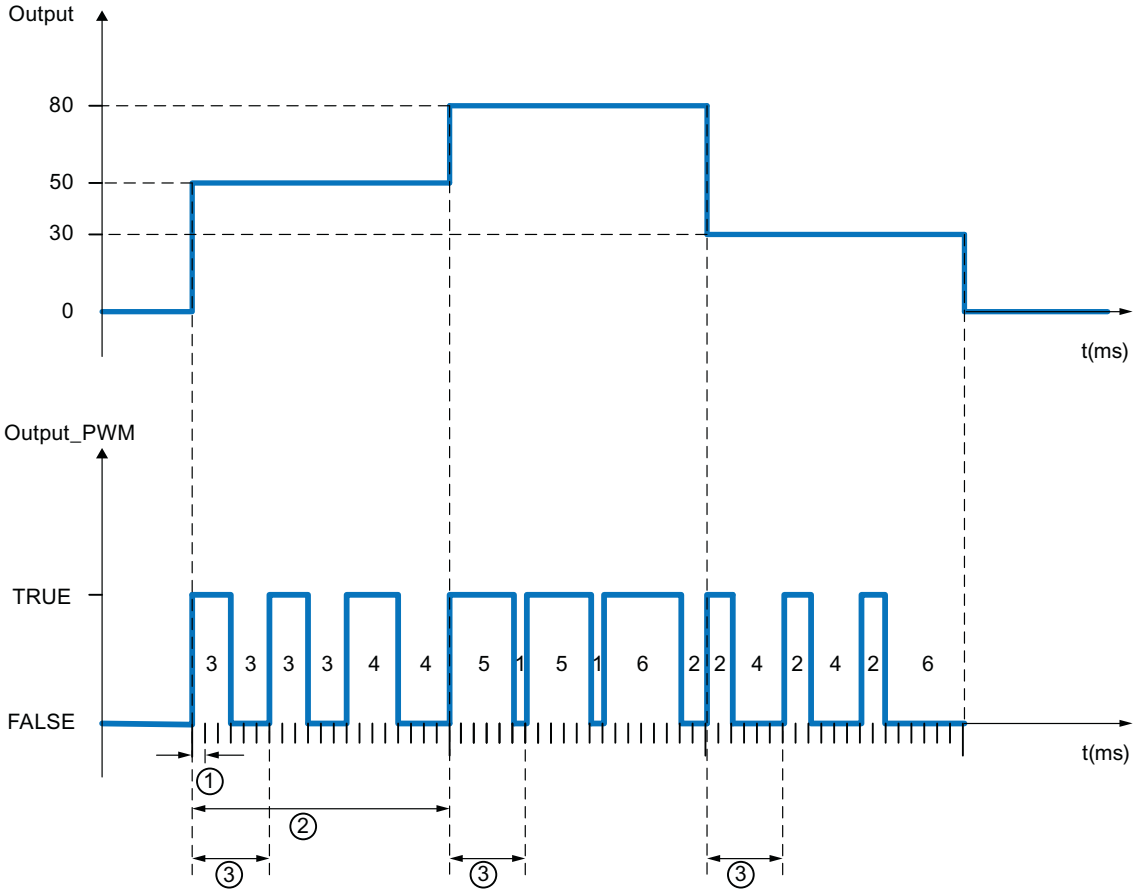
- Cool.PwmPeriode = 0.0 and cooling factor (Config.AdvancedCooling = FALSE):
  The sampling time of the PID algorithm for heating (Retain.CtrlParams.Heat.Cycle) is used as time period of the PWM.
- Cool.PwmPeriode = 0.0 and PID parameter switching (Config.AdvancedCooling = TRUE):
  The sampling time of the PID algorithm for cooling (Retain.CtrlParams.Cool.Cycle) is used as time period of the PWM.
- Cool.PwmPeriode > 0.0:
  The value is rounded off to an integer multiple of the PID_Temp sampling time (CycleTime.Value) and used as time period of the PWM.
  The value must meet the following conditions:
  - Cool.PwmPeriode ≤ Retain.CtrlParams.Cool.Cycle or Retain.CtrlParams.Heat.Cycle
  - Cool.PwmPeriode > Config.Output.Cool.MinimumOnTime
  - Cool.PwmPeriode > Config.Output.Cool.MinimumOffTime

Config.Output.Cool.PwmPeriode is only effective if the cooling output is activated (Config.ActivateCooling =TRUE).

When you use PwmPeriode, the accuracy of the PWM output signal is determined by the relationship of PwmPeriode to the PID_Temp sampling time (cycle time of the OB). PwmPeriode should be at least 10 times the PID_Temp sampling time.

If the sampling time of the PID algorithm is not an integer multiple of PwmPeriode, each last period of the PWM within the sampling time of the PID algorithm is extended accordingly.

Example for OutputHeat_PWM



① PID_Temp sampling time = 100.0 ms (cycle time of the calling cyclic interrupt OB, CycleTime.Value tag)

② PID algorithm sampling time = 2000.0 ms (Retain.CtrlParams.Heat.Cycle tag)

③ Time period of the PWM for heating = 600.0 ms (Config.Output.Heat.PwmPeriode tag)

11.6.5 Communication

11.6.5.1 S7 communication

Data consistency

Definition

A data block which cannot be modified by concurrent processes is called consistent data area. A data block which is larger than the consistent data area can thus be falsified as a whole during transmission. This means that a data block which belongs together and which is larger than consistent data area can consist in part of new and of old consistent data at the same time.

Example

An inconsistency can occur when an instruction for communication is interrupted, for example, by a hardware interrupt OB with higher priority. If the user program in this OB now changes the data that has already been partly processed by the instruction, the transferred data originates:

- In part from the time before the hardware interrupt was processed
- And in part from the time after the hardware interrupt was processed

This means that these data are inconsistent (not coherent).

Ensuring data consistency

If the communication process can be interrupted by an interrupt OB, you must ensure that the data is transferred consistently. Make sure that only an image of the data and not the data to be transferred is not changed directly by the interrupt OB. Copy the image of the data to the transfer area of the communication instruction prior to the next data transfer.

- If the user program contains a communication instruction that accesses common data, access to this data area can be coordinated, for example, by means of the DONE parameter. The data consistency of the communication areas which are transferred locally with a communication instruction can therefore be ensured in the user program.
- In the case of S7 communication instructions "PUT (Page 3615)"/"GET (Page 3612)", the size of the consistent data areas must already be taken into consideration during programming or configuration, because a communication block is not available in the user program of the target device (server) to synchronize communication data to the user program.

- For the S7-300 and C7-300 (exception: CPU 318-2 DP) the communication data are copied consistently into the user memory in blocks of 32 bytes in the cycle control point of the operating system. Data consistency is not guaranteed for larger data areas. If a defined data consistency is required, the communication data in the user program may not exceed 32 bytes (maximum of 8 bytes, depending on the version).
- In the S7-400 and S7-1500, on the other hand, the communication data in 462-byte blocks is not processed at the cycle control point, but in fixed time slices during the program cycle. The consistency of a tag is ensured by the system. These communication areas can then be accessed consistently using the "PUT (Page 3615)" / "GET (Page 3612)" instructions or when reading/writing tags, for example by an OP or an OS.

Note

Additional information on data consistency is provided in the description of the specific instructions.

Effect on interrupt reaction times

The interrupt reaction times of the CPU are slightly extended by copying the data. The greater the quantity of data which must be transferred with absolute consistency, the longer the interrupt reaction time of a system.

Common parameters of instructions for S7 communication

Classification

The parameters of the instructions for S7 communication can be divided into the following five categories according to their functions:

1. Control parameters are used to activate an instruction.
2. Addressing parameters are used to address the remote communication partner.
3. Send parameters point to the data areas that are to be sent to the remote partner.
4. Receive parameters point to the data areas where the data received from remote partners will be entered.
5. Status parameters are used to monitor whether the instruction has completed its task without error or for the analysis of any errors that have occurred.

Control parameter

Data exchange will only be activated if the appropriate control parameters have a defined value (for example, are set) when the instruction is called or when the value has undergone a specific change since the previous call (for example, a positive edge).

Addressing parameters

Parameter	Description
ID	Reference to the local connection description (specified by the configuration of the connection).
R_ID	With the R_ID parameter, you specify that a send and a receive instruction belong together: The R_ID parameter must match in the instruction at the sending end and the instruction at the receiving end. This allows the communication of several instruction pairs via the same logic connection. • R_ID must be specified in the form DW#16#wxyzWXYZ. • The instruction pairs of a logical connection specified in R_ID must be unique for this connection.

Note

Addressing parameters ID and R_ID

You can reassign the addressing parameters ID and R_ID during runtime. The new parameters are validated with each new job after the previous job has been closed.

You can use the following options to reduce the number of instance DBs and therefore the work memory required:

1. With tag IDs, you can use several connections via one data instance block.
2. With tag R_IDs, you can define several pairs of sending and receiving instructions for one job with a single instance.
3. You can combine cases 1 and 2.

Please note that the new parameters are valid after the last job is executed. When you activate the sending operation, the R_ID parameter in the instruction at the sending end must match its counterpart at the receiving end.

Status parameter

With the status parameters, you monitor whether the instruction has completed its task correctly or whether it is still active. The status parameters also indicate errors.

Note

The status parameters are valid for one cycle only, namely from the first command following the call until the next call. As a result, you must evaluate these parameters after each instruction cycle.

Send and receive parameters

For communication instructions configured at both ends

- The number of the SD_i and RD_i parameters used must match at the send and receive end.
- The data types of the SD_i and RD_i parameters that belong together must match at the send and receive end.
- The amount of data to be sent according to the SD_i parameter must not exceed the range made available by the corresponding RD_i (does not apply to "BSEND (Page 3621)" / "BRCV (Page 3623)"). The RD_i parameters must (with exception of "BSEND"/"BRCV") have the identical data size.

If you do not keep to the rules above, this is indicated by ERROR = 1 and STATUS = 4.

Note

Supplying the send and receive parameters

With the VARIANT data type, send and receive parameters must always be supplied any time a communication instruction is called. It is not possible, for example, to supply the send parameters of the communication instructions at startup and to only trigger the send job in cyclic operation.

User data size

With the "USEND (Page 3618)", "URCV (Page 3619)", "GET (Page 3612)" and "PUT (Page 3615)" instructions, the amount of data to be transferred must not exceed a defined user data size. The maximum user data size depends on:

- The instruction used
- The communication partner.

The guaranteed minimum size of the user data for an instruction with 1-4 tags is listed in the following table:

Instruction	Partner: S7-300	Partner: S7-400	Partner: S7-1200	Partner: S7-1500
PUT / GET	160 bytes	400 bytes	160 bytes	880 bytes
USEND / URCV	160 bytes	440 bytes	-	920 bytes
BSEND / BRCV	32768/65534 bytes	65534 bytes	-	• 65534 bytes with standard access • 65535 bytes with optimized access

Further information on the user data size can be found in the technical data of the respective CPU.

Exact user data size

If the user data size specified above is insufficient you can determine the maximum byte length of the user data as follows:

First read the data block size valid for communication from the following table:

Local CPU	Remote CPU	Data block size in bytes
S7-1200	Any	240
S7-1500	S7-300	240
	S7-400	480
	S7-1200	240
	S7-1500	960

Use this value in the following table to read the maximum possible user data length in bytes as total of the parameters used. It applies for even lengths of the areas SD_i, RD_i, and ADDR_i.

For each range of uneven length the maximum possible user data length is reduced by one byte.

		Number of SD_i, RD_i, ADDR_i parameters used			
Data block size	Instruction	1	2	3	4
240 (S7-300)	PUT/GET/ USEND	160	-	-	-
240 (S7-300 via integrated interface)	PUT	212	-	-	-
	GET	222	-	-	-
	USEND	212	-	-	-
240 (S7-400)	PUT	212	196	180	164
	GET	222	218	214	210
	USEND	212	-	-	-
480 (S7-400)	PUT	452	436	420	404
	GET	462	458	454	450
	USEND	452	448	444	440
240 (S7-1200)	PUT	212	196	180	164
	GET	222	218	214	210
960 (S7-1500)	PUT	932	916	900	884
	GET	942	938	934	930
	USEND	932	928	924	920

GET: Read data from a remote CPU

Description

With the instruction "GET", you can read data from a remote CPU.

The instruction is started on a positive edge at control input REQ:

- The relevant pointers to the areas to be read out (ADDR_i) are then sent to the partner CPU. The partner CPU can be in RUN or STOP mode.
- The partner CPU returns the data:
  - If the reply exceeds the maximum user data length, this is displayed with error code "2" at the STATUS parameter.
  - The received data is copied to the configured receive areas (RD_i) at the next call.
- Completion of this action is indicated by the status parameter NDR having the value "1".

Reading can only be activated again after the previous reading process has been completed. Errors and warnings are output via ERROR and STATUS if access problems occurred while the data was being read or if the data type check results in an error.

Changes in the data areas addressed on the partner CPU are not registered by the "GET" instruction.

Requirements for using the instruction

- The "Permit access with PUT/GET communication from remote partner" function was activated in the properties of the partner CPU under "Protection".
- The blocks which you access with the "GET" instruction were created with the access type "standard".
- Make sure that the areas defined with the parameters ADDR_i and SD_i match in terms of number, length and data type.
- The area to be read (ADDR_i parameter) cannot be larger than the area for data storage (RD_i parameter).

Parameters

The following table shows the parameters of the "GET" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Control parameter request, activates the data exchange on a positive edge.
ID	Input	WORD	I, Q, M, D, L or constant	Addressing parameters for specifying the connection to the partner CPU.
NDR	Output	BOOL	I, Q, M, D, L	Status parameter NDR: • 0: Job not yet started or still running. • 1: Job successfully completed.

Parameter	Declaration	Data type	Memory area	Description
ERROR	Output	BOOL	I, Q, M, D, L	Status parameters ERROR and STATUS, error code: • ERROR=0 STATUS has the value: – 0000H: Neither warning nor error – <> 0000H: Warning, STATUS supplies detailed information. • ERROR=1 An error has occurred. STATUS supplies detailed information on the type of error.
STATUS	Output	WORD	I, Q, M, D, L	
ADDR_1	InOut	REMOTE	I, Q, M, D	Pointers to the areas on the partner CPU that are to be read. When the REMOTE pointer accesses a DB, the DB must always be specified. Example: P#DB10.DBX5.0 Byte 10.
ADDR_2	InOut	REMOTE		
ADDR_3	InOut	REMOTE		
ADDR_4	InOut	REMOTE		
RD_1	InOut	VARIANT	I, Q, M, D, L	Pointers to the areas on the local CPU in which the read data is entered.
RD_2	InOut	VARIANT		
RD_3	InOut	VARIANT		
RD_4	InOut	VARIANT		

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameters ERROR and STATUS

The following table contains all specific error information for the "GET" instruction that can be output via the ERROR and STATUS parameters.

ERROR	STATUS (decimal)	Explanation
0	11	Warning: New job not active because the previous job is still busy.
0	25	Communication has started. The job is being processed.
1	1	Communication problems, for example • Connection description not loaded (local or remote) • Connection interrupted (for example: cable, CPU off, CP in STOP mode) • Connection to partner not yet established
1	2	• Negative acknowledgment from the partner device. The function cannot be executed. • Response from the remote station exceeds the maximum user data length (see: Common parameters of instructions for S7 communication (Page 3609)). • Access protection is activated on the partner CPU. Deactivate access protection in the CPU settings.
1	4	Error in the pointers to the data storage RD_i: • Data types of the parameters RD_i and ADDR_i are not compatible with each other. • The length of the area RD_i is smaller than the length of the data of the ADDR_i parameter that is to be read.
1	8	Access error on the partner CPU.

ERROR	STATUS (decimal)	Explanation
1	10	Access to the local user memory not possible (for example, access to a deleted DB).
1	20	• Maximum number of parallel jobs exceeded. • The job is currently being processed in a priority class with low priority (first call).

Note

Data consistency

Data is received consistently if you read the part of the receive area RD_i currently being used completely before initiating another job.

PUT: Write data to a remote CPU

Description

You can write data to a remote CPU with the instruction "PUT".

The instruction is started on a positive edge at control input REQ:

- The pointers to the areas to be written (ADDR_i) and the data (SD_i) are then sent to the partner CPU. The partner CPU can be in RUN or STOP mode.
- The data to be sent is copied from the configured send areas ((SD_i). The partner CPU saves the sent data under the addresses supplied with the data and returns an execution acknowledgment.
- If no errors occur, this is indicated at the next instruction call with status parameter DONE = "1". The writing process can only be activated again after the last job is complete.

Errors and warnings are output via ERROR and STATUS if access problems occurred while the data was being written or if the execution check results in an error.

Requirements for using the instruction

- The "Permit access with PUT/GET communication from remote partner" function was activated in the properties of the partner CPU under "Protection".
- The blocks which you access with the "PUT" instruction were created with the access type "standard".
- Make sure that the areas defined with the parameters ADDR_i and SD_i match in terms of number, length and data type.
- The area to be written (ADDR_i parameter) must be as large as the send area (SD_i parameter).

Parameters

The following table shows the parameters of the "PUT" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Control parameter request, activates the data exchange on a positive edge.
ID	Input	WORD	I, Q, M, D, L or constant	Addressing parameters for specifying the connection to the partner CPU.
DONE	Output	BOOL	I, Q, M, D, L	Status parameter DONE: • 0: Job not yet started or still executing • 1: Job executed without errors.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameters ERROR and STATUS, error code: • ERROR=0 STATUS has the value: – 0000H: Neither warning nor error – <> 0000H: Warning, STATUS supplies detailed information. • ERROR=1 An error has occurred. STATUS supplies detailed information on the type of error.
STATUS	Output	WORD	I, Q, M, D, L	
ADDR_1	InOut	REMOTE	I, Q, M, D	Pointers to the areas on the partner CPU to which the data will be written. When the REMOTE pointer accesses a DB, the DB must always be specified. Example: P#DB10.DBX5.0 Byte 10. When transferring data structures (e.g., Struct) the data type CHAR must be used at the ADDR_i parameters.
ADDR_2	InOut	REMOTE		
ADDR_3	InOut	REMOTE		
ADDR_4	InOut	REMOTE		
SD_1	InOut	VARIANT	I, Q, M, D, L	Pointers to the areas on the local CPU which contain the data to be sent. Only the data types BOOL, BYTE, CHAR, WORD, INT, DWORD, DINT, REAL are permitted. When transferring data structures (e.g., Struct) the data type CHAR must be used at the SD_i parameters.
SD_2	InOut	VARIANT		
SD_3	InOut	VARIANT		
SD_4	InOut	VARIANT		

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameters ERROR and STATUS

The following table contains all specific error information for the "PUT" instruction that can be output via the ERROR and STATUS parameters.

ERROR	STATUS (decimal)	Explanation
0	11	Warning: New job not active because the previous job is still busy.
0	25	Communication has started. The job is being processed.
1	1	Communication problems, for example • Connection description not loaded (local or remote). • Connection interrupted (for example, cable, CPU off, CP in STOP mode). • Connection to partner not yet established.
1	2	• Negative acknowledgment of partner CPU. The function cannot be executed. • Access on the partner CPU was not granted. Activate the access in the CPU settings.
1	4	Error in the pointers to the data storage: • Data types of the parameters SD_i and ADDR_i are not compatible with each other. • The length of the area SD_i is greater than the length of the data of the ADDR_i parameter that is to be written. • Not possible to access SD_i. • Maximum user data size exceeded. • Number of the parameters SD_i and ADDR_i does not match.
1	8	Access error with the partner CPU (e.g. DB not loaded or write-protected).
1	10	Access to the local user memory not possible (for example, access to a deleted DB).
1	20	• Maximum number of parallel jobs exceeded. • The job is currently being processed in a priority class with low priority (first call).

Data consistency

When a send operation is activated (positive edge at REQ), the data to be sent from the send area SD_i is copied from the user program. After the block call, you can write to these areas without corrupting the current send data.

Note

The send operation is only complete when the DONE status parameter has the value "1".

Other

USEND: Send data uncoordinated

Description

The "USEND" instruction sends data to a remote partner instruction of type "URCV (Page 3619)". The sending process is carried out without coordination with the partner instruction. This means that the data transfer is carried out without acknowledgment by the partner instruction.

When a send operation is activated (positive edge at REQ), the data to be sent from the send areas SD_i are copied from the user program. After the instruction call, you can write to these send areas again without corrupting the current send data.

Successful completion of the send operation is indicated by the value of the DONE status parameter being set to "1".

Parameters

The following table shows the parameters of the "USEND" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Control parameter request, activates the data exchange on a positive edge.
ID	Input	CONN_PRG	I, Q, M, D, L, P or constant	Addressing parameters for specifying the connection to the partner CPU.
R_ID	Input	CONN_R_ID	I, Q, M, D, L or constant	Addressing parameter R_ID for defining the instruction pairs "USEND" and "URCV". See also: Common parameters of instructions for S7 communication (Page 3609)
DONE	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Job not yet started or still executing. • 1: Job executed without errors.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Neither warning nor error. • 1: An error has occurred. STATUS supplies detailed information on the type of error.

Parameter	Declaration	Data type	Memory area	Description
STATUS	Output	WORD	I, Q, M, D, L	Status parameter See "ERROR and STATUS parameters" table.
SD_i (1≤ i ≤4)	InOut	VARIANT	I, Q, M, D	Pointer on the i-th send area. Only the BOOL data types are permitted (not permitted: bit array), BYTE, CHAR, WORD, INT, DWORD, DINT, REAL or STRUCT. The maximum user data size for SD_i parameters depends on the partner CPU ("URCV" instruction) and on the number of parameters used. Additional information is available in: Common parameters of instructions for S7 communication (Page 3609)

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameters ERROR and STATUS

ERROR	STATUS (decimal)	Explanation
0	11	Warning: New job not active because the previous job is still busy.
0	25	Communication has started. The job is being processed.
1	1	Communication problem has occurred. Possible causes: • Connection description not loaded (local or remote) • Connection interrupted (for example: cable, CPU off, CP in STOP mode) • Connection to partner not yet established
1	4	• Errors in the send area pointers SD_i relating to the data length or the data type. • Maximum user data length was exceeded.
1	10	Access to the local user memory not possible (for example, access to a deleted DB).
1	18	Value at R_ID parameter already exists in the connection specified at the ID parameter (R_ID value must be unique for the connection).
1	20	• Maximum number of parallel jobs exceeded. • The job is currently being processed in a priority class with lower priority (first call).

URCV: Receive data uncoordinated

Description

The "URCV" instruction receives data asynchronously from a remote partner instruction of type "USEND (Page 3618)" and copies this data into the configured receive areas.

The instruction is ready to receive if there is a logical 1 at the EN_R input. An active job can be canceled with EN_R=0.

The receive data areas are referenced by the parameters RD_1 to RD_4. Make sure that the areas defined by the parameters RD_i / RD_1 and SD_i / SD_1 (with the associated partner instruction "USEND (Page 3618)") match in terms of number and length.

Successful completion of the copy operation is indicated when the value of the NDR status parameter is set to logical "1". Once the status parameter NDR has changed to "1", there will be new receive data in your receive areas (RD_i). A new block call may cause these data to be overwritten with new receive data. If you want to prevent this, call "URCV" (for example, during cyclic block processing) with the value 0 at EN_R until you have finished processing the received data.

Parameters

The following table shows the parameters of the "URCV" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN_R	Input	BOOL	I, Q, M, D, L or constant	Control parameter enabled to receive, signals ready to receive if the input is set.
ID	Input	CONN_PRG	I, Q, M, D, L, P or constant	Addressing parameters for specifying the connection to the partner CPU.
R_ID	Input	CONN_R_ID	I, Q, M, D, L or constant	Addressing parameter for defining the instruction pairs "USEND" and "URCV". See also: Common parameters of instructions for S7 communication (Page 3609)
NDR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Job not yet started or still running. • 1: Job successfully completed.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Neither warning nor error • 1: An error has occurred. STATUS supplies detailed information on the type of error.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter See "ERROR and STATUS parameters" table.
RD_i (1≤ i ≤4)	InOut	VARIANT	I, Q, M, D	Pointer to the i-th receive area: Only the BOOL data types are permitted (not permitted: bit array), BYTE, CHAR, WORD, INT, DWORD, DINT, REAL or STRUCT. Additional information is available in: Common parameters of instructions for S7 communication (Page 3609)

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameters ERROR and STATUS

ERROR	STATUS (decimal)	Explanation
0	9	Warning: older received data were overwritten by newer received data.
0	11	Warning: The received data is already being processed in a priority class with lower priority (error can occur when copying data to the receive area).
0	25	Communication has started. The job is being processed.

ERROR	STATUS (decimal)	Explanation
1	1	Communication problem has occurred. Possible causes: • Connection description not loaded (local or remote) • Connection interrupted (for example: cable, CPU off, CP in STOP mode) • Connection to partner not yet established
1	4	Errors in the receive area pointers RD_i relating to the data length or the data type.
1	10	Access to the local user memory not possible (for example, access to a deleted DB).
1	18	Value at R_ID parameter already exists in the connection specified at the ID parameter (R_ID value must be unique for the connection).
1	19	The associated "USEND (Page 3618)" instruction sends data faster than it can be copied to the receive areas by "URCV".
1	20	• Maximum number of parallel jobs exceeded. • The job is currently being processed in a priority class with lower priority (first call).

BSEND: Send data in segments

Description

The "BSEND" instruction sends data to a remote partner instruction of type "BRCV (Page 3623)". With this type of data transfer, more data can be transported between the communication partners than is possible with all other communication instructions for configured S7 connections. In each case, the maximum data volume amounts to 65534 bytes (standard access) or 65535 bytes (optimized access) for the integrated interface and for SIMATIC Net CP.

Functional description

You specify the instruction pair "BSEND" and "BRCV" with the input parameter R_ID. The R_ID parameter must be identical in the related instructions.

The send job is activated after the instruction is called and a positive edge is detected at control input REQ. After the call, "BSEND" is not processed in the background, which means the data can only be read within the user program.

The data area to be transmitted is segmented. Each segment is sent individually to the partner. Each segment is acknowledged by the partner after the application of this segment by "BRCV (Page 3623)". If the data is segmented, "BSEND" must be called multiple times until all segments have been transferred.

The data area of the data to be sent is specified by SD_1. To ensure data consistency, you may only write to the part of the currently used sending area SD_1 after the current send operation is complete. This is the case when the value of the status parameter DONE changes to "1".

The length of the send data is specified by LEN based on the job. With LEN = "0", all data addressed with the SD_1 parameter is sent.

If there is a positive edge at control input R, the current sending process is canceled.

Due to the asynchronous data transfer, a new data transfer can only be initiated if the previous data has been fetched by a partner instruction call. When the data has been collected, the status parameter "NDR" is set in the partner instruction "BRCV".

Note

Migration of S7-400 user programs

An S7-400 CPU interprets the parameter SD_1 as pointer and not as data area.

With S7-1500, LEN may not exceed the area of SD1. This was permitted with S7-400. Recommendation: Use the maximum size for the LEN parameter (65534 bytes for the integrated interface) as size of the data area at the SD_1 parameter.

Parameters

The following table shows the parameters of the "BSEND" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Control parameter request, activates the data exchange at a positive edge
R	Input	BOOL	I, Q, M, D, L or constant	Control parameter reset, activates an abort of the current data exchange at a positive edge
ID	Input	CONN_PRG	I, Q, M, D, L, P or constant	Addressing parameters for specifying the connection to the partner CPU.
R_ID	Input	CONN_R_ID	I, Q, M, D, L or constant	Addressing parameter for defining the instruction pairs "BSEND" and "BRCV (Page 3623)". See also: Common parameters of instructions for S7 communication (Page 3609)
SD_1	InOut	VARIANT	I, Q, M, D	Pointer to send area
LEN	InOut	WORD	I, Q, M, D, L	Length of the block of data to be sent in bytes. With LEN = "0", all data is sent by SD_1.
DONE	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Job not yet started or still executing. • 1: Job executed without errors.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Neither warning nor error. • 1: An error has occurred. STATUS supplies detailed information on the type of error.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter See "ERROR and STATUS parameters" table.

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameters ERROR and STATUS

The following table contains all specific error information for "BSEND" that can be output via the ERROR and STATUS parameters.

ERROR	STATUS (decimal)	Explanation
0	11	Warning: New job not active because the previous job is still busy.
0	25	Communication has started. The job is being processed.
1	1	Communication problem has occurred. Possible causes: • Connection description not loaded (local or remote) • Connection interrupted (for example: cable, CPU off, CP in STOP mode) • Connection to partner not yet established
1	2	Negative acknowledgment of partner instruction. The instruction cannot be executed.
1	3	R_ID is unknown on the connection specified by the ID or the receive block has not yet been called.
1	4	• Error in the data length or data type in the send area pointer SD_1. • Value for LEN is greater than area SD_1.
1	5	Reset request was executed.
1	6	Partner instruction is in DISABLED status (EN_R has the value "0"). Also check the input parameters of "BRCV (Page 3623)" for consistency with "BSEND".
1	7	"BRCV (Page 3623)" partner instruction not called since the last data transfer.
1	8	Access to remote object in the user memory was rejected: The destination area for the associated "BRCV (Page 3623)" is too small. ERROR = 1, STATUS = 4 or ERROR = 1, STATUS = 10 reported at the output parameters of "BRCV (Page 3623)".
1	10	Access to the local user memory not possible (for example, access to a deleted DB).
1	18	R_ID already exists in the connection.
1	20	• Maximum number of parallel jobs exceeded. • The job is currently being processed in a priority class with lower priority (first call).

BRCV: Receive data in segments

Description

The "BRCV" instruction receives data from a remote partner instruction of type "BSEND (Page 3621)". The R_ID parameter must be identical in the related instructions.

The instruction is ready to receive data (STATUS = 25) after it is called with the value "1" at control input EN_R. An active job can be canceled with EN_R=0.

The maximum receive area is specified by RD_1. Data will be received consistently if you fully evaluate the part of the RD_1 receive area currently in use before calling the block again with value 1 at control input EN_R.

After each received data segment, an acknowledgment is sent to the partner instruction. If there are multiple segments it will be necessary to call "BRCV" several times until all of the segments have been received. Asynchronous data receipt is indicated by STATUS = 17. The

amount of data currently received is indicated at the parameter LEN. The RD_1 parameter must remain constant during the operation.

Value "1" at the NDR status parameter indicates that all data segments have been received without error. The received data remains unchanged until the next call with EN_R=1.

Parameters

The following table shows the parameters of the "BRCV" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN_R	Input	BOOL	I, Q, M, D, L or constant	Control parameter enabled to receive, signals ready to receive if the input is set.
ID	Input	CONN_PRG	I, Q, M, D, L, P or constant	Addressing parameters for specifying the connection to the partner CPU.
R_ID	Input	CONN_R_ID	I, Q, M, D, L or constant	Addressing parameter for defining the instruction pairs "BSEND (Page 3621)" and "BRCV". See also: Common parameters of instructions for S7 communication (Page 3609)
RD_1	InOut	VARIANT	I, Q, M, D	Pointer to the receive area.
LEN	InOut	WORD	I, Q, M, D, L	Length of the data already received in bytes.
NDR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Job not yet started or still running. • 1: Job successfully completed.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Neither warning nor error • 1: An error has occurred. STATUS supplies detailed information on the type of error.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter See "ERROR and STATUS parameters" table.

For additional information on valid data types, refer to "Overview of the valid data types (Page 1908)".

Parameters ERROR and STATUS

The following table contains all specific error information for "BRCV" that can be output via the ERROR and STATUS parameters.

ERROR	STATUS (decimal)	Explanation
0	17	Warning: Instruction receives data asynchronously. The LEN parameter shows the amount of data already received in bytes.
0	25	Communication has started. The job is being processed.
1	1	Communication problem has occurred. Possible causes: • Connection description not loaded (local or remote) • Connection interrupted (for example: cable, CPU off, CP in STOP mode) • Connection to partner not yet established

ERROR	STATUS (decimal)	Explanation
1	2	Function cannot be executed (protocol error)
1	4	Error in the receive area pointer RD_1 relating to the data length or data type. The block of data sent is longer than the receive area.
1	5	Reset request received, incomplete transfer.
1	8	Access error in associated "BSEND (Page 3621)": After the last valid data segment has been sent, ERROR = 1 and STATUS = 4 or ERROR = 1 and STATUS = 10 is reported.
1	10	Access to the local user memory not possible (for example, access to a deleted DB).
1	18	Value at R_ID parameter already exists in the connection specified at the ID parameter (R_ID value must be unique for the connection).
1	20	• Maximum number of parallel jobs exceeded. • The job is currently being processed in a priority class with lower priority (first call).

11.6.5.2 Open User Communication

TSEND_C: Send data via Ethernet

TSEND_C: Send data via Ethernet

Description

The "TSEND_C" instruction sets up and establishes a TCP or ISO-on-TCP communication connection. Once the connection has been set up and established, it is automatically maintained and monitored by the CPU. The connection description specified at the CONNECT parameter is used to set up the communication connection.

The instruction is executed asynchronously and has the following functions:

- A communication connection is set up and established:
  The communication connection is set up and established with CONT=1. Once the connection is successfully established, the DONE parameter is set to "1" for one cycle. An existing connection is terminated and the connection which has been set up is removed when the CPU goes into STOP mode. To set up and establish the connection again, you must execute "TSEND_C" again. For information on the number of possible communication connections, refer to the technical specifications for your CPU.
- Sending data via an existing communication connection:
  You specify the send area with the DATA parameter. This includes the address and the length of the data to be sent. Do not use a data area with the data type BOOL or Array of BOOL at the DATA parameter. If you use purely symbolic values at the DATA parameter, the LEN parameter must have the value "0".

- The send job is executed when a rising edge is detected at the REQ parameter. With the LEN parameter, you specify the maximum number of bytes sent with a send job. When sending data (rising edge at the REQ parameter), the CONT parameter must have the value "1" in order to establish or maintain a connection. The data to be sent must not be edited until the send job is completed. If the send job executes successfully, the DONE parameter is set to "1". Signal state "1" at the DONE parameter is not confirmation that the data sent has already been read by the communication partner.
- Terminating the communication connection:
  The communication connection is terminated when the CONT parameter is set to "0" even if an ongoing data transmission is not complete yet. This does not apply if you are using an already configured connection for "TSEND_C".

When setting the COM_RST parameter to "1", the currently established connection or a current data transmission can be reset at any time. This terminates the existing communication connection and a new connection is established. If data is being transferred when it executes again, this can lead to a loss of data.

To enable "TSEND_C" again after the execution (DONE = 1), call the instruction once with REQ = 0.

Parameters

The following table shows the parameters of the "TSEND_C" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L	Starts the send job on a rising edge.
CONT	Input	BOOL	I, Q, M, D, L	Controls the communication connection: • 0: Disconnect the communication connection • 1: Establish and maintain the communication connection When sending data (rising edge at the REQ parameter), the CONT parameter must have the value TRUE in order to establish or maintain a connection.
LEN	Input	UINT	I, Q, M, D, L or constant	Maximum number of bytes to be sent with the job. If you use purely symbolic values at the DATA parameter, the LEN parameter must have the value "0".
CONNECT	InOut	TCON_Param	D	Pointer to the connection description See also: Auto-Hotspot
DATA	InOut	VARIANT	I, Q, M, D, L	Pointer to the send area containing the address and the length of the data to be sent (maximum length: 8192 bytes).
COM_RST	InOut	BOOL	I, Q, M, D, L	Restarts the instruction: • 0: Irrelevant • 1: Complete restart of the instruction causing an existing connection to be terminated and a new connection to be established.

Parameter	Declaration	Data type	Memory area	Description
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or still in progress • 1: Job completed without error
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or already completed • 1: Job not yet completed. A new job cannot be started.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameters BUSY, DONE and ERROR

You can check the status of the job with the BUSY, DONE, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. With the DONE parameter, you can check whether or not a job executed successfully. The ERROR parameter is set when errors occurred during execution of "TSEND_C". The error information is output at the STATUS parameter.

The following table shows the relationship between the BUSY, DONE and ERROR parameters:

BUSY	DONE	ERROR	Description
1	-	-	The job is being processed.
0	1	0	The job was completed successfully.
0	0	1	The job ended with an error. The cause of the error is specified in the STATUS parameter.
0	0	0	No new job was assigned.

Parameters ERROR and STATUS

ERROR	STATUS* (W#16#...)	Description
0	0000	Job completed without error.
0	0001	The connection establishment is complete.
0	0003	The connection termination is complete.
0	7000	No job processing active.
0	7001	• Start execution of the job • Establish connection • Wait for connection partner
0	7002	Data was sent.
0	7003	Connection is being terminated.
0	7004	Connection established and monitored, no job processing active.

ERROR	STATUS* (W#16#...)	Description
1	80A0	Group error for error codes 80A1 and 80A2.
1	80A1	• Connection or port already being used by user. • Communication error: – The specified connection has not yet been established. – The specified connection is being terminated. Transfer via this connection is not possible. – The interface is being re-initialized.
1	80A2	Local or remote port is being used by the system.
1	80A3	Attempt being made to terminate a non-existent connection.
1	80A4	IP address of the remote endpoint of the connection is invalid, in other words, it matches the IP address of the local partner.
1	80A7	Communication error: You called the instruction with COM_RST = 1 before the send job was complete.
1	80AA	A connection is currently being established with the same connection ID by another block. Repeat the job with a new rising edge at the REQ parameter.
1	80B2	The CONNECT parameter points to a data block that was generated with the attribute "Only store in load memory".
1	80B3	Inconsistent parameter assignment: Group error for error codes 80A0 to 80A2, 80A4, 80B4 to 80B9.
1	80B4	You have violated one or both of the following conditions for passive connection establishment (active_est = FALSE) when using the ISO-on-TCP protocol variant (connection_type = B#16#12): "local_tsap_id_len >= B#16#02", and/or "local_tsap_id[1] = B#16#E0".
1	80B5	Only passive connection establishment is permitted for connection type 13 = UDP.
1	80B6	Parameter assignment error in the connection_type parameter of the data block for connection description.
1	80B7	Error in one of the following parameters of the data block for connection description: block_length, local_tsap_id_len, rem_subnet_id_len, rem_staddr_len, rem_tsap_id_len, next_staddr_len.
1	8085	The LEN parameter is larger than the highest permitted value.
1	8086	The ID parameter within the CONNECT parameter is outside the permitted range.
1	8087	Maximum number of connections reached; no additional connection possible.
1	8088	The value at the LEN parameter does not correspond to the receive area set at the DATA parameter.
1	8089	The CONNECT parameter does not point to a data block.
1	8091	Maximum nesting depth exceeded.
1	809A	The CONNECT parameter points to a field that does not correspond to the length of the connection description.
1	809B	The ID of the local device in the connection description does not correspond to the CPU.
1	80C3	• All connection resources are in use. • A block with this ID is already being processed in a different priority group.
1	80C4	Temporary communication error: • The connection cannot be established at this time. • The interface is receiving new parameters or the connection is being established. • The configured connection is currently being removed by a "TDISCON" instruction. • The connection used is being terminated by a call with COM_RST= 1.
1	80C6	Remote network error. Remote partner cannot be reached.

ERROR	STATUS* (W#16#...)	Description
1	8722	Parameter CONNECT: The source area is invalid. The area does not exist in the DB.
1	873A	Parameter CONNECT: Access to the connection description is not possible (for example, DB does not exist).
1	877F	Parameter CONNECT: Internal error.
1	8822	Parameter DATA: Invalid source area, the area does not exist in the DB.
1	8824	Parameter DATA: Area error in the VARIANT pointer.
1	8832	Parameter DATA: The DB number is too high.
1	883A	Parameter CONNECT: Access to specified connection data not possible (e.g. because the DB does not exist).
1	887F	Parameter DATA: Internal error, e.g. invalid VARIANT reference.
1	893A	Parameter DATA: Access to send area not possible (e.g. because the DB does not exist).
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".		

Note

Error messages of the instructions "TCON", "TSEND", "T_DIAG" and "TDISCON"

Internally, the "TSEND_C" instruction uses the instructions "TCON (Page 3662)", "TSEND (Page 3674)", "T_DIAG (Page 3694)", "T_RESET (Page 3693)" and "TDISCON (Page 3669)". The error messages of these instructions can also be output at the STATUS parameter. The meaning of the error codes is described in the corresponding instructions. In the event of identical error codes for internally used instructions with different meanings, the instance data block of "TSEND_C" can be used to determine which instruction output the error.

TSEND_C: Send data via Ethernet

Description

The "TSEND_C" instruction sets up and establishes a communications connection. Once the connection has been set up and established, it is automatically maintained and monitored by the CPU.

The instruction is executed asynchronously and has the following functions:

- Setting up and establishing a communication connection
- Sending data via an existing communication connection
- Terminating or resetting the communication connection

Internally, the instruction "TSEND_C" uses the communication instructions TCON", "TSEND", "T_DIAG", "T_RESET" and "TDISCON".

Setting up and establishing a communication connection

The communication connection is set up and established with CONT=1. For information on the number of possible communication connections, refer to the technical specifications for your CPU. The connection description specified at the CONNECT parameter is used to set up the communication connection. The following connection types can be used:

- Programmed connections (structure of connection via "TCON"):
  - TCP / UDP: Connection description via the TCON_IP_v4 system data type
  - ISO-on-TCP: Connection description via the TCON_IP_RFC system data type
  - ISO: Connection description via the TCON_ISOnative system data type (for CP1543-1 only)
- Configured connections
  - Specify an existing connection in the TCON_Configured system data type.

An existing connection is terminated and the connection which has been set up is removed when the CPU goes into STOP mode. To set up and establish the connection again, you must execute "TSEND_C" again.

Sending data via an existing communication connection

The send job is executed when a rising edge is detected at the REQ parameter. As described above, the communication connection is established first.

You specify the send area with the DATA parameter. This includes the address and the length of the data to be sent. Do not use a data area with the data type BOOL or Array of BOOL at the DATA parameter. With the LEN parameter, you specify the maximum number of bytes sent with a send job. If you use a send area with optimized access at the DATA parameter, the LEN parameter must have the value "0".

The data to be sent must not be edited until the send job is completed.

Terminating and resetting the communication connection

The communication connection is terminated when the CONT parameter is set to "0" even if an ongoing data transmission is not complete yet. This does not apply if you are using a configured connection for "TSEND_C".

The connection can be reset at any time by setting the parameter COM_RST to "1". This terminates the existing communication connection and a new connection is established. If data is being transferred at this time, this can lead to data loss.

Parameters

The following table shows the parameters of the "TSEND_C" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L, T, C or constant	Starts the send job on a rising edge.
CONT	Input	BOOL	I, Q, M, D, L	Controls the communication connection: • 0: Disconnect the communication connection. • 1: Establish and maintain the communication connection.
LEN	Input	UDINT	I, Q, M, D, L or constant	Optional parameter (hidden) Maximum number of bytes to be sent with the job. If you use a send area with optimized access at the DATA parameter, the value "0" must be used at the LEN parameter.
CONNECT	InOut	VARIANT	D	Pointer to the structure of the connection description: • Programmed connection: – For TCP or UDP, use the TCON_IP_v4 system data type For description, refer to:Auto-Hotspot – For ISO-on-TCP, use the TCON_IP_RFC system data type For description, refer to: Auto-Hotspot – For ISO, use the TCON_ISOnative system data type (only for CP1543-1) For description, refer to instruction "TCON (Page 3664)". • Configured connection: – For existing connections, use the TCON_Configured system data type For a description see "System data type for configured connections" below
DATA	InOut	VARIANT	I, Q, M, D, L	Pointer to the send area containing the address and the length of the data to be sent.
ADDR	InOut	VARIANT	D	Optional parameter (hidden) Pointer to the address of the recipient.
COM_RST	InOut	BOOL	I, Q, M, D, L	Optional parameter (hidden) Resets the connection: • 0: Irrelevant • 1: The existing connection is reset. The COM_RST parameter is reset after evaluation by the "TSEND_C" instruction and should not, therefore, be interconnected statically.

Parameter	Declaration	Data type	Memory area	Description
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Send job not yet started or still in progress. • 1: Send job executed without error. This state is only displayed for one cycle. The output parameter DONE is set if an intermediate step was completed successfully during processing (connection establishment, sending, connection termination) and if the execution of "TSEND_C" was completed successfully.
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Send job not yet started or already completed. • 1: Send job not yet completed. A new send job cannot be started.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred during connection establishment, data transmission or connection termination. The output parameter ERROR can be set due to an error in the "TSEND_C" instruction or the communication instructions used internally.
STATUS	Output	WORD	I, Q, M, D, L	Status of instruction (see the "ERROR and STATUS" parameters" description).

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

REQ, CONT and COM_RST parameters

The parameter CONT controls the connection establishment of the "TSEND_C" instruction regardless of the REQ parameter. The behavior of the CONT parameter partially depends on whether a programmed or a configured connection is used:

- With CONT = "0": No data is sent (regardless of whether a programmed or a configured connection is used).
- When changing CONT = "0" to "1":
  - With a programmed connection, it is established with "TCON".
  - With a configured connection, it is checked with "T_DIAG".
- With CONT = "1":
  - As long as no data is sent (REQ="0"), the connection is checked with "T_DIAG".
  - If the internally used communication instructions signal that no connection end point exists, the connection is automatically reestablished with "TCON".
- When changing CONT = "1" to "0":
  - With a programmed connection, it is terminated with "TDISCON".
  - With a configured connection, it is reset with "T_RESET".

The parameter COM_RST resets the connection when changing from "0" to "1":

- If a connection is established, it is reset with "T_RESET" (regardless of whether a programmed or configured connection is used).
- If no connection is established, the setting of the parameter has no effect.

The REQ and COM_RST parameters only have an effect if CONT has been set to "1". The following table shows the relationship between the REQ, CONT and COM_RST parameters:

REQ	CONT	COM_RST	Status of the instruction	Description
irrelevant	0	irrelevant	Not yet executed	No job active (STATUS = 7000).
irrelevant	0	irrelevant	Initialization	Connection is being terminated. The instruction is being reset.
irrelevant	0 > 1	irrelevant	Connection establishment	Connection is being established. Data is not being transferred yet.
0	1	0	Connection established	The connection is established and is monitored with the instruction "T_DIAG".
irrelevant	1	0 > 1	Connection established	The connection is interrupted by "T_RESET" briefly and reset.
0 > 1	1	0	Connection established	Instruction starts sending.
irrelevant	1	0 > 1	Data is being sent	Data transmission is interrupted. The connection is being reset.

System data type for configured connections

For configured connections at the CONNECT parameter, use the following structure for connection description to TCON_Configured:

Byte	Parameter	Data type	Start value	Description
0 … 1	InterfaceID	HW_ANY	-	Hardware identifier of the local interface (value range: 0 to 65535).
2 … 3	ID	CONN_OUC	-	Reference to the connection (value range: 1 to 4095). Enter the connection ID of the existing connection.
4	ConnectionType	BYTE	-	Connection type Select 254 (decimal) for a configured connection.

BUSY, DONE and ERROR parameters

You can check the status of the job with the BUSY, DONE, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. With the DONE parameter, you can check whether or not a send job executed successfully. The ERROR parameter is set when errors occurred during execution of "TSEND_C". The error information is output at the STATUS parameter.

The following table shows the relationship between the BUSY, DONE and ERROR parameters:

DONE	BUSY	ERROR	Description
0	0	0	The instruction has not been executed yet (no rising edge at REQ parameter).
0	1	0	The instruction is being executed and calls the internally used communication instructions.
1	0	0	The send job was completed successfully. "0000" is output at the STATUS parameter. DONE = "1" is only displayed for one cycle.
0	0	1	The execution of the instruction or an intermediate step during processing was terminated with an error. If there is a subsequent error due to an internally used communication instruction, the error that occurred first during processing is displayed. This state is only displayed for one cycle.

ERROR and STATUS parameters

ERROR	STATUS* (W#16#...)	Description
0	0000	Send job was executed without error.
0	0001	Communication connection established.
0	0003	Communication connection closed.
0	7000	No active send job execution; no communication connection established.
0	7001	Initial call for establishing a connection.
0	7002	Second call for establishing a connection
0	7003	Communication connection is being terminated.
0	7004	Communication connection has been established and is being monitored. No send job execution active.
0	7005	Data transmission in progress.
1	80A1	• Connection or port already being used by user. • Communication error: – The specified connection has not yet been established. – The specified connection is being terminated. Transfer via this connection is not possible. – The interface is being re-initialized.
1	80A3	The nested "T_DIAG" instruction has reported that the connection has closed.
1	80A4	IP address of the remote endpoint of the connection is invalid or it matches the IP address of the local partner.
1	80A7	Communication error: You called the instruction with COM_RST = 1 before the send job was complete.
1	80AA	A connection is currently being established with the same connection ID by another block. Repeat the job with a new rising edge at the REQ parameter.
1	80B4	You have violated one or both of the following conditions for passive connection establishment (active_est = FALSE) when using the ISO-on-TCP protocol variant (connection_type = B#16#12): • local_tsap_id_len >= B#16#02 • local_tsap_id[1] = B#16#E0
1	80B5	Only passive connection establishment is permitted for connection type 13 = UDP.
1	80B6	Parameter assignment error in the connection_type parameter of the data block for connection description.

ERROR	STATUS* (W#16#...)	Description
1	80B7	Error in one of the following parameters of the data block for connection description: block_length, local_tsap_id_len, rem_subnet_id_len, rem_staddr_len, rem_tsap_id_len, next_staddr_len.
1	8085	The LEN parameter is larger than the highest permitted value.
1	8086	The ID parameter within the CONNECT parameter is outside the permitted range.
1	8087	Maximum number of connections reached; no additional connection possible.
1	8088	The value at the LEN parameter does not correspond to the receive area set at the DATA parameter.
1	8089	The CONNECT parameter does not point to a data block.
1	8091	Maximum nesting depth exceeded.
1	809A	The CONNECT parameter points to a field that does not correspond to the length of the connection description.
1	809B	InterfaceID is invalid. It is either zero or it does not point to a local CPU interface or a CP.
1	80C3	• All connection resources are in use. • A block with this ID is already being processed in a different priority group.
1	80C4	Temporary communication error: • The connection cannot be established at this time. • The interface is receiving new parameters or the connection is being established. • The configured connection is currently being removed by a "TDISCON (Page 3669)" instruction. • The connection used is being terminated by a call with COM_RST = 1.
1	80C6	Remote network error. Remote partner cannot be reached.
1	8722	Parameter CONNECT: The source area is invalid. The area does not exist in the DB.
1	873A	Parameter CONNECT: Access to the connection description is not possible (for example, because the DB is not available).
1	877F	Parameter CONNECT: Internal error.
1	8822	Parameter DATA: Invalid source area, the area does not exist in the DB.
1	8824	Parameter DATA: Area error in the VARIANT pointer.
1	8832	Parameter DATA: The DB number is too high.
1	883A	Parameter CONNECT: Access to specified connection data not possible (e.g. because the DB does not exist).
1	887F	Parameter DATA: Internal error, e.g. invalid VARIANT reference.
1	893A	Parameter DATA: Access to send area not possible (e.g. because the DB does not exist).
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on switching display formats, refer to "See also".		

Note

Error messages of the instructions "TCON", "TSEND", "T_DIAG", "T_RESET" and "TDISCON"

Internally, the "TSEND_C" instruction uses the instructions "TCON (Page 3664)", "TSEND (Page 3674)", "T_DIAG (Page 3694)", "T_RESET (Page 3693)" and "TDISCON (Page 3669)". The error messages of these instructions can also be output at the STATUS parameter. The meaning of the error codes is described in the corresponding instructions. In the event of identical error codes for internally used instructions with different meanings, the instance data block of "TSEND_C" can be used to determine which instruction output the error.

TRCV_C: Receive data via Ethernet

TRCV_C: Receive data via Ethernet

Description

The "TRCV_C" instruction is executed asynchronously and has the following functions:

1. **Setting up and establishing a communication connection:**
   "TRCV_C" sets up and establishes a TCP or ISO-on-TCP communication connection. Once the connection has been set up and established, it is automatically maintained and monitored by the CPU.
   The connection description specified at the CONNECT parameter is used to set up the communication connection. To establish a connection, the CONT parameter must be set to the value "1". Once the connection is successfully established, the DONE parameter is set to "1".
   An existing connection is terminated and the connection which has been set up is removed when the CPU goes into STOP mode. To set up and establish the connection again, you must execute "TRCV_C" again.
   For information on the number of possible communication connections, refer to the technical specifications for your CPU.
2. **Receiving data via an existing communication connection:**
   If the EN_R parameter is set to the value "1", receipt of data is enabled. When receiving data (rising edge at the EN_R parameter), the CONT parameter must have the value TRUE in order to establish or maintain a connection.
   The received data is entered in a receive area. You specify the length of the receive area either with the LEN parameter (if LEN <> 0) or with the length information of the DATA parameter (if LEN = 0) in accordance with the protocol variant used. If you use purely symbolic values at the DATA parameter, the LEN parameter must have the value "0".
   After data has been received successfully, the signal state at the DONE parameter is "1". If errors occur in the data transfer, the DONE parameter is set to "0".
3. **Terminating the communication connection:**
   The communication connection is terminated immediately when the CONT parameter is set to "0".

TRCV_C is executed again when the COM_RST parameter is set. This terminates the existing communication connection and a new connection is established. If data is being received when it executes again, this can lead to a loss of data.

Receive modes of TRCV_C

The following table shows how the received data is entered in the receive area.

Protocol variant	Availability of data in the receive area	connection_type parameter of the connection description	Parameter LEN
TCP (Ad-hoc mode)	The data is immediately available.	Hexadecimal value: B#16#11 Integer value: 17	0
TCP (Receipt of data with specified length)	The data is available as soon as the data length specified at the LEN parameter has been fully received.	Hexadecimal value: B#16#11 Integer value: 17	1 to 8192
ISO on TCP (Message-oriented data transfer)	The data is available as soon as the data length specified at the LEN parameter has been fully received.	Hexadecimal value: B#16#12 Integer value: 18	• 1 to 1452, if a CP is used. • 1 to 8192, if no CP is used.

TCP (Ad-hoc mode)

The ad-hoc mode is only available with the TCP protocol variant. You use the ad-hoc mode to receive data with dynamic length with the "TRCV" instruction.

You set ad-hoc mode by assigning the value "0" to the LEN parameter. All data types can be used for data blocks with standard access when you use ad-hoc mode. Only ARRAY of BYTE or data types with a length of 8 bits can be used for data blocks with optimized access (e.g., CHAR, USINT, SINT, etc.). The data length actually received is output at the RCVD_LEN parameter.

TCP (Receipt of data with specified length)

You use the value of the LEN parameter to specify the length for the data receipt. The data receipt is not complete until the length of data specified at the LEN parameter has been completely received. Only then is the data available in the receive area (DATA parameter). The actually received data length in bytes at the RCVD_LEN parameter corresponds to the data length at the LEN parameter after receipt.

ISO on TCP (Message-oriented data transfer)

Complete message blocks are sent via a connection with the protocol variant ISO on TCP; these are recognized as such by the recipient. When using ISO on TCP, "TRCV_C" signals data receipt as soon as the message block has been completely received. The receive area is defined by the LEN and DATA parameters. If the receive buffer (DATA parameter) is too small for the sent data, "TRCV_C" signals an error. The actually received data length in bytes at the RCVD_LEN parameter corresponds to the data length at the LEN parameter after receipt.

Parameters

The following table shows the parameters of the "TRCV_C" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN_R	Input	BOOL	I, Q, M, D, L	Receive enable
CONT	Input	BOOL	I, Q, M, D, L	Controls the communication connection: • 0: Disconnect the communication connection • 1: Establish and maintain the communication connection When receiving data (rising edge at the EN_R parameter), the CONT parameter must have the value TRUE in order to establish or maintain a connection.
LEN	Input	UINT	I, Q, M, D, L or constant	Maximum length of the data to be received (maximum value: 8192 bytes). If you use purely symbolic values at the DATA parameter, the LEN parameter must have the value "0".
CONNECT	InOut	TCON_Param	D	Pointer to the connection description See also: Auto-Hotspot
DATA	InOut	VARIANT	I, Q, M, D, L	Pointer to the receive area
COM_RST	InOut	BOOL	I, Q, M, D, L	Restarts the instruction: • 0: Irrelevant • 1: Complete restart of the instruction causing an existing connection to be terminated
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or still in progress • 1: Job completed without error
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or already completed • 1: Job not yet completed. A new job cannot be started
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter ERROR: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction
RCVD_LEN	Output	UDINT	I, Q, M, D, L	Amount of data actually received in bytes

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameters BUSY, DONE and ERROR

You can check the status of the job with the BUSY, DONE, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. With the DONE parameter, you can check whether or not a job executed successfully. The ERROR parameter is set when errors occurred during execution of "TRCV_C". The error information is output at the STATUS parameter.

The following table shows the relationship between the BUSY, DONE and ERROR parameters:

BUSY	DONE	ERROR	Description
1	-	-	The job is being processed.
0	1	0	The job was completed successfully.
0	0	1	The job ended with an error. The cause of the error is output at the STATUS parameter.
0	0	0	No new job was assigned.

Parameters ERROR and STATUS

ERROR	STATUS* (W#16#...)	Description
0	0000	Job completed without error.
0	0001	The connection establishment is complete.
0	0003	The connection termination is complete.
0	7000	No job processing active.
0	7001	• Start execution of the job • Establish connection • Wait for connection partner
0	7002	Data is being received.
0	7003	Connection is being terminated.
0	7004	• Connection established and monitored • No job processing active
0	7006	Data is currently being received.
1	8085	• The LEN parameter is larger than the highest permitted value. • The value at the LEN or DATA parameter was changed after the first call.
1	8086	The ID parameter is outside the permitted range.
1	8087	Maximum number of connections reached; no additional connection possible
1	8088	The value at the LEN parameter does not correspond to the receive area set at the DATA parameter.
1	8089	The CONNECT parameter does not point to a data block.
1	8091	Maximum nesting depth exceeded.
1	809A	The CONNECT parameter points to a field that does not correspond to the length of the connection description.
1	809B	The ID of the local device (local_device_id) in the connection description does not correspond to the CPU.
1	80A0	Group error for error codes W#16#80A1 and W#16#80A2.
1	80A1	• Connection or port already being used by user. • Communication error: – The specified connection has not yet been established. – The specified connection is being terminated. Transfer via this connection is not possible. – The interface is being re-initialized.
1	80A2	Local or remote port is being used by the system.

ERROR	STATUS* (W#16#...)	Description
1	80A3	• Attempt being made to re-establish an existing connection. • Attempt being made to terminate a non-existent connection.
1	80A4	IP address of the remote endpoint of the connection is invalid, in other words, it matches the IP address of the local partner.
1	80A7	Communication error: You called the instruction with COM_RST = 1 before the send job was complete.
1	80B2	The CONNECT parameter points to a data block that was generated with the attribute "Only store in load memory".
1	80B3	Inconsistent parameter assignment: Group error for error codes W#16#80A0 to W#16#80A2, W#16#80A4, W#16#80B4 to W#16#80B9.
1	80B4	You have violated one or both of the following conditions for passive connection establishment (active_est = FALSE) when using the ISO-on-TCP protocol variant (connection_type = B#16#12): "local_tsap_id_len >= B#16#02", and/or "local_tsap_id[1] = B#16#E0".
1	80B5	Only passive connection establishment is permitted for connection type 13 = UDP.
1	80B6	Parameter assignment error in the connection_type parameter of the data block for connection description.
1	80B7	Error in one of the following parameters of the data block for connection description: block_length, local_tsap_id_len, rem_subnet_id_len, rem_staddr_len, rem_tsap_id_len, next_staddr_len.
1	80C3	• All connection resources are in use. • A block with this ID is already being processed in a different priority group.
1	80C4	Temporary communication error: • The connection cannot be established at this time. • The interface is receiving new parameters or the connection is being established. • The configured connection is currently being removed by a "TDISCON" instruction. • The connection used is being terminated by a call with COM_RST= 1.
1	80C6	The remote partner cannot be reached (network error).
1	8722	Error in the CONNECT parameter: Invalid source area (area not declared in data block).
1	873A	Error in the CONNECT parameter: Access to connection description is not possible (no access to data block).
1	877F	Error in the CONNECT parameter: Internal error
1	8922	Parameter DATA: Invalid target area; the area does not exist in the DB.
1	8924	Parameter DATA: Area error in the VARIANT pointer.
1	8932	Parameter DATA: The DB number is too high.
1	893A	Parameter CONNECT: Access to specified connection data not possible (e.g. because the DB does not exist).
1	897F	Parameter DATA: Internal error, e.g. invalid VARIANT reference.
1	8A3A	Parameter DATA: No access to the data area, for example because the data block does not exist.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".		

Note

Error messages of the instructions "TCON", "TRCV" and "TDISCON"

Internally, the TRV_C instruction uses the "TCON (Page 3662)", "TRCV (Page 3677)" and "TDISCON (Page 3669)" instructions. The error messages of these instructions are contained in the respective descriptions.

TRCV_C: Receive data via Ethernet

Description

The "TRCV_C" instruction is executed asynchronously and implements the following functions in sequence:

- Setting up and establishing a communication connection
- Receiving data via an existing communication connection
- Terminating or resetting the communication connection

Internally, the instruction "TRCV_C" uses the communication instructions TCON", "TRCV", "T_DIAG", "T_RESET" and "TDISCON".

Setting up and establishing a communication connection

The communication connection is set up and established with CONT=1. For information on the number of possible communication connections, refer to the technical specifications for your CPU. The connection description specified at the CONNECT parameter is used to set up the communication connection. The following connection types can be used:

- Programmed connections (structure of connection via "TCON"):
  - TCP / UDP: Connection description via the TCON_IP_v4 system data type
  - ISO-on-TCP: Connection description via the TCON_IP_RFC system data type
  - ISO: Connection description via the TCON_ISOnative system data type (for CP1543-1 only)
- Configured connections
  - Specify an existing connection in the TCON_Configured system data type.

An existing connection is terminated and the connection which has been set up is removed when the CPU goes into STOP mode. To set up and establish the connection again, you must execute "TRCV_C" again.

Receiving data via an existing communication connection

Receipt of data is enabled when the EN_R parameter is set to the value "1". The received data is entered in a receive area. You specify the length of the receive area either with the LEN parameter (if LEN <> 0) or with the length information of the DATA parameter (if LEN = 0), depending on the protocol variant being used. If you use purely symbolic values at the DATA parameter, the LEN parameter must have the value "0".

Receive modes of TRCV_C:

- **TCP (Ad-hoc mode)**
  The ad-hoc mode is only available with the TCP protocol variant. You use the ad-hoc mode to receive data with dynamic length with the "TRCV_C" instruction.
  You set ad-hoc mode by assigning the value "1" to the ADHOC parameter. All data types can be used for data blocks with standard access when you use ad-hoc mode. Only ARRAY of BYTE or data types with a length of 8 bits can be used for data blocks with optimized access (e.g., CHAR, USINT, SINT, etc.). The data length actually received is output at the RCVD_LEN parameter.
- **TCP (Receipt of data with specified length)**
  Assign the value "0" to the ADHOC parameter for receipt of data with specified length. If ad-hoc mode is disabled, the data reception is not complete until the length of data specified at the LEN parameter has been completely received. Only then is the data available in the receive area (DATA parameter). The actually received data length in bytes at the RCVD_LEN parameter corresponds to the data length at the LEN parameter after receipt.
- **ISO on TCP (Message-oriented data transfer)**
  Complete message blocks are sent via a connection with the protocol variant ISO on TCP; these are recognized as such by the recipient. The receive area is defined by the LEN and DATA parameters. If the receive buffer (DATA parameter) is too small for the sent data, "TRCV_C" signals an error. The actually received data length in bytes at the RCVD_LEN parameter corresponds to the data length at the LEN parameter after receipt.

The following table shows how the received data is entered in the receive area.

Protocol variant	Availability of data in the receive area	connection_type parameter of the connection description	LEN parameter
TCP (Ad-hoc mode)	The data is immediately available.	Hexadecimal value: B#16#11 Integer value: 17	1 up to maximum length (depending on the CPU)
TCP (Receipt of data with specified length)	The data is available as soon as the data length specified at the LEN parameter has been fully received.	Hexadecimal value: B#16#11 Integer value: 17	1 to 8192
ISO on TCP (Message-oriented data transfer)	The data is available as soon as the data length specified at the LEN parameter has been fully received.	Hexadecimal value: B#16#12 Integer value: 18	1 to 8192

Terminating the communication connection

The communication connection is terminated when the CONT parameter is set to "0" even if an ongoing data transmission is not complete yet. This does not apply if you are using a configured connection, however.

The connection can be reset at any time by setting the parameter COM_RST to "1". This terminates the existing communication connection and a new connection is established. If data is being transferred at this time, this can lead to data loss.

Parameters

The following table shows the parameters of the "TRCV_C" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN_R	Input	BOOL	I, Q, M, D, L, T, C or constant	Receive enable
CONT	Input	BOOL	I, Q, M, D, L	Controls the communication connection: • 0: Disconnect the communication connection. • 1: Establish communication connection and maintain after receipt of data.
LEN	Input	UDINT	I, Q, M, D, L or constant	Maximum length of the data to be received. If you use a receive area with optimized access at the DATA parameter, the value "0" must be used at the LEN parameter.
ADHOC	Input	BOOL	I, Q, M, D, L or constant	Optional parameter (hidden) Use ad-hoc mode for the TCP protocol variant.
CONNECT	InOut	VARIANT	D	Pointer to the connection description • Programmed connection: – For TCP or UDP, use the structure TCON_IP_v4 For description, refer to:Auto-Hotspot – For ISO-on-TCP, use the structure TCON_IP_RFC For description, refer to: Auto-Hotspot – For ISO, use the structure TCON_ISOnative (only for CP1543-1) For description, refer to instruction "TCON (Page 3664)": "Structure of the connection description according to TCON_ISOnative" • Configured connection: – For existing connections, use the TCON_Configured system data type. For a description, see "System data type for configured connections" below.
DATA	InOut	VARIANT	I, Q, M, D, L	Pointer to the receive area.
ADDR	InOut	VARIANT	D	Optional parameter (hidden) Pointer to the address of the sender with connection type UDP.

Parameter	Declaration	Data type	Memory area	Description
COM_RST	InOut	BOOL	I, Q, M, D, L	Optional parameter (hidden) Resets the connection: • 0: Irrelevant • 1: The existing connection is reset. The COM_RST parameter is reset after evaluation by the "TRCV_C" instruction and should not, therefore, be interconnected statically.
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Receipt not yet started or still in progress. • 1: Receipt executed without error. This state is only displayed for one cycle. The output parameter DONE is set if an intermediate step was completed successfully during processing (connection establishment, receipt, connection termination) and if the execution of "TRCV_C" was completed successfully.
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Receipt not yet started or already completed. • 1: Receipt not yet completed. A new send job cannot be started.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred during connection establishment, data reception or connection termination. The output parameter ERROR can be set due to an error in the "TRCV_C" instruction or the communication instructions used internally.
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction
RCVD_LEN	Output	UDINT	I, Q, M, D, L	Amount of data actually received in bytes

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

EN_R, CONT and COM_RST parameters

The parameter CONT controls the connection establishment of the "TRCV_C" instruction regardless of the EN_R parameter. The behavior of the CONT parameter partially depends on whether a programmed or a configured connection is used:

- With CONT = "0": No data is received (regardless of whether a programmed or a configured connection is used).
- When changing CONT = "0" to "1":
  - With a programmed connection, it is established with "TCON".
  - With a configured connection, it is checked with "T_DIAG".

- With CONT = "1":
  - As long as no data is received (EN_R="0"), the connection is checked with "T_DIAG".
  - If the internally used communication instructions signal that no connection end point exists, the connection is automatically reestablished with "TCON".
- When changing CONT = "1" to "0":
  - With a programmed connection, it is terminated with "TDISCON".
  - With a configured connection, it is reset with "T_RESET".

The parameter COM_RST resets the connection when changing from "0" to "1":

- If a connection is established, it is reset with "T_RESET" (regardless of whether a programmed or configured connection is used).
- If no connection is established, the setting of the parameter has no effect.

The EN_R and COM_RST parameters only have an effect if CONT has been set to "1". The following table shows the relationship between the EN_R, CONT and COM_RST parameters:

EN_R	CONT	COM_RST	Status of the instruction	Description
irrelevant	0	irrelevant	Not yet executed	No job active (STATUS = 7000).
irrelevant	0	irrelevant	Initialization	Connection is being terminated. The instruction is being reset.
irrelevant	0 > 1	irrelevant	Connection establishment	Connection is being established. Data is not being transferred yet.
0	1	0	Connection established	The connection is established and is monitored with the instruction "T_DIAG".
irrelevant	1	0 > 1	Connection established	The connection is interrupted by "T_RESET" briefly and reset.
0 > 1	1	0	Connection established	Instruction starts receiving.
irrelevant	1	0 > 1	Data is being received	Data transmission is interrupted. The connection is being reset.

System data type for configured connections

For configured connections at the CONNECT parameter, use the following structure for connection description to TCON_Configured:

Byte	Parameter	Data type	Start value	Description
0 … 1	InterfaceID	HW_ANY	-	Hardware identifier of the local interface (value range: 0 to 65535).
2 … 3	ID	CONN_OUC	-	Reference to the connection (value range: 1 to 4095). Enter the connection ID of the existing connection.
4	ConnectionType	BYTE	-	Connection type Select 254 (decimal) for a configured connection.

BUSY, DONE and ERROR parameters

You can check the status of the job with the BUSY, DONE, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. With the DONE parameter, you can check whether or not a job executed successfully. The ERROR parameter is set when errors occurred during execution of "TRCV_C". The error information is output at the STATUS parameter.

The following table shows the relationship between the BUSY, DONE and ERROR parameters:

DONE	BUSY	ERROR	Description
0	0	0	The instruction has not been executed yet (no rising edge at EN_R parameter).
0	1	0	The instruction is being executed and calls the internally used communication instructions.
1	0	0	The receipt has been completed successfully. "0000" is output at the STATUS parameter. DONE = "1" is only displayed for one cycle.
0	0	1	The execution of the instruction or an intermediate step during processing was terminated with an error. If there is a subsequent error due to an internally used communication instruction, the error that occurred first during processing is displayed. This state is only displayed for one cycle.

ERROR and STATUS parameters

ERROR	STATUS (W#16#...)	Description
0	0000	Receive job executed without error.
0	0001	Communication connection established.
0	0003	Communication connection closed.
0	7000	No job processing active.
0	7001	Initial call for establishing a connection.
0	7002	Second call for establishing a connection.
0	7003	Communication connection is being terminated.
0	7004	Communication connection has been established and is being monitored. No receive job processing active.
0	7006	Data is currently being received.
1	8085	• The LEN parameter is larger than the highest permitted value. • The value at the LEN or DATA parameter was changed after the first call.
1	8086	The ID parameter is outside the permitted range.
1	8087	Maximum number of connections reached; no additional connection possible
1	8088	The value at the LEN parameter does not correspond to the receive area set at the DATA parameter.
1	8089	The CONNECT parameter does not point to a data block.
1	8091	Maximum nesting depth exceeded.
1	809A	The CONNECT parameter points to a field that does not correspond to the length of the connection description.
1	809B	InterfaceID is invalid. It is either zero or it does not point to a local CPU interface or a CP.

ERROR	STATUS (W#16#...)	Description
1	80A1	• Connection or port already being used by user. • Communication error: – The specified connection has not yet been established. – The specified connection is being terminated. Transfer via this connection is not possible. – The interface is being re-initialized.
1	80A3	The nested "T_DIAG" instruction has reported that the connection has closed.
1	80A4	IP address of the remote endpoint of the connection is invalid or it matches the IP address of the local partner.
1	80A7	Communication error: You called the instruction with COM_RST = 1 before the send job was complete.
1	80AA	A connection is currently being established with the same connection ID by another block. Repeat the job with a new rising edge at the REQ parameter.
1	80B4	You have violated one or both of the following conditions for passive connection establishment (active_est = FALSE) when using the ISO-on-TCP protocol variant (connection_type = B#16#12): "local_tsap_id_len >= B#16#02", and/or "local_tsap_id[1] = B#16#E0".
1	80B5	Only passive connection establishment is permitted for connection type 13 = UDP.
1	80B6	Parameter assignment error in the connection_type parameter of the data block for connection description.
1	80B7	Error in one of the following parameters of the data block for connection description: block_length, local_tsap_id_len, rem_subnet_id_len, rem_staddr_len, rem_tsap_id_len, next_staddr_len.
1	80C3	• All connection resources are in use. • A block with this ID is already being processed in a different priority group.
1	80C4	Temporary communication error: • The connection cannot be established at this time. • The interface is receiving new parameters or the connection is being established. • The configured connection is currently being removed by a "TDISCON" instruction. • The connection used is being terminated by a call with COM_RST = 1.
1	80C6	The remote partner cannot be reached (network error).
1	8722	Error in the CONNECT parameter: Invalid source area (area not declared in data block).
1	873A	Error in the CONNECT parameter: Access to connection description is not possible (no access to data block).
1	877F	Error in the CONNECT parameter: Internal error
1	8922	Parameter DATA: Invalid target area; the area does not exist in the DB.
1	8924	Parameter DATA: Area error in the VARIANT pointer.
1	8932	Parameter DATA: The DB number is too high.
1	893A	Parameter CONNECT: Access to specified connection data not possible (e.g. because the DB does not exist).
1	897F	Parameter DATA: Internal error, e.g. invalid VARIANT reference.
1	8A3A	Parameter DATA: No access to the data area, for example because the data block does not exist.

Note

Error messages of the instructions "TCON", "TRCV" and "TDISCON"

Internally, the TRV_C instruction uses the "TCON (Page 3664)", "TRCV (Page 3677)" and "TDISCON (Page 3669)" instructions. The error messages of these instructions are contained in the respective descriptions.

TSEND_C: Send data via Ethernet (Page 3629)

TMAIL_C: Transfer email

Description of TMAIL_C

Description

You can use the "TMAIL_C" instruction to send an e-mail via the Ethernet interface of the S7-1500 CPU or S7-1200 > V4.0, a communication module (CM), or a communication processor (CP).

The instruction can only be used once the hardware has been configured and if the network infrastructure allows for a communication connection to the mail server.

You define the content of the e-mail, and the connection data, using the following parameters:

- You define the recipient addresses with the parameters TO_S and CC.
- You define the content of the e-mail with the parameters SUBJECT and TEXT.
- You can define an attachment using VARIANT pointers at the ATTACHMENT and ATTACHMENT_NAME parameters.
- The connection data is defined, and addressing and authentication for the mail server executed, using the system data type TMail_V4, TMail_V6 or TMail_FQDN at the MAIL_ADDR_PARAM parameter.
  - If you are using the interface of the S7-1500 CPU, the system data type TMail_V4 must be used. In this case, the e-mail can only be sent via SMTP.
  - Any of the system data types can be used if you are using the interface of a CM/CP. The e-mail can then also be sent via SMTPS.
- You start the sending of an e-mail with an edge change from "0" to "1" for the REQ parameter.
- The job status is indicated by the output parameters "BUSY", "DONE", "ERROR" and "STATUS".

You cannot send an SMS directly with the "TMAIL_C" instruction. Whether or not the e-mail can be forwarded by the mail server as an SMS depends on your telecommunications provider.

Note

Number of e-mails to be sent

You can send more than one e-mail simultaneously using a PLC. When a CP 1243-8 or CP 1543-1 is used, you can only send one e-mail for each CP. When two CPs are used, parallel sending of two e-mails is possible.

Operation of the instruction

The "TMAIL_C" instruction works asynchronously, which means its execution extends over multiple calls. You must specify an instance when you call the instruction "TMAIL_C".

In the following cases, the connection to the mail server will be lost:

- If the CPU switches to STOP while "TMAIL_C" is active.
- If communication problems occur at the Industrial Ethernet bus.

In this case, the transfer of the e-mail will be interrupted and it will not reach its recipient. The connection is also canceled once the instruction has been successfully executed and the e-mail sent.

Notice

Changing user programs

You can change the parts of your user program that directly affect calls of "TMAIL_C" only:

- The CPU is in "STOP" mode.
- No e-mail is being sent (REQ = 0 and BUSY = 0).

This relates, in particular, to deleting and replacing program blocks that contain "TMAIL_C" calls or calls for the instance of "TMAIL_C".

Ignoring this restriction can tie up connection resources. The automation system can change to an undefined status with the TCP/IP communication functions via Industrial Ethernet.

A warm or cold restart of the CPU is required after the changes are transferred.

Data consistency

The TO_S, CC, SUBJECT, TEXT, ATTACHMENT and MAIL_ADDR_PARAM parameters are applied by the "TMAIL_C" instruction while it is running, which means that they may only be changed after the job has been completed (BUSY = 0).

SMTP authentication

Authentication refers here to a procedure for verifying identity, for example, with a password query.

If you are using the S7-1500 CPU interface, the instruction "TMAIL_C" supports the SMTP authentication procedure AUTH-LOGIN which is required by most mail servers. For information about the authentication procedure of your mail server, please refer to your mail server manual or the website of your Internet service provider.

- Before you can use the AUTH-LOGIN authentication procedure, the "TMAIL_C" instruction requires the user name with which it is to log on to the mail server. This user name corresponds to the user name with which you set up a mail account on your mail server. It is transferred via the UserName parameter to the structure at parameter MAIL_ADDR_PARAM.
  If no user name is specified at the MAIL_ADDR_PARAM parameter, the AUTH-LOGIN authentication procedure is not used. The e-mail is then sent without authentication.
- To log on, the "TMAIL_C" instruction also requires the associated password. This password corresponds to the password you specified when you set up your mail account. It is transferred via the PassWord parameter to the structure at parameter MAIL_ADDR_PARAM.

Parameters

The following table shows the parameters of the "TMAIL_C" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L, T, C or constant	Control parameter REQUEST: Activates the sending of an e-mail upon a rising edge.
TO_S (Page 3652)	Input	STRING	D, L or constant	Recipient addresses STRING with a maximum length of 240 characters (bytes). For the e-mail address format, see the example in the parameter description.
CC (Page 3652)	Input	STRING	D, L or constant	CC recipient addresses (optional) STRING with a maximum length of 240 characters (bytes). Same e-mail address format as for the TO_S parameter. If an empty string is assigned here, the e-mail is not sent to a CC recipient.
SUBJECT	Input	STRING	D, L or constant	Subject of the e-mail STRING with a maximum length of 240 characters (bytes).
TEXT	Input	STRING	D, L or constant	Text of the e-mail (optional) STRING with a maximum length of 240 characters (bytes). If an empty string is assigned at this parameter, the e-mail is sent without text.
ATTACHMENT	Input	VARIANT	D	E-mail attachment (optional) Reference to a byte/word/double word field (ArrayOfByte, ArrayOfWord or ArrayOfDWord) with a maximum length of 64 Kb. If no value is assigned, the e-mail is sent without an attachment.

Parameter	Declaration	Data type	Memory area	Description
ATTACHMENT_NAME	Input	STRING	D, L or constant	E-mail attachment name (optional) Reference to a character string with a maximum length of 50 characters (bytes) to define the file name of the attachment. If an empty string is assigned at this parameter, the e-mail attachment will be sent with the file name "attachment.bin".
MAIL_ADDR_PARAM (Page 3652)	Input	VARIANT	D	Connection parameter and address of the e-mail server To define the connection parameters, use the structure TMail_V4, TMail_V6 or TMail_FQDN (see parameter description).
DONE (Page 3655)	Output	BOOL	I, Q, M, D, L	Status parameter • DONE = 0: Job not yet started or still executing. • DONE = 1: Job was executed without errors.
BUSY (Page 3655)	Output	BOOL	I, Q, M, D, L	Status parameter • BUSY=0: The processing of "TMAIL_C" was stopped. • BUSY = 1: E-mail transmission is not yet complete.
ERROR (Page 3655)	Output	BOOL	I, Q, M, D, L	Status parameter • ERROR = 0: No error has occurred. • ERROR = 1: An error occurred during processing. STATUS supplies detailed information on the type of error.
STATUS (Page 3656)	Output	WORD	I, Q, M, D, L	Status parameter Return value or error information of the "TMAIL_C" instruction (see parameter description).

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Note

Optional parameters

The optional parameters CC, TEXT, and ATTACHMENT are only sent with the e-mail if the corresponding parameters contain a string of length > 0.

Example

You can find an example for sending e-mails with the TMAIL_C instruction under the following link: Example: Sending an e-mail with TMAIL_C (Page 3659)

TO_S and CC parameters

Description

The TO_S and CC parameters are strings, for example, with the following content:

- <wenna@mydomain.com>, <ruby@mydomain.com>
- <admin@mydomain.com>, <judy@mydomain.com>

Note the following rules when entering the parameters:

- A space and an opening pointed bracket "<" must be entered before each address.
- A closing pointed bracket ">" must be entered after each address.
- A comma must be entered between the addresses in TO and CC.

For runtime and memory space reasons, the "TMAIL_C" instruction does not perform a syntax check of parameter TO_S or CC.

MAIL_ADDR_PARAM parameter

Description

At the MAIL_ADDR_PARAM parameter, you define the connection for sending the e-mail in the structure TMail_V4, TMail_V6 or Tmail_FQDN, and save the e-mail server address and login details.

The structure you use at the MAIL_ADDR_PARAM parameter depends on the format in which the e-mail server is to be addressed:

- TMail_V4: Addressing by IP address to IPv4.
- TMail_V6: Addressing by IP address to IPv6.
- TMail_FQDN: Addressing by fully qualified domain name (FQDN).

Which structure you can use depends on the interface addressed at the InterfaceId parameter:

- If you want to use the "TMAIL_C" instruction with the internal interface, the TMail_V4 structure must be used at the MAIL_ADDR_PARAM parameter.
- If you are using a communication processor (CP) or communication module (CM), you can use all three addressing options (IPv4, IPv6 and FQDN).

Table 11-94 **TMail_V4: Addressing the mail server by IP address (IPv4)**

Parameter	Data type	Description
TMail_V4	Struct	
InterfaceId	LADDR	Hardware identifier of the interface
ID	CONN_OUC	Connection ID
ConnectionType	BYTE	Connection type. Select 16#20 as the connection type for IPv4.
ActiveEstablished	BOOL	Status bit. Set to "1" once the connection is established.
CertIndex	BYTE	• =0: SMTP used (**S**imple **M**ail **T**ransfer **P**rotocol). SMTP must be used if the e-mail is being sent via the interface of an S7-1500 CPU. • ≠0: SMTPS used to secure the connection before it is established (with CPs/CMs). You use the CertIndex parameter to specify the certificate to be used (see "Project navigation" > "Global security settings" > "Certificate manager").
WatchDogTime	TIME	Execution watchdog. Use this parameter to define the maximum execution time for the send operation. Note: Connection establishment can take longer (approx. one minute) if the connection is slow. When you specify the WATCH_DOG_TIME parameter, remember to allow for the time required to establish the connection. The connection is terminated once the specified time has elapsed.
MailServerAddress	IP_V4	IP address of the mail server. IPv4 in the following format: XXX.XXX.XXX.XXX (decimal). Example: 192.142.131.237.
UserName	STRING[254]	Mail server login name
PassWord	STRING[254]	Mail server password
From	EMAIL_ADDR	E-mail sender address, which is defined using the following two STRING parameters. For example: "myname@mymailserver.com".
LocalPartPlusAtSign	STRING[64]	Local part of sender address, including @ sign. Example: "myname@".
FullQualifiedDomainName	STRING[254]	Fully Qualified Domain Name (FQDN for short) of the mail server. Example: "mymailserver.com".

Table 11-95 **TMail_V6: Addressing the mail server by IP address (IPv6)**

Parameter	Data type	Description
TMail_V6	Struct	
InterfaceId	LADDR	Hardware identifier of the interface
ID	CONN_OUC	Connection ID
ConnectionType	BYTE	Connection type. Select 16#21 as the connection type for IPv6.
ActiveEstablished	BOOL	Status bit. Set to "1" once the connection is established.
CertIndex	BYTE	• =0: SMTP used (**S**imple **M**ail **T**ransfer **P**rotocol). SMTP must be used if the e-mail is being sent via the interface of an S7-1500 CPU. • ≠0: SMTPS used to secure the connection before it is established (with CPs/CMs). You use the CertIndex parameter to specify the certificate to be used (see "Project navigation" > "Global security settings" > "Certificate manager").
WatchDogTime	TIME	Execution watchdog. Use this parameter to define the maximum execution time for the send operation. Note: Connection establishment can take longer (approx. one minute) if the connection is slow. When you specify the WATCH_DOG_TIME parameter, remember to allow for the time required to establish the connection. The connection is terminated once the specified time has elapsed.
MailServerAddress	IP_V6	IP address of the mail server (IPv6) in the following format: XXXX.XXXX.XXXX.XXXX.XXXX.XXXX.XXXX.XXXX (hexadecimal). The address is divided into 8 blocks of 2 bytes each (16 bytes in total). Example: 2001:db8:1f11:08d3:290:27ff:0370:2093
UserName	STRING[254]	Mail server login name
PassWord	STRING[254]	Mail server password
From	EMAIL_ADDR	E-mail sender address, which is defined using the following two STRING parameters. For example: "myname@mymailserver.com".
LocalPartPlusAtSign	STRING[64]	Local part of sender address, including @ sign. Example: "myname@".
FullQualifiedDomainName	STRING[254]	Fully Qualified Domain Name (FQDN for short) of the mail server. Example: "mymailserver.com".

Table 11-96 **TMail_FQDN: Addressing the mail server by FQDN**

Parameter	Data type	Description
TMail_V6	Struct	
TMail_FQDN	LADDR	Hardware identifier of the interface
ID	CONN_OUC	Connection ID
ConnectionType	BYTE	Connection type. Select 16#22 as the connection type for FQDN.
ActiveEstablished	BOOL	Status bit. Set to "1" once the connection is established.
CertIndex	BYTE	• =0: SMTP used (**S**imple **M**ail **T**ransfer **P**rotocol). SMTP must be used if the e-mail is being sent via the interface of an S7-1500 CPU. • ≠0: SMTPS used to secure the connection before it is established (with CPs/CMs). You use the CertIndex parameter to specify the certificate to be used (see "Project navigation" > "Global security settings" > "Certificate manager").
WatchDogTime	TIME	Execution watchdog. Use this parameter to define the maximum execution time for the send operation. Note: Connection establishment can take longer (approx. one minute) if the connection is slow. When you specify the WATCH_DOG_TIME parameter, remember to allow for the time required to establish the connection. The connection is terminated once the specified time has elapsed.
MailServerAddress	STRING[254]	FQDN (**F**ully **Q**ualified **D**omain **N**ame) of the mail server. The mail server is addressed using the fully qualified domain name. Example: "www.mymailserver.com.".
UserName	STRING[254]	Mail server login name
PassWord	STRING[254]	Mail server password
From	Struct	E-mail sender address, which is defined using the following two STRING parameters. For example: "myname@mymailserver.com".
LocalPartPlusAtSign	STRING[64]	Local part of sender address, including @ sign. Example: "myname@".
FullQualifiedDomainName	STRING[254]	Fully Qualified Domain Name (FQDN for short) of the mail server. Example: "mymailserver.com".

DONE, BUSY and ERROR parameters

Description

The output parameters DONE, BUSY and ERROR are each displayed for only one cycle if the status of the BUSY output parameter changes from "1" to "0".

The following table shows the relationship between DONE, BUSY, and ERROR. Using this table, you can determine the current status of the instruction "TMAIL_C and when the sending of the e-mail is complete.

DONE	BUSY	ER-ROR	Description
0	1	0	The job is being processed.
1	0	0	Job successfully completed.
0	0	1	The job ended with an error. The cause of the error can be found in the STATUS (Page 3656) parameter.
0	0	0	The "TMAIL_C" instruction was not assigned a (new) job.

STATUS parameter

Description

The following table shows the return values of "TMAIL_C" at the STATUS parameter:

Return value STATUS* (W#16#...):	Explanation	Notes
0000	The processing of "TMAIL_C" was completed without errors.	Error-free completion of "TMAIL_C" does not mean that the e-mail sent will necessarily arrive. Incorrectly entering the recipient addresses does not generate a status error of the "TMAIL_C" instruction. In this case, there is no guarantee that the e-mail will be sent to other recipients, even if these were entered correctly.
7001	"TMAIL_C" is active (BUSY = 1).	First call: Job triggered.
7002	"TMAIL_C" is active (BUSY = 1).	Intermediate call: Job already active.
8xxx	The processing of "TMAIL_C" was completed with an error code of the communication instructions called internally.	For detailed information, please refer to the STATUS parameter descriptions for the "TCON (Page 3664)", "TDISCON (Page 3669)", "TSEND (Page 3674)" and "TRCV (Page 3677)" communication instructions.
8010	Error during connection establishment	You can find further information on evaluation in the SFB_STATUS parameter of the instance data block. The error code displayed at the SFB_STATUS parameter is explained in the STATUS parameter description for the "TCON (Page 3664)" instruction.
8011	Error sending the data	You can find further information on evaluation in the SFB_STATUS parameter of the instance data block. The error code displayed at the SFB_STATUS parameter is explained in the STATUS parameter description for the "TSEND (Page 3674)" instruction.

Return value STATUS* (W#16#...):	Explanation	Notes
8012	Error receiving the data	You can find further information on evaluation in the SFB_STATUS parameter of the instance data block. The error code displayed at the SFB_STATUS parameter is explained in the STATUS parameter description for the "TRCV (Page 3677)" instruction.
8013	Error during connection establishment	You can find further information on evaluation in the SFB_STATUS parameter of the instance data block. The error code displayed at the SFB_STATUS parameter is explained in the STATUS parameter description for the TCON (Page 3664)" and "TDISCON (Page 3669)" instructions.
8014	Establishment of a connection is not possible.	You may have entered an incorrect mail server IP address (MailServerAddress (Page 3652)) or too short a time span (WatchDogTime (Page 3652)) for connection establishment. It is also possible that the CPU has no connection to the network or that the CPU configuration is incorrect.
8015	Incorrect data type for MAIL_ADDR_PARAM	The only valid data types are the system data types (structures) TMail_V4, TMail_V6 and TMail_FQDN.
8016	Incorrect data type for the ATTACHMENT parameter	The only valid data types are ArrayOfByte, ArrayOfWord and ArrayOfDWord.
8017	Incorrect data length for the ATTACHMENT parameter	Data length must be <= 65534 bytes.
8401	No channels available. Possible cause: There is already an e-mail connection via the CP. A second connection cannot be established in parallel.	Specific error for CP 1543
8403	A TCP/IP connection to the mail server was not possible.	Specific error for CP 1543
8405	Server has denied login request.	Specific error for CP 1543
8406	SMTP client has detected an internal SSL error or a problem with the certificate structure.	Specific error for CP 1543
8407	Request to use SSL denied.	Specific error for CP 1543
8408	Client unable to identify socket for establishing a TCP/IP connection to the mail server.	Specific error for CP 1543
8409	Writing via the connection not possible. Possible cause: The communication partner has reset the connection or the connection has been lost.	Specific error for CP 1543
8410	Reading via the connection not possible. Possible cause: The communication partner has reset the connection or the connection has been lost.	Specific error for CP 1543

Return value STATUS* (W#16#...):	Explanation	Notes
8411	E-mail could not be sent. Cause: Insufficient memory space to execute the send operation.	Specific error for CP 1543
8412	DNS server configured was unable to resolve the specified domain name.	Specific error for CP 1543
8413	An internal error in the DNS subsystem prevented domain name resolution.	Specific error for CP 1543
8414	Empty character string entered as domain name.	Specific error for CP 1543
8415	An internal error has occurred in the cURL module. Execution was stopped.	Specific error for CP 1543
8416	An internal error has occurred in the SMTP module. Execution was stopped.	Specific error for CP 1543
8417	Request to SMTP on a channel already in use or invalid channel ID. Execution was stopped.	Specific error for CP 1543
8418	E-mail send job aborted. Possible causes: Execution time exceeded (WatchDogTime parameter) or CP transition from start to stop.	Specific error for CP 1543
8419	Channel interrupted and cannot be used before the connection is closed.	Specific error for CP 1543
8420	Server certificate string could not be verified with CP root certificate.	Specific error for CP 1543
8421	Internal error occurred. Execution was stopped.	Specific error for CP 1543
82xx, 84xx, or 85xx	The error message originates from the mail server and corresponds, except for the "8", to the error number of the SMTP protocol. The following lines list several error codes that can occur.	You can find more detailed information on the SMTP error code and other error codes in the SMTP protocol on the Internet or in the error documentation of the mail server. You can also view the most recent error message from the mail server in your instance DB in the BUFFER1 parameter. You can find the last data sent by the "TMAIL_C" instruction under DATEN in the instance DB.
8450	Action not executed: Mailbox not available/cannot be reached	Try again later.
8451	Action aborted: Local processing error	Try again later.
8500	Syntax error: Error not recognized. This also includes the error when a command string is too long. This can also occur when the e-mail server does not support the LOGIN authentication procedure.	Check the parameters of "TMAIL_C". Try to send an e-mail without authentication. To do this, replace the content of the UserName parameter with an empty string. If no user name is specified, the LOGIN authentication procedure is not used.

Return value STATUS* (W#16#...):	Explanation	Notes
8501	Syntax error: Incorrect input at a parameter	Possible cause: Incorrect address at the TO_S or CC parameter (see also: TO_S and CC parameters (Page 3652)).
8502	Command unknown or not implemented	Check your entries, in particular the FROM parameter. It may be incomplete and you may have forgotten the "@" or "." (see also: TO_S and CC parameters (Page 3652)).
8504	Command parameters not implemented	Check your entries, in particular the FROM parameter. It may be incomplete and you may have forgotten the "@" (see also: TO_S and CC parameters (Page 3652)).
8535	SMTP authentication incomplete	You have possibly entered an incorrect user name or incorrect password.
8550	Mail server cannot be reached. You have no access rights.	You may have entered an incorrect user name or password, or the mail server may not support your login. Another cause of error could be a mistake in the domain name after the "@" or a missing "." at the TO_S, CC and FROM parameters (see also: TO_S and CC parameters (Page 3652)).
8552	Action aborted: Assigned memory size has been exceeded	Try again later.
8554	Transfer failed	Try again later.
8555	Error due to incorrect entry of the e-mail address.	If multiple addresses were entered, these need to be separated by a comma.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".		

Example: Sending an e-mail with TMAIL_C

Introduction

The following call example shows you how the TMAIL_C instruction works.

Requirements

Hardware must be configured beforehand for sending e-mail and the infrastructure of the network must allow a communication connection to the mail server. In addition, you need to create two structures to supply the input parameters of TMAIL_C: One for the e-mail attachment, the other for the connection information and address data.

E-mail attachment

The e-mail should be sent with an attachment. Create an Array of Byte with the name "Data" in a global data block as a source for the attachment. The array will be interconnected with the ATTACHMENT input parameter at a later time.

MyDBMailAttachment

	Name	Datentyp	Startwert
1	Static		
2	Data	Array[0..99] of Byte	
3	<Hinzufügen>		

Connection information and address data

You enter the connection information of the CPU and address data of the mail server in the TMail_V4 system data type:

- Create a "Par1" tag with the "TMail_V4" data type in a global data block.
- In the following structure, enter the parameters of your CPU based on the configuration and the connection data of your mail server. For more information, refer to the description of the MAIL_ADDR_PARAM (Page 3652) input parameter.

The "Par1" tag will be interconnected with the MAIL_ADDR_PARAM input parameter later.

MyDBSendMail

	Name	Datentyp	Startwert
1	Static		
2	Par1	TMail_V4	
3	InterfaceId	HW_ANY	64
4	ID	CONN_OUC	100
5	ConnectionType	Byte	16#20
6	ActiveEstablished	Bool	false
7	CertIndex	Byte	16#0
8	WatchDogTime	Time	T#5ms
9	MailServerAddress	IP_V4	
10	ADDR	Array[1..4] of Byte	
11	ADDR[1]	Byte	192
12	ADDR[2]	Byte	168
13	ADDR[3]	Byte	100
14	ADDR[4]	Byte	10
15	UserName	String[254]	'myusername'
16	PassWord	String[254]	'mypassword'
17	From	EMAIL_ADDR	
18	LocalPartPlusAt...	String[64]	'station1@'
19	FullQualifiedD...	String[254]	'mycpu.com'

Calling the instruction

Create a new function block in the SCL language with the following interfaces:

- InOut
  - Name: SendEMail
  - Data type: Bool
- Static
  - Name: STATUS
  - Data type: Word

Copy the following source code with the call for TMAIL_C to the programming window:

Call TMAIL_C

```
BEGIN
    IF #SendEMail = true THEN
     "TMAIL_C_DB"(REQ := NOT "TMAIL_C_DB".BUSY,
                  TEXT := 'The cpu switched to run',
                  ATTACHMENT := "MyDBMailAttachment".Data,
                  MAIL_ADDR_PARAM := "MyDBSendMail".Par1);
     IF ("TMAIL_C_DB".BUSY = false) AND ("TMAIL_C_DB".DONE = false)
AND
     ("TMAIL_C_DB".ERROR = false) THEN
         #SendEMail := false;
     END_IF;
     IF ("TMAIL_C_DB".DONE = false) OR ("TMAIL_C_DB".ERROR = true) THEN
         #STATUS := "TMAIL_C_DB".STATUS;
       END_IF;
    END_IF;
```

Result

This instruction must be called once with SendEMail = true. In the following calls, SendEMail should not be allocated when calling. SendEMail is reset by the instruction shown, as soon as an e-mail has been sent or an error has occurred during sending.

If the email was not sent successfully, the STATUS parameter contains the corresponding value of the STATUS parameter from the TMAIL_C instruction.

Description of TMAIL_C (Page 3648)

Other

TCON: Establishing a communication connection

TCON: Establish communication connection

Description

You use the "TCON" instruction to set up and establish a communication connection. Once the connection has been set up and established, it is automatically maintained and monitored by the CPU. "TCON" is executed asynchronously.

The connection data specified for the CONNECT and ID parameters are used to set up the communication connection. To establish the connection, a rising edge must be detected at the REQ parameter. Once the connection is successfully established, the DONE parameter is set to "1".

Number of possible connections

For information on the number of possible communication connections, refer to the technical specifications for your CPU.

Connection with TCP and ISO-on-TCP

Both communication partners call the "TCON" instruction to set up and establish the communication connection. During parameter assignment, you specify which partner is the active communication end point and which is the passive one.

If the connection aborts, for example due to a line break or due to the remote communication partner, the active partner attempts to reestablish the configured connection. You do not have to call "TCON" again. This applies only if "TCON" has been executed successfully once (DONE = 1).

An existing connection is terminated and the connection set up is removed when the "TDISCON (Page 3669)" instruction is executed or when the CPU changes to STOP mode. To set up and establish the connection again, you will need to execute "TCON" again.

Parameters

The following table shows the parameters of the "TCON" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Starts the job to establish the connection specified in the ID upon a rising edge.
ID	Input	CONN_OUC	I, Q, M, D, L or constant	Reference to the assigned connection. Range of values: W#16#0001 to W#16#0FFF
CONNECT	InOut	TCON_Param	D	Pointer to the connection description See also: Auto-Hotspot

Parameter	Declaration	Data type	Memory area	Description
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or still in progress • 1: Job completed without error
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or already completed • 1: Job not yet completed. A new job cannot be started
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter ERROR: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

BUSY, DONE and ERROR parameters

You can check the status of the job with the BUSY, DONE, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. You use the DONE parameter to check whether or not a job has been executed successfully. The ERROR parameter is set when errors occurred during execution of "TCON". The error information is output at the STATUS parameter.

The following table shows the relationship between the BUSY, DONE and ERROR parameters:

BUSY	DONE	ERROR	Description
1	0	0	The job is being processed.
0	1	0	The job was completed successfully.
0	0	1	The job ended with an error. The cause of the error is output at the STATUS parameter.
0	0	0	No new job was assigned.

ERROR and STATUS parameters

ERROR	STATUS* (W#16#...)	Explanation
0	0000	Connection successfully established.
0	7000	No job processing active
0	7001	Start job execution, establish connection.
0	7002	Connection is being established (REQ irrelevant).
1	8085	Connection ID (ID parameter) is already being used by a configured connection.
1	8086	The ID parameter is outside the valid range.
1	8087	Maximum number of connections reached; no additional connection possible
1	8089	The CONNECT parameter does not point to a data block.
1	809A	The CONNECT parameter points to a field that does not correspond to the length of the connection description.

ERROR	STATUS* (W#16#...)	Explanation
1	809B	The element InterfaceId within the TCON_xxx structure does not reference a hardware identifier of a CPU or CM/CP interface or has the value "0".
1	80A0	Group error for error codes W#16#80A1 and W#16#80A2.
1	80A2	Local or remote port is being used by the system.
1	80A3	Attempt being made to re-establish an existing connection.
1	80A4	IP address of the remote endpoint of the connection is invalid, in other words, it matches the IP address of the local partner.
1	80A5	Connection ID is already in use.
1	80A7	Communication error: You executed "TDISCON (Page 3669)" before "TCON" had completed.
1	80B2	The CONNECT parameter points to a data block that was generated with the attribute "Only store in load memory".
1	80B4	You have violated one or more of the following conditions for passive connection establishment with the ISO-on-TCP protocol variant (connection_type = B#16#12): • local_tsap_id_len >= B#16#02 • local_tsap_id[1] = B#16#E0 • With local_tsap_id_len >= B#16#03, local_tsap_id[1] is an ASCII character. • local_tsap_id[1] is an ASCII character and local_tsap_id_len >= B#16#03.
1	80B5	Only passive connection establishment is permitted for connection type 13 = UDP.
1	80B6	Parameter assignment error at the connection_type parameter of the SDT TCON_Param.
1	80B7	Error in one of the following parameters of the data block for connection description: block_length, local_tsap_id_len, rem_subnet_id_len, rem_staddr_len, rem_tsap_id_len, next_staddr_len.
1	80B8	Connection description of the structure element ID and the block parameter ID are not identical.
1	80C3	All connection resources are in use.
1	80C4	Temporary communication error: • The connection cannot be established at this time. • The interface is currently receiving new parameters. • The configured connection is currently being removed by a "TDISCON (Page 3669)" instruction.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".		

TCON: Establish communication connection

Description

You use the "TCON" instruction to set up and establish a communication connection. Once the connection has been set up and established, it is automatically maintained and monitored by the CPU. "TCON" is executed asynchronously.

The connection data specified for the CONNECT and ID parameters are used to set up the communication connection.

- At the CONNECT parameter, if possible, only use the predefined structures as created by the connection parameter assignment in the Inspector window of the program editor.
- If the CONNECT parameter is not interconnected with a structure listed in the parameter table or if the structure includes an error, the error code 8089 is output at the STATUS parameter.

To establish the connection, a rising edge must be detected at the REQ parameter. Once the connection is successfully established, the DONE parameter is set to "1".

The "TCON" ≥ V3.0 instruction can also be used with CPU S7-1200 version ≥ 4.0.

Number of possible connections

For information on the number of possible communication connections, refer to the technical specifications for your CPU.

Connection with TCP and ISO-on-TCP

Both communication partners call the "TCON" instruction to set up and establish the communication connection. During parameter assignment, you specify which partner is the active communication end point and which is the passive one.

If the connection aborts, for example due to a line break or due to the remote communication partner, the active partner attempts to reestablish the configured connection. You do not have to call "TCON" again. This applies only if "TCON" has been executed successfully once (DONE = 1).

An existing connection is terminated and the connection set up is removed when the "TDISCON (Page 3669)" instruction is executed or when the CPU changes to STOP mode. To set up and establish the connection again, you will need to execute "TCON" again.

Parameters

The following table shows the parameters of the "TCON" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Starts the job to establish the connection specified on a rising edge.
ID	Input	CONN_OUC	I, Q, M, D, L or constant	Reference to the assigned connection. Value range: W#16#0001 to W#16#0FFF

Parameter	Declaration	Data type	Memory area	Description
CONNECT	InOut	VARIANT	D	Pointer to the connection description • For TCP or UDP, use the structure TCON_IP_v4 For description, refer to: Auto-Hotspot • For ISO-on-TCP, use the structure TCON_IP_RFC For description, refer to: Auto-Hotspot • For ISO, use the structure TCON_ISOnative (only for CP1543-1) For description, refer to: "Structure of the connection description according to TCON_ISOnative"
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or still in progress • 1: Job completed without error
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or already completed • 1: Job not yet completed. A new job cannot be started
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter ERROR: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

BUSY, DONE and ERROR parameters

You can check the status of the job with the BUSY, DONE, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. You use the DONE parameter to check whether or not a job has been executed successfully. The ERROR parameter is set when errors occurred during execution of "TCON". The error information is output at the STATUS parameter.

The instruction "TCON" generates an error message in version 3.0 if an active connection establishment to a remote partner fails. Create a rising edge at the REQ parameter to establish a connection once again.

The following table shows the relationship between the BUSY, DONE and ERROR parameters:

BUSY	DONE	ERROR	Description
1	0	0	The job is being processed.
0	1	0	The job was completed successfully.
0	0	1	The job ended with an error. The cause of the error is output at the STATUS parameter.
0	0	0	No new job was assigned.

Structure of the connection description according to TCON_ISOnative

A connection description DB with a structure according to TCON_ISOnative is used to assign the communication connection parameters for ISO. The fixed data structure of the TCON_ISOnative contains all parameters that are required to establish the connection.

Byte	Parameter	Data type	Start value	Description
0 … 1	InterfaceId	HW_ANY	64	Hardware identifier of the local interface (value range: 0 to 65535).
2 … 3	ID	CONN_OUC	1	Reference to this connection (unique ID in the value range: 1 to 4095).
4	ConnectionType	BYTE	16#16	Connection type: ISO
5	ActiveEstablished	BOOL	TRUE	ID for the manner in which the connection is established: • FALSE: Passive connection establishment • TRUE: Active connection establishment
8 … 13	RemoteMacAddress	ARRAY [1..6] of BYTE	-	MAC address of the partner end point, for example, for 00-74-41-FD-AE-84: • MacAddr[1] = 00 • MacAddr[2] = 74 • MacAddr[3] = 41 • MacAddr[4] = FD • MacAddr[5] = AE • MacAddr[6] = 84
14 … 19	LocalMacAddress	ARRAY [1..6] of BYTE	-	MAC address of the local end point, for example, for 00-74-41-FD-AE-84: • MacAddr[1] = 00 • MacAddr[2] = 74 • MacAddr[3] = 41 • MacAddr[4] = FD • MacAddr[5] = AE • MacAddr[6] = 84
20 … 53	RemoteTSelector	Struct	-	TSelector of the remote connection partner: • Bytes 20 to 21 = TSelLength • Bytes 22 to 53: = TSel[1-32]
	TSelLength	UINT	-	Value range from 0 to 32
	TSel	ARRAY [1..32] of BYTE	-	Value range in each case 0 to 255 in bytes
54 … 87	LocalTSelector	Struct	-	TSelector of the remote connection partner: • Bytes 20 to 21 = TSelLength • Bytes 22 to 53: = TSel[1-32]
	TSelLength	UINT		Value range from 0 to 32
	TSel	ARRAY [1..32] of BYTE	-	Value range in each case 0 to 255 in bytes
88 … 89	CrRetransmitionTime	UINT	-	Duration until connection attempt is repeated in seconds.

Byte	Parameter	Data type	Start value	Description
90 .. . 91	DataRetransmition-Time	UINT	100 ms	Duration until data transfer is repeated in milliseconds.
92 .. . 93	MaxRetransmition-Count	UINT	-	Maximum number of repetitions.
94 .. . 95	InactivityTime	UINT	-	in seconds
96 .. . 97	WindowTime	UINT		in seconds

ERROR and STATUS parameters

ERROR	STATUS* (W#16#...)	Explanation
0	0000	Connection successfully established.
0	7000	No job processing active
0	7001	Start job execution, establish connection.
0	7002	Connection is being established (REQ irrelevant).
1	8085	Connection ID (ID parameter) is already being used by a configured connection.
1	8086	The ID parameter is outside the valid range.
1	8087	Maximum number of connections reached; no additional connection possible
1	8089	The CONNECT parameter does not point to a connection description or the connection description was created manually.
1	809A	The structure at the CONNECT parameter is not supported or the length is invalid.
1	809B	The element InterfaceId within the TCON_xxx structure does not reference a hardware identifier of a CPU or CM/CP interface or has the value "0".
1	80A2	Local or remote port is being used by the system. The following ports are reserved locally: 20, 21, 80, 102, 135, 161, 162, 443, 34962, 34963, 34964 as well as the area 49152 to 65535.
1	80A3	ID is used by a connection created by the user program, which uses the same connection description at the CONNECT parameter.
1	80A4	IP address of the remote endpoint of the connection is invalid or it corresponds to the IP address of the local partner.
1	80A7	Communication error: You executed "TDISCON (Page 3669)" before "TCON" had completed.
1	80B4	Only with TCON_IP_RFC: The local T selector was not specified or the first byte does not contain the value 0x0E (only with a length of T selector = 2) or the local T selector starts with "SIMATIC-".
1	80B5	Only passive connection establishment is permitted for connection type 13 = UDP (parameter ActiveEstablished of the structure TCON_IP_v4 / TCON_PARAM has the value TRUE).
1	80B6	Parameter assignment error in the ConnectionType parameter of the data block for connection description. • Only valid with TCON_IP_v4: 0x11, 0x0B and 0x13. • Only valid with TCON_IP_RFC: 0x0C and 0x12

ERROR	STATUS* (W#16#...)	Explanation
1	80B7	With TCON_IP_v4: • TCP (active connection establishment): Remote port is "0". • TCP (passive connection establishment): Local port is "0". • UDP: Local port is "0". With TCON_IP_RFC: • Local (LocalTSelector) or remote (RemoteTSelector) T selector was specified with a length of more than 32 bytes. • For TSelLength of the T selector (local or remote), a length greater than 32 was entered. • Error in the length of the IP address of the specific connection partner.
1	80B8	Parameter ID in the local connection description (structure at CONNECT parameter) and parameter ID of the instruction are different.
1	80C3	All connection resources are in use.
1	80C4	Temporary communication error: • The connection cannot be established at this time. • The interface is currently receiving new parameters. • The configured connection is currently being removed by a "TDISCON (Page 3669)" instruction.
1	80C5	The connection partner refuses to establish the connection, has terminated the connection or actively ended it.
1	80C6	The connection partner cannot be reached (network error).
1	80C7	Execution timeout.
1	80C8	Value at the ID parameter is already being used by a connection that was created using the user program. The connection uses the identical ID, but different connection settings at the parameter CONNECT.
1	80C9	Validation of the connection partner failed. The connection partner that wants to establish the connection does not match the defined partner of the structure at the CONNECT parameter.
1	80CE	The IP address of the local interface is 0.0.0.0.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on switching display formats, refer to "See also".		

TDISCON: Terminate communication connection

Description

The "TDISCON" instruction terminates a communications connection from the CPU to a connection partner.

Functional description

"The TDISCON" instruction works asynchronously, which means its job processing extends over multiple calls. You start the job for terminating a connection by calling the "TDISCON" instruction with REQ = 1.

After "TDISCON" has been successfully executed, the ID specified for "TCON" is no longer valid and cannot be used for sending or receiving.

The job status is indicated by the output parameters BUSY and STATUS. Here, STATUS corresponds to the output parameter RET_VAL of the asynchronous instructions (see also: Meaning of the parameters REQ, RET_VAL and BUSY with asynchronous instructions (Page 2193)).

The following table shows the relationship between BUSY, DONE and ERROR. Using this table, you can recognize the current status of "TDISCON" or when the establishment of the connection is completed.

BUSY	DONE	ERROR	Description
1	0	0	The job is being processed.
0	1	0	Job successfully completed.
0	0	1	The job ended with an error. The cause of the error can be found in the STATUS parameter.
0	0	0	The instruction was not assigned a (new) job.

Parameters

The following table shows the parameters of the instruction "TDISCON":

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
REQ	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Control parameter REQUEST starts the job for terminating the connection specified by ID. The job starts on a rising edge.
ID	Input	CONN_OUC (WORD)	D, L or constant	I, Q, M, D, L or constant	Reference to the connection to be terminated (connection ID) Range of values: W#16#0001 to W#16#0FFF
DONE	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Status parameter: • 0: Job not yet started or still executing. • 1: Job executed without errors
BUSY	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Status parameter: • BUSY = 1: The job is not yet completed. • BUSY = 0: The job is completed or has not started yet.
ERROR	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Status parameter: • ERROR=0: No error. • ERROR=1: Error occurred during processing. STATUS supplies detailed information on the type of error
STATUS	Output	WORD	I, Q, M, D, L	I, Q, M, D, L	Status parameter: Error information (see "Parameters ERROR and STATUS")

You will find more detailed information on valid data types in "Overview of the valid data types (Page 1908)".

Parameters ERROR and STATUS

ERROR	STATUS* (W#16#...)	Explanation
0	0000	Connection terminated successfully.
0	7000	No job processing active.
0	7001	Start of job processing, connection being terminated.
0	7002	Intermediate call (REQ irrelevant), connection being terminated.
1	8086	The ID parameter is not in the permitted value range.
1	80A3	Attempt is being made to terminate a non-existent connection or the connection is already terminated.
1	80C4	Temporary communication error: New parameters are being assigned to the interface or the connection is currently being established.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".		

TSEND: Send data via communication connection

TSEND: Send data via communication connection

Description

The following description of the "TSEND" instruction is valid for the CPU S7-1200 to version 3.0.

You use the "TSEND" instruction to send data over an existing communication connection. "TSEND" is executed asynchronously.

You specify the send area with the DATA parameter. This includes the address and the length of the data to be sent. All data types except BOOL and Array of BOOL can be used for the data to be sent.

The send job is executed when a rising edge is detected at the REQ parameter.

With the LEN parameter, you specify the maximum number of bytes sent with a send job.

- When data is transferred with TCP (streaming protocol), the "TSEND" instruction provides no information about the length of the data sent to "TRCV (Page 3677)".
- When data is transferred with ISO-on-TCP (message-oriented protocol), the length of the data sent is communicated to "TRCV (Page 3677)". The amount of data sent with "TSEND" as packet must also be received again at the receiving end ("TRCV (Page 3677)"):
  - If the receive buffer is too small for the sent data, an error occurs at the receiving end.
  - If the receive buffer is sufficiently large, "TRCV" returns with DONE=1 as soon as the data packet is received.

The data to be sent must not be edited until the send job is completed. If the send job executes successfully, the DONE parameter is set to "1". Signal state "1" at the DONE parameter is not confirmation that the data sent has already been read by the communication partner.

Parameters

The following table shows the parameters of the "TSEND" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Starts the send job on a rising edge.
ID	Input	CONN_OUC	I, Q, M, D, L or constant	Reference to the connection established with "TCON". Range of values: W#16#0001 to W#16#0FFF
LEN	Input	UINT	I, Q, M, D, L or constant	Maximum number of bytes to be sent with the job.
DATA	InOut	VARIANT	I, Q, M, D	Pointer to the send area containing the address and the length of the data to be sent. The address references: • The process image of the inputs • The process image of the outputs • A bit memory • A data block
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or still in progress • 1: Job completed without error
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or already completed • 1: Job not yet completed. A new job cannot be started.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

LEN and DATA parameters

- With LEN = 0 , all the data specified with the DATA parameter is sent.
- If the number of bytes at the LEN parameter is larger than the length of the data to be sent that was defined with the DATA parameter, the error code 8088 is output at the STATUS parameter (see description of the STATUS parameter below).
- If a structure (Struct) is referenced via the DATA parameter, LEN can be shorter than the structure. In this case, only the data up to the length of the LEN parameter is transferred.

- With data types STRING and WSTRING, all data is transferred if the parameter LEN = 0. When LEN > 0, the length must be at least the maximum number of bytes plus two additional bytes which contain the length information. You can find more detailed information on the structure of the data types in: "Overview of the valid data types (Page 1908)".
- The maximum number of bytes that can be transmitted is 65534.
- When you use structured tags from optimized DBs, the address of the structured tag should be interconnected at the DATA parameter and the parameter LEN = 0. This guarantees type-safe transmission of the entire structure if the same structure is used at the receiving end.

BUSY, DONE and ERROR parameters

You can check the status of the job with the BUSY, DONE, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. With the DONE parameter, you can check whether or not a job executed successfully. The ERROR parameter is set when errors occurred during execution of "TSEND". The error information is output at the STATUS parameter.

The following table shows the relationship between the BUSY, DONE and ERROR parameters:

BUSY	DONE	ERROR	Description
1	0	0	The job is being processed.
0	1	0	The job was completed successfully.
0	0	1	The job ended with an error. The cause of the error is specified in the STATUS parameter.
0	0	0	No new job was assigned.

Note

Because "TSEND" is executed asynchronously, you must keep the data in the send area consistent until the DONE parameter or the ERROR parameter changes to the value "1".

ERROR and STATUS parameters

ERROR	STATUS* (W#16#...)	Description
0	0000	Send job completed without error.
0	7000	No job processing active.
0	7001	Start of job execution, data is being sent. When processing this job, the operating system accesses the data in the DATA send area.
0	7002	Job executing (REQ irrelevant). When processing this job, the operating system accesses the data in the DATA send area.
1	8085	• The LEN parameter is greater than the highest permitted value (65536). • DATA and LEN parameters both have the value "0".
1	8086	The ID parameter is outside the permitted address range (1..0xFFF).
1	8088	The LEN parameter is greater than the area specified in DATA.

ERROR	STATUS* (W#16#...)	Description
1	80A1	Communication error: • The specified connection has not yet been established. • The specified connection is being terminated. Transfer via this connection is not possible. • The interface is being re-initialized.
1	80B3	The protocol variant (ConnectionType parameter in the connection description) is set to UDP. Use the instruction "TUSEND" with a UDP connection.
1	80C3	• A block with this ID is already being processed in a different priority group. • Internal lack of resources.
1	80C4	Temporary communication error: • The connection cannot be established to the partner at this time. • The interface is receiving new parameter settings or the connection is being established.
1	80C5	Connection terminated by the communication partner.
1	80C6	Network error. Communication partner cannot be reached.
1	80C7	Execution timeout.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".		

TSEND: Send data via communication connection

Description

The following description of the "TSEND" instruction is valid for the CPU S7-1500 and S7-1200 ≥ V4.0.

You use the "TSEND" instruction to send data over an existing communication connection. "TSEND" is executed asynchronously.

You specify the send area with the DATA parameter. This includes the address and the length of the data to be sent. All data types except BOOL and Array of BOOL can be used for the data to be sent.

The send job is executed when a rising edge is detected at the REQ parameter.

With the LEN parameter, you specify the maximum number of bytes sent with a send job.

- When data is transferred with TCP (streaming protocol), the "TSEND" instruction provides no information about the length of the data sent to "TRCV (Page 3677)".
- When data is transferred with ISO-on-TCP (message-oriented protocol), the length of the data sent is communicated to "TRCV (Page 3677)". The amount of data sent with "TSEND" as packet must also be received again at the receiving end ("TRCV (Page 3677)"):
  - If the receive buffer is too small for the sent data, an error occurs at the receiving end.
  - If the receive buffer is sufficiently large, "TRCV" returns with DONE=1 as soon as the data packet is received.

The data to be sent must not be edited until the send job is completed. If the send job executes successfully, the DONE parameter is set to "1". Signal state "1" at the DONE parameter is not confirmation that the data sent has already been read by the communication partner.

Parameters

The following table shows the parameters of the "TSEND" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Starts the send job on a rising edge.
ID	Input	CONN_OUC	I, Q, M, D, L or constant	Reference to the connection established with "TCON". Value range: W#16#0001 to W#16#0FFF
LEN	Input	UDINT	I, Q, M, D, L or constant	Maximum number of bytes that are sent with the job (maximum permissible value for S7-1200: 8192, maximum permissible value for S7-1500: 65536).
DATA	InOut	VARIANT	I, Q, M, D, L	Pointer to the send area containing the address and the length of the data to be sent. The address references: • The process image of the inputs • The process image of the outputs • A bit memory • A data block • Local data
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or still in progress • 1: Job completed without error
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or already completed • 1: Job not yet completed. A new job cannot be started.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameters LEN and DATA

- With LEN = 0 , all the data specified with the DATA parameter is sent.
- If the number of bytes at the LEN parameter is larger than the length of the data to be sent that was defined with the DATA parameter, the error code 8088 is output at the STATUS parameter (see description of the STATUS parameter below).
- If a structure (Struct) is referenced via the DATA parameter, LEN can be shorter than the structure. In this case, only the data up to the length of the LEN parameter is transferred.
- With data types STRING and WSTRING, all data is transferred if the parameter LEN = 0. When LEN > 0, the length must be at least the maximum number of bytes plus two additional bytes which contain the length information. You can find more detailed information on the structure of the data types in: "Overview of the valid data types (Page 1908)".

- The maximum number of bytes that can be transmitted depends on the device.
- When you use structured tags from optimized DBs, the address of the structured tag should be interconnected at the DATA parameter and the parameter LEN = 0. This guarantees type-safe transmission of the entire structure if the same structure is used at the receiving end.

Parameters BUSY, DONE and ERROR

You can check the status of the job with the BUSY, DONE, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. With the DONE parameter, you can check whether or not a job executed successfully. The ERROR parameter is set when errors occurred during execution of "TSEND". The error information is output at the STATUS parameter.

The following table shows the relationship between the BUSY, DONE and ERROR parameters:

BUSY	DONE	ERROR	Description
1	0	0	The job is being processed.
0	1	0	The job was completed successfully.
0	0	1	The job ended with an error. The cause of the error is specified in the STATUS parameter.
0	0	0	No new job was assigned.

Note

Because "TSEND" is executed asynchronously, you must keep the data in the send area consistent until the DONE parameter or the ERROR parameter changes to the value "1".

Parameters ERROR and STATUS

ERROR	STATUS* (W#16#...)	Description
0	0000	Send job completed without error.
0	7000	No job processing active.
0	7001	Start of job execution, data is being sent. When processing this job, the operating system accesses the data in the DATA send area.
0	7002	Job executing (REQ irrelevant). When processing this job, the operating system accesses the data in the DATA send area.
1	8085	• The LEN parameter is greater than the maximum permissible value (for S7-1200: 8192, for S7-1500: 65536). • DATA and LEN parameters both have the value "0".
1	8086	The ID parameter is outside the permitted address range (1..0xFFF).
1	8088	The LEN parameter is greater than the area specified in DATA.
1	80A1	Communication error: • The specified connection has not yet been established. • The specified connection is being terminated. Transfer via this connection is not possible. • The interface is being re-initialized.

ERROR	STATUS* (W#16#...)	Description
1	80B1	You changed the DATA parameter before the current job finished.
1	80B3	The protocol variant (ConnectionType parameter in the connection description) is set to UDP. Use the instruction "TUSEND" with a UDP connection.
1	80C3	• A block with this ID is already being processed in a different priority group. • Internal lack of resources.
1	80C4	Temporary communication error: • The connection cannot be established to the partner at this time. • The interface is receiving new parameter settings or the connection is being established.
1	80C5	Connection terminated by the communication partner.
1	80C6	Network error. Communication partner cannot be reached.
1	80C7	Execution timeout.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".		

TRCV: Receive data via communication connection

TRCV: Receive data via communication connection

Description

The following description of the "TRCV" instruction is valid for the CPU S7-1200 up to version 3.0.

You use the "TRCV" instruction to receive data over an existing communication connection. "TRCV" is executed asynchronously.

Receipt of data is enabled when the EN_R parameter is set to the value "1". The received data is entered in a receive area. You specify the length of the receive area either with the LEN parameter (if LEN <> 0) or with the length information of the DATA parameter (if LEN = 0), depending on the protocol variant being used.

While data is being received, you cannot make changes to the DATA parameter or the defined receive area to ensure consistency of the received data.

After successful receipt of data, the NDR parameter is set to the value "1". You can query the amount of data actually received at the RCVD_LEN parameter.

Receive modes of "TRCV"

The following table shows how the received data is entered in the receive area.

Protocol variant	Availability of data in the receive area	connection_type* parameter of the connection description	LEN parameter
TCP (Ad-hoc mode)	The data is immediately available.	Hexadecimal value: B#16#11 Integer value: 17	0
TCP (Receipt of data with specified length)	The data is available as soon as the data length specified at the LEN parameter has been fully received.	Hexadecimal value: B#16#11 Integer value: 17	1 to 8192
ISO on TCP (Message-oriented data transfer)	The data is available as soon as the data length specified at the LEN parameter has been fully received.	Hexadecimal value: B#16#12 Integer value: 18	• 1 to 1452, if a CP is used. • 1 to 8192, if no CP is used.
* See "Auto-Hotspot".			

TCP (Ad-hoc mode)

The ad-hoc mode is only available with the TCP protocol variant. You use the ad-hoc mode to receive data with dynamic length with the "TRCV" instruction.

You set ad-hoc mode by assigning the value "0" to the LEN parameter. All data types can be used for data blocks with standard access when you use ad-hoc mode. Only ARRAY of BYTE or data types with a length of 8 bits can be used for data blocks with optimized access (e.g., CHAR, USINT, SINT, etc.). When ad-hoc mode is active, receipt of data is already signaled after a received byte at the NDR parameter.

TCP (Receipt of data with specified length)

For receipt of data with a specified length, enter the length of the data at the LEN parameter. The data receipt is not complete until the length of data specified at the LEN parameter has been completely received. Only then is the data available in the receive area (DATA parameter). The receipt of data is signaled by the NDR output parameter. The actually received data length in bytes at the RCVD_LEN parameter corresponds to the data length at the LEN parameter after receipt.

ISO on TCP (Message-oriented data transfer)

Complete message blocks are sent via a connection with the protocol variant ISO on TCP; these are recognized as such by the recipient. When using ISO on TCP, "TRCV" signals data receipt as soon as the message block has been completely received. The receive area is defined by the LEN and DATA parameters. If the receive buffer (DATA parameter) is too small for the sent data, "TRCV" signals an error. The successful receipt of data is signaled by the NDR output parameter. The actually received data length in bytes at the RCVD_LEN parameter corresponds to the data length at the LEN parameter after receipt.

Parameters

The following table shows the parameters of the "TRCV" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN_R	Input	BOOL	I, Q, M, D, L or constant	Receive enable
ID	Input	CONN_OUC	I, Q, M, D, L or constant	Reference to the connection established with "TCON (Page 3662)". Range of values: W#16#0001 (1) to W#16#0FFF (4095)
LEN	Input	UDINT	I, Q, M, D, L or constant	Length of the receive area in bytes (hidden). If you use a memory area with optimized access at the DATA parameter, the LEN parameter must have the value "0".
DATA	InOut	VARIANT	I, Q, M, D	Pointer to the receive area
NDR	Output	BOOL	I, Q, M, D, L	Status parameter (New Data Received): • 0: Job not yet started or still in progress • 1: Job completed without error
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: Job not yet started or already completed • 1: Job not yet completed. A new job cannot be started
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter: Output of status and error information.
RCVD_LEN	Output	UDINT	I, Q, M, D, L	Amount of data actually received in bytes

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

LEN, DATA and RCVD_LEN parameters

- If LEN = 0, the received data is saved in the receive area specified at the DATA parameter. The number of bytes received is indicated at the RCVD_LEN parameter.
- If the length specified at the LEN parameter is greater than the length of the data received at the DATA parameter, the error code 8088 is output at the STATUS parameter (see description of the STATUS) parameter in the following.
- If a structure (Struct) is referenced via the DATA parameter, LEN can be shorter than the structure. In this case, only the data up to the length of the LEN parameter is transferred.
- If the DATA parameter references a data block with optimized access, the LEN parameter must be set to "0".

- If a STRING data type is referenced via the DATA parameter, the length specified at the LEN parameter must be 0 or >=2 (LEN = 1 is not permitted).
- If a WSTRING data type is referenced via the DATA parameter, the length specified at the LEN parameter must be 0 or >=5.

BUSY, NDR and ERROR parameters

You can check the status of the job with the BUSY, NDR, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. With the NDR parameter, you can check whether or not a job executed successfully. The ERROR parameter is set when errors occurred during execution of TRCV. The error information is output at the STATUS parameter.

The following table shows the relationship between the BUSY, NDR and ERROR parameters:

BUSY	NDR	ERROR	Description
1	-	-	The job is being processed.
0	1	0	The job was completed successfully.
0	0	1	The job ended with an error. The cause of the error is output at the STATUS parameter.
0	0	0	No new job was assigned.

Note

Because "TRCV" is executed asynchronously, the data in the receive area is only consistent when the NDR parameter is set to the value "1".

ERROR and STATUS parameters

ERROR	STATUS* (W#16#...)	Explanation
0	0000	Job completed successfully. The current length of the received data is output at the RCVD_LEN parameter.
0	7000	Block not ready to receive.
0	7001	Block is ready to receive, receive job was activated.
0	7002	Interim call, the receive job is executing. Note: While the job is being processed, data is written to the receive area. Access to the receive area during this time may provide inconsistent data.
1	8085	• The LEN parameter is larger than the highest permitted value. • The value of the LEN or DATA parameter was changed after the first call. • Both LEN parameters and the DATA parameter have the value "0" or LEN is longer than the maximum permitted value (65536).
1	8086	The ID parameter is outside the permitted address range (1 .. 0x0FFF).
1	8088	• Receive area is too small. • The value at the LEN parameter is larger than the receive area set at the DATA parameter.

ERROR	STATUS* (W#16#...)	Explanation
1	80A1	Communication error: • The specified connection has not yet been established. • The specified connection is being terminated. Receive job over this connection is not possible. • The connection is being re-initialized.
1	80B3	The protocol variant (connection_type parameter in the connection description) is set to UDP. Use the instruction "TURCV" with a UDP connection.
1	80C3	• A block with this ID is already being processed in a different priority group. • Internal lack of resources.
1	80C4	Temporary communication error: • The connection cannot be established to the partner at this time. • The interface is receiving new parameter settings or the connection is being established.
1	80C5	The remote partner has terminated the connection.
1	80C6	The remote partner cannot be reached (network error).
1	80C7	Execution timeout.
1	80C9	The length of the receive area is smaller than the length of the sent data.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".		

TRCV: Receive data via communication connection

Description

The following description of the "TRCV" instruction is valid for the CPU S7-1500 and S7-1200 ≥ V4.0.

You use the "TRCV" instruction to receive data over an existing communication connection. "TRCV" is executed asynchronously.

Receipt of data is enabled when the EN_R parameter is set to the value "1". The received data is entered in a receive area. You specify the length of the receive area either with the LEN parameter (if LEN <> 0) or with the length information of the DATA parameter (if LEN = 0), depending on the protocol variant being used.

While data is being received, you cannot make changes to the DATA parameter or the defined receive area to ensure consistency of the received data.

After successful receipt of data, the NDR parameter is set to the value "1". You can query the amount of data actually received at the RCVD_LEN parameter.

Receive modes of "TRCV"

The following table shows how the received data is entered in the receive area.

Protocol variant	ADHOC parameter	Availability of data in the receive area	connection_type parameter of the connection description	Parameter LEN
TCP (Ad-hoc mode)	1 (ad-hoc activated)	The data is immediately available.	Hexadecimal value: B#16#11 Integer value: 17	1 up to maximum length (depending on the CPU)
TCP (Receipt of data with specified length)	0 (ad-hoc deactivated)	The data is available as soon as the data length specified at the LEN parameter has been fully received.	Hexadecimal value: B#16#11 Integer value: 17	1 to 8192
ISO on TCP (Message-oriented data transfer)	-	The data is available as soon as the data length specified at the LEN parameter has been fully received.	Hexadecimal value: B#16#12 Integer value: 18	• 1 to 1452, if a CP is used. • 1 to 8192, if no CP is used.

TCP (Ad-hoc mode)

The ad-hoc mode is only available with the TCP protocol variant. You use the ad-hoc mode to receive data with dynamic length with the "TRCV" instruction.

You set ad-hoc mode by assigning the value "1" to the ADHOC parameter. All data types can be used for data blocks with standard access when you use ad-hoc mode. Only ARRAY of BYTE or data types with a length of 8 bits can be used for data blocks with optimized access (e.g., CHAR, USINT, SINT, etc.). When ad-hoc mode is active, receipt of data is already signaled after a received byte at the NDR parameter.

TCP (Receipt of data with specified length)

Assign the value "0" to the ADHOC parameter for receipt of data with specified length. If ad-hoc mode is disabled, the data reception is not complete until the length of data specified at the LEN parameter has been completely received. Only then is the data available in the receive area (DATA parameter). The successful receipt of data is signaled by the NDR output parameter. The actually received data length in bytes at the RCVD_LEN parameter corresponds to the data length at the LEN parameter after receipt.

ISO on TCP (Message-oriented data transfer)

Complete message blocks are sent via a connection with the protocol variant ISO on TCP; these are recognized as such by the recipient. When using ISO on TCP, "TRCV" signals data reception as soon as the message block has been completely received. The receive area is defined by the LEN and DATA parameters. If the receive buffer (DATA parameter) is too small for the sent data, "TRCV" signals an error. The successful receipt of data is signaled by the NDR output parameter. The actually received data length in bytes at the RCVD_LEN parameter corresponds to the data length at the LEN parameter after receipt.

Parameters

The following table shows the parameters of the "TRCV" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN_R	Input	BOOL	I, Q, M, D, L or constant	Receive enable
ID	Input	CONN_OUC	I, Q, M, D, L or constant	Reference to the connection established with "TCON". Value range: W#16#0001 to W#16#0FFF
LEN	Input	UDINT	I, Q, M, D, L or constant	Length of the receive area in bytes (hidden) (maximum value for S7-1200: 8192, maximum value for S7-1500: 65536). If you use a receive area with optimized access at the DATA parameter, the LEN parameter must have the value "0".
ADHOC	Input	BOOL	I, Q, M, D, L or constant	Use ad-hoc mode for the TCP protocol variant (hidden).
DATA	InOut	VARIANT	I, Q, M, D, L	Pointer to the receive area
NDR	Output	BOOL	I, Q, M, D, L	Status parameter (New Data Received): • 0: Job not yet started or still in progress • 1: New data received
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or already completed • 1: Job not yet completed. A new job cannot be started
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter ERROR: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction
RCVD_LEN	Output	UDINT	I, Q, M, D, L	Amount of data actually received in bytes

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameters LEN, DATA and RCVD_LEN

- If LEN = 0, the received data is saved in the receive area specified at the DATA parameter. The number of bytes received is indicated at the RCVD_LEN parameter.
- If the length specified at the LEN parameter is greater than the length of the data received at the DATA parameter, the error code 8088 is output at the STATUS parameter (see description of the STATUS) parameter in the following.
- If a structure (Struct) is referenced via the DATA parameter, LEN can be shorter than the structure. In this case, only the data up to the length of the LEN parameter is transferred.
- If the DATA parameter references a data block with optimized access, the LEN parameter must be set to "0". If the length of the data does not match for elementary data types, the data will not be received and the error code 8088 is output at the STATUS parameter.

- If a STRING data type is referenced via the DATA parameter, the length specified at the LEN parameter must be 0 or >=2 (LEN = 1 is not permitted).
- If a WSTRING data type is referenced via the DATA parameter, the length specified at the LEN parameter must be 0 or >=5.

Parameters BUSY, NDR and ERROR

You can check the status of the job with the BUSY, NDR, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. With the NDR parameter, you can check whether or not a job executed successfully. The ERROR parameter is set when errors occurred during execution of TRCV. The error information is output at the STATUS parameter.

The following table shows the relationship between the BUSY, NDR and ERROR parameters:

BUSY	NDR	ERROR	Description
1	-	-	The job is being processed.
0	1	0	The job was completed successfully.
0	0	1	The job ended with an error. The cause of the error is output at the STATUS parameter.
0	0	0	No new job was assigned.

Note

Because "TRCV" is executed asynchronously, the data in the receive area is only consistent when the NDR parameter is set to the value "1".

Parameters ERROR and STATUS

ERROR	STATUS* (W#16#...)	Explanation
0	0000	Job completed successfully. The current length of the received data is output at the RCVD_LEN parameter.
0	7000	Block not ready to receive.
0	7001	Block is ready to receive, receive job was activated.
0	7002	Interim call, the receive job is executing. Note: While the job is being processed, data is written to the receive area. Access to the receive area during this time may provide inconsistent data.
1	8085	• The LEN parameter is greater than the maximum permissible value (for S7-1200: 8192 bytes, for S7-1500: 65536 bytes). • The value of the LEN or DATA parameter was changed after the first call. • Both LEN parameters and the DATA parameter have the value "0" or LEN is longer than the maximum permissible value (for S7-1200): 8192 bytes, for S7-1500: 65536 bytes).
1	8086	The ID parameter is outside the permitted value range (1 .. 0x0FFF).
1	8088	• Receive area is too small. • The value at the LEN parameter is larger than the receive area set at the DATA parameter.

ERROR	STATUS* (W#16#...)	Explanation
1	80A1	Communication error: • The specified connection has not yet been established. • The specified connection is being terminated. Receive job over this connection is not possible. • The connection is being re-initialized.
1	80B1	You changed the DATA parameter before the current job finished.
1	80B3	The protocol variant (connection_type parameter in the connection description) is set to UDP. Use the instruction "TURCV" with a UDP connection.
1	80C3	• A block with this ID is already being processed in a different priority group. • Internal lack of resources.
1	80C4	Temporary communication error: • The connection cannot be established to the partner at this time. • The interface is receiving new parameter settings or the connection is being established.
1	80C5	The remote partner has terminated the connection.
1	80C6	The remote partner cannot be reached (network error).
1	80C7	Execution timeout.
1	80C9	The length of the receive area is smaller than the length of the sent data.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".

TRCV: Receive data via communication connection (Page 3677)

TCON: Establish communication connection (Page 3664)

Structure of the address information for the remote partner with UDP

Overview

When using a UDP connection, the address information for the remote partner is stored in the system data type TADDR_Param:

- By using the instruction "TUSEND (Page 3687)" the address information of the recipient is assigned to the parameter ADDR via TADDR_Param.
  The stored address data of the remote partner are read from the system data type by the instruction.
- By using the instruction "TURCV (Page 3690)" the address of the sender is received at the parameter ADDR via TADDR_Param.
  The address data is written by the instruction in the system data type.

Structure of the address information according to TADDR_Param

The system data type TADDR_Param contains the address information of the remote partner and consists of the IP address and the port number.

The system data type TADDR_Param has the following structure:

Byte	Parameter	Data type	Start value	Description
0 to 3	rem_ip_addr	ARRAY [1..4] of USINT	B#16#00 ...	IP address of the remote partner, e.g. 192.168.002.003: • rem_ip_addr[1] = B#16#C0 (192) • rem_ip_addr[2] = B#16#A8 (168) • rem_ip_addr[3] = B#16#02 (002) • rem_ip_addr[4] = B#16#03 (003) The IP address can be taken from the Devices & networks view in the interface properties of the remote partner. As an alternative these are also displayed in the properties of the UDP connection under Address details.
4 to 5	rem_port_nr	UINT	B#16#00 ...	Remote port-number (possible values see: Auto-Hotspot): • rem_port_nr[1] = high byte of the port no. in hexadecimal notation • rem_port_nr[2] = low byte of port no. in hexadecimal notation The port number can be taken from the Devices & networks view in the UDP connection properties. The port number is indicated under Address details as a decimal value. Example: Port number = 2000 (decimal) / W#16#07D0 (hexadecimal) • rem_port_nr[1] = 07 (high byte) • rem_port_nr[2] = D0 (low byte)
6 to 7	reserved	WORD	B#16#00 ...	Not used. Leave the value "0" at this parameter.

Creating TADDR_Param in a data block

You have the following options for creating TADDR_Param:

- Create a new data block and select TADDR_Param as type in the dialog "Add new data block".
- Open an existing data block create a new tag and enter in the column Data type TADDR_Param.

A data block can contain several system data types TADDR_Param.

TUSEND: Send data via Ethernet (UDP)

Description

The "TUSEND" instruction sends data to the remote partner addressed by the ADDR parameter using UDP.

Warning

Data transfer via UDP

Data transferred via UDP to RFC 768 to the remote partner are sent without acknowledgement and are therefore unsecured. This means the data can be lost without any indication at the block.

Note

For sequential send operations to different partners, you only need to adjust the ADDR parameter when calling "TUSEND". You do not need to call the "TCON (Page 3662)" and "TDISCON (Page 3669)" instructions again. The UDP port must be set up at the specific remote partner in order for this partner to receive data.

Functional description

"The TUSEND" instruction works asynchronously, which means its job processing extends over multiple calls. Create a rising edge at the REQ parameter to establish a connection once again.

The output parameters BUSY, DONE, ERROR and STATUS indicate the status of the job.

See also: Meaning of the parameters REQ, RET_VAL and BUSY with asynchronous instructions (Page 2193).

The following table shows the relationship between BUSY, DONE and ERROR. Using this table, you can determine the current status of "TUSEND" or when the send process is concluded.

BUSY	DONE	ERROR	Description
TRUE	FALSE	FALSE	The job is being processed.
FALSE	TRUE	FALSE	Job successfully completed.
FALSE	FALSE	TRUE	The job ended with an error. The cause of the error can be found in the STATUS parameter.
FALSE	FALSE	FALSE	The instruction was not assigned a (new) job.

Note

Due to the asynchronous operation of "TUSEND", make sure the data in the send area remains consistent until the DONE parameter or the ERROR parameter has the value TRUE.

Parameters

The following table shows the parameters of the "TUSEND" instruction:

Parameters	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Control parameter REQUEST starts the send job on a rising edge. The data is transferred from the area specified by DATA and LEN.
ID	Input	CONN_OUC	I, Q, M, D, L or constant	Reference to the associated connection between the user program and the communication layer of the operating system. ID must be identical to the associated parameter ID in the local connection description with the instruction "TCON". Value range: W#16#0001 to W#16#0FFF
LEN	Input	UINT	I, Q, M, D, L or constant	Number of bytes to be sent with the job Value range: 1 to 1472
DONE	Output	BOOL	I, Q, M, D, L	Status parameter DONE: • 0: Job not yet started or still executing. • 1: Job executed without errors. This value is only displayed for one cycle.
BUSY	Output	BOOL	I, Q, M, D, L	• BUSY = 1: The job is not yet completed. A new job cannot be triggered. • BUSY = 0: The job is completed.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter ERROR: • ERROR=1: An error has occurred during processing, STATUS supplies detailed information on the type of error.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter STATUS: Error information
DATA	InOut	VARIANT	I, Q, M, D	Send area, contains address and length The address refers to: • The process image of the inputs • The process image of the outputs • A bit memory • A data block
ADDR	InOut	VARIANT	D	Pointer to the system data type TADDR_Param. Store the address information of the remote partner (IP address and port number) in a data block with the system data type TADDR_Param. See also: Structure of the address information for the remote partner with UDP (Page 3685)

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

ERROR and STATUS parameters

ERROR	STATUS* (W#16#...)	Explanation
0	0000	Send job completed without error
0	7000	No job processing active
0	7001	Start of job processing, data being sent Note: During this processing phase, the operating system accesses the data in the DATA send area.
0	7002	Intermediate call (REQ irrelevant), job is being processed Note: During this processing phase, the operating system accesses the data in the DATA send area.
1	8085	The LEN parameter has the value "0" or is greater than the highest permitted value.
1	8086	The ID parameter is not in the permitted value range.
0	8088	The LEN parameter is greater than the memory area specified in DATA.
1	8089	The ADDR parameter does not point to a data block with the TADDR_Param structure.
1	80A1	Communication error: • The specified connection between user program and communication layer of the operating system has not yet been established. • The specified connection between the user program and the communication layer of the operating system is currently being terminated. Transmission over this connection is not possible. • The interface is being reinitialized.
1	80B1	You changed the DATA parameter before the current job finished.
1	80A4	IP address (at the ADDR parameter) of the remote connection end point is invalid; it may correspond to the local partner's own IP address.
1	80B3	• The protocol variant (connection_type parameter in the connection description) is not set to UDP. Please use "TSEND (Page 3674)". • ADDR parameter: Invalid information for port no.
1	80B7	The length of the structure referenced by the parameter ADDR is not 8 bytes.
1	80C3	• A block with this ID is already being processed in a different priority class. • Internal lack of resources.
1	80C4	Temporary communication error: • The connection between the user program and the communication layer of the operating system cannot be established at this time. • New parameter settings are being assigned to the interface.
1	80C5	The remote partner has terminated the connection.
1	80C6	The remote partner cannot be reached (network error).
1	80C7	Execution timeout.
-	General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on switching display formats, refer to "See also".		

TURCV: Receive data via Ethernet (UDP)

Description

The "TURCV" instruction receives data via UDP. After successful completion of "TURCV", the ADDR parameter will show you the address of the remote partner (the sender).

Warning

Unsecured data transfer

Data transferred via UDP to RFC 768 to the remote partner are sent without acknowledgement and are therefore unsecured. This means the data can be lost without any indication at the block.

Functional description

"The TURCV" instruction works asynchronously, which means its job processing extends over multiple calls. You start the receive job by calling "TURCV" with EN_R = 1.

The output parameters BUSY, DONE, ERROR and STATUS indicate the status of the job.

See also: Meaning of the parameters REQ, RET_VAL and BUSY with asynchronous instructions (Page 2193).

The following table shows the relationship between BUSY, NDR and ERROR. Using this table, you can determine the current status of TURCV or when the receive process is concluded.

BUSY	NDR	ERROR	Description
TRUE	FALSE	FALSE	The job is being processed.
FALSE	TRUE	FALSE	Job successfully completed. New data was received.
FALSE	FALSE	TRUE	The job ended with an error. The cause of the error can be found in the STATUS parameter.
FALSE	FALSE	FALSE	The instruction was not assigned a (new) job.

Note

Due to the asynchronous operation of "TURCV", the data in the receive area is only consistent when the NDR parameter has the value TRUE.

Parameters

The following table shows the parameters of the "TURCV" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN_R	Input	BOOL	I, Q, M, D, L or constant	Control parameter enabled to receive When EN_R = 1, "TURCV" is ready to receive. The receive job is being processed.
ID	Input	WORD	I, Q, M, D, L or constant	Reference to the associated connection between the user program and the communication layer of the operating system. ID must be identical to the corresponding parameter ID in the local connection description. Value range: W#16#0001 to W#16#0FFF
LEN	Input	UINT	I, Q, M, D, L or constant	Length of the receive area in bytes: 0 (recommended) or 1 to 1472
NDR	Output	BOOL	I, Q, M, D, L	Status parameter NDR: • NDR = 0: Job not yet started or still running • NDR = 1: Job successfully completed
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter ERROR: • ERROR=1: Error occurred during processing. STATUS supplies detailed information on the type of error
BUSY	Output	BOOL	I, Q, M, D, L	• BUSY = 1: The job is not yet completed. A new job cannot be triggered. • BUSY = 0: The job is completed.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter STATUS: Error information
RCVD_LEN	Output	UINT	I, Q, M, D, L	Amount of data actually received in bytes
DATA	InOut	VARIANT	I, Q, M, D, L	Receive area The address references: • The process image of the inputs • The process image of the outputs • A bit memory • A data block
ADDR	InOut	VARIANT	D	Pointer to the system data type TADDR_Param. The address information of the remote partner (IP address and port number) is written in a data block with the system data type TADDR_Param. See also: Structure of the address information for the remote partner with UDP (Page 3685)

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

ERROR and STATUS parameters

ERROR	STATUS* (W#16#...)	Explanation
0	0000	New data was accepted. The current length of the received data is shown in RCVD_LEN.
0	7000	Block not ready to receive
0	7001	Block is ready to receive, receive job was activated
0	7002	Intermediate call, receive job being processed Note: During this processing phase, "TURCV" writes data to the receive area. For this reason, an error could result in inconsistent data in the receive area.
1	8085	The LEN parameter is greater than the largest permitted value, or you changed the value of the LEN or DATA parameter since the first call
1	8086	The ID parameter is not in the permitted value range
1	8088	• Receive area is too small • Value in LEN is higher than the receive area specified by DATA
1	8089	The ADDR parameter does not point to a data block with the TADDR_Param structure.
1	80A1	Communication error: • The specified connection between user program and communication layer of the operating system has not yet been established. • The specified connection between the user program and the communication layer of the operating system is currently being terminated. A receive job over this connection is not possible. • New parameter settings are being assigned to the interface.
1	80B1	You changed the DATA parameter before the current job finished.
1	80B3	The protocol variant (connection_type parameter in the connection description) is not set to UDP. Please use "TRCV (Page 3677)".
1	80B7	The length at ADDR parameter does not correspond to 8 bytes.
1	80C3	• A block with this ID is already being processed in a different priority class. • Internal lack of resources.
1	80C4	Temporary communication error: New parameter settings are being assigned to the interface.
1	80C5	The remote partner has terminated the connection.
1	80C7	Execution timeout.
1	80C9	With RFC1006 / UDP: The received data is longer than expected (size of receive buffer exceeded).
-	General error information	See also: GET_ERR_ID: Get error ID locally (Page 2417)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on switching display formats, refer to "See also".		

See also

TCON: Establish communication connection (Page 3662)

TDISCON: Terminate communication connection (Page 3669)

T_RESET: Resetting the connection

Description

The "T_RESET" instruction terminates and then reestablishes an existing connection.

The local end points of the connection are retained. They are generated automatically:

- If a connection has been configured and loaded to the CPU.
- If a connection has been generated by the user program, for example, by calling the instruction "TCON (Page 3662)".

The instruction "T_RESET" can be executed for all connection types (TCP, UDP, ISO-on-TCP, etc.). It does not matter whether the local interface of the CPU or the interface of a CM/CP was used for the connection.

Once the instruction "T_RESET" has been called using the REQ parameter, the connection specified with the ID parameter is terminated and, if necessary, the data send and receive buffer cleared. Canceling the connection also cancels any data transfer in progress. There is therefore a risk of losing data if data transfer is in progress. The CPU defined as the active connection partner will then automatically attempt to restore the interrupted communication connection. You therefore do not need to call the "TCON (Page 3662)" instruction to reestablish the communication connection.

The output parameters DONE, BUSY and STATUS indicate the status of the job.

Parameters

The following table shows the parameters of the "T_RESET" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Control parameter REQUEST starts the job for terminating the connection specified by ID. The job starts on a rising edge.
ID	Input	CONN_OUC	I, Q, M, D, L or constant	Reference to the connection to the passive partner ID being interrupted must be identical to the corresponding parameter ID in the local connection description. Range of values: W#16#0001 to W#16#0FFF
DONE	Output	BOOL	I, Q, M, D, L	Status parameter DONE • 0: Job not yet started or still executing. • 1: Job executed without errors
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter BUSY • 0: Job is complete. • 1: The job is not yet completed.

Parameter	Declaration	Data type	Memory area	Description
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter ERROR • 0: No error occurred. • 1: Error occurred during processing. The STATUS parameter supplies detailed information on the type of error
STATUS	Output	WORD	I, Q, M, D, L	Status parameter STATUS Error information (see "STATUS parameter" table).

You will find more detailed information on valid data types in "Overview of the valid data types (Page 1908)".

Parameter STATUS

STATUS* (W#16#...)	Explanation
0000	No error.
0001	Connection has not been established.
7001	Connection termination launched.
7002	Connection being terminated.
8081	Unknown connection specified at the ID parameter.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

T_DIAG: Checking the connection

Description

You use the "T_DIAG" instruction to check the status of a connection and read further information on the local end point of this connection.

- The connection is referenced by the ID parameter. You can read both connection end points configured in the connection editor and programmed connection end points (e.g. with the "TCON" instruction).
  Temporary connection end points (for example end points created when you connect to an engineering station) cannot be diagnosed, as no connection ID is generated in this process.
- The connection information read is stored in a structure referenced by the RESULT parameter.
- The output parameter STATUS indicates whether it was possible to read the connection information. The connection information in the structure at the RESULT parameter is only valid if the "T_DIAG" instruction has been completed with STATUS = W#16#0000 and ERROR = FALSE.
  Connection information cannot be evaluated if an error occurs.

Possible connection information

Two different structures can be used to read the connection information at the RESULT parameter:

- The "TDiag_Status" structure only contains the most important information about a connection end point, for example the protocol used, the connection status and the number of data bytes sent or received.
- The structure "TDiag_StatusExt" supplies not just the most important information, but also the number of connection attempts, the reason for a connection abort, etc.

The structure and parameters of the two structures are described below (see the "TDIAG_Status and TDIAG_StatusExt structures" table).

Parameters

The following table shows the parameters of the "T_DIAG" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Starts the instruction to check the connection specified in the ID parameter when there is a positive edge.
ID	Input	CONN_OUC (WORD)	I, Q, M, D, L or constant	Reference to the assigned connection. Value range: W#16#0001 to W#16#0FFF
RESULT	InOut	VARIANT	D	Pointer to the structure in which the connection information is stored. The structure TDiag_Status or TDiag_StatusExt can be used at the RESULT parameter (for a description, see the "TDIAG_Status and TDIAG_StatusExt structures" table).
DONE	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: Instruction not yet started or still in progress. • 1: Instruction executed without errors.
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: Instruction not yet started or already completed. • 1: Instruction not yet completed. A new job cannot be started.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: No error. • 1: Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Parameters BUSY, DONE and ERROR

You can check the status of "T_DIAG" instruction execution with the BUSY, DONE, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. You use the DONE parameter to check whether or not an instruction has been executed successfully. The ERROR parameter is set if errors occur during execution of "T_DIAG".

The following table shows the relationship between the BUSY, DONE and ERROR parameters:

BUSY	DONE	ER-ROR	Description
1	-	-	The instruction is being processed.
0	1	0	The instruction has been executed successfully. The data in the structure referenced by RESULT are only valid if this is the case.
0	0	1	Instruction completed with an error. The cause of the error is output at the STATUS parameter.
0	0	0	No new instruction has been assigned.

Parameter STATUS

The following table shows the meaning of the values at the STATUS parameter:

STA-TUS* (W#16#...)	Explanation
0000	The instruction "T_DIAG" has been executed successfully. The data in the structure referenced at the RESULT parameter can be evaluated.
7000	No instruction processing active.
7001	Instruction processing launched.
7002	Connection information is being read (REQ parameter irrelevant).
8086	The value at the ID parameter is outside the valid range (W#16#0001 ... W#16#0FFF).
8089	The RESULT parameter points to an invalid data type (structures TDIAG_Status and TDIAG_StatusExt only).
80A3	The ID parameter references a connection end point which does not exist. With programmed connections, this error can also occur after the "TDISCON" instruction is called.
80C4	Internal error. Access to the connection end point is temporarily unavailable.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Structures TDIAG_Status and TDIAG_StatusExt

The table below details the form of the TDIAG_Status and TDIAG_StatusExt structures:

- From the InterfaceID to the ReceivedBytes parameter, the "TDIAG_StatusExt" and "TDIAG_Status" structures are identical.
- The structure TDIAG_StatusExt also includes the parameters ConnTrials to LastDisconnTimeStamp.

The value of each element is only valid if the instruction has been executed without errors. If an error occurs, the content of the parameters will not change.

Name	Data type	Description
The following parameters are in both the TDIAG_Status and the TDIAG_StatusExt structure:		
InterfaceID	HW_ANY	Interface ID (LADDR) of the CPU or the CM/CP.
ID	CONN_OUC	ID of the connection diagnosed. Following a successful call, the value of this element is identical to the parameter ID of the "T_DIAG" instruction.
ConnectionType	BYTE	Protocol type used for connection: • 0x01: Not used. • ... • 0x0B: TCP protocol (IP_v4) • 0x0C: ISO-on-TCP protocol (RFC1006) • 0x0D: TCP protocol (DNS) • 0x0E: Dial-in protocol • 0x0F: WDC protocol • 0x10: SMTP protocol • 0x11: TCP protocol • 0x12: TCP and ISO-on-TCP protocol (RFC1006) • 0x13: UDP protocol • 0x14: Reserved • 0x15: PROFIBUS bus access protocol (FDL) • 0x16: ISO 8073 transport protocol (ISO native) • ... • 0x20: SMTP or SMTPS protocol - based on IPv4 • 0x21: SMTP or SMTPS protocol - based on IPv6 • 0x22: SMTP or SMTPS protocol - based on FQDN (**F**ully **Q**ualified **D**omain **N**ame) • ... • 0x70: S7 connection • Other: Reserved
ActiveEstablished	BOOL	• FALSE: Locally, the passive connection end point • TRUE: Locally, the active connection end point

Name	Data type	Description
State	BYTE	Current status of the connection end point • 0x00: Not used. • 0x01: Connection terminated. Temporary status, for example, after the "T_RESET" instruction is called. The system then automatically attempts to reestablish the connection. • 0x02: The active connection end point is attempting to establish a connection to the remote communication partner. • 0x03: The passive connection end point is waiting for establishment of the connection to the remote communication partner. • 0x04: Connection established. • 0x05: The connection is being terminated. This may be because the "T_RESET" or "T_DISCON" instruction has been called. Other possible reasons are protocol errors and line breaks. • 0x06..0xFF: Not used.
Kind	BYTE	Mode of the connection end point: • 0x00: Not used. • 0x01: Configured, static connection which has been configured and loaded to the CPU. • 0x02: Configured, dynamic connection which has been configured and loaded to the CPU (not currently supported). • 0x03: Programmed connection generated in the user program with the instruction "TCON". A call of the instruction "TDISCON" or a transition to CPU STOP status has destroyed the connection end point. • 0x04: Temporary, dynamic connection established by the engineering station (ES) or operator station (OS), for example. (this connection type cannot currently by diagnosed as there is no ID). • 0x05..0xFF: Not used.
SentBytes	UDINT	Number of data bytes sent.
ReceivedBytes	UDINT	Number of data bytes received.
The following parameters only occur in the TDiag_StatusExt structure:		
ConnTrials	UDINT	Number of connection attempts. Once a connection has been established, ConnTrials has the value 0. If this element is not equal to 0, there are connection problems. Note: With a passive connection end point, this value is never greater than 1.
ConnTrialsSuccess	UDINT	Number of successful connection attempts. This element is never reset during the life cycle of a connection end point, and returns to 0 after reaching 0xFFFF FFFF. Note: This parameter is 1 if there has never been a problem in this connection.

Name	Data type	Description
LastConnErrReason	UDINT	Error ID output during the last connection attempt with errors (the error messages are identical to those at the LastDisconnReason parameter): • 0x4F01: Remote connection end point cannot be reached (this error usually occurs during connection establishment). • 0x4F02: Connection terminated locally. • 0x4F03: Connection terminated by remote communication partner. • 0x4F04: Connection terminated by a protocol error. • 0x4F05: Connection terminated by a network problem detected locally. • 0x4F06: Connection terminated by a network problem detected remotely. • 0x4F07: Connected terminated due to timeout in protocol. • 0x4F08: Incorrect parameter assignment: Connection to be established to local partner's own address. • 0x4F09: Connection temporarily reset by a call of the instruction "T_RESET". • 0x4F0A: Insufficient connection resources available (quantity exceeded) • 0x4F0B: Internal error: Incorrect addressing parameters • 0x4F0C: Internal CPU communication error • 0x4F0D: Internal AS communication error between CPU and CM/CP • 0x4F0E: The local TCP/UDP port (or RFC1006-T selector) specified is already in use.
LastConnErrTimeStamp	LDT	Time of the last connection attempt with errors.
LastDisconnReason	UDINT	Error ID which led to the last connection termination (the error messages are identical to those at the LastConnErrReason parameter): • 0x4F01: Remote connection end point cannot be reached (this error usually occurs during connection establishment). • 0x4F02: Connection terminated locally. • 0x4F03: Connection terminated by remote communication partner. • 0x4F04: Connection terminated by a protocol error. • 0x4F05: Connection terminated by a network problem detected locally. • 0x4F06: Connection terminated by a network problem detected remotely. • 0x4F07: Connected terminated due to timeout in protocol. • 0x4F08: Incorrect parameter assignment: Connection to be established to local partner's own address. • 0x4F09: Connection temporarily reset by a call of the instruction "T_RESET". • 0x4F0A: Insufficient connection resources available (quantity exceeded) • 0x4F0B: Internal error: Incorrect addressing parameters • 0x4F0C: Internal CPU communication error • 0x4F0D: Internal AS communication error between CPU and CM/CP • 0x4F0E: The local TCP/UDP port (or RFC1006-T selector) specified is already in use.
LastDisconnTimeStamp	LDT	Time of the last connection termination.

T_CONFIG: Configure interface

Description T_CONFIG

Description

The "T_CONFIG" instruction is used for the program-controlled configuration of the integrated PROFINET interfaces of the CPU or the interface of a CP/CM.

You can change the Ethernet address of the PROFINET device name from the user program via the instruction. The existing configuration data is overwritten.

You can make the following changes via the instruction "T_CONFIG":

- Settings for the IP protocol
  - IP address
  - Subnet mask
  - Router address
- Settings for PROFINET
  - Assignment of the PROFINET device name

The settings correspond with the configuration options under "IP protocol" and "PROFINET" in the dialog "Ethernet addresses". This is displayed in the view "devices & networks" under the properties of the PROFINET interface.

Warning

Restart of CPU after execution of the "T_CONFIG" instruction

The CPU is restarted after you have executed the instruction to change an IP parameter. The CPU goes to STOP mode, a warm restart is carried out and the CPU starts up again (RUN mode).

Make sure that the control process is in a secure operating mode after the CPU has been restarted following execution of the instruction. Uncontrolled operation can result in serious material damage or personal injury due to malfunctions or programming errors, for example. Non-retentive data could be lost.

Requirement

In order to use the instruction must be explicitly specified in the hardware configuration that the assignment of IP address parameters and device name must be made by the user program.

- For this purpose open the properties of the PROFINET interface in the device view. Activate the following options in the dialog "Ethernet addresses":
  - In order to change the IP address parameters with "T_CONFIG": Select the setting "IP address is set directly at the device" under "IP protocol".
  - In order to change the PROFINET device name with "T_CONFIG": Select the setting "PROFINET device name is set directly at the device" under "PROFINET".
- The configuration data must be stored in the following system data types and assigned at the parameter CONF_DATA (Page 3703):
  - Store the IP address, subnet mask, and the router address in the system data type IF_CONF_V4.
  - Store the device name in the system type IF_CONF_NOS. Observe the restrictions that exist for assigning the name of the device (see parameter CONF_DATA (Page 3703)).

Functional description

The "T_CONFIG" instruction works asynchronously, which means its execution extends over multiple calls. The configuration process is started by calling "T_CONFIG" with REQ = 1. Only one job can be active at any time.

The block is edge triggered which means that after BUSY= FALSE the block must be re-called with REQ=FALSE to enable the instance.

Parameters

The following table shows the parameters of the "T_CONFIG" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Calling the instruction with REQ = 1 starts processing of the instruction.
INTERFACE	Input	HW_INTERFACE	I, Q, M, D, L or constant	Hardware identifier of the interface The hardware ID is displayed in the properties of the interface in the device view, and in the system constants of the PLC tags.
CONF_DATA (Page 3703)	Input	VARIANT	D, L	Pointer to the parent structure that contains the system data types IF_CONF_HEADER, IF_CONF_V4 and IF_CONF_NOS (see description of the parameters CONF_DATA).
DONE (Page 3707)	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: Processing not yet complete. • 1: Processing of instruction finished successfully.
BUSY (Page 3707)	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: Processing of the instruction has not started, completed or canceled yet. • 1: Processing of instruction is in progress
ERROR (Page 3707)	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: No error • 1: Error

Parameter	Declaration	Data type	Memory area	Description
STATUS (Page 3707)	Output	DWORD	I, Q, M, D, L	Detailed status information: Detailed error and status information in the form of an error code are output at the parameter STATUS.
ERR_LOC (Page 3707)	Output	DWORD	I, Q, M, D, L	Error location: • 0: Error during execution of the instruction or when assigning parameters. • > 0: Errors in the structure or content of the configuration data at the parameter CONF_DATA.

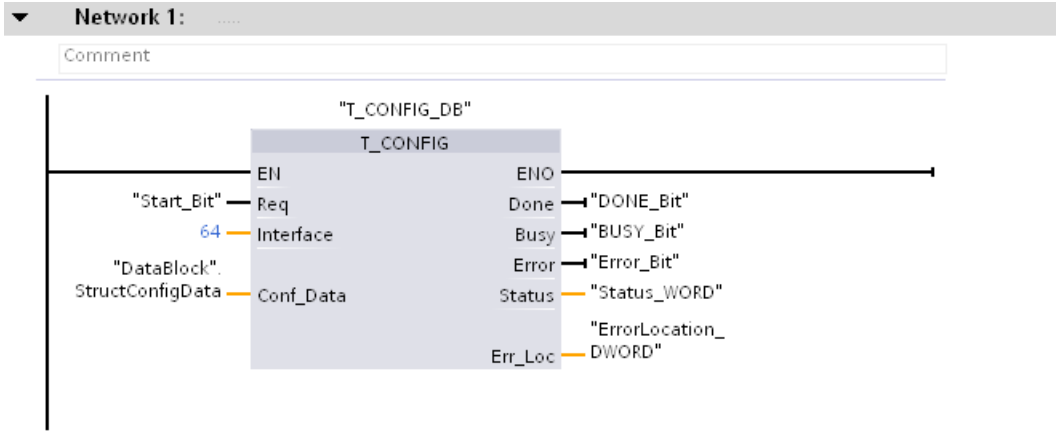
You can find additional information on valid data types under "Overview of the valid data types (Page 1908)".

Example

In the following example the device name of an IO device is changed with the instruction "T_CONFIG".

Call of instruction

- The execution of the instruction is started with REQ=1.
- The hardware ID of the PROFINET interface is specified at the parameter Interface.
- The structure "StructConfigData" is referenced at the parameter CONF_DATA. The structure was created in the global data block "DataBlock".



Parameters CONF_DATA

The structure "StructConfigData" at the parameter CONF_DATA contains the following information:

- In the Header (IF_CONF_HEADER).
  SubfieldCount = 1: Indicates that only one additional structure (nos) is used below.
- In the structure "nos" (system data type IF_CONF_NOS)
  - Lenght = 11: Information on overall length of the structure NOS (5 bytes for the device name "myplc" + 6 bytes for the parameters Id, Length and Mode)
    Note: Instead of an absolute length, you can use the default start value (Lenght = 0) for a dynamic length.
  - Mode = 1: Permanent change of the device name in "myplc".
  - NOS[1] ... NOS[5]: Device name (1 character / byte)

DataBlock

	Name	Data type	Start value
1	Static		
2	StructConfigData	Struct	
3	Header	IF_CONF_Header	
4	FieldType	UInt	0
5	FieldId	UInt	0
6	SubfieldCount	UInt	1
7	nos	IF_CONF_NOS	
8	Id	UInt	40
9	Length	UInt	11
10	Mode	UInt	1
11	NOS	array [1..240] of Byte	
12	NOS[1]	Byte	'm'
13	NOS[2]	Byte	'y'
14	NOS[3]	Byte	'p'
15	NOS[4]	Byte	'l'
16	NOS[5]	Byte	'c'
17	NOS[6]	Byte	16#0
18	NOS[7]	Byte	16#0
19	NOS[8]	Byte	16#0
20	NOS[9]	Byte	16#0
21	NOS[10]	Byte	16#0
22	NOS[11]	Byte	16#0

Evaluating errors with output parameter RET_VAL (Page 2195)

Parameter CONF_DATA

Structure of the configuration data

The configuration data at the parameter CONF_DATA can be stored in a global data block or in the section "Static" of the block interface.

The configuration data must be stored according to the following structure:

Name		Data type	Description
ConfData		Struct	Parent structure that is assigned at the parameter CONF_DATA.
	Header	IF_CONF_HEADER	The header is used to define the number of these system data types. The system data type IF_CONF_HEADER must always be included.
	IPData	IF_CONF_V4	The IP address, subnet mask and router address are stored in this system data type. Only create IF_CONF_V4 if you also want to change the Ethernet address with "T_CONFIG".
	NoS	IF_CONF_NOS	The PROFINET device names are stored in this system data type. Only create IF_CONF_NOS if you also want to change the device names with "T_CONFIG".

The system data types IF_CONF_HEADER, IF_CONF_V4 and IF_CONF_NOS are created by entering the name of the system data type in the column "data type" of the data block or the block interface. The name for the system data types can be freely assigned.

System data type IF_CONF_Header

Use the system data type IF_CONF_Header to specify the number of system data types IF_CONF_V4 and IF_CONF_NOS that are used during the execution of "T_CONFIG".

Byte	Parameter	Data type	Start value	Description
0 ... 1	FieldType	UINT	0	Field type: Must always have the value "0".
2 ... 3	FieldId	UINT	0	Error ID: Must always have the value "0".
4 ... 5	SubfieldCount	UINT	0	Number of system data types IF_CONF_V4 and IF_CONF_NOS: • 1: Only one of the system data types is used. • 2: Both system data types are used

System data type IF_CONF_V4

The IP address, subnet mask and router address are defined with the system data type IF_CONF_V4.

Byte	Parameter	Data type	Start value	Description
0 ... 1	Id	UINT	30	System data type ID The start value of this parameter may not be changed.
2 ... 3	Length	UINT	18	Length of the system data type IF_CONF_V4 The start value must be used for the length specification since the parameters of IF_CONF_V4 have a fixed length and structure.
4 ... 5	Mode	UINT	0	Validity of addressing: • 1: Permanent validity of the configuration data • 2: Temporary validity of the configuration data including the deletion of existing permanent configuration data
6 ... 9	InterfaceAddress	IP_V4 *	0.0.0.0	IP address
10 ... 12	SubnetMask	IP_V4 *	0.0.0.0	Subnet mask

Byte	Parameter	Data type	Start value	Description
14 ... 16	DefaultRouter	IP_V4 *	0.0.0.0	Router address
* The data type IP_V4 is a structure of 4 BYTE, which includes the respective address of the respective parameter (e.g. at parameter SubnetMask the four-digit address of the subnet mask of the IP protocol).				

Subfield IF_CONF_NOS

Use the subfield IF_CONF_NOS to specify the station name to be assigned during execution of the instruction "T_CONFIG".

Byte	Parameter	Data type	Start value	Description
0 ... 1	Id	UINT	40	System data type ID The start value of this parameter may not be changed.
2 ... 3	Length	UINT	246	Length of the system data type IF_CONF_NOS in bytes. • For an absolute length, the value for the Lenght parameter consists of: – 6 bytes for the parameter Id, Length and Mode. – up to 240 bytes for the device name (parameter NOS). Example: An overall length of 10 is the result for the device name "plc1" with a length of 4 characters (=4 bytes). • Use the default start value 246 at the Lenght parameter for a dynamic length. Make sure that you enter the value "0" after the name (see description for NOS parameter).

Byte	Parameter	Data type	Start value	Description
4 ... 5	Mode	UINT	0	Validity of the device name change: • 1: Permanent validity of the device name. • 2: Temporary validity of the device name.
6 ... 244	NOS	ARRAY [1...240] of Byte	0	Device name (Name of Station) • You must occupy the ARRAY from the first byte. The station name is deleted if "0" is assigned as the first byte. • The minimum length for the name is 2 bytes. The maximum length for a name is 240 bytes. • If the device name is shorter than specified at the parameter Length then a zero byte (16#0 hex) must be entered after the actual station name (according to IEC 61185-6-10). Otherwise NOS will be rejected and the instruction "T_CONFIG" outputs the error codeDW#16#C0809400 at the parameter STATUS. • If the device name is longer than specified at the parameter Length then the device name will only be written up to to specified length. The following restrictions apply for the device name: • The name must be specified in ASCII code. • Only lowercase letters, numbers, hyphen or dots may be used for the name. – The name may not begin or end with a hyphen. – The name may not begin with numbers. – The name may not have the form n.n.n.n (n = 0, ... 999). – The name may not begin with the string "port-xyz" or "port-xyz-abcde" (a, b, c, d, e, x, y, z = 0, ... 9). • A name component between two points may be up to 63 characters long. • No special characters such as umlauts, brackets, underscore, slash, blank etc. The error code C080_9400 is output at the parameter STATUS if an invalid character is used.

DONE, BUSY and ERROR parameters

Description

The following table shows the relationship between BUSY, DONE and ERROR. Using this table, you can determine the current status of the instruction and when the transfer of configuration data is concluded.

BUSY	DONE	ERROR	Description
TRUE	FALSE	FALSE	The job is being processed.
FALSE	TRUE	FALSE	Job successfully completed.
FALSE	FALSE	TRUE	The job ended with an error. The cause of the error can be found in the parameter STATUS (Page 3707).
FALSE	FALSE	FALSE	The instruction was not assigned a (new) job.

Parameter STATUS and ERR_LOC

Description

The status and error messages of the instruction "T_CONFIG" are output at the parameters STATUS and ERR_LOC.

- The cause of the error is output at the parameter STATUS.
- The location of the error that occurred is output at the parameter ERR_LOC. The following options are available here:
  - 16#0000_0000: Error when calling the instruction (e.g. errors when assigning parameters to the instruction or in communication with the PROFINET interface).
  - 16#0001_0000: Error with the configuration data in the parameters of the system data type IF_CONF_HEADER.
  - 16#0001_0001: Error with the configuration data in the parameters of the system types IF_CONF_V4 or IF_CONF_NOS.

The following table shows the possible values for the parameters STATUS and ERR_LOC:

STATUS*	ERR_LOC*	Explanation
0000_0000	0000_0000	Order processing completed without errors.
0070_0000	0000_0000	No job processing active.
0070_0100	0000_0000	Start of the order processing.
0070_0200	0000_0000	Intermediate call (REQ irrelevant).
C08x_yy00	0000_0000	General error information. See also: GET_ERR_ID: Get error ID locally (Page 2417)
C080_8000	0000_0000	Error at call of the instruction: The hardware ID at the parameter Interface is invalid.
C080_8100	0000_0000	Error at call of the instruction: The hardware ID at the parameter Interface does not address a PROFINET interface.
C080_8700	0000_0000	Error at call of the instruction: Incorrect length of the data block at the parameter CONF_DATA.

STATUS*	ERR_LOC*	Explanation
C080_8800	0001_0000	Error in the system data type IF_CONF_HEADER: The parameter FieldType has an invalid value. Use the value "0" for FieldType.
C080_8900	0001_0000	Error in the system data type IF_CONF_HEADER: The parameter FieldId has an invalid value or was used several times. Use the value "0" for FieldId.
C080_8A00	0001_0000	Error in the system data type IF_CONF_HEADER: Incorrect number at the parameter SubfieldCount. Enter the correct number of system data types IF_CONF_V4 and IF_CONF_NOS in use.
C080_8B00	0001_0001	Error in the system data type IF_CONF_V4 or IF_CONF_NOS: The parameter Id has an invalid value. Use "30" and IF_CONF_NOS "40" for IF_CONF_V4.
C080_8C00	0001_0001	Error in the system data type IF_CONF_V4 or IF_CONF_NOS: Incorrect data type system used, wrong order or multiple use of a system data type.
C080_8D00	0001_0001	Error in the system data type IF_CONF_V4 or IF_CONF_NOS: The parameter Length has an incorrect or invalid value.
C080_8E00	0001_0001	Error in the system data type IF_CONF_V4 or IF_CONF_NOS: The parameter Mode has an incorrect or invalid value. Only the values "1" (permanent) or "2" (temporary) are valid.
C080_9000	0001_0001	Error in the system data type IF_CONF_V4 or IF_CONF_NOS: Configuration data cannot be applied. Possible cause: The setting "Set IP address on device" or "Set PROFINET device name on device" was not selected in the hardware configuration.
C080_9400	0001_0001	Error in the system data type IF_CONF_V4 or IF_CONF_NOS: A parameter value is undefined or invalid.
C080_9500	0001_0001	Error in the system data type IF_CONF_V4 or IF_CONF_NOS: The values of two parameters are inconsistent.
C080_C200	0000_0000	Error at call of the instruction: The configuration data can not be transferred. Possible cause: The PROFINET interface is not accessible.
C080_C300	0000_0000	Error at call of the instruction: Insufficient resources (e.g., multiple calling of "T_CONFIG" with different parameters).
C080_C400	0000_0000	Error at call of the instruction: Temporary communication error. Time indication for change to daylight saving time.
C080_D200	0000_0000	Error at call of the instruction: Call not possible. Instruction is not supported by the selected PROFINET interface.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".		

Differences in Open User Communication libraries V3.1 and V4.0

New library version OUC V4.0

Introduction

CPU S7-1200 as of firmware version 4.1 supports new instruction versions for Open User Communication (OUC). The new instructions are included in the library with version 4.0.

If you want to use this library, changes must be made to the application program, since some of the new instructions for Open User Communication behave differently.

This section describes the differences in detail, especially in the call behavior of the instructions.

Note

Description only relevant when upgrading from the CPU S7-1200 ≤ V4.0 to S7-1200 ≥ V4.1

If you are using an S7-1500 CPU, changes between the library versions are not relevant. The same applies if you are using an S7-1200 ≥ Version 4.1 and do not convert the library for the Open User Communication to Version 4.0.

Differences between version 3.1 and 4.0 of the Open User Communication library

The following table shows the instructions in the Open User Communication library that differ between version 3.1 and 4.0. Click on the name of the instruction for detailed information.

Instruction	Version in library V3.1 (CPU FW ≤ V4.0)	Version in library V4.0 (CPU FW ≥ V4.1)
TSEND_C (Page 3709)	V2.1	V3.0
TRCV_C (Page 3711)	V2.1	V3.0
TMAIL_C *	V2.1	V3.0
TCON (Page 3713)	V3.0	V4.0
TDISCON	V2.1	V2.1 (identical to library V3.1)
TSEND (Page 3715)	V3.0	V4.0
TRCV (Page 3717)	V3.0	V4.0
TUSEND (Page 3715)	V3.0	V4.0
TURCV (Page 3717)	V3.0	V4.0
T_RESET *	V1.1	V1.2
T_DIAG *	V1.1	V1.2
T_CONFIG	V1.0	V1.0 (identical to library V3.1)
MB_CLIENT (Page 3720)	V3.1	V4.0
MB_SERVER (Page 3720)	V3.1	V4.0
* There are no differences in the versions that affect the user program.		

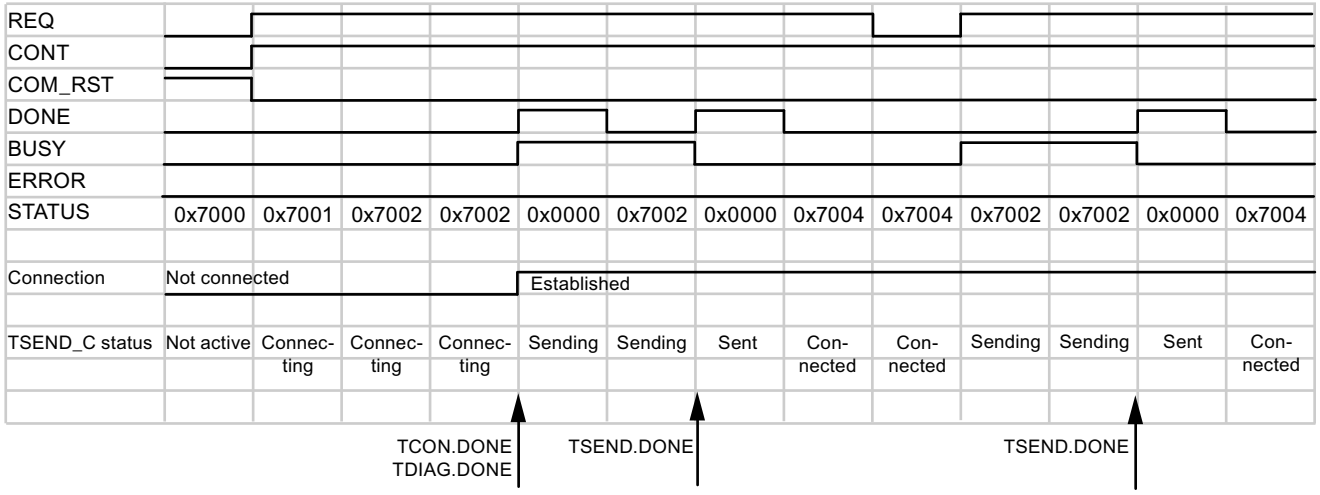
Changed behavior of instructions

Changes with the TSEND_C instruction

Call behavior of TSEND_C (V<3.0)

Up to version 2.1 of the TSEND_C instruction, the DONE output parameter is set twice: Once when a connection is established by the internally used TCON instruction and then after a send operation by the internally used TSEND instruction.

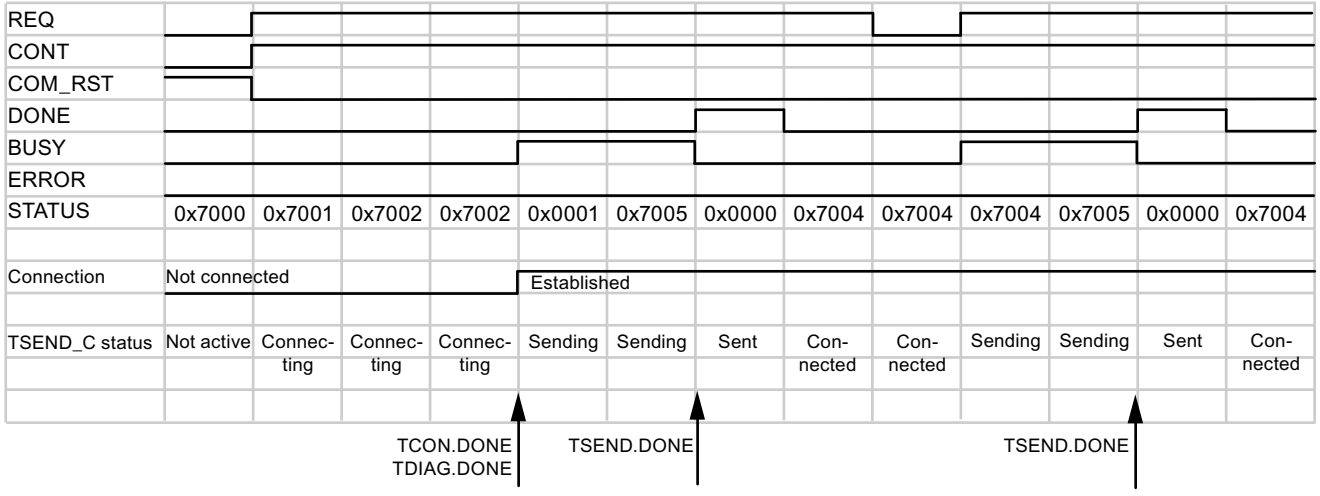
The following diagram shows the connection establishment and the sending of data with TSEND_C V2.1:



When setting the COM_RST parameter to "1", the current connection establishment or a current data transmission can be reset at any time. This terminates the existing communication connection and a new connection is established.

Call behavior of TSEND_C (V≥3.0)

As of the TSEND_C version, the DONE parameter is only set when data transfer has been completed by the internally used TSEND instruction (STATUS = 0000).



The existing connection is temporarily interrupted and reset when the COM_RST parameter is set to "1". However, unlike TSEND_C V2.1, the connection endpoint is retained.

Note

Additional protocols with TSEND_C as of version 3.0

Version 3.0 of the TSEND_C instruction also supports UDP and UDP Broadcast via the interface of the CPU and via CM/CP.

See also

TSEND_C: Send data via Ethernet (Page 3625)

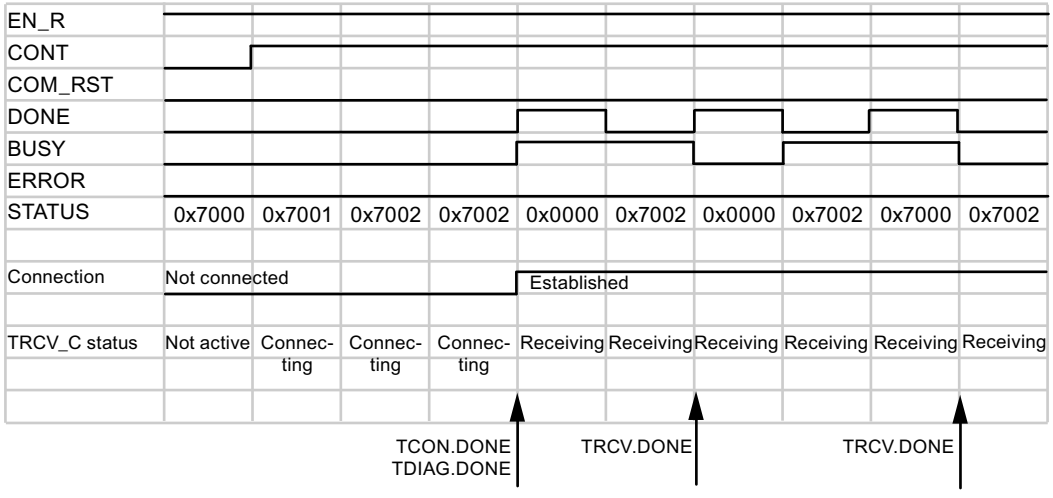
TSEND_C: Send data via Ethernet (Page 3629)

Changes with the TRCV_C instruction

Call behavior of TRCV_C (V<3.0)

Up to version 2.1 of the TRCV_C instruction, the DONE output parameter is set after the connection is established. The STATUS output parameter does not distinguish whether the connection or the data transfer has been completed.

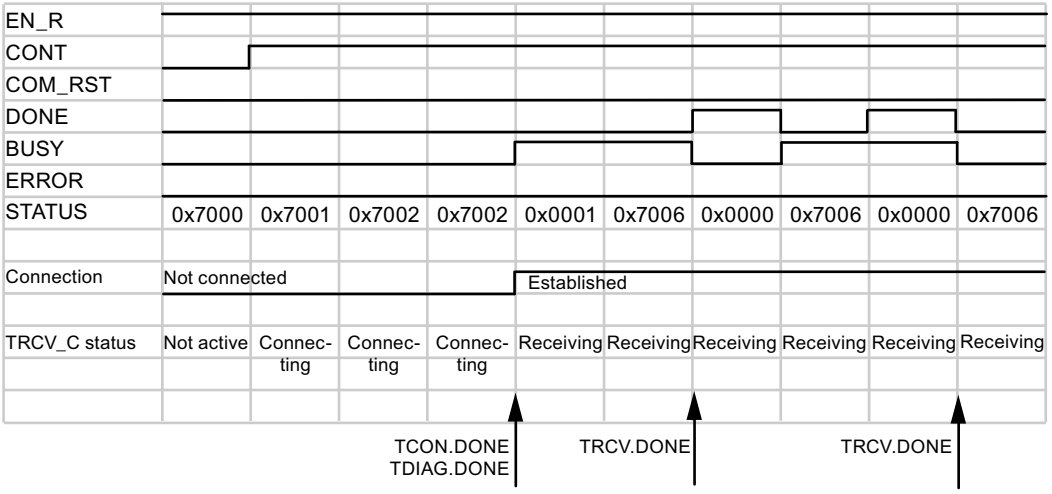
The following diagram shows the connection establishment and the sending of data with TRCV_C V2.1:



The current connection establishment or a current data transmission can be reset at any time by setting the COM_RST parameter to "1". This terminates the existing communication connection and a new connection is established.

Call behavior of TRCV_C (V≥3.0)

As of the TRCV_C version, the DONE parameter is only set when data transfer has been completed by the internally used TRCV instruction (STATUS = 0000). The completion of the connection establishment by the internally used TCON instruction is displayed by the output value 0x0001 at the STATUS parameter.



The existing connection is temporarily interrupted and reset when the COM_RST parameter is set to "1". However, unlike TSEND_C V2.1, the connection endpoint is retained.

Note

Additional protocols with TRCV_C as of version 3.0

Version 3.0 of the TRCV_C instruction also supports UDP and UDP Broadcast via the interface of the CPU and via CM/CP.

Note

ADHOC mode for the TCP protocol variant

In accordance with the TRCV instruction, with TRCV_C up to version 2.1, ADHOC mode is activated by assigning the value "0" to the LEN parameter. As of version 3.0 of the instruction, you use the ADHOC parameter for this. You can find detailed information in the descriptions of the instructions.

Changes with the TRCV/TURCV instructions (Page 3717)

TRCV_C: Receive data via Ethernet (Page 3636)

TRCV_C: Receive data via Ethernet (Page 3641)

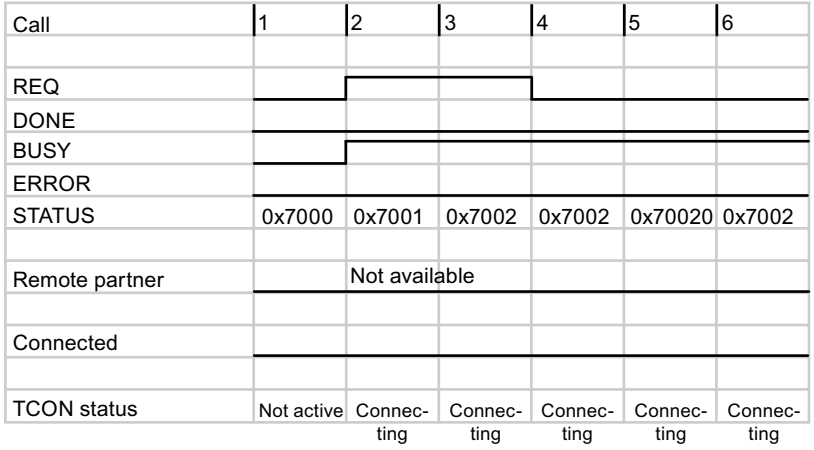
Changes with the TCON instruction

Changed call behavior with connection errors

Previous call behavior of TCON (V<4.0)

- The previous TCON instruction (V<4.0) is activated with a rising edge at the REQ input parameter.
- If the remote communication partner cannot be reached, the instruction sets the BUSY output parameter.
- An error message is not output.

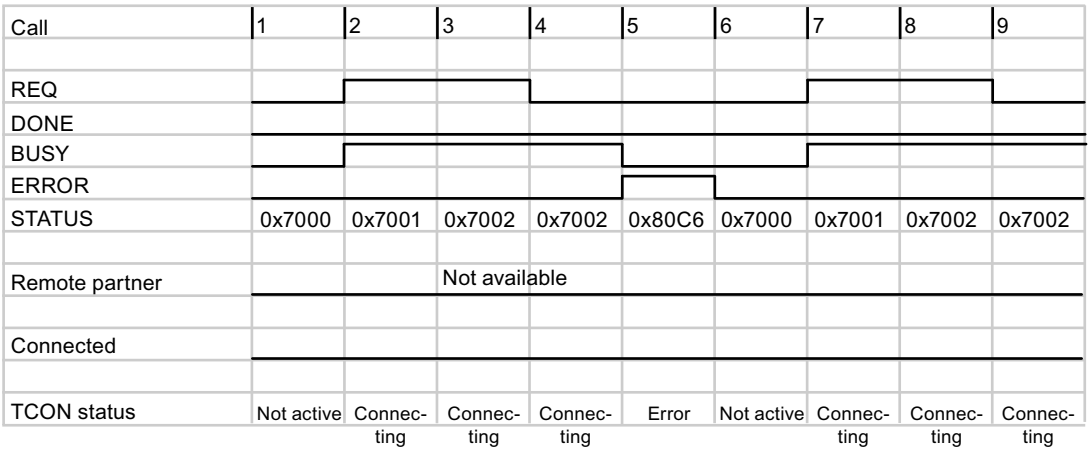
The following diagram shows the behavior of TCON on the part of the active connection partner. If no connection is made, the instruction is not called again.



New call behavior of TCON (V≥4.0)

- The new TCON instruction is also activated with a rising edge at the REQ input parameter.
- Unlike before, an error message is output when the remote communication partner cannot be reached. The error can be queried and the call started again by a new edge at the REQ parameter.
- The following changes result for the user program:
  - Additional error messages of TCON that can be evaluated (see description of TCON (Page 3664)).
  - The connection establishment can be re-initialized via a new rising edge. To do this, query the DONE and ERROR parameters to ensure that an error is present.

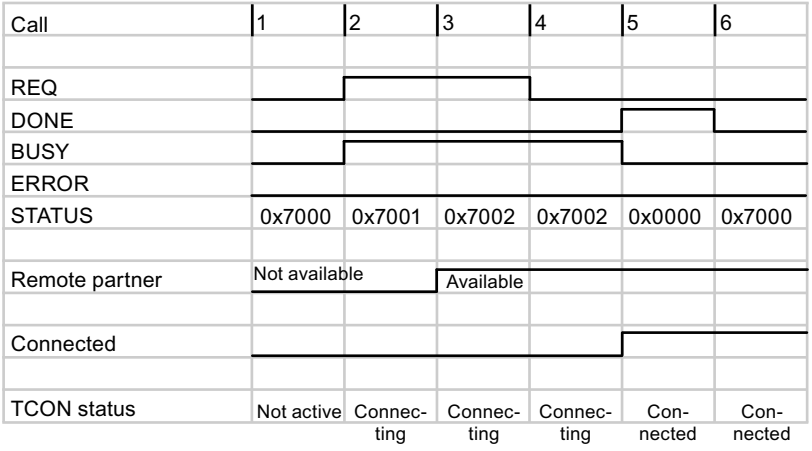
The following diagram shows the behavior of TCON on the part of the active connection partner. The instruction is called again after a network error (error code 80C6).



Call behavior without communication errors

If there is no connection error, the TCON versions have the same behavior.

The following diagram shows the behavior of TCON on the part of the active connection partner.



See also

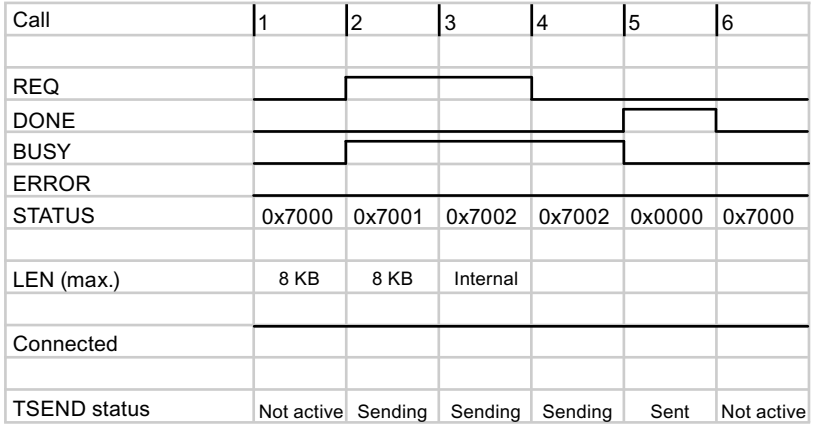
TCON: Establish communication connection (Page 3662)

Changes with the TSEND/TUSEND instructions

Send operation with an established connection

If no delay or interruption occurs during sending, versions 3.0 and 4.0 of the TSEND/TUSEND instructions behave the same way:

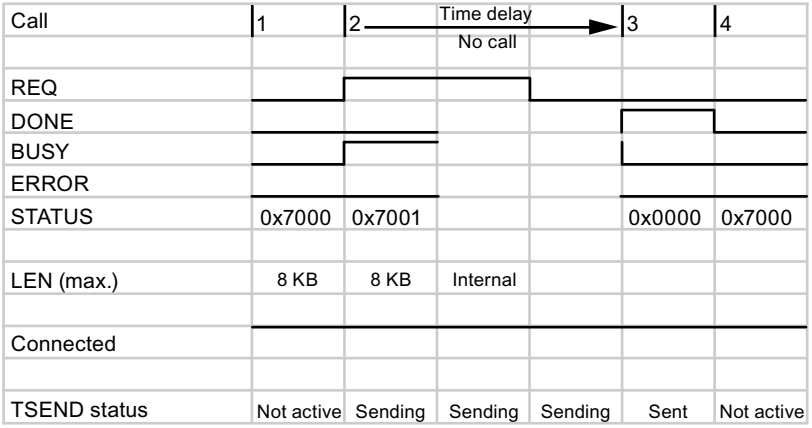
- The instruction is started with a positive edge at the "REQ" parameter. The instruction is executed asynchronously, i.e. it must be called until the full execution is indicated by the DONE parameter.
- A maximum of 8 KB of data can be sent with TSEND. A maximum of 1472 bytes can be sent with TUSEND. The amounts are based on the full execution of the instruction, i.e. all required calls until the DONE parameter is set.
- Data transmission takes place in three steps:
  - The data is written from the operand area to an internal buffer (indicated by STATUS=7001).
  - The transmission to the remote communication partner follows.
  - If the transmission is successful, DONE is set to "1" and STATUS is reset to "0" (see call 5 in the diagram below).



Send operation with time-delayed call

If the send operation is not performed via a communication module (CM) or a communication processor (CP), versions 3.0 and 4.0 of the TSEND/TUSEND instructions behave the same way:

- In the following example, TSEND or TUSEND are only called once with a rising edge at the REQ parameter (see call 2 in the diagram below).
- If the time delay is sufficiently long and the data could be transferred, the DONE parameter is set directly to "1" in the next call (call 3 here).

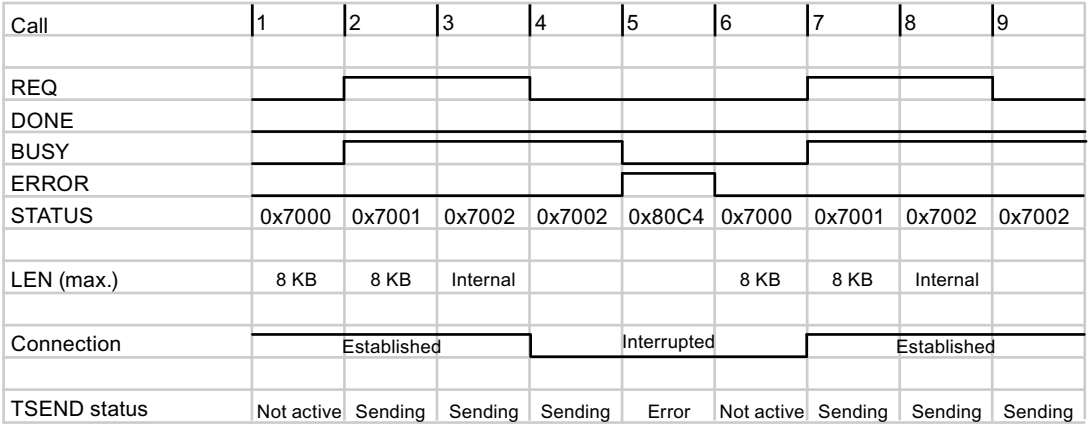


If the send operation is performed via a CM/CP, version 4.0 of the TSEND/TUSEND instructions behaves differently. In this case, the instruction must be called multiple times until the receipt of data is confirmed by the NDR parameter of the TRCV/TURCV instructions.

Send operation with interrupted connection

If the connection is interrupted during the send operation, the ERROR and STATUS parameters indicate the error and its cause. In the following example, the connection was interrupted during call number 5 and this error is indicated accordingly with the STATUS parameter.

As of version 4.0 of the TSEND/TUSEND instructions, more STATUS alarms are available that can be correspondingly evaluated (see description of TSEND (Page 3674)/TUSEND (Page 3687)) .



See also

TSEND: Send data via communication connection (Page 3671)

Changes with the TRCV/TURCV instructions

Receive operation with an established connection

If no delay or interruption occurs during sending, version 3.0 and 4.0 of the TRCV/TURCV instructions behave the same way:

- A maximum of 8 KB of data can be sent with TRCV. A maximum of 1472 bytes can be received with TURCV. The amounts are based on the full execution of the instruction, i.e. all required calls until the DONE parameter is set.
- The instruction receives data if the EN_R parameter is set to "1".
- The data reception is not complete until the length of data specified at the the LEN parameter has been completely received. The length of the received data is output at the RCVD_LEN output parameter. Only then does the data in the area defined at the DATA parameter become available.

Call	1	2	3	4	5	6
EN_R						
LEN (max.)	8 KB	8 KB	Internal			
NDR						
BUSY						
ERROR						
STATUS	0x7000	0x7001	0x7002	0x7002	0x0000	0x7000
RCVD_LEN	0	0	0	0	max. 8 KB	0
Connection				Established		
TRCV status	Not active	Receiving	Receiving	Receiving	Receiving	Not active

Receive operation with time-delayed call

If the send operation is not performed via a communication module (CM) or a communication processor (CP), versions 3.0 and 4.0 of the TRCV/TURCV instructions behave the same way:

- In the following example, TRCV or TURCV are only called once with a rising edge at the EN_R parameter (see call 2 in the diagram below).
- If the time delay is sufficiently long and the data could be transferred, the NDR parameter is set directly to "1" in the next call (call 3 here).

Call	1	2	Delay / No call		3	4
EN_R						
LEN (max.)	8 KB	8 KB	Internal			
NDR						
BUSY						
ERROR						
STATUS	0x7000	0x7001			0x0000	0x7000
RCVD_LEN	0	0	0	0	max. 8 kB	0
Connection	Established					
TRCV status	Not active	Receiving	Receiving	Receiving	Receiving	Not active

If the send operation is performed via a CM/CP, version 4.0 of the TSEND/TUSEND instructions behaves differently. In this case, the instruction must be called multiple times until the receipt of data is confirmed by the NDR parameter.

Receive operation with interrupted connection

If the connection is interrupted during receiving, the ERROR and STATUS parameters indicate the error and its cause. In the following example, call number 5 resulted in a temporary communication error, which is accordingly indicated by the STATUS parameter.

Call	1	2	3	4	5	6	7	8	9
EN_R									
LEN									
NDR									
BUSY									
ERROR	0x7000	0x7001	0x7002	0x7002	0x80C4	0x7000	0x7001	0x7002	0x7002
STATUS	8 KB	8 KB	Internal			8 KB	8 KB	Internal	
RCVD_LEN								Established	
Connection	Established								
TRCV state	Not active	Sending	Sending	Sending	Error	Not active	Sending	Sending	Sending

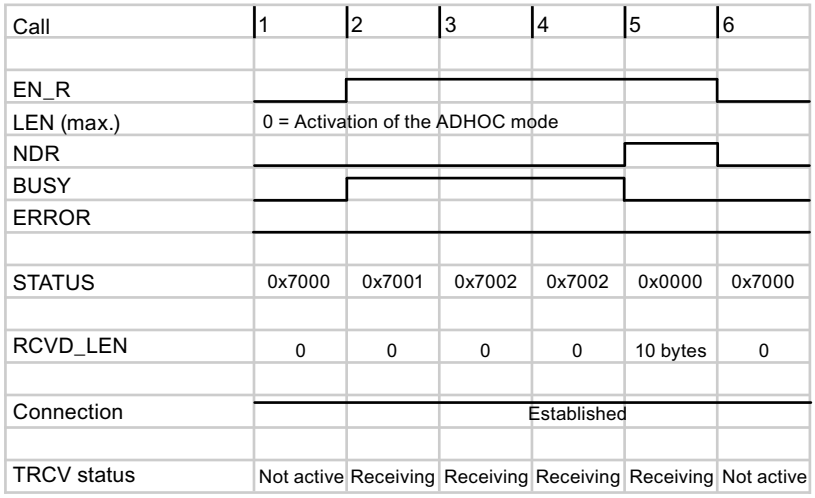
As of version 4.0 of the TRCV/TURCV instructions, more STATUS alarms are available that can be correspondingly evaluated (see description of TRCV (Page 3681)/TURCV (Page 3690)).

Receive operation using ADHOC mode

ADHOC mode is only available with the TCP protocol variant. You can use ADHOC mode to receive data of variable length with the TRCV/TURCV instruction. If ADHOC mode is active, the receipt of data is confirmed at the NDR parameter when at least one byte has been transferred.

Data reception in ADHOC mode with TRCV < 3.0 (S7-1200 < V4.0)

In the older version of TRCV (Page 3677), ADHOC mode was activated by setting the LEN parameter to "0". In the following example, 10 bytes of data are transferred with call 5.



Data receipt in ADHOC mode with TRCV ≥ 3.0 (S7-1200 ≥ V4.0 or S7-1500)

As of version 3.0 of the TRCV instruction, ADHOC mode is activated with its own parameter (ADHOC).

Call	1	2	3	4	5	6
EN_R						
LEN	Max. 8 KB	Max. 8 KB	Internal			
ADHOC						
NDR						
BUSY						
ERROR						
STATUS	0x7000	0x7001	0x7002	0x7002	0x0000	0x7000
RCVD_LEN	0	0	0	0	10 bytes	0
Connection			Established			
TRCV status	Not active	Receiving	Receiving	Receiving	Receiving	Not active

If an error occurs during execution, as of version 4.0 of the TRCV instructions, there are more STATUS alarms available which can be evaluated accordingly.

If the send operation is performed via a CM/CP, version 4.0 of the TRCV/TURCV instructions behaves differently. In this case, the instruction must be called multiple times until the receipt of data is confirmed by the NDR parameter.

Changes with the MB_SERVER/MB_CLIENT instructions

Differences between versions 3.1 and 4.0 of the Modbus instructions

The following differences between versions exist with the MB_SERVER/MB_CLIENT MODBUS instructions:

- Address parameter
  - In version 3.1, the address data for the Modbus TCP server is specified via the input parameters "IP_x".
  - Version 4.0 uses TCON_IP_V4 and TCON_Configured system data types at the CONNECT input parameter for this purpose.
- If an error occurs during execution, as of version 4.0 of the Modbus instructions, there are more STATUS alarms available which can be evaluated accordingly.

You can find detailed information in the instruction descriptions for MB_CLIENT (V3.1) (Page 3770) and MB_CLIENT (V4.0) (Page 3788) and in the descriptions for MB_SERVER (V3.1) (Page 3778) and MB_SERVER (V4.0) (Page 3800).

11.6.5.3 Web server

WWW: Synchronizing user-defined web pages

Description

The instruction WWW initializes the Web server of the CPU or synchronizes user-defined web pages with the user program in the CPU.

User-defined web pages together with the Web server make it possible for the CPU to access freely designed web pages of the CPU with a web browser.

Use script instructions (such as Javascript) and HTML code in user-defined web pages to transfer data via a web browser for further processing to the CPU and to display data from the operand area of the CPU in the web browser. Call the WWW instruction in the user program for synchronization of the user program and the Web server as well as initialization.

Initialization

User-defined web pages are "packaged" in data blocks for processing by the CPU. You will have to generate appropriate data blocks from the source files (HTML files, screens, Javascript files, ...) during configuration. The Web Control DB takes on a special role (default: DB 333). It contains status and control information as well as links to additional data blocks with coded web pages. The data blocks with coded web pages are called fragment DBs.

When the data block is downloaded into the CPU, the CPU does not "know" that user-defined web pages are coded inside it. The instruction "WWW" in the startup OB, for example, will inform the CPU which DB is the Web Control DB. The user-defined web pages can be accessed via a web browser after this initialization.

Synchronization

If you want the user program to interact with the user-defined web pages, then the instruction WWW must be used in the cyclical program part.

Examples of interaction between user program and web page:

- Check received data
- Assemble and send back data to the web browser making the request

In this case it must be possible to evaluate the current status information and the Web server must receive control information, such as release of a web page requested by a web browser.

Parameter

The following table shows the parameters of the instruction "WWW":

Parameter	Declaration	Data type	Memory area	Description
CTRL_DB	Input	DB_WWW	I, Q, M, D, L or constant	Data block that describes the user-defined web pages (Web Control DB)
RET_VAL	Output	INT	I, Q, M, D, L	Error information

For additional information on valid data types, refer to Overview of the valid data types (Page 1908).

Parameter RET_VAL

Error code (W#16#...)	Explanation
0000	No error occurred. There are no web page requests that have to be released by the user program.
00xy	x: indicates whether an error has occurred during initialization of the Web Control DB (CTRL_DB): x=0: No errors occurred. x=1: Error occurred. The error is coded in the byte "CTRL_DB.last_error" of the Web Control DB, see description of Web Control DB. y: Number of the pending request. Several requests are possible (e. g. requests "0" and "1" are pending: y="3". y="1": Request "0" y="2": Request "1" y="4": Request "2" y="8": Request "3"
803A	The specified Web Control DB does not exist on the CPU.
8081	Incorrect version or incorrect format of the Web Control DB.
80C1	There are no resources to initialize the web application, for example, because only two or four web applications may be running.

11.6.5.4 Communications processor

Point-to-point

PORT_CFG: Configure communication parameters dynamically

Description

The instruction "PORT_CFG" allows dynamic configuration of communications parameters for a point-to-point communications port.

You set up the original static configuration of the port in the hardware configuration. You can change this configuration by executing the "PORT_CFG" instruction. You can also use this function to save created blocks in libraries and to avoid configuration in the hardware configuration when you reuse it.

With "PORT_CFG" you can influence the following communications parameter settings:

- Parity
- Baud rate
- Number of bits per character
- Number of stop bits
- Type and properties of flow control

The changes made by the "PORT_CFG" instruction are not stored permanently on the target system.

You can transfer serial data via the electrical connections RS-232 (half and full duplex) and RS-485 (half duplex).

Parameters

The following table shows the parameters of the "PORT_CFG" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Activates the configuration change on a rising edge
PORT	Input	PORT	I, Q, M, D, L or constant	Identification of the communication port (HW-ID)
PROTOCOL	Input	UINT	I, Q, M, D, L or constant	Transmission protocol: • 0: Point-to-point communication protocol • 1..n: Future definition for specific transmission protocols
BAUD	Input	UINT	I, Q, M, D, L or constant	Baud rate of the port: • 1: 300 baud • 2: 600 baud • 3: 1200 baud • 4: 2400 baud • 5: 4800 baud • 6: 9600 baud (default) • 7: 19200 baud • 8: 38400 baud • 9: 57600 baud • 10: 76800 baud • 11: 115200 baud
PARITY	Input	UINT	I, Q, M, D, L or constant	Parity of the port: • 1: No parity (default) • 2: Even parity • 3: Odd parity • 4: Mark parity • 5: Space parity

Parameter	Declaration	Data type	Memory area	Description
DATABITS	Input	UINT	I, Q, M, D, L or constant	Bits per character: • 1: 8 bits per character (default) • 2: 7 bits per character
STOPBITS	Input	UINT	I, Q, M, D, L or constant	Number of stop bits: • 1: 1 stop bit (default) • 2: 2 stop bits
FLOWCTRL	Input	UINT	I, Q, M, D, L or constant	Data flow control: • 1: None (default) • 2: XON/XOFF • 3: Hardware flow control (RTS always activated) • 4: Hardware flow control (RTS can be deactivated during transmission)
XONCHAR	Input	CHAR	I, Q, M, D, L or constant	Indicates the character used as XON character. The character DC1 (11H) is set as default.
XOFFCHAR	Input	CHAR	I, Q, M, D, L or constant	Indicates the character used as XOFF character. The character DC3 (13H) is set as default.
WAITTIME	Input	UINT	I, Q, M, D, L or constant	Specifies the wait time for XON or CTS after the start of the transmission. The specified value must be greater than 0. 2000 milliseconds are set as default.
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or is still executing • 1: Job executed without errors
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction

You will find more detailed information on valid data types in "Overview of the valid data types (Page 1908)".

STATUS parameter

Error code* (W#16#...)	Description
80A0	The specified protocol is invalid.
80A1	The specified baud rate is invalid.
80A2	The specified parity rate is invalid.
80A3	The specified number of bits per character is invalid.
80A4	The specified number of stop bits is invalid.
80A5	The specified type of flow control is invalid.
80A6	Incorrect value at the WAITTIME parameter When the data flow control is enabled, the value at the WAITTIME parameter must be greater than zero.

Error code* (W#16#...)	Description
80A7	Invalid values at XONCHAR and XOFFCHAR parameters.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

You will find more detailed information on general error codes of the communication instructions in: "General status information of the communications blocks (Page 3741)".

SEND_CFG: Configure serial transmission parameters dynamically

Description

The instruction "SEND_CFG" allows dynamic configuration of serial transmission parameters for a point-to-point communications port. All the messages waiting for transfer are discarded after execution of SEND_CFG.

You set up the original static configuration of the port in the hardware configuration. You can change this configuration by executing the "SEND_CFG" instruction. You can also use this function to save created blocks in libraries and to avoid configuration in the hardware configuration when you reuse it. With "SEND_CFG" you can influence the following transmission parameter settings:

- Time between the activation of RTS (Request to Send) and the start of the transmission
- Time between the end of transmission and the deactivation of RTS
- Define bit times for breaks

The changes made by the "SEND_CFG" instruction are not stored permanently on the target system.

You can transfer serial data via the electrical connections RS-232 (half and full duplex) and RS-485 (half duplex).

Parameters

The following table shows the parameters of the "SEND_CFG" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Activates the configuration change on a rising edge
PORT	Input	PORT	I, Q, M, D, L or constant	Identification of the communication port (HW-ID)
RTSONDLY	Input	UINT	I, Q, M, D, L or constant	The time that should elapse after activating RTS until the start of transmission. Valid values for this parameter are as follows: • 0 (default) • 0 to 65535 ms in steps of 1 ms This parameter does not apply to RS-485 modules.

Parameter	Declaration	Data type	Memory area	Description
RTSOFFDLY	Input	UINT	I, Q, M, D, L or constant	Time that should elapse after the end of transmission until deactivation of RTS. Valid values for this parameter are as follows: • 0 (default) • 0 to 65535 ms in steps of 1 ms This parameter does not apply to RS-485 modules.
BREAK	Input	UINT	I, Q, M, D, L or constant	Specifies the bit times for a break, which are sent at the start of the message. 12 bit times are set as default. A maximum of 25000 bit times can be specified.
IDLELINE	Input	UINT	I, Q, M, D, L or constant	Specifies the bit times for idle line after the break at the start of the message. 12 bit times are set as default. A maximum of 25000 bit times can be specified.
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or is still executing • 1: Job executed without errors
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction

You will find more detailed information on valid data types in "Overview of the valid data types (Page 1908)".

STATUS parameter

Error code* (W#16#...)	Description
80B0	The configuration of a transmission interruption is not permitted.
80B1	The specified break time exceeds the permitted maximum of 25000 bit times.
80B2	The specified time for idle line exceeds the permitted maximum of 25000 bit times.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

You will find more detailed information on general error codes of the communication instructions in: "General status information of the communications blocks (Page 3741)".

RCV_CFG: Configure serial receive parameters dynamically

Description

The instruction "RCV_CFG" allows dynamic configuration of serial receive parameters for a point-to-point communications port. You can use this instruction to configure the conditions that specify the start and end of the message to be transmitted. The receipt of messages that correspond to these conditions can be enabled by the "RCV_PTP (Page 3737)" instruction.

You set up the original static configuration of the port in the properties of the hardware configuration. Execute the "RCV_CFG" instruction in your program to change the configuration. You can also use this function to save created blocks in libraries and to avoid configuration in the hardware configuration when you reuse it. The changes made by the "RCV_CFG" instruction are not stored permanently on the target system.

All the messages waiting for transfer are discarded after execution of the "RCV_CFG" instruction.

Parameters

The following table shows the parameters of the "RCV_CFG" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Activates the configuration change on a rising edge.
PORT	Input	PORT	I, Q, M, D, L or constant	Identification of the communication port (HW-ID)
CONDITIONS	Input	CONDITIONS	D, L	Data structure defining the conditions for start and end of data transmission.
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or is still executing • 1: Job executed without errors
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction

You will find more detailed information on valid data types in "Overview of the valid data types (Page 1908)".

Data type CONDITIONS

You can use the CONDITIONS structure to define the start and end conditions for the message transmission. The structure CONDITIONS is included in the instance DB of the "RCV_CFG" instruction. Use the structure CONDITIONS to define the start and end conditions when the transmission of a message is complete and when the next message transfer is to start:

- You define the start conditions for the data transfer in the START structure.
- You define the end conditions for the data transfer in the END structure.

You can define one or more start and end conditions for this. If you specify multiple start or end conditions these are linked by an OR logic instruction.

The following table shows the "CONDITIONS" structure:

Parameters		Data type	Description
START		STRUCT	Start conditions
	STARTCOND	UINT	Specifies the start condition (details, see below). The start condition can be specified as a 16-bit hexadecimal value. Possible values for the start condition are: • 1: Start character • 2: Any character (default) • 4: Line break • 8: Idle line • 16: Character string 1 • 32: Character string 2 • 64: Character string 3 • 128: Character string 4 Multiple start conditions can also be defined at the STARTCOND parameter. The total from the values of the individual conditions is specified for this. If, for example, you want to define "Idle line" OR "Character string 1" OR "Character string 4" as start condition, the value "152" must be specified.
	IDLETIME	UINT	Specifies the maximum idle time of the line before receipt is started. Valid values for this parameter are as follows: • 40 bit times (default) • 0 to 2500 bit times
	STARTCHAR	BYTE	Specifies the start character. This setting is only enabled when the configured start condition is "Start character". Valid values for this parameter are as follows: • 02 (STX): Default setting • B#16#00 to B#16#FF
	SEQ[1].CTL	BYTE	Character string 1: Control sequence for each character You can use the bit position of the character to define which characters of the character string will be considered or ignored. To evaluate the characters, the corresponding bits have to be set. • Bit 0: 1 character • Bit 1: 2 characters • Bit 2: 3 characters • Bit 3: 4 characters • Bit 4: 5 characters A character is ignored when the corresponding bit is reset.
	SEQ[1].STR	CHAR[5]	Character string 1: Start character (5 characters)
	SEQ[2].CTL	BYTE	Character string 2: Ignore/compare control sequence for each character
	SEQ[2].STR	CHAR[5]	Character string 2: Start character (5 characters)
	SEQ[3].CTL	BYTE	Character string 3: Ignore/compare control sequence for each character
	SEQ[3].STR	CHAR[5]	Character string 3: Start character (5 characters)
	SEQ[4].CTL	BYTE	Character string 4: Ignore/compare control sequence for each character
	SEQ[4].STR	CHAR[5]	Character string 4: Start character (5 characters)

Parameters	Data type	Description
END	STRUCT	End conditions

Parameters		Data type	Description
	ENDCOND	UINT	Specifies the end condition (details, see below). The end condition can be specified as a 16-bit hexadecimal value. Possible values for the end condition are: • 1: Reply timeout • 2: Message timeout • 4: Timeout within the character string • 8: Maximum length • 16: N+LEN+M; the information on the message length in integrated in the message and will be evaluated. • 32: Character string 1 Multiple end conditions can also be defined at the ENDCOND parameter. The total from the values of the individual end conditions is specified for this. If, for example, you want to define the end condition "Maximum length" OR "Sequence 1", the value "40" must be specified.
	MAXLEN	UINT	Specifies the maximum number of characters in a message. Valid values* for this parameter are as follows: • 1 character (default) • 0 to 1024 characters This setting is only enabled if the "Maximum length" end condition is set at the ENDCOND parameter.
	N	UINT	Offset of the length field in the message Valid values for this parameter are as follows: • 0 characters (default) • 0 to 1024 characters This setting is only enabled if the "N+LEN+M" end condition is set at the END-COND parameter.
	LENGTHSIZE	UINT	Size of the length field in bytes Valid values* for this parameter are as follows: • 0 bytes (default) • 1 byte • 2 bytes • 4 bytes This setting is only enabled if the "N+LEN+M" end condition is set at the END-COND parameter.
	LENGTHM	UINT	Specifies the number of end characters that follow the length field but are not contained in the length of the message. Valid values for this parameter are as follows: • 0 characters (default) • 0 to 255 characters This setting is only enabled if the "N+LEN+M" end condition is set at the END-COND parameter.
	RCVTIME	UINT	Specifies the maximum duration for the receipt of the first character of a message. Valid values for this parameter are as follows: • 200 ms (default)

Parameters		Data type	Description
			• 0 to 65535 ms in steps of 1 ms This setting is only enabled if the "Reply timeout" end condition is set at the ENDCOND parameter.
	MSGTIME	UINT	Specifies the maximum duration of the receipt of a message. Valid values for this parameter are as follows: • 200 ms (default) • 0 to 65535 ms in steps of 1 ms This setting is only enabled if the "Message timeout" end condition is set at the ENDCOND parameter.
	CHARGAP	UINT	Specifies the time interval between received consecutive characters. Valid values for this parameter are as follows: • 12 bit times (default) • 0 to 2500 bit times This setting is only enabled if the "Timeout within the character string" end condition is set at the ENDCOND parameter.
	SEQ.CTL	BYTE	Character string: Control sequence for each character You can use the bit position of the character to define which characters of the character string will be considered or ignored. To evaluate the characters, the corresponding bits have to be set. • Bit 0: 1 character • Bit 1: 2 characters • Bit 2: 3 characters • Bit 3: 4 characters • Bit 4: 5 characters A character is ignored when the corresponding bit is reset.
	SEQ.STR	CHAR[5]	Character string: Start character (5 characters)
	* These value ranges also apply to the corresponding hardware settings for specifying the end of message.		

Start conditions for the message receipt (STARTCOND parameter)

The start of the message is recognized by the receiver if a configured start condition applies. The following conditions can be defined as start conditions for message receipt:

- Start character: The start of a message is recognized when a certain character occurs. This character is stored as first character of the message. All characters received before the start character are rejected.
- Any character: Any character can define the start of a message. This character is stored as first character of the message.
- Line break: The start of a message is recognized if the received data stream is interrupted for longer than one character length.

- Idle line: The start of a message is recognized when the send transmission line is in the idle state for a certain time (specified in bit times) followed by renewed transmission of characters.
- Character string (sequence): The start of a message is recognized when a specified character sequence occurs in the data stream. You can specify up to four character sequences with up to five characters each.
  Example: A received hexadecimal message includes the following characters: "68 10 aa 68 bb 10 aa 16". The configured start character sequences are listed in the following table. Start character sequences will be evaluated once the first character 68H has been received successfully. After the fourth character has been received successfully (the second 68H), the start condition "1" has been met. Once the start conditions have been met, evaluation of the end conditions will start.
  Processing of the start character sequence can end due to different errors in parity, framing or time intervals between characters. These errors will prevent reception of the message, because the start condition has not been met.

Start condition	First character	First character +1	First character +2	First character +3	First character +4
1	68H	xx	xx	68H	xx
2	10H	aaH	xx	xx	xx
3	dcH	aaH	xx	xx	xx
4	e5H	xx	xx	xx	xx

End conditions for the message receipt (ENDCOND parameter)

The start of a message is recognized by the receiver if a configured end condition applies. The following conditions can be defined as end conditions for message receipt:

- Reply timeout: The receipt of messages will end when the specified maximum duration for the receipt of a character is exceeded. The maximum duration is defined at the RCVTIME parameter. The defined time starts to run down as soon at the last transmission is completed and the RCV_PTP instruction enables the receipt of the message. If no character was received within the defined time (RCVTIME), the RCV_PTP instruction reports an error.
- Message timeout: The receipt of messages will end when the specified maximum duration for the receipt of a message is exceeded. The maximum duration is defined at the MSGTIME parameter. The defined time starts to run down as soon as the first character of the message is received.
- Timeout within the character string: The receipt of messages will end when the time interval between the receipt of two consecutive characters is longer than the value at the CHARGAP parameter.
- Maximum length: The receipt of messages will end when the length of the message defined at the MAXLEN parameter is exceeded.

- Reading message length (N+LEN+M): The receipt of messages will end when a certain message length is reached. This length is calculated by the values of the following parameters:
  - N: Position of the character in the message from which the length field begins.
  - LENGTHSIZE: Size of the length field in bytes
  - LENGTHM: Number of end characters that follow the length field. These characters are not taken into account in the evaluation of the message length.
- Character string: The receipt of messages will end when a defined character sequence is received. The character string can contain a maximum of five characters. For each character of the character string, you can use the bit position to define if this will be considered or ignored in the evaluation.

STATUS parameter

Error code* (W#16#...)	Description
80C0	Error in start condition
80C1	• Error in end condition • No end condition defined
80C2	Receive interrupt enabled
80C3	A value that is equal to 0 or greater than 4132 was entered at the MAXLEN parameter while the "Maximum length" end condition was set.
80C4	A value that is greater than 4131 was entered at the N parameter while the "N+LEN+M" end condition was set.
80C5	A value that is equal to 0 or invalid was entered at the LENGTHSIZE parameter while the "N+LEN+M" end condition was set.
80C6	A value that is greater than 255 was entered at the LENGTHM parameter while the "N+LEN+M" end condition was set.
80C7	A message length greater than 4132 was calculated while the "N+LEN+M" end condition was set.
